Background: There is no proven evidence that combination therapy of TACE with sorafenib (TS group) prolong progression-free survival (PFS) and/or overall survival (OS) compared to TACE alone (T group) in patients with unresectable HCC. **Methods:** In this randomized, open label, multicenter, comparative trial (NCT01217034), patients with unresectable HCC, Child-Pugh score ≤7, ECOG performance status 0-1, no vascular invasion (VI), no extrahepatic spread (EHS), size≤10 cm and number≤10 and adequate organ function were randomized 1:1 (stratification by institution, Milan criteria in or out, and number of previous TACE 0 or 1-2) to T or TS. In TS group, sorafenib 400 mg once daily was pretreated for 2-3 weeks prior to TACE followed by 800mg once daily during on-demand conventional TACE sessions until the time to unTACEable progression (TTUP), which was defined as the time to the date of a state when TACE continuation is not possible due to untreatable tumor progression, deterioration to Child-Pugh C or appearance of VI/EHS. Co-primary endpoints are PFS and OS. Multiplicity is adjusted using a gatekeeping hierarchical testing. PFS event in this trial was defined as death or time to TTUP. Key secondary endpoints were time to progression and safety. PFS is expected to 40% extension from 18 months (control arm) to 25 months, target HR was 0.71, with a power of 0.80. **Results:** The trial was conducted in 33 institutions and a total of 156 patients were randomized to T (n = 76) or TS (n = 80). Median PFS in the T group and TS group was 13.5 and 25.2 months (HR = 0.59, 95%CI 0.41-0.87; p = 0.006), respectively. The number of OS events has not reached. Median TTP was 13.5 and 24.1 months in the T and TS groups (HR = 0.56, 95%CI 0.38-0.83; p = 0.004). Median TTUP was 20.6 and 26.7 months in the T and TS groups (HR = 0.57, 95%CI 0.35-0.92; p = 0.02), respectively. There was no unexpected toxicity. **Conclusions:** Sorafenib in combination with TACE significantly improved PFS over TACE alone in patients with unresectable HCC. Adverse events were consistent with the known safety profile with previous TACE combination trials. Clinical trial information: NCT01217034.

4018 Poster Discussion Session; Displayed in Poster Session (Board #207), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 4:45 PM-6:00 PM

Outcomes of patients (pts) with hepatocellular carcinoma (HCC) treated with transarterial chemoembolization (TACE): Global OPTIMIS final analysis. *First Author: Markus Peck-Radosavljevic, Medical University of Vienna/ Klinikum Klagenfurt am Wörthersee, Vienna/Klagenfurt, Austria*

Background: TACE is often used to treat unresectable HCC (uHCC). However, there is no globally accepted consensus on the indication and definition of TACE failure. It is critical to reassess the risk/benefit of continuing TACE after failure as it may delay or prevent pts from receiving subsequent treatments. **Methods:** OPTIMIS, an international, prospective, observational study, enrolled pts with uHCC for whom a decision to treat with TACE was made at study entry. Practice patterns, safety, subsequent treatments, and outcomes data were collected. TACE ineligibility was defined and consistent with international and regional guidelines. Data were analyzed using descriptive statistical methods. **Results:** Overall, 1650 pts received TACE; 529 pts (32%) were BCLC stage C, 118 (7%) had extrahepatic spread, and 123 (7%) had portal vein thrombosis. At inclusion visit, 636 pts (39%) received TACE despite being TACE ineligible according to protocol-specified criteria. After first TACE, the proportion of pts with chronic liver function deterioration (worsening in CTCAE grade 30–90 days post TACE) ranged from 11% to 29% across assessed liver parameters. Complete and partial response rates to first TACE (N=1650) were 14% and 26%, respectively, which decreased by second (10% and 16%; n=1002), third (10% and 15%; n=580), and fourth (8% and 17%; n=338) TACE. Progressive disease rate increased by number of TACE procedures: 18%, 21%, 25%, and 27% for first, second, third, and fourth TACE, respectively. In total, only 507 pts (31%) became TACE ineligible during the study. Of those 507 pts, 47 (9%) received sorafenib at the time of TACE ineligibility and 460 (91%) received sorafenib later or not at all. Considerable imbalances between the 2 cohorts were observed; a propensity score analysis is planned to analyze overall survival from TACE ineligibility. **Conclusions:** These results indicate that real-world TACE use appears to deviate from treatment guidelines. This heterogeneity highlights the need for a globally accepted consensus on the indication and definition of TACE failure. These observations also indicate the importance of monitoring liver function in pts receiving TACE. Clinical trial information: NCT01933945.

Cabozantinib (C) versus placebo (P) in patients (pts) with advanced hepatocellular carcinoma (HCC) who have received prior sorafenib: Results from the randomized phase 3 CELESTIAL trial. *First Author: Ghassan K. Abou-Alfa, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: C, an inhibitor of MET, VEGFR, and AXL, has previously shown clinical activity in pts with advanced HCC. This phase 3 trial (NCT01908426) evaluated C vs P in previously treated pts with advanced HCC. **Methods:** In this double-blind, global, phase 3 trial, pts were randomized 2:1 to C (60 mg qd) or matched P stratified by etiology, geographic region, and presence of extrahepatic spread and/or macrovascular invasion (EHS/MVI). Eligible pts had pathologic diagnosis of HCC, Child-Pugh score A, and ECOG PS ≤1. Pts must have received prior sorafenib, were allowed to receive up to 2 lines of prior systemic therapy for HCC, and must have progressed following at least one. The primary endpoint was overall survival (OS). Secondary endpoints were investigator-assessed progression-free survival (PFS) and objective response rate (ORR) per RECIST 1.1. The study was designed to detect a hazard ratio (HR) for OS of 0.76 (90% power, 2-sided $\alpha = 0.05$) at the final analysis with 2 prespecified interim analyses at 50% and 75% of the planned 621 events. **Results:** As of 1 Jun 2017, 707 pts were randomized, and 484 deaths had occurred (317 out of 470 for C; 167 out of 237 for P). Baseline characteristics were balanced between the arms: median age was 64 years, 82% were male, 38% had HBV, 24% had HCV, 25% enrolled in Asia, 85% had EHS/MVI, and 27% had received 2 prior systemic regimens for advanced HCC. The study met the primary endpoint at the second planned interim analysis with median OS 10.2 mo for C vs 8.0 mo for P (HR 0.76, 95% CI 0.63–0.92; p = 0.0049). Median PFS was 5.2 mo for C vs 1.9 mo for P (HR 0.44, 95% CI 0.36–0.52; $p < 0.0001$), and ORR was 4% vs 0.4% (p = 0.0086). The most common grade 3/4 adverse events (predominantly grade 3) with higher incidence in the C vs P arm included hand-foot skin reaction (17% vs 0%), hypertension (16% vs 2%), increased aspartate aminotransferase (12% vs 7%), fatigue (10% vs 4%), and diarrhea (10% vs 2%). Subgroup analyses of OS and PFS by baseline characteristics will also be presented. **Conclusions:** C significantly improved OS and PFS vs P in previously treated pts with advanced HCC. Adverse events were consistent with the known safety profile of C. Clinical trial information: NCT01908426.

4020 Poster Discussion Session; Displayed in Poster Session (Board #209), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 4:45 PM-6:00 PM

Pembrolizumab (pembro) in patients with advanced hepatocellular carcinoma (HCC): KEYNOTE-224 update. *First Author: Andrew X. Zhu, Massachusetts General Hospital Cancer Center and Harvard Medical School, Boston, MA*

Background: Initial results from KEYNOTE-224 (NCT02702414), an open label, phase 2 trial showed that pembro, an anti-PD-1 antibody, was active and safe in pts with advanced HCC previously treated with sorafenib. Here we report updated clinical results and biomarker studies. **Methods:** Eligible pts were age ≥18 y with histologically confirmed HCC, radiographic progression on/intolerance to sorafenib and disease not amenable to curative treatment, Child Pugh A, ECOG PS 0-1 and BCLC stage C or B. Pts received pembro 200 mg IV Q3W for 2 y or until disease progression, unacceptable toxicity, withdrawal of consent or investigator decision. Response was assessed every 9 wk. Primary endpoint was ORR (RECIST v1.1, central review). Secondary endpoints were DOR, DCR, PFS, OS and safety. Exploratory endpoint was relationship of PD-L1 IHC combined positive and tumor proportion scores (CPS and TPS; n = 52), and T cell inflamed gene expression profile (GEP; n = 42) with response. Data cutoff date was Nov 24, 2017. **Results:** Of 104 treated pts, 18 remained on therapy. Median age was 68 y (range 43-87), 21.2% were HBV^+, 26% were HCV^+, 94.2% were Child Pugh A, 79.8% had PD on sorafenib and 64.4% had extrahepatic disease. ORR was 16.3% (95% CI, 9.8 to 24.9, n = 17) and similar across differing etiologies; 66% of responders had duration ≥12 mo (Kaplan Meier) and median response duration was not reached (3.1 - 12.5+ mo). Best response was CR in 1 pt (1.0%), PR in 16 (15.4%), SD in 47 (45.2%) and PD in 34 (32.7%); DCR was 61.5%. Median PFS (95% CI) was 4.9 mo (3.4 to 7.0) and OS was 12.9 mo (9.7 to NA). PFS and OS 12 mo rates were 25.4% and 53.6%, respectively. Safety was similar to that observed for pembrolizumab in other indications. Immune-mediated hepatitis occurred in 3 (2.9%) pts; no cases of HBV/HCV flare were seen. Higher PD-L1 CPS in tumor and immune cells was associated with higher ORR and longer PFS, while PD-L1 TPS in tumor cells alone and GEP showed less robust associations with outcomes. **Conclusions:** These results confirm that pembro may be a promising treatment option for pts with advanced HCC. PD-L1 CPS was associated with clinical response to pembro while results for PD-L1 TPS and GEP were less robust; further study is needed to better define these relationships. Clinical trial information: NCT02702414.

4021 Poster Session (Board #210), Sun, 8:00 AM-11:30 AM

Two novel registry-based prediction models for overall survival in patients with metastatic esophageal or gastric cancer. *First Author: Héctor van den Boorn, Academic Medical Center, Amsterdam, Netherlands*

Background: Prediction models for decision-making in oncology are increasingly being used, but few are available for esophagogastric cancer, particularly in the metastatic setting. The aim of this study is to construct prediction models for overall survival in patients with metastatic esophageal or gastric cancer. **Methods:** Data from patients with metastatic esophageal (N = 8670) and gastric (N = 4804) cancer diagnosed in the period 2005-2015 were retrieved from the nationwide Dutch cancer registry. Multivariate Cox regression models, extended with treatment interactions, were created to predict overall survival. Multiple imputations were used to handle missing data. Predictor selection was performed via the Akaike Information Criterion (AIC) and was extended by a Delphi consensus among experts in the field of palliative esophagogastric cancer. Validation was performed with an 11-fold temporal validation. Both the concordance-index (c-index) and calibration were used to assess model quality. **Results:** The Delphi consensus yielded seven important predictors of survival and are shown with the AIC-selected predictors in Table 1. The c-indices show consistent discriminative ability during validation, i.e. 0.71 and 0.68 for respectively the esophageal and gastric cancer models. There is close agreement between predicted and observed survival, with an error of 1.7% and 2.2% for respectively the esophageal and gastric cancer models. **Conclusions:** The models yield fair discrimination and high calibration levels, and provide a good foundation for further investigation in clinical practice to determine their added value in decision-making.

Overview of selected predictors in the esophageal and gastric cancer models (#: selected during Delphi consensus).

Predictor	Esophageal cancer model	Gastric cancer model
Gender	X	X
Age#	X	X

Oxaliplatin plus capecitabine (XELOX) in the perioperative treatment of locally advanced gastric adenocarcinoma in combination with D2 gastrectomy (NEO-CLASSIC). *First Author: Tianshu Liu, Zhongshan Hospital, Fudan University, Shanghai, China*

Background: This multicenter, open-label study (NEO-CLASSIC) evaluated the efficacy and safety of oxaliplatin and capecitabine (XELOX), plus gastrectomy, in localized resectable gastric cancer. **Methods:** Patients aged 18–75 years with histologically confirmed gastric adenocarcinoma (stage T2–3/N+M0, or T4aN+M0) were given eight cycles of XELOX (four preoperatively, four postoperatively). Each 3-week cycle comprised capecitabine 1000 mg/m^2 twice daily on days 1–14, and oxaliplatin 130 mg/m^2 as an intravenous infusion over 2 hours on day 1. Curative D2 gastrectomy was scheduled 2–4 weeks after the last preoperative cycle. **Results:** Fifty-five patients were enrolled, and one was excluded because of screening failure. R0 resections were achieved in 45 of 54 intent-to-treat patients (83.3%), and four patients received R1 resections. There were no complete responses, 27 (50.0%) partial responses, 24 cases (44.4%) of stable disease, and 3 (5.6%) of progressive disease. The objective response rate was 50.0%. Median follow-up was 31.9 (range 17.4–48.1) months: 29 patients (54.7%) had disease progression, and median progression-free survival was 18.13 (95% confidence interval: 4.70, 31.56) months; median overall survival was not reached. Fifty-four patients completed 209 cycles of preoperative chemotherapy; 42 patients received 133 cycles of postoperative chemotherapy. The rate of grade 3–4 adverse events was 8.5% (29/342 cycles): the most frequent events were neutropenia (9/342 cycles) and leukopenia (4/342 cycles). **Conclusions:** These findings suggest that combination therapy with capecitabine and oxaliplatin as neoadjuvant chemotherapy, followed by D2 gastrectomy, is effective in late-stage, locally advanced gastric cancer. Clinical trial information: NCT01880632.

Clinical response in the intent-to-treat population (n = 54).

Response evaluation[a]	Number of patients	% patients
Objective response rate	27	50.0
Disease control rate	49	90.7
Complete response	0	0.0
Partial response	27	50.0
Stable disease	24	44.4
Progressive disease	3	5.6

[a]Response Evaluation Criteria in Solid Tumors (RECIST) version 1.1.

4023 Poster Session (Board #212), Sun, 8:00 AM-11:30 AM

Final analysis of single-arm confirmatory study of diagnostic endoscopic resection(ER) plus selective chemoradiotherapy (CRT) for stage I esophageal squamous cell carcinoma (ESCC): JCOG0508. *First Author: Keiko Minashi, Clinical Trial Promotion Department, Chiba Cancer Center, Chiba, Japan*

Background: For clinical stage I submucosal (cT1b-SM) ESCC, surgery is the standard treatment and CRT is optional. We conducted a single-arm confirmatory study of diagnostic ER plus selective CRT for cT1bN0M0 ESCC and reported the 3-year survival at 2016 ASCO Annual Meeting. We will report the final data of survival analysis after 5-year follow-up with a cutoff date of Aug 2017. **Methods:** Clinical stage I ESCC (cSM1-2, N0M0), tumor size ≤ 5 cm and circumference ≤ 3/4 was eligible. After ER, additional treatment was selected based on the histological evaluation: Group A, pT1a with negative resection margin and no lymphovascular invasion (LVI) -no additional treatment; Group B, pT1b with negative resection margin and pT1a with LVI -prophylactic CRT; Group C, pT1b with positive resection margin -definitive CRT. CRT consisted of concurrent 2 courses of chemotherapy (5-fluorouracil and cisplatin with 4-week interval, and radiotherapy of 41.4 Gy/23 fr (Group B) or 50.4Gy/28 fr (Group C). Primary endpoint was 3-year overall survival (OS) of Group B. The sample size was 82 for primary analysis, with one-sided alpha of 0.05 and power of 90%, based on the expected and threshold 3-year OS as 90% and 80%. Final analysis was planned after 5-year follow-up for all pts. **Results:** Between Dec 2006 and July 2012, 177 pts were enrolled from 23 institutions in Japan. 176 pts underwent ER and Group A/B/C were 74/87/15, respectively. The 3- and 5-year OS of Group B was 90.8% (90% CI; 84.1- 94.8) and 89.7% (95% CI; 81.1-94.5). The 3- and 5-year OS of all pts was 92.6% (90% CI; 88.6-95.3) and 90.9% (95% CI; 85.6-94.3). Twenty pts relapsed (Group A; 1 primary, 1 distant LN, Group B; 4 primaries , 8 regional LNs, 2 distant, Group C; 2 regional LNs, 2 distant), 7 pts underwent salvage esophagectomy. Univariable analysis in 83 pts of Group B showed that vascular invasion , one course of chemotherapy, SM2 with LVI had lower progression-free survival. **Conclusions:** Five-year survival data was comparable to that of surgery or CRT for c stage I ESCC. Vascular invasion, one course of chemotherapy, SM2 with LVI may be a risk factor of recurrence for prophylactic CRT after ER. Clinical trial information: UMIN000000553.

4024 Poster Session (Board #213), Sun, 8:00 AM-11:30 AM

Updated report of a randomized phase III trial comparing 4 and 8 courses of S-1 adjuvant chemotherapy for p-stage II gastric cancer: JCOG1104 (OPAS-1). *First Author: Masanori Terashima, Shizuoka Cancer Center, Nagaizumi, Japan*

Background: Postoperative S-1 for 1 year (corresponding to 8 courses) is one of standard adjuvant chemotherapies for p-stage II gastric cancer. We reported 4-courses of S-1 was inferior to 8-courses of S-1 in terms of relapse-free survival (RFS) for p-stage II gastric cancer at the first planned interim analysis (ESMO2017). Here, we report the updated results of this trial. **Methods:** Patients with p-stage II except T1Nany and T3N0 (7th edition of TNM), performance status 0-1, R0 resection were randomized either 8-courses or 4-courses. Primary endpoint was RFS. The total sample size was determined to be 1,000 with a non-inferiority margin of hazard ratio (HR) of 1.37, with one-sided alpha of 5% and power of 80%. **Results:** Between Feb 2012 and Mar 2017, 590 (295 in each arm) patients were enrolled and analyzed. Proportion of patients in treatment of S-1 at 6 months was 76.9% for the 8-courses and was 80.1% for the 4-courses, and that at 12 months was 59.3% in 8-courses. The RFS at 3 years was 89.8% for 4-courses and 93.1% for 8-courses (HR 1.84, 95% CI 0.93-3.63). The overall survival at 3 years was 92.6% for 4-courses and 96.1% for the 8-courses (HR 3.34, 95% CI 1.22-9.12). The cumulative incidence of recurrence at 3 years was 7.7% for the 8-coursesand 5.5% for the 4-courses (HR 1.59, 95% CI 0.75-3.39). For safety analysis, 8 patients who did not receive the protocol treatment were excluded. Adverse events were mild in both arms, but slightly less frequent in the 4-courses arm than in the 8-courses arm. **Conclusions:** The updated primary results confirmed that non-inferiority of 4-courses S-1 were not demonstrated in RFS. S-1 adjuvant chemotherapy for p-stage II gastric cancer should be continued for one year considering the efficacy, acceptable toxicities, and high compliance. Clinical trial information: UMIN000007306.

4025 Poster Session (Board #214), Sun, 8:00 AM-11:30 AM

PD-L1 and IDO1 expression and clinical outcome in 305 patients with surgically resected esophageal cancer. *First Author: Yoshifumi Baba, Department of Gastroenterological Surgery, Graduate School of Medical Sciences, Kumamoto University, Kumamoto, Japan*

Background: Immunotherapy with the PD-1/PD-L1 inhibitors has produced potent long-lasting antitumor activity in patients with esophageal cancer. However, as responses are observed in only a fraction of patients and treatment responses are sometimes transient, additional strategies to reverse elements of immune suppression imposed by cancer are needed. IDO1 is the primary enzyme that generates immunosuppressive metabolite, and IDO1 inhibitors are being intensively developed and tested in clinical trials for various human cancers. Nonetheless, prognostic and immunological features of PD-L1 and IDO1 expressions remain still unknown in esophageal cancer. **Methods:** Using a non-biased database of 305 curatively resected esophageal cancers, PD-L1 expression, IDO1 expression, CD8 expression, and FOXP3 (a maker of Treg) were evaluated by immunostaining. The term "prognostic marker" is used throughout this article according to the REMARK Guidelines. **Results:** Compared with PD-L1 negative cases (n = 252), PD-L1 positive cases (n = 53) showed significantly worse overall survival [log-rank P = 0.016; hazard ratio (HR): 1.71; 95% confidence interval (CI): 1.08–2.61; P = 0.024; multivariate HR: 1.69; 95% CI: 1.05–2.67; P = 0.033]. The effect of PD-L1 was not significantly modified by any clinical factors ($P > 0.05$ for all interactions). Second, IDO1 expression was significantly correlated with poor overall survival (log-rank P = 0.0041), low CD8 expression (P = 0.044) and high counts of FOXP3 positive cells (P = 0.02). Importantly, a stratification based on PD-L1 expression and IDO1 expression was also significantly associated with overall survival (log rank P = 0.0013); both positive cases experienced unfavorable clinical outcome compared with other cases. **Conclusions:** PD-L1 and IDO1 expressions were associated with clinical outcome in esophageal cancer patients. In addition, the subgroups defined on the basis of PD-L1 and IDO1 status possessed diverse prognostic features. PD-L1 and IDO1 expressions in esophageal cancer may serve as a predictive tissue biomarker and may be used for patient selection in clinical trials of drugs targeting the PD-L1 pathway and IDO1.

4026 Poster Session (Board #215), Sun, 8:00 AM-11:30 AM

Survival outcomes in gastric and gastroesophageal junction adenocarcinoma treated with peri-operative chemotherapy with or without pre-operative radiotherapy. *First Author: Sibo Tian, Department of Radiation Oncology, Winship Cancer Institute of Emory University, Atlanta, GA*

Background: Peri-operative chemotherapy (POC) is one approach in treating resectable cancers of the stomach and gastroesophageal junction (GEJ). Pre-operative chemoradiotherapy plus adjuvant chemotherapy (PCRT) is a strategy under investigation with unclear outcomes. We aimed to compare survival between PCRT and POC using a large database. **Methods:** The National Cancer Data Base was queried for patients diagnosed between 2004 -2013 with clinical stage Ib-IIIC (excluding T2N0) adenocarcinoma of the stomach or GEJ. Patients treated with definitive surgery, POC with or without pre-operative radiotherapy of 41-54 Gy were included. Overall survival (OS) was defined from date of definitive surgery to death or last follow-up and estimated using Kaplan-Meier methods; distributions were compared using log-rank tests. 14 patient and treatment variables were used for propensity score matching (PSM). **Results:** 1,048 patients were analyzed: 53.2% received POC and 46.8% PCRT. The primary site was GEJ for 69.1% of cases, and stomach for 30.9% of cases. Median age at diagnosis was 60 years. The number of lymph nodes (LN) sampled were 1-14 for 35.8%, 15-29 LNs for 45.2%, and ≥30 LNs for 16% of patients. 90-day mortality was 1% in both POC and PCRT (p = 0.93). The use of PCRT was associated with a greater pathologic complete response (pCR) rate of 12.9% vs 8.1% (p = 0.01). In the univariate setting POC was associated with superior OS with hazard ratio (HR) 0.83 (POC vs PCRT, p = 0.043). OS was greater in patients who achieved pCR (HR 0.58, p = 0.002), and for gastric primaries (HR 0.76, $p < 0.01$). Treatment group was not significant for OS in the multivariable model (HR 0.83, p = 0.106). Using PSM cohorts, POC was associated with superior OS (HR 0.70, p = 0.015). Median OS was 45.1 vs 31.4 months, 1-year OS was 90.8 vs 84.6%, and 5-year OS 40.7% vs 33.1% (POC vs PCRT). Survival favored POC in both gastric (HR 0.41, p = 0.07) and GEJ subgroups (HR 0.77, p = 0.08). **Conclusions:** The addition of pre-operative radiotherapy to POC does not appear to benefit resectable gastric and GEJ cancers. Until results from the randomized setting on PCRT are known, POC should remain a standard of care.

4027 Poster Session (Board #216), Sun, 8:00 AM-11:30 AM

Racial disparities in surgical management and survival in hispanic patients with potentially resectable esophageal cancer. *First Author: Dave Gupta, Emory University, Atlanta, GA*

Background: Practice patterns for potentially resectable disease are highly variable due to limited objective data to guide optimal management. Expanding on the well-known disparity in mortality among Black and White patients with esophageal cancer, we explored differences in epidemiology, tumor characteristics, surgical resection, and mortality for Hispanic and White patients with locoregional disease. **Methods:** Using the Surveillance, Epidemiology, and End Results (SEER) registry, we identified 6,250 cases of locoregional esophageal cancer (Stage I-III) occurring in Hispanic (n = 575) or White patients (n = 5675) between ages 18 and 65 (2003-2014). Cases were categorized by age, gender, education, tumor grade, histology, primary tumor site, and surgical status. Postdiagnosis survival was examined over time and compared by race and stratified by surgical status. **Results:** Hispanic patients with locoregional esophageal cancer are significantly less likely to receive surgery than White patients (46% vs 60%; $p < 0.001$), despite having comparable demographics (age, gender, income) and tumor characteristics (grade, histology, and primary site). There was a statistically significant difference in survival, with median OS of 22 months vs 29 months and long-term survival at 8 years of 24% vs 29% (p = 0.01) for Hispanics and Whites respectively. Patients who did not receive surgery had universally poor outcomes, with median OS of 15 vs 12 months and 8-year-survival of 15% vs 13% ($p > 0.10$). Patients treated with surgery had better overall survival with median OS of 40 vs 55 months and 8-year-survival of 35% vs 40% (p = 0.11), despite similar 1-year-survival of 83% vs 85%. **Conclusions:** Hispanic esophageal cancer patients experience higher mortality and use lower rates of potentially curative surgical management compared to White patients. These data support the need to better address patient barriers to surgical treatment and systemic biases present in medical care.

4028 Poster Session (Board #217), Sun, 8:00 AM-11:30 AM

Single-arm confirmatory trial of laparoscopy assisted total or proximal gastrectomy with nodal dissection for clinical stage I gastric cancer: Japan Clinical Oncology Group study JCOG1401. *First Author: Hitoshi Katai, National Cancer Center Hospital, Tokyo, Japan*

Background: Laparoscopy-assisted distal gastrectomy (LADG) for gastric cancer is safe and feasible. Several phase III studies try to confirm non-inferiority of LADG to open surgery for early disease. No prospective study evaluating laparoscopy-assisted total gastrectomy (LATG) and laparoscopy-assisted proximal gastrectomy (LAPG) has been completed yet in terms of both safety and long-term survival. Considering that results of phase III trial to evaluate the long-term outcome of LADG (JCOG0912) would guarantee that of LATG/LAPG, we conducted a single-arm confirmatory trial to evaluate the safety of LATG/LAPG for clinical stage I (T1N0/T1N1/T2N0) proximal gastric cancer. **Methods:** Laparoscopic operators were limited to credentialed surgeons. The extent of nodal dissection was selected based on the Gastric Cancer Treatment Guidelines in Japan. The mini-laparotomy incision was required to be shorter than 6 cm. The primary endpoint was the proportion of a grade 2 (CTCAE ver. 4.0) or greater esophageal anastomotic leak. Sample size was determined to be 245 considering threshold of 8% and expected value of 3% with one-sided alpha error of 2.5% and statistical power of 90%. **Results:** Between April 2015 and February 2017, 245 eligible patients were enrolled. LATG/LAPG was performed in 195/50. Among them, only 6 patients (2.4%) converted to open surgery. Clinical T1N0/T1N1/T2N0 was 213/9/24. Extent of dissection was D1 in 0, D1+ in 230, and D2 in 15. Median operation time was 309 minutes (IQR: 265-350). Median blood loss was 30 ml (IQR: 10-85). Grade 2 or greater esophageal anastomotic leak was 2.4% (6/245; 95% CI, 0.9–5.3; one-sided p = 0.0002). The overall proportion of in-hospital grade 3 or 4 adverse events was 29% (71/245). The proportion of intra-abdominal abscess, anastomotic stricture, and pancreatic fistula was 3.7%, 3.3%, and 2.0%, respectively. There were no treatment-related deaths. **Conclusions:** This trial confirmed the safety of LATG/LAPG. When non-inferiority of LADG is confirmed in our phase III trial, LATG or LAPG will be established as one of the standard treatments for clinical stage I gastric cancer. Clinical trial information: UMIN000017155.

4029 Poster Session (Board #218), Sun, 8:00 AM-11:30 AM

Biomarker study for trastuzumab continuation beyond progression in a randomized phase II trial of weekly paclitaxel±trastuzumab in patients with HER2-positive advanced gastric or gastro-esophageal junction cancer refractory to trastuzumab combined with fluoropyrimidine and platinum (WJOG7112G). *First Author: Yasutaka Sukawa, Division of Gastroenterology and Hepatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan*

Background: WJOG7112G study, comparing paclitaxel plus trastuzumab (PT; n = 44) with paclitaxel alone (P; n = 45), did not demonstrate survival benefit of trastuzumab continuation beyond progression (TBP) in HER2-positive gastric or gastro-esophageal junction cancer. As a collaborative study, we analyzed biomarkers possibly associating with TBP efficacy. **Methods:** We prospectively collected tumor tissues and serum samples after progression of prior chemotherapy from patients enrolled into the WJOG7112G trial. HER2 status in tumor tissues was examined by immunohistochemitory (IHC) and fluorescent in situ hybridization (FISH). HER2 amplification in serum cell-free DNA (cfHER2amp) was assessed by droplet PCR. Serum level of neuregulin-1 (NRG1), a ligand of HER3 and an activator of HER2 heterodimerization, was measured by ELISA. **Results:** Tumor tissues and serum samples were collected from 18 (P; n = 10, PT; n = 8) and 68 (P; n = 33, PT; n = 35) patients, respectively. IHC 3+, 2+, and FISH positive tumors were 3 (17%), 3 (17%), and 8 (44%), respectively. All IHC 3+ and 2+ tumors were FISH positive except 1 unevaluable tumor. cfHER2amp was positive in 41 (60%) patients (P; n = 21, PT; n = 20). There was no benefit of TBP in progression free survival (PFS) regardless of cfHER2amp (+) and (-) [hazard ratio (HR) 0.93, 95% CI 0.49 - 1.76, and HR 0.81, 95% CI 0.36 - 1.85, respectively]. Serum NRG1 was detectable in 16 (24%) patients, and significantly associated with shorter survival in patients treated with PT (median PFS; 2.6 and 3.8 months, log-rank test p = 0.045, median OS; 7.4 and 10.9 months, p = 0.013). **Conclusions:** Two third of patients lost tumor HER2-positivity after the progression of prior trastuzumab-containing chemotherapy. Serum cfHER2amp was not associated with the efficacy of TBP. NRG1 might be a resistant marker to TBP in HER2 positive gastric or gastro-esophageal cancer. Clinical trial information: UMIN000009297.

4030 Poster Session (Board #219), Sun, 8:00 AM-11:30 AM

Margetuximab (M) plus pembrolizumab (P) in ERBB2-amplified PD-L1+ gastroesophageal adenocarcinoma (GEA) post trastuzumab (T). *First Author: Daniel V.T. Catenacci, University of Chicago Pritzker School of Medicine, Chicago, IL*

Background: T + chemo is standard 1st line therapy (tx) for HER2+ GEA patients (pts). However, pts typically progress within 6-8 months, with up to 30% demonstrating loss of HER2 positivity. No HER2 targeted agents have been shown effective in the post-T setting. We report the results of M, a novel anti-HER2 monoclonal antibody + P (anti-PD-1) in HER2+ GEA pts in 2nd line post T progression and describe a biomarker enrichment strategy that compensates for tumor heterogeneity. **Methods:** HER2+ (pre-T testing) PD-L1-unselected GEA pts were enrolled. Endpoints include safety, objective response rate (ORR) by RECIST, and progression free survival (PFS). Exploratory endpoints include *ERBB2* amplification (amp) status pre-M+P tx circulating-tumor DNA (ctDNA) by NGS (Guardant360) and PD-L1 on archival tissue by IHC (22C3 pharmDx). **Results:** As of 1/10/18, 60 pts were dosed in cohort expansion; 30 in North America (NA), 30 in Asia (A). Tx was well tolerated, with 13% of pts having TRAE ≥ grade 3, 3 drug-related SAEs, and 2 cases of autoimmune hepatitis and 1 pneumonitis. *ERBB2* amp was detected by ctDNA in 61% of pts tested, mainly distal gastric cancer (GC) over proximal GEJ pts, and was inversely correlated with acquired driver mutations. PD-L1 was positive in 34% of pts tested, and was independent of clinical metrics but was enriched in ctDNA *ERRB2*+ pts (41% vs. 33%). Of 57 evaluable pts to date in expansion (30 NA and 27 A), best ORR was 16% and disease control rate (DCR) was 54%. Both ctDNA *ERBB2* amp and PD-L1 positivity predicted response (24% vs. 0% [p = .0655] and 36% vs. 5% [p = .0367], respectively). In ctDNA *ERBB2*+/PD-L1+ pts, which were all GC, the ORR was 57% and DCR 86%. **Conclusions:** M+P is a well-tolerated regimen with antitumor activity in 2nd line HER2+ GEA. Consistent with prior tissue-based reports, many GEA pts progressing on T have lost *ERBB2*amp. *ERBB2* status by ctDNA NGS post-T could predict response to M+P, particularly in PD-L1+ pts. Our results suggest that M+P has encouraging preliminary activity in patients with advanced GC, and that biomarker selection based on ctDNA *ERBB2* and PD-L1 could enrich for the responding population. Clinical trial information: NCT02689284.

4031 Poster Session (Board #220), Sun, 8:00 AM-11:30 AM

Safety and efficacy of durvalumab in combination with tremelimumab, durvalumab monotherapy, and tremelimumab monotherapy in patients with advanced gastric cancer. *First Author: Ronan Joseph Kelly, Johns Hopkins Medicine, Baltimore, MD*

Background: The combination of durvalumab (D; anti–PD-L1) and tremelimumab (T; anti–CTLA-4) has the potential to amplify T-cell responses against tumors through immune checkpoint blockade, resulting in antitumor activity. **Methods:** This is an ongoing Phase Ib/II study in patients (pts) with metastatic or recurrent gastric or gastroesophageal junction carcinoma. An initial safety run-in was conducted in 6 pts who received D 20 mg/kg and T 1 mg/kg IV Q4W for 4 cycles followed by D 10 mg/kg Q2W for ≤12 mo. For Phase II expansion, all pts were immunotherapy naive and had progressed after systemic platinum- or fluoropyrimidine-based chemotherapy. Second-line (2L) pts were randomized 2:2:1 to D+T, D 10 mg/kg Q2W up to 12 mo, or T 10 mg/kg Q4W for 7 doses then Q12W for 2 doses. Third-line (3L) pts received D+T. Tumor cell PD-L1 expression was assessed by IHC (Ventana SP263). **Results:** As of Sept 13, 2017, 58 pts received D+T (35% PD-L1 > 1%), 24 pts received D (38% PD-L1 > 1%), and 12 pts received T (50% PD-L1 > 1%); median duration of follow-up was 9.2, 3.5, and 9.2 mo, respectively. Drug-related grade 3/4 adverse events (AEs) occurred in 17 pts (29%) who received D+T; most frequent was colitis (5%). Six (50%) and 4 (17%) pts had grade 3/4 AEs related to T or D alone, respectively. Ten pts (17%) who received D+T discontinued due to drug-related AEs; most frequent was colitis (5%). One pt (4%) with D and 4 pts (33%) with T discontinued due to drug-related AEs. There were no drug-related deaths. In the T cohort, 1 pt (8%) had a confirmed PR; progression-free survival (PFS) and overall survival (OS) rates are not presented due to small sample size. Clinical activity in the other cohorts is shown below. **Conclusions:** D+T has a manageable safety profile in 2L and 3L advanced gastric cancer, with encouraging OS versus D monotherapy. Clinical trial information: NCT02340975.

	2L D+T n = 27	3L D+T n = 25	2L D n = 24
Confirmed + unconfirmed ORR, n (%)	3 (11.1)	3 (12.0)	2 (8.3)
95% CI	2.4–30.2	3.0–36.3	1.5–36.4
DCR—8 wk, n (%)	12 (44.4)	11 (44.0)	3 (12.5)
95% CI	25.5–64.7	24.4–65.1	2.7–32.4
Median PFS (95% CI), mo	1.8 (1.6–3.3)	1.8 (1.6–3.5)	1.6 (1.0–1.8)
Median OS (95% CI), mo	9.2 (4.2–12.8)	10.6 (4.8–17.0)	3.2 (1.7–4.4)

4032 Poster Session (Board #221), Sun, 8:00 AM-11:30 AM

Safety and clinical activity of durvalumab monotherapy in patients with gastroesophageal cancers. *First Author: Antoine Hollebecque, Gustave Roussy Cancer Campus, Villejuif Cedex, France*

Background: PD-(L)1 checkpoint blockade has shown clinical benefits in gastroesophageal (GE) cancers. Durvalumab, a selective, high-affinity, engineered human immunoglobulin G1 anti-PD-(L)1 monoclonal antibody, has demonstrated durable clinical activity and a manageable safety profile in multiple tumor types. Here we present the first report of safety and activity in the GE cohort of the dose-expansion portion of an ongoing Phase I/II, multicenter, open-label study. **Methods:** Patients with histologically or cytologically confirmed GE cancers received durvalumab 10 mg/kg IV Q2W for 12 months or until unacceptable toxicity or disease progression. The primary objective was safety. A secondary objective was antitumor activity (investigator-assessed by RECIST v1.1). **Results:** As of Oct 16, 2017, 51 patients received durvalumab with median follow-up of 41.3 months (range, 1.3–49.2). 98% had received prior treatment, including 69% with ≥2 prior therapies (39% with ≥3 prior therapies). 7.8% completed the 12-month treatment period. Treatment-related adverse events (TRAEs) occurred in 56.9% of patients, most commonly fatigue (35.3%), nausea (13.7%), and diarrhea (13.7%). Grade 3–4 TRAEs were reported in 15.7% of patients (none immune-related), most commonly fatigue (11.8%) and vomiting (3.9%). TRAEs led to dose delays or interruptions in 7.8% of patients. There were no serious TRAEs or TRAEs leading to discontinuation or death. Confirmed overall response rate was 3.9% (2 patients; 1 complete response [CR] and 1 partial response [PR], both of which were ongoing at data cutoff; duration of response 9.7+ to 27.0+ months). Disease control rate 24 (CR + PR + stable disease ≥24 weeks) was 11.8% (95% CI, 4.4–23.9) and median time to response was 3.27 months (95% CI, 2.9–3.6). Median PFS was 1.4 months (95% CI, 1.2–2.4) and the 6-month rate was 9.5%; median overall survival was 4.9 months (95% CI, 2.6–9.1) and the 12-month rate was 31.9%. **Conclusions:** Findings are consistent with earlier reports from this and other studies; durvalumab showed a tolerable safety profile and evidence of antitumor activity in this mostly second line+ cohort of GE cancer patients. Clinical trial information: NCT01693562.

4033 Poster Session (Board #222), Sun, 8:00 AM-11:30 AM

A phase II study of perioperative intraperitoneal paclitaxel plus S-1/paclitaxel for curatively resectable gastric cancer with serosal invasion: The GAPS study. *First Author: Seiji Ito, Aichi Cancer Center Hospital, Aichi, Japan*

Background: The prognosis of gastric cancer with serosal invasion is extremely poor. Despite various perioperative adjuvant therapies, peritoneal recurrence is still difficult to control. Since the clinical efficacy of intraperitoneal (IP) paclitaxel (PTX) was suggested for the treatment of gastric cancer with peritoneal metastasis and positive cytology, IP PTX is a promising strategy for curatively resectable gastric cancer with serosal invasion. This multicenter, phase II study evaluated the efficacy and safety of IP PTX plus S-1/PTX for this target. **Methods:** Eligibility criteria included pathologically confirmed gastric adenocarcinoma with serosal invasion, but no peritoneal or distant metastases. Patients received three courses of preoperative IP PTX plus S-1/PTX (IP PTX 20 mg/m^2, intravenous PTX 50 mg/m^2 on days 1 and 8, and S-1 80 mg/m^2/day on days 1-14, q3 weeks) followed by D2 gastrectomy, and they then received three courses of IP PTX plus intravenous PTX postoperatively. The primary endpoint was the proportion of the completion of protocol treatment (% protocol completion). Secondary endpoints were safety, overall survival, and the response rate (RR). The sample size was calculated to be 50 cases, under the hypothesis of expected % protocol completion of 80% and threshold % protocol completion of 60% with one-sided testing at the 2.5% significance level and power of 80%. **Results:** Between May 2014 and August 2016, 51 patients were enrolled. Among the 51 eligible patients with a median age of 66 years, 41 completed the protocol treatment (80.4% completion; 95% confidence interval 66.9–90.2%, p = 0.0016). During perioperative chemotherapy, grade 3/4 neutropenia occurred in 31.4%, and grade 3/4 non-hematological adverse events occurred in 19.6%. The incidence of adverse events related to surgery was 19.1%. There were no treatment-related deaths. Follow-up for long-term survival is continuing. The clinical RR of preoperative chemotherapy was 71.4% (5/7). The pathological RR (residual tumor $<$ 2/3) was 68.1% (32/47). **Conclusions:** Perioperative IP PTX plus S-1/PTX is a safe and promising treatment for gastric cancer with serosal invasion. Clinical trial information: UMIN000013109.

4034 Poster Session (Board #223), Sun, 8:00 AM-11:30 AM

Lymph node ratio as a clinical determinant for selecting adjuvant chemotherapy regimen in curative D2 resected gastric cancer. *First Author: Jun-Eul Hwang, Department of Hemato-Oncology, Chonnam National University Hwasun Hospital, Hwasun, Republic of (South), Korea*

Background: Adjuvant chemotherapy in gastric cancer improves survival outcomes after curative D2 gastrectomy, especially in stage III. We investigated the clinical prognostic significance and usefulness of lymph node ratio (LNR: ratio between metastatic lymph nodes and examined lymph nodes) for selecting adjuvant chemotherapy regimen in D2 resected stage II/III gastric cancer. **Methods:** We reviewed the data of 741 patients who underwent curative D2 gastrectomy and received adjuvant chemotherapy. 275 patients received platinum-based chemotherapy, and 466 received TS-1 including oral 5-fluorouracil. The disease-free survival (DFS) was evaluated for the influence of LNR on the clinical outcomes, and the patients were categorized initially into 4 groups, according to LNR (0, $>$ 0-0.1, $>$ 0.1-025, $>$ 0.25), then group 0 and $>$ 0-0.1 were merged because of similar DFS of two groups (0-0.1, $>$ 0.1-0.25, $>$ 0.25). **Results:** The patients were well discriminated according to LNR irrespective of the adjuvant chemotherapy regimen and stage. On multivariate analysis, LNR was most potent independent prognostic factor for DFS (hazard ratio 2.589, 95% confidence interval 1.874-3.576, P $<$ 0.001). Platinum-based chemotherapy improved 3-year DFS compared with oral regimen (TS-1+oral 5-fluorouracil) in stage III and LNR $>$ 0.25 (P = 0.026). LNR $>$ 0.1 is the discriminant factor that favor platinum-base adjuvant chemotherapy in patients with combined stage III and lymphovascular invasion positivity (P = 0.037, platinum vs. oral regimen, median DFS: 46.867 vs. 21.767 months). **Conclusions:** The LNR has an important clinical prognostic significance, and the easily identifiable clinical determinant for selecting adjuvant chemotherapy regimen in gastric cancer patients underwent curative D2 resection, especially in stage III gastric cancer.

4035 Poster Session (Board #224), Sun, 8:00 AM-11:30 AM

Oxaliplatin, 5FU and nab-paclitaxel as neoadjuvant regimen in patients with resectable oesogastric adenocarcinoma: A GERCOR phase 2 study (FOXAGAST). *First Author: Sarah Sophie Watson, Institut Mutualiste Montsouris, Paris, France*

Background: Peri-operative chemotherapy is the standard of care in Resectable OesoGastric Adenocarcinoma (ROGA), with several validated regimens such as Cisplatin-5FU, FOLFOX, ECF/X, or FLOT. Nanoparticle-bound (Nab) paclitaxel is active in OGA. Tumor regression grade (TRG) is an objective parameter for assessing efficacy of neoadjuvant chemotherapy (NACT). The study objective was to evaluate TRG with Nab-paclitaxel combined with FOLFOX in ROGA patients (pts). **Methods:** HER2-negative ROGA pts over 18 yrs received Nab-paclitaxel (150mg/m2) and FOLFOX (oxaliplatin 85 mg/m2; 5FU 2400mg/m2 over 48h, and leucovorin 400mg/m2) on D1 q2w for 6 cycles in preoperative setting. 6 postoperative cycles were kept at investigator's discretion. Primary endpoint was pathological complete response rate (TRG1) after NACT. According to Fleming design 49 pts had to be included to test H0 (10% TRG1) and H1 (25% TRG1) with unilateral α of 5% and ß of 10%. To reject H_0, TRG1 had to be achieved in at least 8 pts. **Results:** 49 pts (36 male, median age 63.7 yrs, 53% N+) were included between 6/2015 and 3/2017. Median number of NACT cycles was 6 (range 3-6). Median dose-intensity was 96% (38-103), 97% (47-103) and 99% (50-112) for Nab-paclitaxel, oxaliplatin, and 5FU, respectively. Surgery could not be performed in 5 (10.2%) pts due to tumor progression or poor performance status. Tumor resection was R0 for 42/44 (95.5%) pts. Centrally blinded review classified tumors as TRG1 to TRG5 for 8 (16.3%), 11 (22.5%), 4 (8.2%), 18 (36.7%) and 3 (6.1%) pts, respectively. With a median follow-up of 14.2 m, 12 m-PFS was 88.4 % (95% CI: 74.2-95.0). Grade 3 or worse toxicities in NACT phase were non febrile neutropenia in 10 pts (20.4%), nausea in 4 (8.2%), diarrhea in 4 (8.2%) and neuropathy in 3 (6.1%). 14/44 (31.8%) pts experienced per or post-operative complications, including fistulas (5 pts), ischemic complications (4), infections (3), and anesthesia-related complications (2). 3/44 (6.8%) pts died from surgical complications. **Conclusions:** This regimen shows promising activity in ROGA with a high rate of TRG1/TRG2 responses. Toxicity is manageable but a high rate of surgical complications was observed. Clinical trial information: NCT02486601.

4036 Poster Session (Board #225), Sun, 8:00 AM-11:30 AM

Randomized, double-blind, phase 2 study of S-1 plus oxaliplatin (SOX) with or without ramucirumab (RAM) as first-line therapy followed by paclitaxel plus RAM as second-line therapy in patients with advanced gastric or gastroesophageal junction adenocarcinoma (AGC). *First Author: Kei Muro, Department of Clinical Oncology, Aichi Cancer Center Hospital, Nagoya, Japan*

Background: RAM (a human IgG1 antibody against vascular endothelial growth factor receptor-2) plus paclitaxel has been found to improve overall survival compared with paclitaxel alone as second-line therapy in patients with AGC. This Asian phase 2 study (RAINSTORM) assessed whether adding RAM to SOX as first-line therapy could improve progression-free survival (PFS). **Methods:** Chemotherapy-naive patients with AGC were randomized to receive SOX (S-1: 80-120 mg/day, twice daily, Days 1-14; oxaliplatin: 100 mg/m^2, Day 1) with RAM (8 mg/kg, Days 1, 8) or placebo (PBO; Days 1, 8) in Part A (21-day cycle); patients received paclitaxel (80 mg/m^2, Days 1, 8, 15) and RAM (8 mg/kg, Days 1, 15) in Part B (28-day cycle). PFS (primary endpoint), objective response rate (ORR), disease control rate (DCR), and safety for Part A are reported. The PFS hazard ratio (HR) was estimated using a stratified Cox regression model, with a stratified log-rank test *P*-value of $<$ 0.2 interpreted as RAM+SOX being a useful regimen for first-line therapy in patients with AGC. **Results:** RAM+SOX (n = 96) did not show an improvement in PFS compared with PBO+SOX (n = 93) (median PFS: RAM+SOX, 6.34 months; PBO+SOX, 6.74 months; HR [80% CI]: 1.07 [0.86, 1.33]; *P* = 0.698). Among patients with measurable disease, the ORR was 58.2% and 50.0% (odds ratio [80% CI]: 1.37 [0.84, 2.24]; *P* = 0.402), and the DCR was 90.9% and 87.0% (odds ratio [80% CI]: 1.53 [0.68, 3.43]; *P* = 0.501), in the RAM+SOX (n = 55) and PBO+SOX (n = 54) arms, respectively. The most common treatment-emergent adverse events in both arms were peripheral sensory neuropathy (RAM+SOX: 58.3%; PBO+SOX: 75.3%), decreased appetite (56.3%; 62.4%), and nausea (56.3%; 39.8%). The most common adverse events of special interest in the RAM+SOX arm (vs PBO+SOX arm) were bleeding/hemorrhage events (37.5% vs 23.7%), hypertension (29.2% vs 12.9%), and proteinuria (25.0% vs 15.1%). **Conclusions:** Addition of RAM using a new scheduling regimen (8 mg/kg, Days 1 and 8 every 21 days) to a standard SOX regimen did not improve PFS in patients with AGC. Clinical trial information: NCT02539225.

4037 Poster Session (Board #226), Sun, 8:00 AM-11:30 AM

Psychiatric comorbidities among esophageal cancer survivors in South Korea: A nationwide population-based, longitudinal study. *First Author: Jaesung Heo, Department of Radiation Oncology, Ajou University School of Medicine, Suwon, Korea, Republic of (South)*

Background: Esophageal cancer has a relatively poor prognosis (< 15% overall 5-year survival), owing to a lack of initial symptoms and delayed diagnosis. Also, patients with this fatal cancer tend to have a high rate of mental disorders. The psychological problems can affect treatment compliance and could increase mortality in cancer survivors. **Methods:** The aim of this longitudinal study was to analyze the prevalence of mental disorders in esophageal cancer survivors using claims data in South Korea. We confirmed mental disorders in a nationwide cohort of 8,879 patients who were diagnosed with esophageal cancer between January 1, 2010 and December 31, 2014. We categorized the prevalence of mental disorders based on the age and the time of diagnosis. **Results:** In esophageal cancer, a total of 738 patients were diagnosed with a mental disorder, 1 year prior to the cancer treatment. Of those patients, 231 were diagnosed with depression (31.3%) and 245 with anxiety (33.2%) during their first visit. The overall frequency of mental disorders peaked within 2 months after the cancer treatment. The highest rate of increase after treatment was confirmed in stress reaction/adjustment disorders. Age and sex was a significant predictive factor for mental disorders ($p < 0.05$). Female patients were at a higher risk for mental disorders (hazard ratio: 1.30, $p = 0.002$), whereas patients with initial treatment as surgery were more likely to have mental disorders compared with radiotherapy (hazard ratio: 1.33, $p < 0.001$). **Conclusions:** Mental disorders in esophageal cancer survivors showed different patterns of prevalence depending on the nature of disease. Timely diagnosis and intervention for psychological distress could increase the quality of life for esophageal cancer survivors.

The frequency of mental disorders in esophageal cancer survivors (N = 8,879).

Age	Total number of esophageal cancer	Mental disorder	Substance abuse	Depressive disorder	Anxiety disorder	Stress/ adjustment disorder	Somatoform/ conversion disorder
10-39	25	2	1	1	0	0	0
40-49	367	34	14	7	8	3	2
50-59	2,072	174	51	53	41	9	20
60-69	3,212	285	50	83	91	29	32
70-99	3,203	243	13	87	92	22	29
Total	8,879	738	129	231	232	63	83

4038 Poster Session (Board #227), Sun, 8:00 AM-11:30 AM

Multicenter observational study on re-evaluation of HER2 status in patients with HER2-positive advanced or recurrent gastric cancer refractory to trastuzumab. *First Author: Tomomi Kashiwada, Division of Hematology, Respiratory Medicine and Oncology, Department of Internal Medicine, Faculty of Medicine, Saga University, Saga, Japan*

Background: Addition of trastuzumab to cisplatin and fluoropyrimidine-based doublet chemotherapy is the standard first-line treatment for patients with human epidermal growth factor receptor 2 (HER2)-positive advanced or recurrent gastric cancer. However, second-line anti-HER2 therapy did not demonstrate a survival advantage. We assessed the change in HER2 status in cases of HER2-positive gastric cancer refractory to trastuzumab, and analyzed potential biomarkers associated with resistance to trastuzumab. **Methods:** Key inclusion criteria were as follows; advanced or recurrent gastric adenocarcinoma with HER2-positive status (IHC3+ or IHC2+ with FISH amplification) before trastuzumab treatment; radiologically or clinically diagnosed with progressive disease following trastuzumab treatment; pathologically confirmed adenocarcinoma within 3 months following completion of trastuzumab treatment without receipt of any other anti-tumor agents. We collected biopsy samples from patients who had developed resistance to trastuzumab and evaluated HER2 status before and after. Amplification of EGFR and c-met, as well as PIK3CA mutation were also comparatively analyzed if samples were available. **Results:** Biopsy samples and clinical data were collected from 33 eligible patients as the full analysis set. HER2 loss was identified in 20 patients (60.6%) with refractory disease. IHC showed that HER2 overexpression was remarkably decreased after treatment (pre-HER2 IHC 3+: 24 [72.7%]; 2+: 9 [27.3%] vs. post-HER2 3+: 13 [39.4%]; 2+: 1 [3.0%]; 1+: 18 [54.5%]; 0: 1 [3.0%]). EGFR amplification, c-met amplification, and PIK3CA gene mutation before and after trastuzumab treatment was observed in 7.7% and 4.2%, 15.8% and 6.7%, and 6.3% and 7.1% of cases, respectively. **Conclusions:** HER2 loss occurred in a considerable number of patients who were initially diagnosed with HER2-positive gastric cancer, resulting in resistance to trastuzumab. EGFR, c-met and PIK3CA were rarely associated with acquired resistance. Re-evaluation of HER2 status might provide valuable clues with regard to anti-HER2 targeted therapy beyond disease progression.

4039 Poster Session (Board #228), Sun, 8:00 AM-11:30 AM

Development of non-hematological adverse events in apatinib-treated gastric cancer and their association with clinical outcome: Results from a phase IV study. *First Author: Yi Ba, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China*

Background: Ahead-G201, a multicenter Phase IV study, is conducting to evaluate apatinib as third-line or beyond therapy in a routine practice setting of gastric cancer patients (pts). **Methods:** This analysis was undertaken to evaluate the non-hematological adverse events (AEs), and to explore their potential associations with survival. **Results:** This analysis was based on 1468 pts as of 12/21/2017. The most common non-hematological AEs were hypertension (HTN; 22.8%), proteinuria (PTN; 18.1%), fatigue (16.7%), diarrhea (11.9%) and hand-foot-skin reaction (HFSR; 9.7%), irrespective of the relationship with medication. They were not correlated with progression free survival (PFS); however, pts with diarrhea or HFSR had a statistically longer overall survival (OS) (8.41 *vs.* 6.14 mos, $p = 0.0048$; 8.31 *vs.* 5.98 mos, $p < 0.0001$) (Table). After adjusting for baseline characteristics and treatment dose, presence of HFSR was an independent predictor for prolonged OS (HR: 0.62 [95%CI, 0.44–0.88]). Besides, we assessed hepatotoxicity and cardiotoxicity in pts. 269 (18.3%) pts who developed hepatotoxicity had a statistically longer PFS (4.70 *vs.* 3.38 mos; $p = 0.0458$). A low incidence of cardiotoxicity (2.1%) was detected, and it was not related to survival. **Conclusions:** Occurrence of HFSR could be an effective prognostic factor for OS in apatinib-treated gastric cancer pts, whereas hepatotoxicity might predict PFS. Clinical trial information: NCT02426034.

Relationship between non-hematological AEs and survival.

4040 Poster Session (Board #229), Sun, 8:00 AM-11:30 AM

Role of neoadjuvant chemotherapy or chemoradiotherapy in oesophageal carcinoma. *First Author: Herui Yao, Guangdong Provincial Key Laboratory of Malignant Tumor Epigenetics and Gene Regulation, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China*

Background: The role of neoadjuvant chemotherapy (NAC) or chemoradiotherapy (NACR) in patients with oesophageal carcinoma continues to be debated. This study aimed to assess the comparative efficacy and safety of NAC or NACR for oesophageal carcinoma. **Methods:** Randomized clinical trials reporting on NAC or NACR with local operable oesophageal carcinoma were identified. The primary endpoint was overall survival (OS). All trial results were combined and analysised using a fixed or random-effects meta-analysis. Quality of evidence was appraised with GRADE criteria. The PROSPERO registry number is CRD42017072242. **Results:** 40 trials with 8,393 patients were included. High-quality evidence indicated that NAC was associated with a significant benefit on OS (hazard ratio [HR] 0.86, 95% CI 0.80 to 0.92; $P = 0.000$) and relapse-free survival (RFS) (HR 0.78, 95% CI 0.72 to 0.84; $P = 0.000$) versus surgery alone, with an absolute difference at 5 years of 10% (6 to 13), and the treatment effect on survival was especially in favor of adenocarcinoma (HR 0.81, 0.72 to 0.91), but no significant difference in squamous-cell carcinoma (SCC) (HR 0.93, 0.81 to 1.08). High-quality evidence revealed that treatment with NACR, as compared with surgery alone, prolonged OS (HR 0.74, 95% CI 0.67 to 0.81; $P = 0.000$) and RFS (HR 0.74, 95% CI 0.65 to 0.84; $P = 0.000$), corresponding to an absolute difference at 5 years of 14% (9 to 20), with similar survival for different histological types of tumor: 0.73 (0.65 to 0.83) for SCC and 0.73 (0.62 to 0.93) for adenocarcinoma. There was moderate-quality evidence that the overall direct and indirect comparison of NACR with NAC showed a survival advantage (HR 0.83, 95% CI 0.73 to 0.94; P = 0.004), with results for SCC (HR 0.74, 0.63 to 0.89) and for adenocarcinoma (HR 0.89, 0.74 to 1.10). **Conclusions:** This study confirmed that a significant clinical benefit is evident for NACR in both adenocarcinomas and SCC of the esophagus, and NAC in patients with adenocarcinoma of the oesophagus. To our knowledge, this is the first evidence-based finding which provided advantage of NACR over NAC in patients with oesophageal carcinoma.

4041 Poster Session (Board #230), Sun, 8:00 AM-11:30 AM

Laparoscopy-assisted versus open D2 distal gastrectomy for advanced gastric cancer: Five year overall survival and morbidity results from a randomized phase II multicenter clinical trial (COACT 1001). *First Author: Young Woo Kim, National Cancer Center, Goyang, Korea, Republic of (South)*

Background: For advanced gastric cancer (AGC), D2 gastrectomy is the standard treatment. However, a laparoscopic D2 gastrectomy(LG) is technically challenging surgery. Our previous report of COACT 1001 study, which is randomized phase II study to evaluate the feasibility of LG compared with open surgery(OG) for AGC, showing primary endpoint of non-compliance of lymph node dissection and three-year disease-free survival supported role of LG for AGC. Herein we report five-year overall and disease-free survival outcome of the study. **Methods:** Patients with cT2-T4a and cN0-2 (AJCC 7th staging system) distal gastric cancer were randomly but not blindingly assigned to LG or OG groups. Patients were followed up for recurrence and survival for 5 years. **Results:** Between Jun 2010 and Oct 2011, 204 patients were enrolled and underwent either LADG (n = 105) or ODG (n = 99). Of those, 196 patients (100 in LADG and 96 in ODG) were included in the intention-to-treat analysis. There were no significant differences in the five-year overall survival between LG and OG groups (85.1% vs 84.1%, respectively; p = 0.749). In the subgroup analysis, five-year overall survival was not different in between the groups according to the clinical stage (stage I: 95.7 % vs 95.5 %; p = 0.988, stage II: 96.1 % vs 84.6 %; p = 0.057, stage III: 48.3 % vs 74.1 %; p = 0.156) and pathological stage (stage I: 97.5 % vs 94.4 %; p = 0.512, stage II: 100 % vs 90.8 %; p = 0.099, stage III: 48.7 % vs 72.7 %; p = 0.151, stage IV: 100 % vs 0 %; p = 0.18). Five-year disease-free survival also was not significantly different between two groups (74.5 % vs 78.7 %, respectively; p = 0.604). The trend of overall and disease-free survival was favorable for LG in stage II but OG in stage III. **Conclusions:** LG was feasible for AGC based on the five-year overall and disease-free survival rate. Further research should be done in large scale for stage III gastric cancer. Clinical trial information: NCT01088204.

4042 Poster Session (Board #231), Sun, 8:00 AM-11:30 AM

International retrospective cohort study of conversion therapy for stage IV gastric cancer 1 (CONVO-GC-1). *First Author: Masanori Terashima, Shizuoka Cancer Center, Nagaizumi, Japan*

Background: In spite of the recent advancement of palliative chemotherapy for stage IV gastric cancer (GC), its median survival time (MST) still remains around 13 to 16 months. Much attention has been paid to conversion therapy, however, its definition, operative indication nor survival benefit has not been demonstrated so far. CONVO-GC-1, a retrospective international cohort study, was designed to investigate the role of conversion surgery in Japan, Korea and China. **Methods:** Conversion therapy of GC was defined as a surgical treatment aiming at an R0 resection after chemotherapy, for tumors that were originally technically and/or oncologically unresectable or marginally resectable. Primary endpoint was the rate of operative complications (Clavien Dindo Grading) and the secondary endpoint was overall survival (OS) according to the 4 category criteria which we have previously published (Gastric Cancer:19; 2016.) (Category 1: resectable metastasis. Category 2: marginally resectable metastasis. Category 3: Macroscopically peritoneal dissemination. Category 4: non-curable metastasis with peritoneal and other organ metastasis.) **Results:** 1902 patients from 55 institutions were enrolled and 1206 patients (category 1: 206, category 2: 583, category 3:300, category 4: 117) were performed surgery after chemotherapy with curative intent. Operative complications were observed in 290 (24.0%) in all grade including pancreatic fistula and SSI etc, which were consistent with other studies (category 1: 19.9%, category 2:29.0%, category 3:18.3%, category 4: 21.4%). The MST of all resected patients were 36.7M (category 1: 42.4 M, category 2: 38.7 M, category 3: 33.4 M, category 4: 34.1 M). The MST of R0 resected patients was 56.6 M (category 1: 49.1 M, category 2: 82.2 M, category 3: 44.9 M, category 4: not reached) and R1 was 25.8 M (category 1: 26.8 M, category 2: 20.3 M, category 3: 30.4 M, category 4: 23.4 M) and R2 was 21.7 M (category 1: 25.0 M, category 2: 22.1 M, category 3: 18.5 M, category 4: 23.5 M), respectively. **Conclusions:** Conversion therapy for stage IV GC is a safe and might be a new therapeutic strategy to improve the survival of the patients, especially with R0 resection. Clinical trial information: UMIN000022321.

4043 Poster Session (Board #232), Sun, 8:00 AM-11:30 AM

Association between *Helicobacter pylori* infection and outcome in advanced gastric cancer patients treated with S-1 adjuvant chemotherapy. *First Author: Satoshi Nishizuka, Iwate Medical University School of Medicine, Morioka, Japan*

Background: The beneficial and deleterious effects of *Helicobacter pylori* (*H. pylori*) infection remain to be fully elucidated. A clear understanding of the infectious mechanism is crucial since the potential effect may result in a survival benefit for life-threatening diseases. To understand the potential beneficial effect in advanced gastric cancer, we analyzed survival for patients treated with surgery-only or adjuvant chemotherapy on the basis of *H. pylori* infection status. **Methods:** A cohort of 491 patients who underwent R0 resection for locally-advanced gastric cancer between 2000 and 2009 at 12 institutions in northern Japan from the Northern Japan Gastric Cancer Consortium was included. *H. pylori* infection status was assessed from paraffin-embedded formalin-fixed samples. Overall survival (OS) and disease-free survival (DFS) in surgery-only (Surgery) and adjuvant chemotherapy (S-1) groups were analyzed. A propensity score matching was employed to correct for confounding factors by indication. To evaluate the local immune response from the immune-evasion status of the tumor, immunostaining of Programmed Death-Ligand 1 (PD-L1) protein was performed with PharmDx antibody clone 22C3. **Results:** *H. pylori* infection was positive in 175 patients and negative in 316 patients. *H. pylori*-positive patients showed significantly better survival than *H. pylori*-negative patients in both OS [hazard ratio (HR) 0.59, 95% confidence interval (CI) 0.42-0.84; $p = 0.003$)] and DFS (HR 0.68, 95% CI 0.49-0.94; $p = 0.018$). There were no significant interactions between *H. pylori* infection status and the clinicopathological background except for S-1 doses in DFS ($p = 0.0482$). Propensity score matching further confirmed that S-1 was virtually only effective when tumors were *H. pylori*-positive. The PD-L1 protein expression pattern suggests that *H. pylori*-positive status confers an advantage that might suppress immune-evasion of tumor cells. **Conclusions:** The favorable outcome of *H. pylori*-positive patients suggests that the host immune system is modulated by *H. pylori* enhancing postoperative chemotherapeutic efficacy (NCT01905969).

4044 Poster Session (Board #233), Sun, 8:00 AM-11:30 AM

Effect of post-discontinuation therapy (PDT) on survival in metastatic gastric-gastroesophageal junction (G-GEJ) adenocarcinoma patients from the RAINFALL trial: An exploratory analysis. *First Author: Kohei Shitara, National Cancer Center Hospital East, Kashiwa, Japan*

Background: The global, randomized, placebo (PL)-controlled phase 3 RAINFALL trial evaluated if addition of ramucirumab (RAM) to first-line (1L) cisplatin plus fluoropyrimidine (chemo) improved survival. Imbalances in PDT (including cross over) could confound OS analysis comparison of 1L therapies. We report the PFS & OS, as previously disclosed at ASCO-GI 2018, and investigated the impact of PDT on survival in a post-hoc analysis. **Methods:** Study blinding was continued until final OS data-lock. Investigators could choose any treatment for PDT. To compare OS from randomization as well as from the start of second-line (2L) treatment (Landmark OS), PDT were categorized into RAM or Non-RAM containing, RAM+paclitaxel(PTX), or All Others. Analyses were stratified by ECOG PS, primary tumor location, disease measurability & geographic region. **Results:** 326 pts were randomized to chemo+RAM (8 mg/kg iv D1, D8, every 21d) & 319 pts to chemo+PL (ITT, *N*= 645). The primary endpoint of investigator-assessed PFS was met (HR, 0.75; 95% CI 0.61–0.94; p = 0.011; median, 5.7 vs 5.4 mo) while no OS benefit was observed (HR, 0.96; 95% CI 0.80–1.16; p = 0.68; median, 11.2 vs 10.7 mo). 150 pts (46%) in the RAM arm received PDT compared to 164 (51%) in the PL arm. Subgroup results are summarized in Table. **Conclusions:** PDT use was balanced in both arms. OS from Randomization and Landmark OS is numerically higher in patients who received RAM containing PDT compared to Non-RAM PDT. Despite the small sample size, the results are consistent with previously demonstrated OS benefit with RAM+PTX as 2L therapy. Clinical trial information: NCT02314117.

Summary of PDT* Results (any subsequent line).

	Median months, (95% CI)	(*n*)	Median months, (95% CI)	(*n*)
	All PDT pts		**All Non-PDT pts**	
OS from Randomization	13.4 (12.8, 15.2)	*314*	7.1 (6.5, 7.8)	*331*
OS from Randomization	**RAM Containing**		**Non-RAM Containing**	
1L RAM	16.2 (11.7, 19.4)	*40*	13.2 (11.9, 16.3)	*110*
1L PL	14.9 (12.6, 18.9)	*53*	13.0 (11.4, 15.0)	*111*
Landmark OS	**RAM + Paclitaxel**		**All Others**	
1L RAM	9.6 (6.0, 14.6)	*37*	6.5 (5.7, 7.9)	*113*
1L PL	8.6 (5.2, 10.9)	*46*	6.8 (5.5, 7.8)	*117*

* = overall, the most frequent PDTs included: PTX, RAM, & irinotecan in both arms

4045 Poster Session (Board #234), Sun, 8:00 AM-11:30 AM

Trastuzumab plus docetaxel and capecitabine for first-line treatment of Her2-positive advanced gastric cancer: A phase II, multi-center, open-label, single-arm study. *First Author: Feng Wang, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Gastric cancer (GC) is one of the most common tumors in China. The ToGA study has shown trastuzumab in combination with fluoropyrimidine plus cisplatin prolonged overall survival (OS) in patients with HER2-positive advanced GC (AGC). Although docetaxel plus capecitabine (DX) is a standard regimen for AGC, combination of trastuzumab plus DX has not been studied. In this study, the efficacy and safety of trastuzumab in combination with DX was evaluated in Chinese patients with HER2-positive advanced GC. **Methods:** This phase II, multi-center, open label, single arm study enrolled patients with HER2-positive metastatic gastric or gastro-esophageal junction adenocarcinoma who have not received prior treatment for metastatic disease. Patients were treated with trastuzumab (8 mg/kg loading dose followed by 6 mg/kg on day 1), capecitabine (1000mg/m^2 twice daily, d1-14) and docetaxel (60mg/m^2 on day1 for 6 cycles), every 3 weeks. Primary endpoint is progression-free survival (PFS) and secondary endpoints are objective response rate (ORR), OS and toxicity profiles. **Results:** 67 patients with AGC were enrolled from 14 centers and 64 patients were in Full Analysis Set (median age 58, 73.4% male, 78.1% ECOG PS 1, 79.7% HER2 IHC 3+, 17.2% GE junction). Until November 2017, among 64 patients, the median PFS was 8.1 months (95 % CI: 5.6-12.8) and the median OS was 20.9 months (95 % CI: 15.1-33). Response was evaluated in 59 patients (5 missing in FAS), five patients achieved CR and thirty-five patients achieved PR, the ORR was 67.8%. In 67 patients who received at least one cycle of treatment, the most common adverse events of grade 3 or above were neutropenia (17.9%), leucopenia (19.4%), hand-foot syndrome (9%), febrile neutropenia (4.5%) and anemia (3%). **Conclusions:** Combination of trastuzumab and docetaxel/capecitabine is a well-tolerated and highly effective regimen in patients with HER2-positive advanced gastric cancer. Clinical trial information: NCT02004769.

4046 Poster Session (Board #235), Sun, 8:00 AM-11:30 AM

Randomized phase III trial of gastrectomy with or without neoadjuvant S-1 plus cisplatin for type 4 or large type 3 gastric cancer: Japan Clinical Oncology Group study (JCOG0501). *First Author: Yoshiaki Iwasaki, Department of Surgery, IMS Tokyo-Katsushika General Hospital, Tokyo, Japan*

Background: Schirous type cancer, such as linitis plastica (type 4) or large (> = 8 cm) ulcero-invasive-type (type 3) gastric cancer (GC) is characterized by poorly differentiated adenocarcinoma including signet-ring cell histologically and by frequent peritoneal dissemination clinically. Based on the promising results in our previous phase II study (JCOG0210) evaluating neoadjuvant chemotherapy (NAC) with S-1 plus cisplatin (CDDP), we proceeded to phase III study to confirm the efficacy of NAC in these subtypes of GC. **Methods:** Eligibility criteria included histologically proven adenocarcinoma of the stomach; clinically resectable gastric cancer of type 4 or large type 3. Patients were randomized to surgery followed by adjuvant chemotherapy (S-1, days 1–28, q42 days for 1 year) (Arm A) or NAC (S-1, 80–120 mg/body, days 1–21 and cisplatin, 60 mg/m2, day 8, q28, 2 courses) followed by gastrectomy plus same adjuvant chemotherapy (Arm B). Primary endpoint was overall survival (OS). A total of 300 eligible patients were required to detect 10% difference in 3-year OS (hazard ratio = 0.74) with a one-sided 5% significance level and power of 80%. OS for the two treatments arms will be compared using a stratified log-rank test. Results: Between February 2007 and July 2013, 300 patients (149 in Arm A, 151 in Arm B) were enrolled. 98 (65.7%) and 112 (74.2%) patients underwent R0 resection in Arms A and B, respectively. Surgery-related death occurred in two in Arm A and one in Arm B. In the Arm B, NAC was completed in 131 patients (86.8%) and Grade 3/4 non-hematological toxicities were seen in 36 patients (22.4%). Pathological response induced by NAC, defined as disappearance of the primary tumor more than one third, was observed in 51.0% (95% CI, 42.7 to 59.2). At the median follow-up of 4.5 years for the 300 patients, the 3-year OS was 62.4% (95% CI, 54.1 to 69.6) in Arm A and 60.9% (52.7 to 68.2) in Arm B. The hazard ratio of Arm B against Arm A was 0.916 (0.679 to 1.236; p = 0.284). OS of both groups were by far better than those reported in the past. The 3-year progression-free survival was 47.7% (95% CI, 39.4 to 55.4) in Arm A and 47.7% (39.5 to 55.4) in Arm B (hazard ratio 0.976, 95% CI 0.738 to 1.292). Conclusions: S-1 adjuvant chemotherapy for 1-year showed remarkable survival results for type 4 or large type 3 gastric cancer and additional NAC with S-1 plus CDDP is not recommended. Clinical trial information: C000000279.

4047 Poster Session (Board #236), Sun, 8:00 AM-11:30 AM

Preliminary result of phase 1/2 study of ramucirumab plus nivolumab in patients with previously treated advanced gastric adenocarcinoma (NivoRam study). *First Author: Daisuke Takahari, Department of Gastroenterology, Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo, Japan*

Background: Nivolumab (Nivo) has a significant survival benefit in salvage line of advanced gastric cancer (AGC) patients (pts) in ATTRACTION-2 trial. Based on synergistic anti-tumor effect induced by simultaneous blockade of PD-1 and VEGFR-2 in preclinical data, phase I/II study was conducted to investigate the safety and efficacy of Nivo plus ramucirumab (Ram) in the 2nd line chemotherapy for AGC. **Methods:** AGC pts with measurable lesions, ECOG PS 0-1, disease progression on 1st line chemotherapy containing platinum were eligible. Pts received Nivo (3mg/kg, Q2W) in combination with Ram (8mg/kg, Q2W) until unacceptable toxicity or disease progression. After feasibility was evaluated in six patients (phase I part), additional 40 patients were enrolled in a phase II part with the primary endpoint of a 6-months progression-free survival rate. Secondary endpoints included overall response rate, disease control rate, overall survival, and safety. PD-L1 tumor expression was assessed by immunohistochemistry (28-8 pharmDx assay) with a cut-off value for PD-L1 positivity set at 1% in tumor cells. **Results:** From 17-Jan-2017 to 31-Dec-2017, 46 AGC pts were enrolled. Patient characteristics were: median age 66 years, male 64%, ECOG PS1 40%, prior gastrectomy 35%, PD-L1 positive rate 44%. There were no dose limiting toxicities observed in phase I part. With median protocol treatment duration of 2.1 months, 40(87%) pts experienced any treatment-related AE (TRAE). Six (13%) pts had grade 3-4 TRAEs: hypertension (4%), hemorrhage (2%), colitis (2%), autoimmune pancreatitis (2%), liver dysfunction (2%), cholangitis (2%), hematoma (2%), and proteinuria (2%). There were no treatment-related deaths. Partial response was obtained in 10 (22%) pts with disease control rate (DCR) of 59%. With median follow-up time of 8.2 months, 20(44%) pts remain on treatment. **Conclusions:** Combination of Nivo and Ram showed no new safety signals and demonstrated promising antitumor activity in previously treated AGC. Clinical trial information: NCT02999295.

4048 Poster Session (Board #237), Sun, 8:00 AM-11:30 AM

Differential response to adjuvant chemotherapy based on Lauren subtype affects clinical outcome of gastric cancer: A cohort study and meta-analysis. *First Author: Kunning WANG, The First Hospital Affiliated to college of Medicine, Xi'an Jiaotong University, Xi'an, China*

Background: There remains significant questions on the efficacy of adjuvant chemotherapy for Lauren subtype of gastric cancer (GC). We aimed to clarify whether intestinal gastric cancer (IGC) patients have improved response to current chemotherapy regimens resulting in better survival when compared to diffuse gastric cancer (DGC) patients after adjuvant chemotherapy. **Methods:** A dataset comprising 8599 GC patients from 23 publications, combined with our cohort, was included in the meta-analysis. **Results:** In our cohort, the overall survival of IGC receiving adjuvant chemotherapy (chemoIGC) (median OS 5·01 years, IQR 2·63-6·71) was significantly higher than that of DGC receiving adjuvant chemotherapy (chemoDGC) (median OS 1·33 years, IQR 0·78-3·33, P = 0·0001). The HR for OS of the chemoIGC compared to chemoDGC was 0·27 (95% CI 0·13-0·52). There was a significant difference of OS between chemoIGC and IGC (HR 0·32, 95% CI 0·16-0·64, P = 0·001) whereas no difference between chemoDGC and DGC (HR 1·26, 95% CI 0·69-2·29, P = 0·46), indicating that IGC patients benefit more from adjuvant chemotherapy than DGC patients. After adjusting for age, gender and stage, adjuvant chemotherapy was an independent risk factor for survival in Lauren subtype of GC (HR for OS of the chemoIGC / chemoDGC 0·33, 95%CI 0·17-0·65, P < 0·001). Importantly, the meta-analysis results of 24 studies consisting of 4050 chemoIGC and 4549 chemoDGC patients indicated that chemoIGC showed significantly improved OS (HR 0·78; 95% CI, 0·72-0·84; P < 0·0001) and PFS (HR 0·80; 95% CI, 0·64-0·99; P = 0·04) comparing to similarly treated patients of chemoDGC. **Conclusions:** Our results support consideration of a change of clinical practice in the decisions related to administration of adjuvant chemotherapy for DGC patients. We found, DGC patients may not attain the same survival or efficacy as IGC from adjuvant chemotherapy. The Lauren subtype may be useful in treatment decisions in GC patients. We contend that Lauren classification and molecular subgroup should be used to stratify treatment regimens to GC patients, with particular relevance to diffuse subtype which is more difficult to treat with current regimens.

4049 Poster Session (Board #238), Sun, 8:00 AM-11:30 AM

Pembrolizumab for patients with previously treated metastatic adenocarcinoma or squamous cell carcinoma of the esophagus: Phase 2 KEYNOTE-180 study. *First Author: Manish A. Shah, Weill Cornell Medical College, New York Presbyterian Hospital, New York, NY*

Background: Effective therapy for patients (pts) with metastatic esophageal cancer progressing after at least 2 lines of prior therapy is an unmet need. The phase 2, open-label, KEYNOTE-180 (NCT02559687) study evaluated the activity of pembrolizumab (pembro) in pts with previously treated, advanced/metastatic adenocarcinoma (EAC) or squamous cell carcinoma (ESCC) of the esophagus or Siewert type 1 adenocarcinoma of the gastro-esophageal junction. **Methods:** Eligible pts with metastatic esophageal cancer, ≥2 prior lines of therapy, and tumor samples evaluable for biomarker expression, received pembro 200 mg Q3W for up to 2 years, or until disease progression, unacceptable toxicity, or withdrawal. Tumor response was assessed Q9W (RECISTv1.1, central review). PD-L1+ pts had combined positive score ≥10 using IHC (22C3 antibody). Primary endpoint was objective response rate (ORR). Secondary endpoints included safety, DOR, PFS, and OS. **Results:** Of 121 pts enrolled (Jan 12, 2016 to March 21, 2017), 100 (83%) were male, median age was 65 years (range 33-87), 63 (52%) had ESCC, and 58 (48%) had PD-L1+ tumors. As of September 18, 2017, median duration of follow-up was 5.8 mo (range, 0.2-18.3). ORR (CR+PR) was 10% (95% CI, 5%-17%); 12 (10%) pts had PR, 25 (21%) SD). Median DOR was not reached ([NR] range, 1.9+ mo to 14.4+ mo), and median PFS was 2 mo (95% CI, 1.9-2.1) with 6-mo PFS rate of 16% (95% CI, 10-23). Median OS was 5.8 mo (95% CI, 4.5-7.2) with 12-mo OS rate of 28% (95% CI, 20-37). In ESCC, ORR was 14% (95% CI, 7-25), and in EAC ORR was 5% (95% CI, 1-14). In PD-L1+ pts, ORR was 14% (95% CI, 6-25) and in PD-L1- pts ORR was 6% (95% CI, 2-16). Overall, 15 (12%) pts had treatment-related grade 3-5 AEs. Five (4%) pts discontinued due to a treatment-related AE. There was one treatment-related death from pneumonitis. **Conclusions:** Pembro provided durable clinical benefit with manageable safety for pts with heavily pretreated esophageal cancer. A phase 3 study, KEYNOTE-181 (NCT02564263), to evaluate the activity of pembro versus standard therapy in pts with metastatic esophageal carcinoma progressing after first-line therapy is ongoing. Clinical trial information: NCT02559687.

4050 Poster Session (Board #239), Sun, 8:00 AM-11:30 AM

The nationwide cancer genome screening project in Japan SCRUM-Japan GI-SCREEN: Efficient identification of cancer genome alterations in advanced gastric cancer (GC). *First Author: Satoshi Yuki, Department of Gastroenterology and Hepatology, Hokkaido University Hospital, Sapporo, Japan*

Background: We have conducted the Nationwide Cancer Genome Screening Project in Japan since April 2015 using Next Generation Sequencing in advanced non-colorectal gastrointestinal (GI) cancer (aNon-CRC), called as the SCRUM-Japan GI-SCREEN. **Methods:** Patients with aNon-CRC, who plan to or receive chemotherapy were eligible. DNA and RNA were extracted from FFPE tumor samples and were analyzed by the Oncomine Cancer Research Panel (OCP) which allows to detect gene mutation, copy number variant (CNV) and fusions across 143 genes in a CLIA certified CAP accredited laboratory. The detected genomic variant data were classified according to whether genetic drivers of cancer including gain- and loss-of-function or single nucleotide variant based on the Oncomine Knowledgebase. In this presentation, we show the results of advanced gastric cancer (aGC) cohort. **Results:** From April 2015 to March 2017, a total of 696 aGC samples from 20 cancer centers were analyzed. The sequence with the OCP was successfully performed in 513 (73.7%). The frequently detected mutations were *TP53* (47.8%), *PIK3CA* (9.2%), *KRAS* (6.0%), *SMAD4* (5.1%), *APC* (4.1%), *TET2* (3.9%), *ERBB2* (3.3%) and CNVs were *ERBB2* (11.3%), *CCNE1* (11.1%), *KRAS* (3.7%), *FGFR2* (3.3%), *ZNF217* (3.3%), MYC (2.7%), *CCND1* (2.3%) and *CDK6* (2.1%). *FGFR3-TACC3* fusion, *EGFR* vIII, *WIPF2-ERBB2* fusion, and *GOPC-ROS1* fusion were detected in 2, 2, 1, and 1 cases, respectively. Seven patients with druggable genomic alterations were enrolled for clinical trials of targeting therapies. We will show the clinical outcome based on certain key cancer genome alterations. **Conclusions:** This nationwide screening system is efficient to detect rare gene alterations in aGC. This novel knowledge provides an intriguing background to investigate new target approaches and represents a progress toward more precision medicine. This study is still ongoing with newer panel as Oncomine Comprehensive Assay version 3. Clinical trial information: UMIN000016344.

4051 Poster Session (Board #240), Sun, 8:00 AM-11:30 AM

A single-arm confirmatory study of definitive chemoradiotherapy (dCRT) including salvage treatment in patients (pts) with clinical (c) stage II/III esophageal carcinoma (EC) (JCOG0909). *First Author: Yoshinori Ito, Department of Radiation Oncology, Showa University School of Medicine, Tokyo, Japan*

Background: dCRT consisting of 5-fluorouracil (5-FU) and cisplatin (CDDP) with 60 Gy radiotherapy (RT) for cStage II/III EC is a standard treatment for pts refusing surgery (S) in Japan based on the previous trial (JCOG9906). However, poor survival, high incidence of late toxicities, and severe complications of salvage S are problems. We conducted this trial of CRT modifications including salvage treatment to reduce CRT toxicities and facilitate salvage treatment to improve survival. **Methods:** EC pts hoping esophagus preservation as initial treatment, with cStage II/III (UICC 6th, non-T4), PS 0-1, and age 20-75 years were eligible. Chemotherapy (CT) was CDDP (75 mg/m^2 on days 1, 29) and 5-FU (1000 mg/m^2/d on days 1-4, 29-32). RT was administered to a total dose of 50.4 Gy with elective nodal irradiation of 41.4 Gy. Good responders after dCRT received additional 1-2 cycles of CT. For residual or recurrent disease, salvage endoscopic resection (ER) or S was performed based on the prespecified criteria. The primary endpoint was 3-year OS. Key secondary endpoint was salvage treatment related toxicity. The sample size was 95, with one-sided alpha of 5% and power of 80%, expected and threshold 3-year OS as 55% and 42%. **Results:** From 4/2010 to 8/2014, 96 pts were enrolled, two were ineligible and 94 were included in efficacy analysis [M/F, 84/10; Age, median 63 (range 48-75); cStage IIA/IIB/III, 22/38/34]. Two cycles of CT and RT were completed in 93 pts (99%). Complete response was achieved in 55 pts (59%). Salvage ER and S were performed in 5 (5%) and 25 pts (27%). R0 resection of salvage S was achieved in 19 (76%). 3-year OS was 74.2% (90% CI 65.9-80.8%). 3-year progression-free survival and esophagectomy-free survival were 57.0% (95% CI 46.3-66.3%) and 63.6% (95% CI 52.9-72.4%). No complications occurred after salvage ER. Five pts (20%) showed ≥ grade 3 operative morbidities and 1 treatment related death due to bronchus-pulmonary artery fistula occurred after salvage S. Only 9 pts (9.6%) showed grade 3 late toxicities. **Conclusions:** This combined modality treatment of dCRT with salvage treatment could be a new standard treatment for cStage II/III EC. Clinical trial information: UMIN000003534.

4052 Poster Session (Board #241), Sun, 8:00 AM-11:30 AM

Comparison of clinical outcome and safety after minimally invasive esophagectomy: Ivor Lewis versus McKeown—A real-world multicenter observational study from China. *First Author: Yang Liu, Department of Thoracic Surgery,Chinese PLA General Hospital, Beijing, China*

Background: Ivor Lewis (Iv) and McKeown (Mc) are two commonly used minimally invasive esophagectomy. Currently, there are limited data to compare effectiveness and safety between Iv and Mc in China. **Methods:** We conduct the study based on a national collaborative prospective esophageal cancer (EC) database (designed by LinkDoc Technology Co, Ltd.).EC patients who underwent Iv or Mc esophagectomy from Jan.2010 to Jun.2017 and pathologically confirmed stage I~III with middle thoracic and lower thoracic esophagus were enrolled. Log-rank test was used in the comparison of the two surgery groups. And Cox's proportional hazard models and logistic regression were used in the factors analyses. **Results:** Total 1862 patients (1447 males and 415 females) were enrolled, mean age of 61.4.8±7.9. Among the patients, there were 97.2% squamous cell carcinoma, 1% adenocarcinoma and 1.8% others. 667 were performed with Iv esophagectomy and 1195 patients with Mc esophagectomy. Number of lymph nodes examined,mean was 14.4 ±9.02 in Iv group, compared with 21.5±11.57 in Mc group, $p< 0.05$. Recurrence rate was 12.3% in Iv group and 7.6% in Mc group, $p< 0.05$. The 5 years overall survival (OS) was 51% in Iv group and 59% in Mc group, $p< 0.05$. Multivariate analysis showed that risk factors for EC recurrence after esophagectomy include operation type (Iv vs Mc, odds ratio 1.70, CI 1.187-2.430), N stage and T stage, $p< 0.05$. Operation type (Ic vs Mc, HR 1.49, CI 1.153-1.928), N stage and T stage were hazard factors for OS in analysis of multivariate cox's proportional hazard models, $p< 0.05$. Especially, for the subgroup diagnosed as stage T3 at middle thoracic esophagus, Recurrence and OS were significantly different according to surgery type. Median blood loss was 300 mL in Iv group compared with 200 mL in Mc group, $p< 0.05$. Post-operative complications was significantly less in Iv group, $p< 0.05$. **Conclusions:** Our data showed that Mc is preferred with better lymphadenectomy, lower recurrence and improved survival compared with Iv, especially for patients diagnosed as stage T3 at middle thoracic esophagus. And Lv showed significantly less severe post-operative complications than Mc. Clinical trial information: ChiCTR1800014802.

4053 Poster Session (Board #242), Sun, 8:00 AM-11:30 AM

Final results of a phase 3 study of comparing paclitaxel plus 5-fluorouracil versus cisplatin plus 5-fluorouracil in chemoradiotherapy for locally advanced esophageal carcinoma (ESO-Shanghai 1). *First Author: Yun Chen, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: Concurrent chemoradiotherapy (CCR) with cisplatin plus 5-Fu (PF) regimen is a standard modality for locally advanced esophageal squamous cell carcinoma (ESCC) patients. This trial aimed to assess the efficacy and safety of the paclitaxel plus 5-Fu (TF) regimen versus PF regimen in CCR for ESCC patients. **Methods:** ESCC patients presenting with stage IIa to IVa were enrolled in a prospective multicenter phase 3 study. Patients were randomized to either TF or PF group. Patients in TF group were treated with 5 cycles of weekly TF (5-Fu 300 mg/m^2, civ 96h plus paclitaxel 50 mg/m^2, d1) in CCR followed by 2 cycles of monthly TF (5-FU 1800 mg/m^2, civ 72h, plus paclitaxel 175 mg/m^2 d1) in consolidation chemotherapy. Patients in PF group were treated with 2 cycles of CCR followed by 2 cycles of consolidation chemotherapy with PF (cisplatin 25 mg/m^2/d, d1-3, plus 5-Fu 1800 mg/m^2, civ 72h, q28d). The radiotherapy dose was 61.2 Gy delivered in 34 fractions. The primary end-point was the 3-yr OS. **Results:** 436 ESCC patients (217 assigned to TF group and 219 assigned to PF group) in 6 centers were recruited between April 2012 and July 2015. Median follow-up of patients who survived was 44.6 months [IQR 29.3–72.0]. The 3-yr OS was 57% in TF group and 51% in PF group (HR 0.91; 95% CI 0.69-1.18; P = 0.46). No significant differences were recorded in 3-yr DPFS or 3-yr LPFS between TF and PF groups (44.3% vs. 45.3% and 48.8% vs. 49.8%, respectively). TF group had a significant higher incidence of acute Grade 3/4 leukopenia (31.3% vs. 18.3%), dermatitis (5.1% vs. 1.4%), and pneumonitis (9.7% vs. 3.2%), and significant lower incidence of anemia (0.5% vs. 3.2%), thrombocytopenia (0.5% vs. 13.7%), fatigue (6.9% vs. 19.6%), anorexia (1.4% vs. 14.6%), nausea (1.4% vs. 14.2%), and vomiting (2.3% vs. 18.3%) than PF group ($P < 0.05$). There were 3 (1.4%) patients in TF group died of acute pneumonitis, 1 (0.5%) patient in TF group and 2 (0.9%) patients in PF group died of delayed pneumonitis. **Conclusions:** TF might be an option used in CCR in ESCC patients with a different type of side effects compared with PF, although it did not significantly prolong OS. Clinical trial information: NCT01591135.

4054 Poster Session (Board #243), Sun, 8:00 AM-11:30 AM

The activity of crizotinib in chemo-refractory MET-amplified esogastric adenocarcinomas: Results from the AcSé-crizotinib program. *First Author: Thomas Aparicio, Department of Gastroenterology, Saint Louis Hospital, Paris, France*

Background: Crizotinib (czb) is only registered for treating ALK and ROS1-translocated lung cancer. However, Czb is also a MET inhibitor. Several malignancies are characterized by MET amplification (amp). Czb activity in MET-amplified (+) tumors was explored within the French National Cancer Institute (INCa) AcSé program. This included access to tumor molecular diagnoses and an exploratory multi-tumor 2-stage design phase II trial. We herein report the results in patients (pts) with esogastric MET+ adenocarcinomas (adenoK). **Methods:** MET expression, on formalin-fixed, paraffin-embedded tumor samples, was screened in 127 centers and analyzed in 28 regional molecular genetic centers. MET+ was evaluated by FISH in tumor samples with IHC scores ≥2+. Pts with tumors showing > 6 MET copies, whatever the MET/CEN7 ratio, were eligible. Pts were treated with czb 250 mg BID. A two-stage Simon design was planned with a 90% power to detect an objective response rate (ORR) at 8 weeks (w) (CR+PR) above 30% against a 10% rate at the 10% level. The disease control rate (DCR) (CR+PR +SD) was assessed at 16 w. Responses were assessed every 8 w by RECIST v1.1. **Results:** From 08/2013 to 12/2017, MET was prospectively analyzed in 546 esogastric adenoK: amp were found in 33/546 adenoK (28/506 gastric and 5/40 esophagus). Eight pts were enrolled in the trial, median age was 62 years [44–80], WHO performance status 0 in 2 pts, 1 in 5 and 2 in 1 pt. At the cut-off date, 1 pt was still treated, 7 had stopped czb (5 PD, 2 adverse events (AEs)). Among the 7 pts evaluable for response at 8 w, we observed 3 PR and 1 SD, giving an ORR = 42.8% [6.1-79.4]. At 16 w, DCR = 50% [95% CI: 10-90] was achieved in 3/6 evaluable pts. Czb was well tolerated with only 6 grade ≥3 AEs or SAEs. The most common AEs, mainly grade 1, were anemia (87.5%), nausea (75%), hypocalcemia-edema-ASAT increase (62.5% for each), vomiting-constipation-fatigue-loss of appetite-visual disorders (50% for each). **Conclusions:** National biomarker-driven access to czb for MET+ esogastric adenoK pts is feasible. MET amp was observed in around 5% of gastric adenoK and 12% of the oesophagus adenoK. Preliminary results show Czb activity, with PR and SD, in MET+ esogastric adenoK. Clinical trial information: NCT02034981.

4055 Poster Session (Board #244), Sun, 8:00 AM-11:30 AM

PET scan-directed chemoradiation (CRT) for esophageal squamous cell carcinoma (ESCC): No benefit for salvage chemo in PET non-responders (PETnr). *First Author: Megan Greally, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Pre-operative or definitive CRT is standard for locally advanced (LA) ESCC. We previously showed that PET response after induction chemo and prior to CRT and surgery strongly predicts outcomes (Cancer 118:2820; 2012). The CALGB 80803 study also revealed a benefit for changing chemo during CRT in PETnr with E adenocarcinoma (J Clin Oncol 35:1, 2017 [abstr]). **Methods:** We retrospectively reviewed all pts with LA ESCC who received induction chemo and CRT; all had PET scan pre- and post-induction chemo. Survival was calculated from date of repeat PET using Kaplan-Meier analysis and compared between groups using the log-rank test. **Results:** 113 pts were identified, median age 64, median KPS 80%, 75% had uN+ disease. 63 (56%) received induction chemo with platinum/paclitaxel, 43 (38%) with platinum/irinotecan, 6 (5%) with docetaxel/irinotecan +/- cisplatin and 1(1%) with capecitabine/oxaliplatin. 72 pts (64%) were PET responders (PETr; ³35% decrease in mSUV of tumor) and 41 (36%) were PETnr; <35% decrease). All PETr received same chemo during RT. Of PETnr, 16 continued same chemo and 25 were changed to alternate chemo during RT. Of 106 pts evaluable for clinical complete response (cCR), 88% of PETr achieved cCR vs 57% of PETnr/no chemo change vs 60% of PETnr/chemo change ($p<0.01$ for PETr vs PETnr). The cCR rate was not significantly different in the PETnr/chemo change vs PETnr/no chemo change groups (p=0.86). 31 pts had resection, 30 R0; 8 had pathologic CR (7 were PETr and 1 was a PETnr/chemo change). Median progression-free (PFS; 62.1 vs. 7.1 mos, $p<0.01$) and overall survival (OS; 72.2 vs. 17.3 mos, $p<0.01$) were significantly better for PETr vs. PETnr. Median PFS and OS for PETnr/chemo change vs. PETnr/no chemo change were 6.4 vs 8.3 mos (p=0.48) and 14.2 vs 17.2 mos (p=0.79) respectively and not significantly different. **Conclusions:** PET scan after induction chemo highly predicts for outcomes in ESCC pts who received CRT. However, PETnr pts did not benefit from changing chemo during RT, likely reflecting underlying poor biology. Next generation sequencing is ongoing. Future trials should utilize PET after induction chemo to select PETnr pts to receive experimental therapies.

4056 Poster Session (Board #245), Sun, 8:00 AM-11:30 AM

Tumor mutation burden (TMB) and immune-related adverse events (irAEs) compared to antibiotic (abx) use to predict for response to immune checkpoint inhibitors in esophagogastric cancer (EGC). *First Author: Megan Greally, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Immune checkpoint inhibitors (nivolumab and pembrolizumab) have clear activity in EGC. However, benefit is modest in an unselected population. TMB may be of value as a quantitive marker to identify patients (pts) with durable benefit from immunotherapy (Cancer Discov 2018 Jan;8(1): 49-58). We present updated data from an expanded cohort, including irAEs and abx use as determinants of pt outcomes. **Methods:** All pts treated with anti-CTLA-4, PD-1 or PD-L1 Abs were identified. Outcomes were correlated with TMB by MSK-IMPACT NGS panel of up to 468 genes and clinical variables, including irAEs and abx use. The third quartile of TMB was used as the cut-off. Progression-free (PFS) and overall survival (OS) were calculated from the start of immunotherapy. **Results:** Of 120 pts (110 adenoCs, 10 SCC), 90% had received ≥2 prior chemo regimens, 6 received ≥2 IO regimens. 66 (55%), 17 (14%) and 37 (31%) pts respectively received anti-PD-1, anti PD-L1 and anti-CTLA-4 plus anti-PD-1/PD-L1 Abs. The median PFS and OS were 1.8 and 5.9 mos; 2-yr OS 19%; objective response rate of 13% (n = 15, 7 PRs, 8 CRs). In IMPACT tested tumors, excluding low purity samples (n = 62), a TMB cut-off of ≥7.4 mut/Mb stratified TMB-low vs -high pts (46 vs 16), with a trend toward improved OS in the TMB-high group (27.1 vs 8.4 mos, p = 0.063). 7 of 7 dMMR pts were TMB-high. In 41 pts (34%) treated with abx during immunotherapy (and 1 month prior), there was a significant improvement in PFS (3.3 vs 1.6 mos, p = 0.04) vs those who were not; with no difference in OS (7.3 vs 4.7 mos, p = 0.23). irAEs occurred in 36 pts (30%) and were associated with improved OS (18.2 vs 3.7 mos, $p < 0.0001$), irrespective of AE grade. OS (12.7 vs 4.2 mos, p = 0.034) was improved even in pts where irAEs occurred ≤8 weeks from start of immunotherapy. The median PFS and OS in 36 pts (30%) who received chemo following progression were 4.3 and 7.7 mos. **Conclusions:** A TMB of 7.4 may serve as a cut-off to identify EGC pts more likely to benefit from immunotherapy. Abx use did not negatively impact outcomes and occurrence of irAEs was associated with improved OS. Outcomes for post-immunotherapy chemo appear promising in these heavily treated pts.

4057 Poster Session (Board #246), Sun, 8:00 AM-11:30 AM

Feasibility study of trastuzumab (T) and pertuzumab (P) added to neoadjuvant chemoradiotherapy (nCRT) in resectable HER2+ esophageal adenocarcinoma (EAC) patients (pts): The TRAP study. *First Author: Sandor Schokker, Department of Medical Oncology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands*

Background: Around 15% of EACs are HER2+ and treatment with T is effective in metastatic EAC. Given the success of dual neoadjuvant HER2 targeted therapy with P and T in breast cancer, we performed a phase 1B feasibility study of nCRT combined with P and T. **Methods:** HER2-positive pts (IHC 3+, or 2+ with ISH+) with resectable EAC received nCRT with carboplatin and paclitaxel (CROSS regimen), combined with 840 mg P q3w, and T in a loading dose of 4 mg/kg, followed by 2 mg/kg qw for 5 weeks (wks) and 6 mg/kg in wks 7, 10 and 13. Peak and trough serum samples were collected throughout treatment for pharmacokinetics (PK) and shed HER2 (sHER2). Cardiac safety was assessed with pre- and posttreatment MUGA scans. Primary endpoint was feasibility, defined as ≥80% completion of treatment with P and T, for which 40 pts had to be included. **Results:** We enrolled 40 pts (78% males, median age 63) of which 83% completed treatment with P and T. Reasons for non-completion were logistics (n = 3), pt request (n = 3) and death of pulmonary fibrosis during treatment (n = 1). Toxicity was similar to conventional nCRT except for rash (28%) and diarrhea grade 3 (20% of pts). Transient LVEF < 50% or decreases of ≥10% occurred in n = 4 (3 asymptomatic) without delay of surgery or cardiopulmonary complications. One pt had interval metastases preoperatively; 38 pts were operated. No unforeseen complications were reported. Thirteen pts (33%) had a pathological complete response (pCR, Mandard 1). Mandard 2, 3, 4 and 5 was seen in 8, 11, 3 and 3 pts, respectively. One year progression free survival (PFS) and overall survival (OS) were 85% and 90% (median follow up 19.4 months). PK of P was similar to prior reports in metastatic gastric cancer (all trough levels > 20 μg/ml). Median baseline sHER2 was 11.9 μg/ml; levels decreased in wk 4 (median 6.7 μg/ml) to return to baseline in wk 13 (median 10.9 μg/ml). **Conclusions:** Addition of P and T to nCRT in EAC pts is feasible and has limited additional toxicity. It shows a high pCR of 33% compared to 23% after conventional nCRT and a promising 1 year PFS and OS of 85% and 90% compared to 72% and 80% after conventional nCRT, respectively. Further biomarker research is ongoing. Clinical trial information: NCT02120911.

4058 Poster Session (Board #247), Sun, 8:00 AM-11:30 AM

Laparoscopic versus open surgery for advanced gastric cancer. *First Author: Guoxin Li, Nanfang Hospital/ Southern Medical University, Guangzhou, China*

Background: Laparoscopic distal gastrectomy for early gastric cancer is widely accepted with superiority to conventional open surgery. However, oncologic validation for advanced gastric cancer is still being debated. We conducted a multi-center, randomized, controlled trial to compare 3-year disease-free survival (DFS) rates after laparoscopic distal gastrectomy with D2 lymphadenectomy and open surgery for advanced gastric cancer. **Methods:** Between September 2012 and December 2014, we randomly assigned 1056 patients with clinical stage T2, T3, or T4a gastric cancer, without bulky nodes or distant metastases to undergo either laparoscopic or open distal gastrectomy with D2 node dissection in a 1:1 ratio. The primary end point was 3-year DFS rate. **Results:** At 3 years, the DFS rate were 76.5% in the laparoscopic group and 77.8% in the open group; the hazard ratio (HR) for recurrence was 1.069. The 3-year overall survival rates were similar in the two groups (83.1% in the laparoscopic group and 85.2% in the open group; HR for death, 1.162). The clinical recurrence types were comparable between two groups (P = 0.213). **Conclusions:** The long-term oncological outcomes of laparoscopic distal gastrectomy with D2 lymphadenectomy were non-inferior to those of the conventional open surgery for the patients with advanced gastric cancer. (CLASS-01 trial) Clinical trial information: NCT01609309.

4059 Poster Session (Board #248), Sun, 8:00 AM-11:30 AM

Capecitabine plus oxaliplatin versus capecitabine plus oxaliplatin with concurrent radiotherapy in the treatment of gastric cancer after D2 gastrectomy. *First Author: Congying Xie, The First Affiliated Hospital of Wenzhou Medical University, Wenzhou, China*

Background: The role of adjuvant chemoradiotherapy (CRT) in the treatment of gastric cancer patients after D2 resection has not been defined yet. This trial was designed to compare capecitabine plus oxaliplatin (XELOX) versus XELOX combined with concurrent CRT in the treatment of gastric cancer patients after D2 gastrectomy. **Methods:** Patients with histologically confirmed gastric cancer with T3-4/N1-3 after D2 gastrectomy were enrolled and randomly assigned to XELOX for 6 cycles (CT arm) or 2 cycles XELOX plus 45 Gy radiotherapy (RT) with capecitabine concurrently, and then followed by another 4 cycles of XELOX after RT (CRT arm). The primary end point was 3-year disease-free survival (DFS), and the secondary end point was 3-year overall survival (OS). **Results:** From January 2013 to June 2017, a total of 144 Patients were protocol eligible with 74 assigned to the CT arm and 70 to the CRT arm, respectively. With a median follow up of 25.6 months, the 3-year DFS and OS rates were 76.3% and 79.6% in the CT arm, versus 72.8% and 70.9% in the CRT arm, respectively. The addition of RT did not show significant differences on the DFS (P = 0.868) and OS (P = 0.683). The rate of local recurrence-free survival and distant metastasis at 3 years were 98.5% vs. 91.7% (p = 0.281) and 18.7% vs. 18.1% (p = 0.606) for the CT and CRT arms, respectively. For patients with positive lymph nodes (84.5%), the 3-year DFS rate was 70.7% and 71.1% in the CT and CRT arms, respectively. The DFS was a bit shorter in the CT arm than in the CRT arm but without statistical difference (p = 0.920). Common grade 3/4 AEs with chemotherapy and RT were leukopenia, neutropenia, thrombocytopenia. All patients finished at least 4 cycles of XELOX with 82.1% and 75.5% patients in the CT and CRT arms finished 5 cycles of chemotherapy. **Conclusions:** No significant benefits on DFS and OS of CRT observed in the treatment of gastric cancer after D2 gastrectomy. Addition of RT did not show significant on lowering the risk of local recurrence for gastric cancer patients. Adjuvant CRT needs further investigation with larger populations for gastric cancers patients after D2 gastrectomy. Clinical trial information: NCT01711242.

4060 Poster Session (Board #249), Sun, 8:00 AM-11:30 AM

Quality of life in the CRITICS study, a multicenter randomized phase III trial of neo-adjuvant chemotherapy followed by surgery and chemotherapy or by surgery and chemoradiotherapy in resectable gastric cancer. *First Author: Romy Van Amelsfoort, The Netherlands Cancer Institute Antoni Van Leeuwenhoek Hospital, Amsterdam, Netherlands*

Background: Patient-reported outcome is an important objective in clinical trials, as it addresses the impact of the disease and treatment on health-related quality of life (HRQOL). In the multicenter randomized phase III CRITICS study no significant difference in overall survival was found between postoperative chemotherapy and chemoradiotherapy after neo-adjuvant chemotherapy and D2 surgery (5-year OS 42% vs 40%). The CRITICS study investigated health-related quality of life in both treatment groups as one of the secondary objectives. **Methods:** Patient-reported outcome questionnaires were completed at baseline, after preoperative chemotherapy, after surgery, after postoperative chemotherapy (CT) or chemoradiotherapy (CRT) and during follow-up at 12 months after the end of postoperative treatment for 788 patients with adenocarcinoma of the stomach. Cancer-related quality of life was assessed by the European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire-Core 30 (EORTC QLQ-C30). A QLQ-C30 summary score at each time point was calculated as the mean of the combined 13 QLQ-C30 scale scores (max score 100; financial impact and global quality of life scale scores excluded). Linear mixed-modeling was applied to assess differences in the QLQ-C30 summary score between the CT and CRT group, accounting for missing values during follow-up. **Results:** 645 patients out of the 788 patients had at least one evaluable questionnaire. The number of evaluable questionnaires was comparable between the CT and CRT groups. Evolution of QLQ-C30 summary scores over time was non-linear with baseline scores of 86 vs 84, lowest scores after surgery of 77 vs 75 and recovery of the scores to 83 vs 80 after 12 months of follow-up. No significant differences in QLQ-C30 summary scores over time were observed between the CT and CRT group (p = 0.567). **Conclusions:** In the CRITICS study HRQOL summary scores showed no differences over time between the CT and the CRT group. Besides HRQOL, pathological T- and N-stage, resection margin status and histological type contribute to the optimal choice of treatment. Clinical trial information: NCT00407186.

4061 Poster Session (Board #250), Sun, 8:00 AM-11:30 AM

Selumetinib plus docetaxel as second-line chemotherapy in KRAS mutant, KRAS amplified or MEK signatured gastric cancer patients: First arm of the umbrella trial in GC though the molecular screening, VIKTORY trial. *First Author: Jeeyun Lee, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of (South)*

Background: This trial was a phase II study with selumetinib (AZD6244)/ docetaxel as second-line treatment for metastatic GC patients with MEK signature or RAS gene alterations as part of the GC umbrella trial, guided through the molecular screening, the VIKTORY trial (NCT#02299648). **Methods:** Selumetinib was administered orally 75mg twice a day continuously. Docetaxel was administered as an IV infusion over 1 hour at 60 mg/m2 every 3 week of a 21 days schedule. The primary objective was to investigate response rate (RR) and secondary objectives were to perform pre-planned analysis using ctDNA and tumors to identify an optimal biomarker for selumetinib. **Results:** Twenty seven patients who were identified through the VIKTORY screening to harbor KRAS mutation, KRAS amplification or MEK signature were enrolled onto the study. Of 27 patients, 12 patients had GC harboring KRAS mutation and two KRAS amplification. The remaining 13 patients were KRAS wild type with either low MEK signature (N = 7) or high MEK signature (N = 6). Only one of 12 KRAS mutant GC had high MEK signature. Of 25 patients who received the study drug, there were 7 partial responses (PRs), 8 stable diseases (SDs), 6 progressive diseases (PDs) and 4 non-evaluable diseases. The overall RR for the study combination was 28.0% (95 CI, 0.12 – 0.49). The most commonly observed any grade adverse events (AEs) were skin rash (7.4%) but no grade 3 or 4 skin rash. The second common AE was diarrhea (5.5%) which was all grade 1/2. In biomarker analysis, the two patients with had typical KRAS mutation (G12) or KRAS amplification with high MEKsignature achieved a PR from selumetinib/docetaxel . However, three with atypical KRAS mutation (i.e. A146P, Q61R, Q61H) with low/intermediate MEK signature showed PD to the combination therapy. **Conclusions:** Selumetinib plus docetaxel as 2nd line therapy revealed the useful efficacy and tolerable safety in GC patients with MEK signature or RAS gene alterations. Especially, the specific subset of patients with had typical KRAS mutation or KRAS amplification with high MEK signature were likely to benefit from selumetinib/docetaxel. Clinical trial information: NCT02448290.

4062 Oral Abstract Session, Mon, 3:00 PM-6:00 PM

Pembrolizumab (pembro) vs paclitaxel (PTX) for previously treated advanced gastric or gastroesophageal junction (G/GEJ) cancer: Phase 3 KEYNOTE-061 trial. *First Author: Charles S. Fuchs, Smilow Cancer Hospital, Yale New Haven Health, New Haven, CT*

Background: Pembro has shown promising antitumor activity in patients (pts) with pretreated G/GEJ cancer. KEYNOTE-061 (NCT02370498) was a global phase 3 study of pembro vs PTX for previously treated advanced G/GEJ adenocarcinoma that progressed after first-line chemo containing platinum and fluoropyrimidine. **Methods:** Eligible pts were randomized to pembro 200 mg Q3W or standard-dose PTX. Randomization was stratified by geographic region, TTP on first-line therapy, and PD-L1 combined positive score (CPS). Primary end points were OS (efficacy boundary, one-sided $P = .0135$) and PFS in the CPS ≥ 1 population. **Results:** 395/592 pts enrolled had PD-L1 CPS ≥ 1: 196 assigned to pembro, 199 to PTX. After median follow-up of 8 mo, 7.8% of pts completed or remained on pembro vs 0% on PTX. Median OS was 9.1 mo with pembro vs 8.3 mo with PTX (HR 0.82, one-sided $P = .042$) (Table). 12-mo OS rates were 39.8% vs 27.1%; 18-mo rates were 25.7% vs 14.8%. There was no difference in PFS or ORR, but pembro responses were more durable (Table). Pembro treatment effect was more evident in pts with ECOG PS 0 (HR 0.69; 95% CI 0.49-0.97) or GEJ tumors (HR 0.61; 95% CI 0.41-0.90). In post-hoc analysis, the pembro treatment effect for OS was greater for CPS ≥ 5 (HR 0.73; 95% CI 0.52-1.03) and ≥ 10 (HR 0.64; 95% CI 0.41-1.02). In all pts, grade 3-5 drug-related AE incidence was 14.3% with pembro vs 34.8% with PTX; 3.1% vs 5.4% discontinued due to drug-related AEs. **Conclusions:** Pembro reduced the risk of death by 18% vs PTX in pts with previously treated G/GEJ cancer and PD-L1 CPS ≥ 1, although this difference was not statistically significant. Pembro had a better safety profile than PTX. Pembro treatment effect was more evident in pts with ECOG PS 0 and with increasing PD-L1 expression. Trials of pembro in G/GEJ cancer are ongoing. Clinical trial information: NCT02370498.

Co-existing alterations in cell-cycle pathway genes and impact on benefit from trastuzumab in advanced esophagogastric cancers (EGC): Analysis of 527 *Her2*-amplified cases. *First Author: Joseph Chao, City of Hope, Duarte, CA*

Background: The addition of targeted therapies, including trastuzumab, has resulted in limited benefit in EGC. The response rate for trastuzumab in combination with chemotherapy is under 50% in Her2 amplified EGC, reflecting a molecularly heterogeneous disease. The genomic context of Her2 amplification may impact trastuzumab responsiveness. **Methods:** We analyzed clinical samples from EGC patients using hybrid-capture based comprehensive genomic profiling (CGP). Pre-specified literature review was used to determine genomic alterations (GA) associated with de-novo trastuzumab resistance. Clinicopathologic features and outcomes data were abstracted, and descriptive statistics used to examine relationships between GA and outcomes. **Results:** From 2,245 GEJ adenocarcinomas and 1,883 gastric adenocarcinomas (GC) we identified 395 *Her2*-amplified GEJ (18%) and 132 *Her2*-amplified (Her2amp) GC (7.0%) cases. Median *Her2* copy number was 19 in GEJ and 16 in GC samples. *PIK3CA* GA and *MET* amp were observed in ~9% and ~5% of both *Her2*amp and non- *Her2*amp EGC cases; however, co-amplification of cell-cycle mediators *CDK6* and *CCCNE1* were enriched in *Her2*amp cases (Table). *MYC* amp and deleterious *SMAD4* GA were enriched in cases with *Her2*amp. In cases with > 100 estimated *Her2* copies, *PIK3CA* GA were significantly less frequent than cases with 6-99 copies (2.3% vs. 9.8%, P = 0.04). All *Her2*amp cases were microsatellite stable. A clinically annotated *Her2*amp cohort will be presented. **Conclusions:** GA predicted to decrease trastuzumab sensitivity exist in a significant portion of *Her2*amp EGC, although not all are enriched relative to non-*Her2*amp cases. Baseline tumoral heterogeneity and genomic context are anticipated to modify outcome and prospective stratification will be important to optimize therapies.

Diversity of first-line palliative systemic treatments for esophagogastric cancer patients with synchronous metastases: A real world evidence study. *First Author: Willemieke P.M. Dijksterhuis, Department of Medical Oncology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands*

Background: Optimal palliative systemic treatment for metastatic esophagogastric cancer is not well defined, causing variation in treatment. Aim of this study was to explore diversity in first-line systemic treatment in metastatic esophagogastric cancer patients in a real world setting and assess the effect on overall survival (OS) and progression-free survival (PFS). **Methods:** In a retrospective cohort study (2010-2016), esophagogastric cancer patients (n= 2295) with synchronous metastases treated with systemic therapy were included. Systemic therapy was divided in monotherapy, doublets, triplets (all without trastuzumab), and regimens with trastuzumab. Kaplan-Meier curves and Cox proportional hazards regression, with adjustment for age, gender, tumor and metastatic locations, year of diagnosis and performance status, was used to analyze OS and PFS (PFS only available for 2010-2014 patients, n= 1392). **Results:** Up to 69 different systemic treatment regimens were administered, with a median OS of 8.7 and PFS of 4.8 months. Nearly half of patients (48.2%) were treated with doublet therapy, while 752 patients (32.5%) received triplet and 230 (10.0%) monotherapy (Table 1). Median survival was highest in patients with trastuzumab. For patients not treated with trastuzumab, triplet therapy did not show difference in survival compared to doublet therapy. **Conclusions:** Esophagogastric cancer patients with synchronous metastases are treated with a wide variety of palliative systemic treatment. In our cohort we found that patients treated with a trastuzumab regimen had the best survival, and that doublet therapy provided similar overall and progression-free survival compared to triplet chemotherapy.

	Overall survival (n= 2295)				Progression-free survival (n= 1392)

4065 Poster Session (Board #254), Sun, 8:00 AM-11:30 AM

Investigation of PD-L1 expression and response to pembrolizumab (pembro) in gastric cancer (GC) and cervical cancer (CC) using combined positive score (CPS) and tumor proportion score (TPS). *First Author: Karina Kulangara, Dako North America, Agilent Technologies, Carpinteria, CA*

Background: TPS, the percentage of viable tumor cells with partial or complete membrane staining at any intensity, has been invaluable for assessing PD-L1 expression in non–small cell lung cancer (NSCLC) and identifying patients (pts) likely to respond to anti-PD–1/PD-L1 therapy. However, TPS has limited utility beyond NSCLC. We investigated the predictive value of TPS and CPS and their association with response to pembro in pts with GC and CC. **Methods:** Tumor samples from pts with previously treated GC (KEYNOTE-059, NCT02335411) or CC (KEYNOTE-158, NCT02628067) were analyzed for PD-L1 expression per an investigational-use-only-labeled version of the PD-L1 IHC 22C3 pharmDx assay (Agilent Technologies). Response was assessed per RECIST v1.1 by independent review. External reproducibility of CPS, the number of PD-L1–staining cells (tumor cells, lymphocytes, macrophages) divided by the total number of viable tumor cells, multiplied by 100, was assessed. **Results:** Response, prevalence, positive predictive value (PPV), and negative predictive value (NPV) for CPS and TPS at cutoffs of 1 (TPS1, CPS1) and 10 (TPS10, CPS10) are shown in the table. Response to pembro was significantly associated with CPS ($P = 0.002$) but not TPS ($P = 0.224$) in GC, whereas response to pembro was significantly associated with CPS ($P = 0.008$) and TPS ($P = 0.023$) in CC. Intersite and interobserver overall agreement assessments of external reproducibility for CPS were 92.0% (95% CI, 87.4-96.3) and 96.6% (95% CI, 94.0-98.7), respectively, in GC and 95.0% (95% CI, 90.3-99.2) and 99.7% (95% CI, 99.7-100.0), respectively, in CC. **Conclusions:** CPS is a robust, reproducible scoring method that identified more responders than did TPS in GC and CC. Further investigation of CPS in cancers beyond NSCLC is warranted. Clinical trial information: NCT02335411 and NCT02628067.

Scoring and Cutoff	Responders/Total n/N			Prevalence of PD-L1 Expression, %	PPV, %	NPV, %	Odds ratio for Tumor Response

4066 Poster Session (Board #255), Sun, 8:00 AM-11:30 AM

Comparison of bimodality versus trimodality therapy for esophageal or gastroesophageal junction (GEJ) cancer: Experience from the Princess Margaret Cancer Centre. *First Author: Akina Natori, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: There are no phase 3 trials comparing definitive chemoradiation (bimodality) vs. perioperative chemoradiation (trimodality) for locoregional esophageal/GEJ cancer. **Methods:** A retrospective analysis (2011-2016) compared bimodality and trimodality therapy in patients (pts) with locoregional esophageal/GEJ cancer treated with curative intent. Overall survival (OS) and disease-free survival (DFS) were calculated from the date of diagnosis. Uni- and multivariable Cox proportional hazards regression adjusted for patient and disease factors. **Results:** Of 141 patients, 107 (76%) were male. Mean ages were 66.7 $\pm$ 12.4 years (bimodality; N = 57) and 58.6 $\pm$ 11.3 years (trimodality; N = 84). For bimodality pts, 49% had adenocarcinoma (adeno) and 51% had squamous cell carcinoma (SCC). For trimodality pts, 76% had adeno and 24% had SCC. Bimodality pts received a higher radiation dose compared to trimodality pts (59.4 $\pm$ 7.2 vs. 44.9 $\pm$ 5.8 Gy). We found that trimodality therapy significantly improved OS and DFS compared to bimodality therapy (4-year OS: 40% vs. 31%, HR 0.56, 95%CI 0.36-0.87, p = 0.008; 4-year DFS: 33% vs. 23%, HR 0.60, 95%CI 0.40-0.90, p = 0.01). This difference was confined to the subgroup with adeno histology (OS: HR 0.28, 95%CI 0.16-0.47, $p < 0.001$; DFS: HR 0.26, 95%CI 0.16-0.43, $p < 0.001$). In the SCC subgroup, OS and DFS were similar (OS: HR 1.30, 95%CI 0.48-2.64, p = 0.77; DFS: HR 0.91, 95%CI 0.43-1.94, p = 0.82). Using multivariable regression with AIC backward selection, the only retained prognostic factors were treatment modality ($p < 0.001$) and histology (p = 0.002). **Conclusions:** Our findings support preferential use of trimodality therapy for pts with adeno histology given superior OS and DFS, whereas bimodality and trimodality therapy appeared comparable in pts with SCC histology. Pending confirmation in a larger series with longer follow-up, these findings suggest differential treatment algorithms for locoregional esophageal and GEJ cancer based on tumor histology.

4067 Poster Session (Board #256), Sun, 8:00 AM-11:30 AM

Phase III study of intraperitoneal/intravenous adjuvant chemotherapy compared intravenous adjuvant chemotherapy in patients with stage III gastric cancer. *First Author: Yang Yang, The Comprehensive Cancer Center of Drum Tower Hospital, Medical School of Nanjing University and Clinical Cancer Institute of Nanjing University, Nanjing, China*

Background: Peritoneal metastasis is detected as any part of the metastasis/recurrence pattern in most stage III patients after radical surgery and appears to be the most life-threatening type of metastasis in patients with advanced gastric cancer. Previous studies have suggested that the molecular detection of cancer-specific carcinoembryonic antigen (CEA) mRNA levels in the peritoneal lavage has superior value for postoperative peritoneal recurrence in patients with advanced gastric cancer. The efficacy of intraperitoneal (IP) chemotherapy has been shown in gastric cancer patients with peritoneal metastasis. **Methods:** Eligibility criteria included pathologically confirmed stage III gastric adenocarcinoma after radical surgery, and no prior chemotherapy. Patients were first divided into CEA-positive group and CEA-negative group according to the CEA mRNA lever in the peritoneal lavage, and then in each group patients were randomized 1:1 to intraperitoneal (IP) arm and intravenous (IV) arm. Patients in IP arm received 2 cycles intraperitoneal docetaxel with oral S-1 and 4 cycles intravenous docetaxel with oral S-1, while patients in IV arm received 6 cycles intravenous docetaxel with oral S-1. The primary endpoint was 1-year disease-free survival rate (1-year DFS rate). Secondary endpoints were disease-free survival, overall survival, and safety. **Result:** Between April 2015 and June 2016, 161 patients were enrolled and 158 patients included in the efficacy analysis. 65 patients had positive CEA mRNA in peritoneal lavage and 93 had negative CEA mRNA. Baseline patient characteristics were balanced between IP arm and IV arm in both CEA-positive group and CEA-negative group. The 1-year DFS rate for CEA-positive group and CEA-negative group were 41% and 89%, respectively ($p < 0.01$). In CEA-negative group, the 1-year DFS rate for IP arm and IV arm were 86% and 89%, respective (P = 0.720). In CEA-positive group, the 1-year DFS rate for IP arm and IV arm were 66% and 41%, respective (P = 0.035). Both regimens were tolerable. **Conclusion:** The primary analysis showed the statistical superiority and clinical efficacy of the multi-route (intraperitoneal/intravenous/oral) regimen for patients with positive CEA mRNA in peritoneal lavage. It suggested clinical efficacy. Clinical trial information: ChiCTR-IPR-15006202.

4068 Poster Session (Board #257), Sun, 8:00 AM-11:30 AM

Frequency of overexpression of HER3 and prognostic consequences in European patients with early gastric cancer. *First Author: Nieves Martinez Lago, Hospital Clinico de Santiago de Compostela, Santiago De Compostela, Spain*

Background: HER2 status is a predictive biomarker to response to trastuzumab in metastatic gastric adenocarcinomas. However, relatively little is known about the role of HER2 and HER3 in the non-metastatic disease in European population. **Methods:** Immunohistochemical expression of HER2 was analyzed using DAKO-HercepTest™ and gene amplification using DAKO-DuoCISH kit; both were scored according to published criteria. HER3 expresión was analyzed using HER3 clon DAK-H3-ICHER3 HER2 patients with 0-1+ were classified as HER2 negative, patients with 2+ and negative DuoCISH as equivocal and 3+ or 2+ with positive DuoCISH as positive. HER3 pts were classified as negative if 0-1+ or positive 2-3+ by two independent observers. Six subtypes according to HER2 and HER3 status were defined. Relationship between this classification and the clinicopathological characteristics and survival was analyzed retrospectively. **Results:** 106 pts diagnosed between Jan-2007 and Jun-2014 were analyzed. Subtype distribution was: HER2-HER3 (-) (56.6%), HER2 equivocal/HER3 (–) 9 pts (8.5%), HER2 (-) HER3 (+) (15.1%), HER2 equivocal HER3 (+) (6.6%), HER2 (+) HER3 (-) (7.5%) and HER2 (+) HER3 (+) (5.7%). HER2 had a significant association with HER3 (p = 0.018). Strong or moderate HER2 expression was associated with intestinal differentiation (p = 0.020) while tumors with strong or moderate HER2 expression or high HER3 expression were associated with lower grade (p = 0.050). Patients with low expression of HER2 and HER3 had a better specific overall survival ($> 85\%$) than those with HER3 overexpression (66.7-68.6%). Patients with strong or moderate HER2 expression without HER3 expression tumors had the worse survival (50%). **Conclusions:** Our algorithm based in HER2 and HER3 status proposes a classification in 6 groups with clinicopathologic and prognostic correlates. Overexpression of HER3 is a frequent phenomenon in early gastric cancer that modulates the adverse prognosis associated with HER2 overexpression. Patients with HER3 overexpression have an intermediate prognosis between patients with isolated HER2 overexpression and those who lack both drivers.

4069 Poster Session (Board #258), Sun, 8:00 AM-11:30 AM

Circulating tumor DNA dynamics in resectable gastric cancer. *First Author: Alessandro Leal, Johns Hopkins University School of Medicine, Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD*

Background: There is an unmet need for predictive biomarkers of clinical outcomes in resectable gastric cancer (RGC) treated with perioperative chemotherapy. We have used targeted error correction sequencing (TEC-Seq) to analyze 58 driver genes in cell-free circulating tumor DNA (ctDNA) from patients enrolled in the CRITICS study (NCT00407186). **Methods:** We prospectively isolated cell-free DNA (cfDNA) from plasma of 115 patients with stage Ib-IVa RGC enrolled in a phase III trial of neoadjuvant chemotherapy followed by surgery and chemotherapy or by surgery and chemoradiotherapy. Samples were collected prior to neoadjuvant treatment (baseline), as well as prior to and after partial or total gastrectomy. Pathologic responses to neoadjuvant chemotherapy were assessed using tumor regression grade (TRG). Tumor-derived alterations were analyzed using TEC-Seq at the indicated timepoints. **Results:** Patients had a median follow-up of over 60 months. Initial analyses of 84 plasma samples from 52 patients revealed median levels of cfDNA of 9.8 ng/ml (0.8-123.0). We detected 259 somatic mutations in 34 genes. Patients with tubular adenocarcinoma had higher ctDNA concentrations than signet-ring cell carcinoma at baseline, with median mutant allele fractions (MAFs) of 0.25% vs. 0.16%, respectively ($P < 0.001$). ctDNA levels were reduced after neoadjuvant chemotherapy, with MAFs declining from 0.22% to 0.15% ($P < 0.001$). TRG 1-3 responses were associated with longer median overall survival (OS) (not reached (NR) *vs.* 39.4 months, HR = 0.23; 95% CI = 0.06-0.96, $P = 0.04$) and event-free survival (EFS) (NR *vs.* 33.8 months, HR = 0.34; 95% CI = 0.14-0.96, $P = 0.02$). We observed a trend for longer OS and EFS among patients with detectable ctDNA at baseline who were treated with perioperative chemotherapy (median OS NR *vs.* 37.4 months, HR = 0.39; 95% CI = 0.12 to 1.25, $P = 0.1$; median EFS NR *vs.* 30 months, HR = 0.53; CI 95% 0.18-1.6, $P = 0.2$, respectively). **Conclusions:** Our study shows that ctDNA levels differ between histologic subtypes of gastric cancer. The presence of detectable ctDNA at baseline may provide a predictive real-time biomarker of neoadjuvant chemotherapy benefit in patients with resectable disease. Additional ctDNA analyses at all timepoints will be presented. Clinical trial information: NCT00407186.

4070 Poster Session (Board #259), Sun, 8:00 AM-11:30 AM

Induction chemoradiotherapy for esophageal cancer: Comparing CROSS regimen with cisplatin/5-FU. *First Author: Abraham Geller, Harvard Medical School, Boston, MA*

Background: While trimodal therapy with neoadjuvant carboplatin/paclitaxel (CP) has demonstrated superiority over surgery alone for treatment of locally advanced esophageal cancer (LAEC), its superiority to alternative regimens is yet unproven. Here we directly compare CP against cisplatin/5-FU (CF), the historical standard, as a component of trimodal therapy for LAEC. **Methods:** Patients receiving trimodal therapy with either CP or CF for LAEC at a single institution from 2002 to 2017 were included in this retrospective study. Clinical data, treatment regimen, and tumor response were obtained from medical records. The primary outcome was pathologic complete response (pCR). Secondary outcomes were overall (OS) and diseasefree survival (DFS), calculated from the date of surgery until death (OS & DFS) or first recurrence (DFS only). Primary outcomes were measured with logistic regression; survival was estimated with KaplanMeier and Cox Proportional Hazards models. Patient characteristics were compared with Student s T and chi square tests. **Results:** 326 patients were included in this study. 187 patients (57%) received CP; 139 patients (43%) received CF. Mean follow-up was 36 months. The CP group was older (mean age 64 vs. 62, $P < .01$) and had a higher rate of hypertension (49% vs. 35%, P = .02) than the CF group. Distribution of tumor stages was similar between groups (P = .3). CF was associated with improved pCR compared to CP in both univariate (OR 1.8, P = .02) and multivariate (OR 2.2, P = .01) analysis. CF showed improved median OS compared to CP (42 vs. 29 months, P = .04), and trended toward improved DFS (27 vs. 17 months, P = .08). In multivariate analysis controlling for age, performance status, and comorbidities, CF was associated with improved OS (HR .68, P = .03) and DFS (HR .67, P = .02) compared to CP. **Conclusions:** Trimodal therapy with CP has become the standard of care for curative treatment of LAEC, yet most studies compare it against surgery alone rather than trimodal therapy with an alternative regimen. Here we directly compare CP to the historical standard regimen (CF), finding that CP is associated with worse tumor response and survival. These findings warrant further investigation with prospective studies.

4071 Poster Session (Board #260), Sun, 8:00 AM-11:30 AM

Translating molecular subtypes of gastric and gastroesophageal junction cancer (GC and GEJC) to the metastatic (met) setting: Prevalence and outcome dataTranslating molecular subtypes of gastric and gastroesophageal junction cancer (GC and GEJC) to the metastatic (met) setting: prevalence and outcome data. *First Author: Itziar Gardeazabal, Clinica Universidad de Navarra, Pamplona, Spaine*

Background: GC is the third cause of cancer death worldwide. Treatment options are limited and a molecular classification on top of HER2 may help to guide therapy. To date, the reported molecular classifications are based on localized tumors with scarce clinical follow-up. We report the first comprehensive tumor profiling of met GC/GEJC. **Methods:** 171 tumor samples from patients (pts) treated at Vall d'Hebron Institute of Oncology (2010–17) were analyzed by next generation sequencing, HER2 status by immunohistochemistry (IHC) and in situ hybridization (ISH), microsatellite instability (MSI) by IHC and Epstein-Barr virus (EBV) by ISH. Results were correlated with histology and clinical variables. **Results:** Median age was 60 years, 70% men, 22% GEJC. At diagnosis, 63% pts had only 1 met site (43% lymph nodes, 40% peritoneum, 33% liver); 41% diffuse and 40% intestinal subtype. TP53mut was found in 60%, equally in diffuse and intestinal subtypes. Molecular subtypes were defined as Chromosomal Instability TP53mut (CIN), CIN_HER2- (23%) and CIN_HER2+ (23%); no_CIN or TP53wt (19%); MSI (8%) and EBV (3%; 1 East-Europe pt, 2 Spanish pts with lymphoepitelioma-like histology). All subtypes equally distributed along the stomach and GEJ (24% had missing TP53mut status but were HER2, MSI and EBV neg). CIN subtype was associated with liver met (p = 0.004) and non_CIN with peritoneum met (p = 0.025). The median overall survival (mOS) was 24.2 months (m). MSI pts (1 out of 8 received immunotherapy) had lower mOS (9.83m v 22.2m, p = 0.003). None of the other molecular subtypes including CIN_HER2+ was prognostic for mOS. **Conclusions:** To our knowledge, this is the first broad molecular report of met GC/GEJC with clinical annotation. The molecular epidemiology in met disease differs from the previous classifications of localized GC/GEJC. We identify MSI as a poor prognostic factor while HER2+ did not impact on outcome. EBV positivity was predominantly found in rare histologies and East-Europe pts.

4073 Poster Session (Board #262), Sun, 8:00 AM-11:30 AM

Is cytoreductive surgery and hyperthermic intraperitonealchemotherapy reasonable treatment for gastric signet-ring cell adenocarcinoma and linitis plastica with peritoneal metastasis? CYTO-*CHIP* study—Ancillary results. *First Author: Pierre Emmanuel Bonnot, Centre Hospitalier Lyon-Sud, Hospices Civils de Lyon, Pierre-Bénite, France*

Background: Incidence of gastric signet-ring cell adenocarcinoma (SRCa) is increasing. Linitis plastica (LP) is its typical presentation. SRCa are associated with less chemosensitivity and more peritoneal metastasis (PM). Most consider PM from a gastric SRCa as an end-stage disease. Cytoreductive surgery (CRS) and Hyperthermic Intraperitoneal Chemotherapy (HIPEC) are highly debated in those indications. **Methods:** 277 patients treated for gastric cancer with PM by CRS with or without HIPEC in 19 French centers from 1989 to 2014 were included. Diagnosis of an SRCa was based on the presence of isolated carcinoma cells containing mucin. Purpose: to evaluate the impact of CRS and HIPEC in patients with PM from SRCa compared with those with PM from non-SRCa. **Results:** 188 patients had an SRCa with 55.1 % of LP. One tumor was a LP in the 89 patients with a non-SRCa. Patients with SRCa were more frequently female and younger, with more diffuse PM, undifferentiated and pN3 tumors. There was no difference in perioperative treatments. 124 (66%) patients in the SRCa group and 56 (62.9%) in the non-SRCa group underwent an HIPEC. Median Peritoneal Cancer Index (PCI) was higher in HIPEC sub-groups (SRCa: 7 *v* 2; non-SRCa: 5 *v* 1). PM from SRCa was associated with worse survival from surgery. After CRS, with or without HIPEC, 3-year OS was 14% in the SRCa *v* 38.4% in the non-SRCa ($P = < .001$). In the SRCa group, HIPEC was associated with better survival on multivariate analysis than CRS alone (median OS: 16.3 *v* 11 months, HR, 0.526; 95% CI, 0.34- 0.81; $P = .003$). LP, tumor grade, PCI and adjuvant treatment were independent prognostic factors. In the non-SRCa group, effect of HIPEC was more significant with 3 and 5-year OS of 50.1% and 45.4 *v* 17 % and 17 % (P = .004). ASA score, PCI and nodal status were independent prognostic factors. **Conclusions:** PM from gastric SRCa or non-SRCa have distinct prognosis. HIPEC seems a valuable option therapy for resectable PM from SRCa. Concerning PM from non-SRCa, this study is currently the best evidence that HIPEC can offer similar survival rates to non-metastatic tumors on selected patients. *NCT:03253939.*

4074 Poster Session (Board #263), Sun, 8:00 AM-11:30 AM

Safety and clinical activity of 1L atezolizumab + bevacizumab in a phase Ib study in hepatocellular carcinoma (HCC). *First Author: Stacey Stein, Yale School of Medicine, New Haven, CT*

Background: Advanced HCC is a lethal cancer with a high unmet medical need. Single-agent immunotherapy with PD-L1/PD-1 blockade or treatment (Tx) with anti-angiogenic bevacizumab (bev; anti-VEGF) has shown modest activity in HCC. We hypothesized that the combination of atezolizumab (atezo; anti–PD-L1) + bev results in a greater clinical benefit due to the additional immunomodulatory effects of bev (increased DC maturation, enhanced T-cell infiltration, reduced MDSCs and Tregs in tumors), which create a more favorable tumor microenvironment that potentiates the efficacy of atezo. **Methods:** Patients (pts) with unresectable or metastatic HCC who were naive to systemic Tx were enrolled in a Phase Ib study cohort (NCT02715531). Pts received atezo (1200 mg) + bev (15 mg/kg) IV every 3 weeks until loss of clinical benefit or unacceptable toxicity. The primary objective was to assess the safety and tolerability of the combination. Secondary efficacy endpoints included ORR, PFS, DOR and time to progression (TTP) per RECIST v1.1; and OS. **Results:** As of the data cutoff (October 24, 2017), 26 pts were evaluable for safety. Tx-related all-grade AEs occurred in 21 pts (81%). Tx-related grade 3-4 AEs were seen in 9 pts (35%), most commonly hypertension (n = 5 [19%]). No grade 5 AEs were observed. Two pts (8%) experienced 3 Tx-related grade 3 serious AEs (autoimmune encephalitis, mental status change and intra-abdominal hemorrhage). Immune-related AEs requiring corticosteroid Tx occurred in 3 pts (12%). Among 21 efficacy-evaluable pts (minimum follow-up, 16 wk; median survival follow-up, 8.3 mo), confirmed partial responses occurred in 13 pts (62%) regardless of HCC etiology, region (Asia or US), baseline a-fetoprotein levels ($\geq$ or $<$ 400 ng/mL) or extrahepatic spread of tumor. The median estimates for PFS, DOR, TTP and OS have not yet been reached. **Conclusions:** The combination of atezo + bev is safe and well tolerated; no new safety signals were identified beyond the established safety profile for each agent. The confirmed response rate of 62% suggests that atezo + bev in combination has synergistic clinical activity. Expansion of this HCC cohort and evaluation of atezo + bev in a Phase III study are under way. Clinical trial information: NCT02715531.

4075 Poster Session (Board #264), Sun, 8:00 AM-11:30 AM

Anti-programmed death-1 antibody SHR-1210 (S) combined with apatinib (A) for advanced hepatocellular carcinoma (HCC), gastric cancer (GC) or esophagogastric junction (EGJ) cancer refractory to standard therapy: A phase 1 trial. *First Author: Jian-Ming Xu, Cancer Center, 307 Hospital, Academy of Military Medical Sciences, Beijing, China*

Background: A phase 1 (P1) study to assess the safety and efficacy of combination of S, a fully human IgG4 monoclonal antibody against PD-1 with PD-L1/PD-L2 plus Apatinib (A), a VEGFR2 inhibitor in patients (pts) with advanced HCC, GC, EGJ cancer. **Methods:** In P 1a dose escalation, pts received A (125, 250, 500mg, QD, 5 pts per cohort) and S (200 mg, Q2W) until unacceptable toxicity, disease progression. In phase 1b cohort expansion, pts received A at recommended P2 dose (RP2D) + S (200 mg, Q2W). Response was evaluated by RECIST v1.1. **Results:** At the cut-off data (Feb. 2. 2018), 42 pts (P 1a, n = 15; P 1b, n = 27) were enrolled. Median prior lines of therapy in HCC and GC were 1 and 2, respectively. In P1a stage, 3 DLTs (all grade 3 pneumonia) were observed in A 500mg cohort. The RP2D was A 250mg + S. In P 1b stage, the median treatment duration was 19 wks (range, 2-57 wks). 19 pts (58%) had $\geq$ grade 3 treatment-related adverse events (TRAEs). The $\geq$10% grade 3 TRAEs were hypertension (18%), increased AST (15%) and ALT (12%). These AEs were manageable, only 1 pt discontinued treatment due to TR grade 3 hyperbilirubinemia. There were no TR- deaths. The ORR and DCR in 36 evaluable pts in all 3 cohorts were 30.6% (n = 11) and 83.3% (n = 30), respectively. All 11 responses occurred in A 125mg (n = 1) and 250mg (n = 10) cohorts. Among 18 HCC pts (14 evaluable: A 125mg cohort, n = 4; A 250mg cohort, n = 9, A 500mg cohort, n = 1), all infected with HBV. The ORR and DCR were 50.0% and 85.7%, respectively. Notably, 2 pts in A 125mg cohort had initial SD at best response, and achieved PR after escalating A dose to 250 mg, therefore the ORR at A 250 mg dose level was 54.5% (6/11). The median progression-free survival (PFS) was not reached. All 7 pts with PR were still on treatment, 5 lasted for 47 weeks+. Of 24 GC or EGJ cancer pts (22 evaluable: A cohort, 250mg n = 20; 500mg, n = 2), the ORR in A 250mg cohort was 20.0% and DCR was 80.0%. The median PFS was 3.0 months. **Conclusions:** S + A at RP2D demonstrated manageable toxicity in HCC, GC or EGJ cancer pts. Particularly encouraging clinical activity (PR rate 54.5%) was observed in pts with pretreated, advanced HCC. Clinical trial information: NCT02942329.

4076 Poster Session (Board #265), Sun, 8:00 AM-11:30 AM

A phase 1b trial of lenvatinib (LEN) plus pembrolizumab (PEM) in patients (pts) with unresectable hepatocellular carcinoma (uHCC). *First Author: Masafumi Ikeda, National Cancer Center Hospital East, Kashiwa, Japan*

Background: LEN is a multikinase inhibitor of VEGFR 1–3, FGFR 1–4, PDGFRα, RET, and KIT that showed noninferiority with respect to overall survival (OS) compared with sorafenib in the first-line treatment of pts with uHCC in a phase (Ph) 3 trial (REFLECT). PEM is an anti-PD-1 monoclonal antibody that has shown promising activity in HCC. An ongoing Ph 1b study of LEN + PEM has shown promising activity in several solid tumor types. We report preliminary results from a Ph1b trial of LEN + PEM in pts with uHCC. **Methods:** In this open-label, multicenter study, pts with uHCC, BCLC stage B (not eligible for transarterial chemoembolization) or C, Child-Pugh class A, and ECOG PS $\leq$ 1 received LEN (body weight $\geq$ 60 kg: 12 mg/day; $<$ 60 kg: 8 mg/day) daily and 200 mg PEM IV once every 3 wks. Tolerability was evaluated by assessing dose-limiting toxicities (DLTs) during the first cycle in pts who were ineligible for other therapies (3+3 design; Part 1). Once tolerability of the combination was confirmed, additional pts with no prior systemic therapy for uHCC were enrolled (Part 2). The primary endpoint was safety. Secondary and exploratory endpoints included OS, and objective response rate, progression-free survival, and time to progression using modified RECIST (mRECIST). Tumor assessments of complete or partial responses (CR or PR) were confirmed $\geq$ 4 weeks after initial response. **Results:** As of December 1, 2017, 18 pts had received LEN + PEM (Part 1: n = 6; Part 2: n = 12). Pts had BCLC stage B (n = 6) or C (n = 12), Child-Pugh scores of 5 (n = 14) or 6 (n = 4), and 4 pts (22%) had received prior sorafenib. No DLTs were reported in Part 1. All 18 pts remained on study. TEAEs occurred in 17 pts (94%); the most common TEAEs were decreased appetite and hypertension (56% each). No new safety signals were identified. Efficacy outcomes are reported in the Table. At data cutoff, tumor reduction from baseline was observed in all evaluable pts except one. **Conclusions:** LEN + PEM was well tolerated with encouraging anti-tumor activity in pts with uHCC. Clinical trial information: NCT03006926.

	Part 1 (n = 6)	Part 2 (n = 7)	Total (n = 13)
Best Overall Response, n (%)

4077 Poster Session (Board #266), Sun, 8:00 AM-11:30 AM

A multicenter, single arm phase II trial of a small molecule immune-modulator icaritin: Safety, overall survival, immune dynamics, and PD-L1 expression in advanced hepatocellular carcinoma. *First Author: Yan Sun, Department of Medical Oncology, Beijing Key Laboratory of Clinical Study on Anticancer Molecular Targeted Drugs, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China*

Background: HCC was characterized with high heterogeneity and immune "tolerogenic". Despite of immune checkpoint inhibitors have demonstrated promising results with improved overall survival, a significant fraction of advanced HCC patients are still left with limited treatment options and poor survival. The purpose of this study is to determine the safety, clinical activity and immune dynamic biomarkers of a small molecule icaritin, IL-6/STAT3 immune-modulator in advanced HCC. **Methods:** Major eligibility criteria include histologically confirmed unresectable HCC patients with Child-Pugh Class A or B liver function. Total of 70 advanced HCC patients were enrolled and administrated with 600 mg b.i.d. Primary endpoints were TTP, secondary endpoints were safety, OS, and DCR. Local disease control was defined as no progressive disease (PD) by RECIST. Kaplan-Meier analysis was utilized for OS assessment. Immune dynamic of NLR, IL-6 and baseline PD-L1 expression of immune cells was evaluated, retrospectively. **Results:** There was no $\geq$grade III drug related AE observed in all enrolled 70 advanced HCC patients. Objective response evaluation in per-protocol population showed PR (1.6%), SD (32.8%) and PD (59.0%) and median overall survival (OS) 254day (95% CI, 172-296). DCR was achieved 34.4% (95% CI, 22.7-47.7%); Median OS for the PD-L1-positive (n = 9) and negative (n = 24) subgroups were 389 (95% CI, 80-522) vs. 286.5days (95%CI, 135-482), for IL-6-advantage (n = 24) and disadvantage (n = 16) subgroups were 366.5 (95% CI, 277-566) vs. 157days (95% CI, 125-254), for NLR-advantage (n = 27) and disadvantage (n = 23) subgroups were 295(95% CI, 235-509) vs. 178days (95% CI, 135-296), respectively. **Conclusions:** Icaritin has demonstrated its favorable clinical safety and immune-modulation clinical efficacy. The improved OS was implicated in the subgroups of advanced HCC patients including PD-L1-positive immune cell expression. Both safety and immune-response efficacy are warranted for the phase III trial. Clinical trial information: NCT01972672.

4078 Poster Session (Board #267), Sun, 8:00 AM-11:30 AM

Phase I dose-finding study of OPB-111077, a novel STAT3 inhibitor, in patients with advanced hepatocellular carcinoma. *First Author: Changhoon Yoo, Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of (South), Korea*

Background: The signal transducer and activator of transcription 3 (STAT3) signaling pathway might be a promising therapeutic target for hepatocellular carcinoma (HCC). **Methods:** This study was a multicenter, open-label, non-comparative, dose escalating phase I study of OPB-111077, an oral STAT3 inhibitor, in patients with advanced HCC who failed on sorafenib. Continuous dosing (daily administration: 50 mg to 400 mg) and intermittent dosing (4-days on/3-days off administration: 300 mg to 900 mg) regimens were evaluated and the dose-limiting toxicities (DLTs), maximal tolerated dose (MTD), and recommended dose (RD) were the primary endpoints. **Results:** A total of 33 patients (19 for continuous dosing and 14 for intermittent dosing) were enrolled. One patient experienced a DLT with grade 3 dizziness, but the MTD was identified in neither the continuous nor the intermittent dosing cohorts. The RDs were determined to be 250 mg for the continuous dosing regimen and 600 mg for the intermittent dosing regimen. There was no treatment-related death; 6 patients (18%) had grade 3-4 toxicities including thrombocytopenia (6%), fatigue (3%), and dizziness (3%). No patients achieved complete or partial responses and the median progression-free survival was 1.4 months (95% confidence interval, 0.8-2.8). **Conclusions:** OPB-11107 was well tolerated in patients with advanced HCC after sorafenib failure, but only showed limited preliminary efficacy outcomes. Further investigation of the role of the STAT3 signaling pathway in HCC and the development of biomarkers for STAT3 inhibitors are warranted. Clinical trial information: NCT01942083.

4079 Poster Session (Board #268), Sun, 8:00 AM-11:30 AM

Phase Ib study of binimetinib (MEK162) in combination with capecitabine in gemcitabine-pretreated advanced biliary tract cancer. *First Author: Jin Won Kim, Department of Internal Medicine, Seoul National University Bundang Hospital, Seoul National University College of Medicine, Seongnam, Republic of (South), Korea*

Background: In biliary tract cancer (BTC), RAS/RAF/MEK/ERK pathway is known to be activated in up to 20-40%. Binimetinib (MEK162) is allosteric MEK1/2 inhibitor, which shows preclinical activity in BTC. Interestingly, MEK inhibitor and 5-FU shows synergistic effects in BTC cells. With that, we conducted phase Ib study of binimetinib and capecitabine in gemcitabine-pretreated BTC patients. **Methods:** This study consists of dose escalation (DE) part and expansion (EX) part. Binimetinib (B) and capecitabine (C) were dosed twice daily, 2 weeks/1 week on/off. In DE part, 3 dose levels (DL) were tested (DL1: B 15mg, C 1000 mg/m^2; DL2: B 30mg, C 1000 mg/m^2; DL 3: B 30mg, C 1250 mg/m^2) with 3+3 design. The primary end point was maximum tolerated dose in DE part and 3 month-progression free survival (PFS) rate (3m-PFSR) in EX part. **Results:** In DE part, 9 patients (3 per DL) were recruited and there was no dose limiting toxicity up to DL3. Recommended phase 2 dose (RP2D) was determined as DL3. In EX part, 25 patients were enrolled. Median age was 63 years old (range 48-73). Primary tumor origins were gallbladder (29.4%), intrahepatic (29.4%), extrahepatic (26.5%), and ampulla of vater (14.7%). 25 (73.5%) and 9 patients (26.5%) were 2nd-line and 3rd-line setting, respectively. Of 34 evaluable patients, 6 (17.6%) and 20 patients (58.8%) showed partial response and stable disease (SD). Response rate and disease control rate were 17.6% (95% CI, 4.8 - 30.4) and 76.5% (95% CI, 62.1 - 90.7). Median PFS and overall survival (OS) were 3.9 m (95% CI, 3.0 - 4.8) and 8.0 m (95% CI, 4.9 - 11.1). 3m-PFSR was 61.3%. 60% of patients with SD showed prolonged SD ($>$ 12 weeks). In biomarker study, RAS/RAF/MEK/ERK pathway activated patients showed longer PFS (5.4 m vs 2.6 m, p = 0.031) and OS (10.8 m vs 5.3 m, p = 0.011) than non-activated patients. Most of adverse events were grade 1/2 and manageable with G3 anemia (11.8%) and G3 fatigue (5.9%). **Conclusions:** RP2D of binimetinib and capecitabine combination is binimetinib 30mg, capecitabine 1250 mg/m^2, twice daily, 2 weeks on/1 week off. This combination shows acceptable tolerability and promising antitumor efficacy, especially in RAS/RAF/MEK/ERK pathway activated BTC patients. Clinical trial information: NCT02773459.

4080 Poster Session (Board #269), Sun, 8:00 AM-11:30 AM

Phase II trial of sorafenib plus doxorubicin (SD) in patients (Pts) with advanced hepatocellular carcinoma (HCC) after progression of disease (PD) on sorafenib (S). *First Author: Imane H. El Dika, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: SD may synergistically improve outcome after PD on S by promoting ASK-1 mediated apoptosis through RAF-1 inhibition. In a prior retrospective analysis of 14 pts who in the lack of other choices of therapy received SD after PD on S, progression free survival (PFS) and overall survival (OS) were 3.4 and 10.1 months (m) respectively **Methods:** A non-randomized, open label, single institution, single arm phase II study of SD in pts with histologically confirmed advanced HCC. Eligibility: RECIST 1.1 radiologic PD on S, ECOG 0-1, Child-Pugh A, and adequate major organ function. Therapy: S 400mg twice a day (once a day if bilirubin (B) $\geq$1.3mg/dl $\leq$3mg/dl) and D 60mg/m2 (30mg/m2 if B $\geq$1.3 mg/dl $\leq$3mg/dl) on day 1 of 3-week cycle. Cross-sectional imaging was performed every 3 cycles. The primary endpoint was OS at 6m (OS6), based on Simon two-stage design, unacceptable OS6 50%, acceptable OS6 72%, type I and II errors 5 and 15% respectively. Secondary endpoints included PFS, OS, response rate by RECIST 1.1, and associations between duration of prior S and OS and PFS. Baseline and on-treatment biopsies evaluated ASK-1 and p-ERK expression levels (separate report) **Results:** N = 30 pts enrolled. The majority were male (86%), median age 64 years (range 24-82), 16 pts had hepatitis (53%). OS6 was 76.6% [95%CI: 57.2-88.1%]. Median doses of D and S were 94mg and 380mg respectively. OS was 8.6 [95%CI: 7.3-12] m, and PFS was 3.6 [95%CI: 2.4-4.4] m. There were 3 (10.7%) partial responses and 17 (60.7%) stable disease. Median duration of prior S treatment was 3.3 [range: 0.9-27] m. Neither OS nor PFS were associated with previous S duration (p value 0.11 and 0.15 respectively). Grade 3-4 adverse events occurring in $\geq$ 10% of pts: neutropenia (16%), febrile neutropenia (10%), lymphopenia (43%), anemia (10%), thrombocytopenia (10%), elevated AST (23%) and ALT (10%), hypophosphatemia (10%), and fatigue (10%). There was no treatment related death. **Conclusions:** Despite the study meeting its primary endpoint, SD resulted in significant toxicity and a median OS of 8.6 m. Based on front-line evaluation of SD and the results reported herein, further development of SD in HCC is not warranted Clinical trial information: NCT01840592.

4081 Poster Session (Board #270), Sun, 8:00 AM-11:30 AM

A phase II study of ramucirumab for advanced, pre-treated biliary cancers. *First Author: Jonathan Mizrahi, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Biliary cancers (BC) have no clear second-line therapy in advanced disease after progression on standard of care gemcitabine and cisplatin. Angiogenesis has been shown to be a potential target for BC, and ramucirumab, FDA-approved for treatment of advanced gastric, lung and colon cancer, is a novel monoclonal antibody that targets VEGFR2 to inhibit tumor-induced angiogenesis. **Methods:** We conducted a single arm, phase 2 single center study. Eligibility criteria included patients (pts) with advanced BC, ECOG PS 0 or 1, who had received at least 1 prior regimen containing gemcitabine. Pts were treated with IV ramucirumab at a dose of 8 mg/kg every 2 weeks, and restaging imaging was performed every 8 weeks until progression. The primary endpoint was progression free survival (PFS). Secondary endpoints included overall response rate (ORR), disease control rate (DCR), overall survival (OS) and toxicity (tox) of ramucirumab. Exploratory endpoints included correlating baseline gene expression profile and pre- and post-therapy CT imaging features with tumor response. **Results:** 43 of a planned 50 pts were enrolled, 42 receiving treatment. The cohort had a median age of 59.9 yrs (range 42-77), ECOG PS 0/1 (16/26), male/female (20/22), intrahepatic cholangiocarcinoma/extrahepatic/gallbladder (23/9/10), median prior therapies = 1 (range 1 to 5). Pts received a median number of 6 cycles. There were 9 (21%) grade 3 tox including anorexia, dehydration, hypertension, hyponatremia, proteinuria and vomiting. No grade 4 tox were observed, and no pts were taken off study due to tox. 5 pts required dose reductions. After a median follow-up of 3.44 months, the median PFS and OS were 2.73 months (95% CI: 1.91-8.03) and 6.31 months (95% CI: 4.7 – not reached). Of 34 pts evaluable for response, ORR = 0% and DCR = 44%, with 6 pts on treatment for $>$ 24 weeks. Analysis of the correlative endpoints is ongoing. **Conclusions:** Ramucirumab as a single agent was well-tolerated and resulted in a PFS similar to that achieved with more toxic chemotherapy regimens used in the refractory setting. Furthermore, a minority of ramucirumab-treated patients (13%) experienced prolonged PFS $>$ 24 weeks, warranting further investigation of this agent in refractory BC. Clinical trial information: NCT02520141.

4082 Poster Session (Board #271), Sun, 8:00 AM-11:30 AM

Multi institutional phase II trial of single agent regorafenib in refractory advanced biliary cancers. *First Author: Richard D. Kim, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

Background: There is currently an unmet medical need for patients with advanced biliary cancer (BC) who have failed one prior gemcitabine based systemic therapy.Regorafenib is an oral multi-kinase inhibitor that targets both receptor tyrosine kinases (RTKs), as well as the tumor cell proliferation/survival signaling pathway kinases (RAS/RAF/MEK/ERK). **Methods:** Pts with histologically proven BC who progressed on at least one line of systemic therapy received regorafenib 160 mg daily 21 days on 7 days off in a 28 days cycle. The single arm design was used to access 6 month overall survival (OS) as a primary endpoint. The study tested the null hypothesis of $\leq$30% of OS at 6 month against the alternative of $\geq$50% of OS at 6 month (HR = 0.578). With one-sided α of 10% and 86% power, the experimental treatment was deemed to have good activity if $\geq$14 out of 32 evaluable patients (43.8%) survive 6 months or longer. The secondary objectives included median OS, RR and PFS. **Results:** Thirty nine pts received at least 1 dose of regorafenib of whom 32 pts were evaluable for efficacy. Twenty pts failed 1 line of therapy and 12 pts failed two lines of therapy. Median age was 62 (range: 27-88) years and the primary sites of tumor were intrahepatic cholangiocarcinoma (68.8%), extrahepatic (18.8%), and gallbladder (12.5%). Pts were considered evaluable for efficacy if patients received more than 1 cycle of regorafenib. Seven pts were not evaluable because one pt withdrew consent, 5 pts expired due to clinical progression within a month and 1 pt due to toxicity. For 32 evaluable pts, 6 month OS was 50.9% (95% CI: 32.1%-67.0%), 12 month OS was 35% (95% CI 16.2-53.7) and 18 month OS was 35% (95% CI 16.2-53.7). Median PFS was 3.7 months (95% CI: 2.3-5.5) and median OS was 9.9 months (95% CI: 3.7-20.1). PR was achieved in 2 (6.2%) pts, SD in 18 (56.2%) pts with DCR of 62.4%. The overall toxicity profile was as expected with grade 3/4 AE of 71.8%. The most common adverse events were fatigue (56.4%) and hypertension (53.8%). Dose modification was required in 49% of the patients. Plasma samples were collected in all pts with planned correlative studies underway. **Conclusions:** The primary endpoint was met in this study. Further randomized trials are warranted to confirm the efficacy Clinical trial information: NCT02115542.

4083 Poster Session (Board #272), Sun, 8:00 AM-11:30 AM

Phase 1B study of enzalutamide (ENZA) with or without sorafenib (SORA) in patients (pts) with advanced hepatocellular carcinoma (HCC). *First Author: James J. Harding, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY*

Background: Preclinical models indicate that androgen receptor (AR) interference with ENZA is deleterious to HCC; however, ENZA also activates feedback circuitry that may be overcome with the addition of SORA. **Methods:** This is a multicenter, National Comprehensive Cancer Network funded, phase 1B study of ENZA $\pm$ SORA unresectable/metastatic HCC pts (NCT02642913). In PART 1 of the study, a 3 + 3 dose de-escalation design with expansion cohort was used to establish the safety and ENZA recommended phase 2 dose (RP2D). In PART 2, a 3 + 3 dose escalation was used to establish the safety and RP2D of ENZA + SORA. Secondary objectives included response rate (RR) by RECIST 1.1, pharmacokinetics (PK), progression-free (PFS) and overall survival (OS). Correlative analyses included AR determination by immunohistochemistry and enumeration of pretreatment and on-treatment high definition circulating tumor cells (HD-CTCs). **Results:** 16 pts received ENZA 160mg QD on PART 1—median age 70/75% male/19% hepatitis B virus (HBV)/13% hepatitis C virus (HCV)/ 100% Child Pugh A/100% failed prior SORA. No dose limiting toxicity (DLTs) occurred and drug-related Grade 3 AEs were rare—hypertension (1), hyperglycemia (1), transaminitis (1), and electrolyte abnormalities (1). No objective responses were observed. 8/16 (53.3%) pts had stable disease (SD). Median PFS and OS were 1.8 and 9.4 months. 12 pts received ENZA 160mg QD with SORA 400mg QD or BID in PART 2—median age 72/83% male/8.3% HBV/33% HCV/100% Child Pugh A/100% treatment naïve. No DLTs were observed and drug-related Grade 3 AEs included hypertension (2), headache (1) and hypophosphatemia (1). No objective responses were observed. 7/12 (64%) pts had SD. AR was detected in 16/21 (76%) tumor samples and did not associate with RR (p = 0.61). ENZA enhanced the metabolism of SORA leading to a 60% reduction of SORA area under the curve $(AUC)_{0\text{-}8hr}$ at steady state. HD-CTCs were detected in 11/32 (34.3%) samples, and in 13 paired samples, treatment did not affect CTC concentrations (p = 0.9). **Conclusions:** Despite an adequate safety profile, ENZA has no single agent activity in AR (+) or (-) HCCs. ENZA + SORA development is limited by drug-drug interactions. Clinical trial information: NCT02642913.

4084 Poster Session (Board #273), Sun, 8:00 AM-11:30 AM

Selumetinib (Sel) and cisplatin/gemcitabine (CisGem) for advanced biliary tract cancer (BTC): A randomized trial. *First Author: Mark Doherty, Odette Cancer Centre at Sunnybrook Health Sciences Centre, University Health Network, Toronto, ON, Canada*

Background: Sel (AZD6244, ARR142886) is an oral MEK inhibitor, with preclinical evidence of synergy with Gem in BTC. CisGem is standard first-line treatment for advanced BTC. This trial assessed the efficacy of Sel in continuous or sequential combination with CisGem in first-line advanced BTC. **Methods:** This randomized multicentre phase II trial (NCT02151084) enrolled patients (pts) with advanced cholangiocarcinoma (CC) or gallbladder cancer (GBC). CisGem was given at standard doses. Sel started at 75mg BID, daily (continuous – Arm A) or day 1-5, 8-19 every 21 days (sequential – Arm B). Arm C was CisGem alone. Sel starting dose was reduced to 50mg BID for toxicity concerns after 32 enrolled pts (protocol amendment). Primary endpoint was % change in RECIST tumor size of 48 evaluable pts: Arm A or B vs Arm C at 10 wks. Secondary endpoints: PFS, OS, ORR, disease control rate (DCR) and toxicity. **Results:** 57 pts were enrolled: 29 female; 22 intrahepatic CC, 16 extrahepatic CC and 19 GBC. Baseline characteristics were similar across arms. Mean change in tumor size was not significantly different between either Sel arm and the control arm (Arm A p = 0.37, Arm B p = 0.53 [Table]). There were no significant differences in other efficacy endpoints. Toxicities appeared more frequent in Arm A; dose intensity of Gem and Sel were lower. More pts in Arms A and B stopped treatment due to toxicity than Arm C. **Conclusions:** Adding Sel to CisGem failed to improve tumor response at 10 wks, or prolong survival, but added toxicity and led to lower dose intensity. Exploration of biomarkers may identify a group deriving benefit, but it should not be studied further in unselected BTC. Clinical trial information: NCT02151084.

	Arm A (N = 19)	Arm B (N = 19)	Arm C (N = 19)	overall p-value

4085 Poster Session (Board #274), Sun, 8:00 AM-11:30 AM

ADI-PEG 20 and FOLFOX6: A phase 1 study in pts (pts) with advanced hepatocellular carcinoma (HCC). *First Author: James J. Harding, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY*

Background: Arginine depletion interferes with pyrimidine metabolism as well as DNA damage repair pathways, and preclinical data indicate that pairing pegylated arginine deaminase (ADI-PEG 20) with fluoropyrimidines or platinum enhances cytotoxicity *in vitro* and *in vivo* in arginine auxotrophs. **Methods:** An open-label phase 1 trial of ADI-PEG 20 and FOLFOX6 for treatment-refractory HCC and other advanced gastrointestinal (GI) tumors was based on a 3 + 3 dose escalation design. The primary objectives were to define, safety, tolerability, and the recommended phase 2 dose (RP2D). An HCC expansion cohort was used to define best overall response rate (ORR). Secondary objectives included progression-free survival (PFS), overall survival (OS), and exploration of pharmacodynamics and immunogenicity. Eligible patients were treated with intravenous FOLFOX6 biweekly at standard doses and ADI-PEG 20 intramuscularly weekly at 18 (Cohort 1) or 36 mg/m^2 (Cohort 2 and RP2D expansion). **Results:** 27 pts enrolled—23 advanced HCC (and 4 other GI). HCC cohort: median age 64 (44-77) years old/70% male/100% Child Pugh A/57% non-viral/70% extrahepatic disease/39% portal vein involvement/43% $\geq$ 2 lines of treatment. No dose-limiting toxicities were observed and the RP2D for ADI-PEG 20 was 36 mg/m^2 weekly with FOLFOX6. Common adverse events (AEs) any grade: thrombocytopenia, neutropenia, leukopenia, anemia, and fatigue. Among 23 HCC pts, the most frequent treatment related Grade $\geq$ 3 AEs were neutropenia (47.8%), thrombocytopenia (34.7%), leukopenia (21.7%), anemia (21.7%), and lymphopenia (17.4%). The ORR for 23 HCC pts was 21.7% (95% CI: 95 7.5-43.7). Median PFS and OS were 7.3 and 14.5 months. Arginine levels (Mean $\pm$ SEM, baseline 81.7 $\pm$ 8.2, week 1 0.8 $\pm$ 0.2μM) were depleted with therapy despite the emergence of low levels of anti-ADI-PEG 20 antibodies. The degree of arginine depletion, presence of antibodies, and archived tumoral argininosuccinate synthetase-1 levels did not correlate with response. **Conclusions:** Concurrent ADI-PEG-20 and FOLFOX6 is safe with favorable efficacy compared to historic controls. The HCC cohort has been expanded further into a phase II study of the combination in the third-line. Clinical trial information: NCT02102022.

4086 Poster Session (Board #275), Sun, 8:00 AM-11:30 AM

Phase II study of pembrolizumab in advanced, unresectable hepatocellular carcinoma. *First Author: Lynn G. Feun, Sylvester Comprehensive Cancer Center, University of Miami, Miami, FL*

Background: Recently, checkpoint inhibitors have shown modest activity in patients (pts) with advanced, unresectable hepatocellular carcinoma (HCC). In multicenter trials with nivolumab and pembrolizumab, the response rates have been reported to be 14% and 16%, respectively. We report a prospective single-institution investigator-initiated clinical/translational study of pembrolizumab in advanced HCC. **Methods:** A phase II trial is ongoing, with pembrolizumab administered at a fixed dose of 200 mg iv every 3 weeks for advanced HCC patients who may have progressed on, were intolerant of, or refused sorafenib. CT or MRI scans were performed after every 3 doses. RECIST 1.1 was used to assess response. Time to tumor progression (TTP) and overall survival (OS) were estimated by Kaplan-Meier method. Median TTP and median OS were estimated along with the corresponding 95% confidence interval. **Results:** Twenty six patients have been treated and 21 were evaluable for response at this time. Ten of the 21 patients had prior sorafenib. Seven had hepatitis C and 1 had hepatitis B. Sixteen had extrahepatic metastases. The median TTP was 3 months(95%CI:2-7) and median OS was 14 months(95%CI: 3- not estimable). In terms of response, one had complete response and 6 had partial response (PR) for overall response rate of 33%. Two others had stable disease. TTP for responding pts were 6+, 7, 8, 8,9, 9+, and 14 + months with 3 having ongoing responses. Five of these 7 had extrahepatic metastases which responded to treatment. Four of 7 had prior sorafenib. Drug-related toxicity included: hypothyroidism (4 patients) grade 4 neutropenia (1) and reversible, temporary elevation of liver function tests (grade 3 in 3 pts). Other grade 1-2 toxicities included: diarrhea (4), skin rash (5) and fatigue (2). Correlative studies including hepatitis B and C titers, IL1B, IL12, IL18, IL6, TGF beta, gamma interferon, and PD-L1/PD-1 staining are ongoing and will be presented. **Conclusions:** Pembrolizumab has activity in advanced HCC patients, including those with extrahepatic metastases. Toxicity was generally well tolerated and reversible. A set of immunological markers as well as PD-L1/PD-1 staining is being investigated as possible indicator for response. Clinical trial information: NCT02658019.

4087 Poster Session (Board #276), Sun, 8:00 AM-11:30 AM

Phase 2 trial of pembrolizumab (PEM) plus granulocyte macrophage colony stimulating factor (GM-CSF) in advanced biliary cancers (ABC): Clinical outcomes and biomarker analyses. *First Author: Robin Kate Kelley, University of California San Francisco, San Francisco, CA*

Background: The efficacy of immune checkpoint inhibition (CPI) has not been established in ABC. The combination of CPI plus the myeloid cytokine GM-CSF was safe with prolonged overall survival (OS) compared to CPI monotherapy in melanoma. This phase 2 trial evaluates the safety, efficacy, and biomarkers of PEM in combination with 2 cycles of low dose induction GM-CSF in ABC (NCT02703714). **Methods:** Design: Simon's 2-stage. Key eligibility: ABC after $\geq$ 1 standard therapy, no prior CPI, bilirubin $\leq$ 1.5xULN. Treatment: PEM 200 mg IV Q3 weeks plus GM-CSF 250 μg SC days 1-14 Q3 weeks for 2 cycles. Endpoints: 1°: Overall response rate (ORR) by RECIST 1.1 with H_0 5% vs. H_1 20%. Key 2°: Safety, progression-free survival at 6 months (PFS6), OS, tumor PD-L1 expression. Exploratory: CA 19-9 levels, tumor microsatellite (in)stability (MSI, MSS), tumor mutation burden (TMB), tumor and peripheral immune cell profiling. **Results:** Accrual has completed with 27 patients enrolled 5/2016-9/2017: Stage 1/2 9/18; F/M 13/14; median age 61; intra-/extra-hepatic 74%/26%; stage IVA/B 85%, II/III 15%; median prior therapies 2 (range 1-6); MSI/MSS/unknown 1/19/7; TMB high+int./low/unknown 5/11/11. Adverse events (AE): Related $\geq$ grade (Gr)3 AE in 2 (7%) (1 each immune-related (ir)AE of Gr4 diabetes mellitus and Gr3 fever); irAE requiring steroids in 3 (11%); endocrine irAE in 8 (30%). Disposition: 20 pts discontinued for PD, 1 for Gr2 irAE neuropathy/arthralgia, 1 for unrelated AE; 5 remain on treatment. Median cycles: 6 cycles (range 2-28+). ORR: Confirmed partial response (cPR) in 5 (19%) (95% CI: 3-34%) (1 MSI, 4 MSS); cPR or stable disease (SD) $\geq$ 6 months in 9 (33%). PFS6: 35% (95% CI: 15-54%); median OS: not reached. Endocrine irAE, CA 19-9 changes $\geq$ 50%, hepatitis C virus (HCV), and TMB were associated with efficacy in univariate analyses. PD-L1+ in $\geq$ 1% cells was present in 3/10 (30%) pre-treatment samples but was not associated with ORR or PFS6; additional PD-L1 results are pending. **Conclusions:** PEM plus induction GM-CSF is safe and well-tolerated in ABC. Prolonged responses and PFS in MSS ABC along with candidate biomarkers warrant further study in larger sample. Clinical trial information: NCT02703714).

4088 Poster Session (Board #277), Sun, 8:00 AM-11:30 AM

Outcomes in patients (pts) who had received sorafenib (S) as the only prior systemic therapy in the phase 3 CELESTIAL trial of cabozantinib (C) versus placebo (P) in advanced hepatocellular carcinoma (HCC). *First Author: Robin Kate Kelley, University of California San Francisco, San Francisco, CA*

Background: C inhibits tyrosine kinases including MET, VEGFR, and AXL. In the CELESTIAL trial, C improved overall survival (OS) and progression-free survival (PFS) compared with P in pts with advanced HCC after 1 or 2 prior lines of systemic therapy including S. Overall, median OS was 10.2 mo for C vs 8.0 mo for P (HR 0.76, 95% CI 0.63–0.92; p = 0.0049), and median PFS was 5.2 mo for C vs 1.9 mo for P (HR 0.44, 95% CI 0.36–0.52; p $<$ 0.0001). Here, outcomes were analyzed for pts who had received S as the only prior systemic therapy. **Methods:** In the overall study, 707 pts were randomized 2:1 to receive C (60 mg qd) or P stratified by disease etiology, geographic region, and extent of disease. Eligible pts had pathologic diagnosis of HCC, Child-Pugh score A, and ECOG PS $\leq$1. Pts must have received prior S and could have received up to two lines of prior systemic therapy for HCC. Outcomes were analyzed for pts who received only prior S based on duration of prior S ($<$ 3 mo, 3 to $<$ 6 mo, and $\geq$6 mo). **Results:** Out of the 495 pts who received only prior S, 136 (27%) received prior S for $<$ 3 mo, 141 (28%) for 3 to $<$ 6 mo, and 217 (44%) for $\geq$6 mo. OS and PFS were improved for C vs P in pts who had received only prior S; median OS was 11.3 mo for C vs 7.2 mo for P (HR 0.70), and median PFS was 5.5 mo for C vs 1.9 mo for P (HR 0.40). Results for OS and PFS also favored C for subgroups based on duration of prior S (Table). Median OS was generally longer for pts who received prior S for longer durations in both treatment arms. Grade 3/4 adverse events in subgroups were similar to those observed in the overall population in both arms. **Conclusions:** C improved OS and PFS vs P in pts with advanced HCC who had received S as the only prior systemic therapy irrespective of the duration of prior S treatment. Clinical trial information: NCT01908426.

	Prior S Only		Duration of Prior S					
			< 3 mo		3 to < 6 mo		≥6 mo	
	C (N = 331)	P (N = 164)	C (N = 89)	P (N = 47)	C (N = 98)	P (N = 43)	C (N = 143)	P (N = 74)
Median OS, mo	11.3	7.2	8.9	6.9	11.5	6.5	12.3	9.2
OS HR (95% CI)	0.70 (0.55–0.88)*		0.72 (0.47–1.10)		0.65 (0.43–1.00)		0.82 (0.58–1.16)	
Median PFS, mo	5.5	1.9	3.8	1.8	5.4	1.9	5.7	1.9
PFS HR (95% CI)	0.40 (0.32–0.50)*		0.35 (0.23–0.52)		0.37 (0.25–0.56)		0.48 (0.35–0.67)	

*Stratified; all other HRs are unstratified.

4089 Poster Session (Board #278), Sun, 8:00 AM-11:30 AM

Real-time circulating tumor DNA profiling of advanced cholangiocarcinoma (CCA). *First Author: Kabir Mody, Mayo Clinic, Jacksonville, FL*

Background: Cholangiocarcinoma (CCA) has limited treatment options. Genomic analyses have led to development of targeted therapies now in several clinical trials, and may enable the discovery of new treatment options. However, biopsy often yields limited tissue, thus hampering tissue-based profiling opportunities. Data regarding circulating tumor DNA (ctDNA) plasma analysis in CCA during real time clinical practice is limited. **Methods:** We performed ctDNA NGS analysis in patients with advanced CCA (January 2015 – December 2017). ctDNA analysis was performed using Guardant 360, which detects single nucleotide variants, amplifications, fusions, and specific insertion/deletion mutations in up to 73 different genes. Seventeen samples were performed on previous panel versions (3 on a 54-gene, 1 on a 68-gene, and 13 on a 70-gene panel) The mutant allele fraction (MAF) for detected alterations was calculated relative to wild type in ctDNA. Actionability was defined as possible treatments within OncoKB levels I-IV and R1. The study was conducted in accordance with Mayo Clinic Institutional Review Board requirements. **Results:** Among 104 patients and 115 total samples, ctDNA NGS revealed at least one genomic alteration (excluding variants of uncertain significance (VUS) and synonymous mutations) in 80 patients (77%). Median number of alterations per patient was 3 [range, 1-15], with a median mutant allele fraction of 0.42% (range, 0.1% - 94.2%). The total number of unique alterations was 389, with the most commonly altered genes being: *TP53* (84 alterations, 22%), followed by *KRAS* (34 alterations, 9%), *FGFR2* (31 alterations, 8%), *ARID1A* (20 alterations, 5%), APC and PIK3CA (16 alterations each, 4%). Amplifications were noted in 14 genes, including BRAF, CCND1, CCND2, CCNE1, CDK4, CDK6, EGFR, ERBB2, FGFR1, FGFR2, MET, MYC, PDGFRA, and PIK3CA. Fusions of FGFR2 were seen in 3 cases. Potentially actionable alterations were seen in 63 of the 104 patients (61%). **Conclusions:** ctDNA plasma profiling of patients with advanced CCA is a feasible alternative method to gather comprehensive genomic data. Further study of responses to ctDNA NGS-guided over tissue-guided targeted therapy is needed to define the best means to optimize outcomes in CCA.

4090 Poster Session (Board #279), Sun, 8:00 AM-11:30 AM

Outcomes based on age in the phase 3 CELESTIAL trial of cabozantinib (C) versus placebo (P) in patients (pts) with advanced hepatocellular carcinoma (HCC). *First Author: Lorenza Rimassa, Humanitas Clinical and Research Center, Rozzano, Italy*

Background: The incidence of HCC generally increases with age, although the age of onset varies depending on disease etiology and geographic region (Yang, Nat Rev Gastroenterol Hepatol 2010). In the phase 3 CELESTIAL trial (NCT01908426), C, an inhibitor of MET, VEGF receptors, and AXL, improved overall survival (OS) and progression-free survival (PFS) compared with P in pts with previously-treated advanced HCC. Overall, median OS was 10.2 mo for C vs 8.0 mo for P (HR 0.76, 95% CI 0.63–0.92; p = 0.0049), and median PFS was 5.2 mo for C vs 1.9 mo for P (HR 0.44, 95% CI 0.36–0.52; p < 0.0001). Here, we evaluate clinical outcomes based on age in the CELESTIAL trial. **Methods:** 707 pts were randomized 2:1 to receive C (60 mg qd) or P. Eligible pts had pathologic diagnosis of HCC, Child-Pugh score A, ECOG PS ≤1, and must have received prior sorafenib. Randomization was stratified by disease etiology, geographic region, and extent of disease. Outcomes were analyzed for subgroups based on age (< 65 years and ≥65 years). **Results:** Median age at baseline was 64 years; 51% of pts were < 65 years old. Etiology of HBV was more frequent in pts < 65 years vs ≥65 years old (52% vs 22%), while etiology of HCV occurred at a similar frequency in both age groups (24%). Asian race and enrollment in Asia were more frequent in pts < 65 years vs ≥65 years old (46% vs 21% Asian race; 35% vs 14% enrolled in Asia). Median OS was 9.6 mo for C vs 7.7 mo for P (HR 0.81, 95% CI 0.62–1.05) for pts < 65 years old and 11.1 mo for C vs 8.3 mo for P (HR 0.74, 95% CI 0.56–0.97) for pts ≥65 years old. Median PFS was 5.0 mo for C vs 1.9 mo for P (HR 0.45, 95% CI 0.35–0.57) for pts < 65 years old and 5.4 mo for C vs 2.0 mo for P (HR 0.46, 95% CI 0.35–0.59) for pts ≥65 years old. The discontinuation rate due to treatment-related adverse events in the C group was lower in pts < 65 years vs ≥65 years old (11% vs 22%), while the percentage of pts with any dose reduction (61% vs 64%) and the median average daily dose of C (37 mg vs 34 mg) were similar in both age groups. The most common grade 3/4 adverse events in both age groups were consistent with those in the overall population. **Conclusions:** C improved OS and PFS vs P in pts with previously-treated advanced HCC irrespective of age category. Clinical trial information: NCT01908426.

4091 Poster Session (Board #280), Sun, 8:00 AM-11:30 AM

Impact of cholangiocarcinoma (CC) molecular heterogeneity on outcome during first-line chemotherapy and access to targeted therapies in early clinical trials (CT). *First Author: Helena Verdaguer, Vall d'Hebron University Hospital, Barcelona, Spain*

Background: CC has poor prognosis and limited therapeutic options beyond first-line therapy. It is molecularly heterogeneous with several gene alterations (alt) that can be matched to targeted treatments in CT. We investigated the impact of CC molecular profiling in the clinics. **Methods:** From 2011 to 2017, we identified 165 patients (pts) with advanced CC - 129 intrahepatic CC (ICC) and 36 extrahepatic CC (ECC) - whose tumors were analyzed in our center with NGS tests (124 had fusion panels). We retrospectively collected outcome information and access to CT. **Results:** Most pts were diagnosed at stage IV (67%) and received first-line gemcitabine plus platinum (80%). Most common alt found in ICC were mutations (mt) in *TP53* (19%), *IDH1* (14%), *CDKN2A* (9%), *IDH2* (7%), *ATM* (7%), *BAP1* (6%), *PIK3CA* (6%), *KRAS* (6%), *NRAS* (5%), *BRAF* (4%) and fusions in *FGFR2/3* genes (3%). In ECC, we found mt in *TP53* (28%), *CDKN2A* (11%), *PTEN* (11%), *PIK3CA* (6%), *BRCA2* (6%) and mt or amplifications (amp) in *ERBB2* (11%). With a median follow up of 56 months (m), median overall survival (OS) of the overall population was 23 m, with no differences between ICC and ECC (p = 0.83). There was statistically significant difference in OS between pts with *TP53* mt *vs TP53* wild type (wt) tumors (28 m *vs* 15 m, HR 1.8, p = 0.01). During first-line therapy, median progression free survival (PFS) was 6.6 m in *TP53* mt and 3.8 m in *TP53* wt patients (HR 2.3, p < 0.01). 40 pts (24%) were included in a CT, with 24 pts (15%) being matched by molecular alt. Most frequent matches were FGFR inhibitor (inh) (25% of pts with targetable fusion), IDH inh in 5 (21%), PI3K inh in 3 (13%), BRAF inh in 3 (13%). Among pts treated in matched CT, median PFS was 4 m; 2 pts (8%) achieved a partial response (1 MET amp;1 BRAF mut) and 11 (46%) had stable disease as best response. We found no associations between targetable gene alt and OS or PFS during first-line therapy. **Conclusions:** CC is a heterogeneous tumor with a broad spectrum of molecular alt that have prognostic and treatment implications. Matched therapies may confer clinical benefit. Molecular profiling of CC is of growing interest to improve the knowledge of this disease and its therapeutic opportunities.

4092 Poster Session (Board #281), Sun, 8:00 AM-11:30 AM

A bi-institutional phase II study of hepatic arterial infusion (HAI) with floxuridine (FUDR) and dexamethasone (Dex) combined with systemic gemcitabine and oxaliplatin (GemOx) for unresectable intrahepatic cholangiocarcinoma (ICC). *First Author: Andrea Cercek, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Despite advances in systemic therapy for unresectable ICC, median survival remains less than 12 months (mo). HAI FUDR alone and combination systemic therapy both have activity in these patients. This trial investigated HAI FUDR/Dex plus GemOx. **Methods:** Thirty nine patients (pts) with unresectable ICC were enrolled at two institutions between 2013-17. Pts were treated with HAI FUDR and GemOx every 2 weeks. Progression-free survival (PFS) was calculated from date of HAI to progression of disease (POD) or death and compared to historical controls. Secondary outcomes included overall survival (OS), conversion to resection, response rates, and toxicity. PFS and OS were estimated using Kaplan-Meier methods. Twenty nine pts from MSK underwent targeted next generation tumor sequencing of > 400 genes (MSK-IMPACT). **Results:** Median age was 61 (range 38-80), 13 (33%) male. The median PFS was 11.5 mo, (90% CI:9.7mo), exceeding the historical controls of 6-8 mo. Eighteen pts (46%) had partial response (PR) and 20 (51%) had stable disease (SD), for a 97% disease control (PR+SD) rate. Three pts were converted to resectability and were censored at 12, 12 and 16 mo, respectively. Four pts (10%) had grade 4 toxicities requiring removal from the study, including portal hypertension, GDA aneurysm and GDA extravasation related to HAI catheter, and hyperbilirubinemia. The most common grade 3 toxicities were elevated liver enzymes (ALT 54%, AST 33% and bilirubin 18%), abdominal pain 13% and anemia 12%. At a median follow up of 17 mo, the 1 year OS was 86.4% [95%CI:70-94%] and the 2 year OS was 53% [95%CI: 32%-69%]. Most prevalent mutations were IDH1/2 (9/26, 34.6%), BAP1 (8/26, 30.7%), TP53 (4/26, 15.3%). IDH1/2 mutations were associated with OS benefit (p = 0.018). **Conclusions:** Combined HAI FUDR plus GemOx is effective therapy for unresectable ICC due to its high rate of tumor response and control, PFS benefit, and manageable toxicities. The regimen warrants further investigation in a randomized trial. Clinical trial information: NCT01862315.

4093 Poster Session (Board #282), Sun, 8:00 AM-11:30 AM

Understanding quality of life in hepatocellular carcinoma patients. *First Author: Stacie Hudgens, Clinical Outcomes Solutions, Tucson, AZ*

Background: Hepatocellular carcinoma (HCC) is the most common type of primary liver cancer causing morbidity and adversely affects quality of life (QoL) from serious symptom burden. **Methods:** HRQoL collected in a multicenter, randomized, open-label, Phase 3 study compared first-line systemic treatment lenvatinib (LEN) to sorafenib (SOR) in unresectable HCC, were evaluated descriptively. Key QoL outcomes for patients progressing ≤3 months v > 3 months were modeled longitudinally and summarized using area under (AUC) the time curve analyses. The difference in AUC was calculated with contrasting domain parameter estimates of a mixed model with time, group, time*group, and a random intercept at baseline and Day 1 each cycle through Cycle 18. **Results:** 954 patients were randomized to LEN (N = 478) or SOR (N = 476). Trial outcomes: median OS LEN (13.6 mos) v SOR (12.3 mos), HR 0.92; 95% CI, 0.79–1.06; median PFS 7.4 v 3.7 mos, respectively (HR 0.66; 95% CI, 0.57–0.77; *P* < 0.0001). Baseline HRQoL outcomes (e.g. EORTC QLQ-C30, HCC18, and EQ-5D) were markedly worse across most domains for patients who progressed earlier on treatment for both LEN and SOR arms (EQ-5D health utility index = 0.82 and 0.84 (respectively; ≤ 3 months) v 0.88 and 0.86 (respectively; > 3 months). The difference in AUC for EORTC QLQ-C30 role functional status was 0.1644 (95% CI = -0.2281, 0.5569; p-value = 0.4113) and for physical function was 0.0974 (95% CI = -0.3963,0.5911; p-value = 0.6989) favoring LEN. The difference HCC specific symptoms (HCC18) markedly favored LEN on sex life (dif = -0.4244), fatigue (dif = -0.1830), and nutrition (dif = -0.1522) and favored SOR on abdominal swelling (dif = 0.2021). Differences in symptoms related to jaundice, body image, and fever was minimal between treatment arms (dif ≤ 0.05). **Conclusions:** More patients experienced disease progression earlier on therapy with SOR compared to LEN. In our analysis baseline QoL was more severely impacted HCC patients who progress earlier while on therapy, suggesting that patients treated with LEN have an added benefit in terms of QoL as progression occurred later compared to SOR treated patients. Functional and symptom differences in QOL measures, while not statistically significant, also favored patients treated with LEN. Clinical trial information: NCT01761266.

4094 Poster Session (Board #283), Sun, 8:00 AM-11:30 AM

Additional value of tumour growth rate (TGR) in patients (pts) diagnosed with well-differentiated neuroendocrine tumours (NETs) achieving RECIST-defined stable disease (SD): Subgroup analysis of the GREPONET study. *First Author: Angela Lamarca, Department of Medical Oncology, The Christie NHS Foundation Trust, Manchester, United Kingdom*

Background: Response evaluation with RECIST has limitations when applied to slow growing malignancies with low objective response rates, such as NETs, when most pts achieve SD as best response. TGR represents the percentage of change in tumour volume per month and is postulated to overcome such limitations. **Methods:** Pts from 7 centres with advanced, grade (G) 1/2 NETs from the pancreas (P) or small bowel (SB) initiating systemic treatment (ST) or watch and wait (WW) and who achieved SD as best response were eligible. Baseline and follow-up scans were retrospectively reviewed for TGR calculation (%/month) at 3 (+/-1) months (m) of study entry (TGR_{3m}). A previously identified TGR_{3m} cut-off of 0.8 %/m was applied to assess impact of TGR_{3m} on progression-free survival (PFS) (Kaplan-Meier/Cox Regression). **Results:** Out of 222 pts in the GREPONET study, 81 were eligible and included in this analysis: 54.3% SB, 45.7% P; 87.7% metastatic; 61.7% G2; 70.4% treatment-naïve). STs were; somatostatin analogues 34.6%, chemotherapy 22.2%, targeted therapies 12.4%, radionuclide therapy 4.9%; WW 25.9%. Median (med) PFS was 22.9m (95%CI 17.3-30.6); median follow-up 39.8m. TGR_{3m} was available for all 81 pts [med 0 (95%CI -28.7-71.5)]; TGR_{3m} cut-off of 0.8 %/m stratified SD pts in two groups with different outcomes: the pts with $TGR_{3m} < 0.8$ (55 pts; 67.9%; med TGR_{3m} -0.8 [95%CI -1.7-0]) had a significantly longer med PFS (27.4m (95%CI 19.7-39.1)) vs. pts with $TGR_{3m} \geq 0.8$ (26 pts; 32.1%; med TGR_{3m} 3.8 [95%CI 2.9-6.2]; med PFS 9.8m (95%CI 6.4-23.6)); p 0.003. TGR_{3m} and treatment were significant in univariate Cox regression and included in multivariable Cox regression: $TGR_{3m} \geq 0.8$ (HR 3.6 [95%CI 1.9-6.6]; $p < 0.001$) was independent factor related to shorter PFS. **Conclusions:** TGR_{3m} is able to subclassify patients otherwise defined as SD by RECIST in two groups with different outcomes. By applying TGR we identify pts at higher risk of early progression who may require closer radiological follow-up, even if initially defined as SD by RECIST.

4095 Poster Session (Board #284), Sun, 8:00 AM-11:30 AM

Assessing prognosis of neuroendocrine neoplasms: Results of a collaborative multinational effort including over 10.000 european patients—The ENETS registry. *First Author: Ivan Borbath, Department of Gastroenterology, Cliniques Universitaires Saint-Luc, Bruxelles, Belgium*

Background: Global European high quality epidemiologic data on Neuroendocrine Neoplasms (NEN) are lacking. There is limited knowledge on the contribution of prognostic factors on patient (pt) management. **Methods:** The multinational ENETS registry (www.enets.org/the_registry.html) was launched in 2015. To date, data from 7 countries (Belgium, Czech republic, Germany, Greece, Poland, Spain, Switzerland) were analyzed, including age, gender, primary site, functional syndrome, WHO grade, stage according to TNM/ENETS, treatment modalities and overall survival (OS). **Results:** High quality data from 10.102 pts are presented. Median age at diagnosis is 59 y (10-102y), female represent 48%. Pancreas (2722 pts, 26%) and small intestine (2132 pts, 21%) NEN are the most frequent primaries. Functional syndrome is present in 26.9% of pts, 80% being carcinoid syndrome. Stage at diagnosis (n = 6297 pts) is IV in 46%, III in 16%, II in 11% and I in 27%. WHO grading (n = 7400) is G1 in 48%, G2 in 36% and G3 in 16%. Among metastatic pts (46% of total), liver is the most frequent site (77%), followed by lymph nodes (44%), bone, lung and peritoneum (10-15%). Surgery was performed in 71%, somatostatin analogues were given to 1/3 of pts, chemotherapy to 20%, molecular targeted therapies to 8% and PRRT to 9%. Median OS of all pts is 178 months. Five-year and 10-year OS are 74.5% and 60.9% respectively. OS is influenced by grade (G1: 279 months, G2: 167m, G3: 18m) and stage (I: Not reached, II: 225m, III: 160m, IV: 75m). Multivariable analyses show that grade and stage are independent predictors of OS: grade 2 vs grade 1 (HR 1.49, $p < 0.001$), grade 3 vs grade 1 (HR 7.56, $p < 0.001$), stage 3 vs stage 1 (1.59, $p = 0.001$) and stage 4 vs stage 1 (HR 3.99, $p < 0.001$). **Conclusions:** This analysis represents the largest multinational dataset of NEN patients to date, and highlights the crucial role of WHO grading (Ki67) for predicting patients' prognosis. In addition, it provides valuable information on patients' demographics, tumor characteristics and applied therapies.

4096 Poster Session (Board #285), Sun, 8:00 AM-11:30 AM

A phase I/II study of the combination of temozolomide (TM) and pazopanib (PZ) in advanced pancreatic neuroendocrine tumors (PNETs) (NCT01465659). *First Author: Manali A. Bhave, Northwestern University, Chicago, IL*

Background: PNETs are distinguished by increased vascularity and benefit from anti-angiogenic therapies. PZ is a tyrosine kinase inhibitor (TKI) of VEGFR-1-3, PDGFR-α, -β, and c-Kit with single agent activity in PNET (overall response rate (ORR) 22%, median PFS of 14 mo and median OS of 25mo). TM is an oral alkylating agent also with known single agent activity in well-differentiated NETs (PFS of 7 mo). The rationale for the combination of TM and VEGF TKI is based on preclinical synergism through alteration of the tumor microenvironment by VEGF TKI to enhance the activity of TM. **Methods:** This is an open-label phase I/II study to determine the maximum tolerated dose (MTD), safety profile, ORR and pharmacokinetics (PK) of TM and PZ in patients (pts) with advanced well-differentiated PNETs who received 1-4 prior therapies. In a 28-day cycle, TM was given days 1-7 and 15-21 with PZ 400 mg once daily continuously. Dose escalation cohorts of TM: (-2) 75 mg/m^2, (-1) 100 mg/m^2, and (1) 150 mg/m^2. PK analysis was performed for 6 pts at MTD. The phase II portion at MTD is ongoing. **Results:** 28 pts with advanced well-differentiated PNETs were enrolled in phase I between Feb 2013 and Jan 2016 (16 at cohort -2, 5 at cohort -1, and 7 at cohort 1). 2 pts were not evaluable for any endpoint. There were 5 dose-limiting toxicities (DLTs): hepatic dysfunction (2), thrombocytopenia (2) and neutropenia (1). The MTD was at dose level -2, TM 75 mg/m^2 and PZ 400 mg. The most common treatment-emergent adverse events were hepatic toxicity (16%), nausea (5%) and fatigue (5%). Best ORR was PR in 5 pts (25%) and SD in 9 pts (45%). At a median follow-up of 18.5 mo, the median PFS was 12.1 mo (95% CI, 5.7-25.1) and median OS was 36.2 mo (95% CI, 21.4-56.4). **Conclusions:** The combination of TM and PZ was tolerable at a dose level of -2 with hepatic toxicity and myelosuppression as the DLTs. The ORR was 25% with disease control rate of 70% in patients with previously treated advanced well-differentiated PNETs. The phase II component of the study is ongoing. Clinical trial information: NCT01465659.

4097 Poster Session (Board #286), Sun, 8:00 AM-11:30 AM

First in human phase 1/2a study of PEN-221 somatostatin analog (SSA)-DM1 conjugate for patients (PTS) with advanced neuroendocrine tumor (NET) or small cell lung cancer (SCLC): Phase 1 results. *First Author: Melissa Lynne Johnson, Sarah Cannon Research Institute, Nashville, TN*

Background: Somatostatin receptor 2 (SSTR2) is highly expressed in NET and SCLC. PEN-221, a SSA-DM1 conjugate that targets SSTR2, results in complete tumor regressions in SSTR2+ SCLC xenograft models. This study assesses safety, tolerability, pharmacokinetics (PK), and preliminary efficacy of PEN-221. **Methods:** Pts with progressive, advanced, SSTR2+ (by imaging) NET or SCLC were enrolled in escalating cohorts of 2-6 pts. The primary objective was to determine the maximum tolerated dose (MTD) of PEN-221 given every (q) 3 wks. An adaptive Bayesian logistic regression model was used to recommend doses. Intra-patient dose escalation was permitted. Preliminary efficacy was assessed using RECIST 1.1. **Results:** 23 pts (13 M/ 10 F) with NET (GI, pancreatic, lung, renal or pheochromocytoma; n = 9, 5, 5, 1, 2), or SCLC (n = 1) were treated in 7 cohorts (range 1-25 mg). As of 31 Jan 2018, the median/mean number of cycles is 3/5.8 (range 1-18), with 5 pts ongoing. PEN-221 was well tolerated with no dose limiting toxicities (DLTs) in the first 6 cohorts (1-18 mg; 20 pts). In cohort 7 (25 mg), 2 of 3 pts had DLTs that rapidly and fully resolved: Grade(G)3 ALT/AST rise (2 pts), of whom 1 had concurrent G3 total bilirubin rise and G3 mucositis. The MTD was established at 18 mg. The most frequent (≥20% pts) PEN-221 related adverse events were fatigue (43%), nausea (43%), diarrhea (39%), vomiting (26%), abdominal pain (22%), and decreased appetite (22%). PK was dose proportional, median $t_{1/2}$ ~1.7 h, with plasma exposures at MTD above preclinically efficacious levels. Among 15 NET pts who were evaluable for response, 11 had stable disease (SD) at 9 wks, of whom 8 were sustained for 18 – 45 wks, including 2 ongoing pts with SD for 44 and 45 wks. Target lesion shrinkage was observed in 3 pts (dose range 8-18 mg). One pt had a rapid and sustained decrease in chromogranin A and circulating tumor cells. One SCLC pt had SD for 12 wks. **Conclusions:** PEN-221 appears well tolerated with preliminary evidence of antitumor activity. PEN-221 (18 mg q 3 wks) will be evaluated in Phase 2a expansion cohorts enrolling midgut NET, pancreatic NET, and SCLC pts (EudraCT 2016-001468-12; NCT02936323). Clinical trial information: NCT02936323.

4098 Poster Session (Board #287), Sun, 8:00 AM-11:30 AM

Comprehensive genomic profiling of 724 gastroenteropancreatic neuroendocrine tumors (GEP-NETs). *First Author: Alberto Puccini, Division of Medical Oncology, USC Norris Comprehensive Cancer Center, Keck School of Medicine, Los Angeles, CA*

Background: GEP-NETs are rare malignancies and their molecular characteristics are largely undefined. Here, we explored the underlying biology of GEP-NETs and the differences between gastrointestinal (GI) and pancreatic (PNET), high grade (HG) and low grade (LG) tumors. **Methods:** GEP-NETs were analyzed using NextGen sequencing (MiSeq on 47 genes, NextSeq on 592 genes), immunohistochemistry, and in-situ hybridization. Tumor mutation load (TML) was calculated based on somatic nonsynonymous missense mutations, and microsatellite instability (MSI) was evaluated by NGS of known MSI loci. **Results:** In total, 724 GEP-NETs were examined and categorized by location and grade: GI (N = 469), PNET (N = 255), HG (N = 135), and LG (N = 336). Demographics were as follow: female/male 51%/49%, median age 59 (19-90 yr). Among LG tumors, the most frequently mutated genes were *ATRX* (13%), *ARID1A* (10%) and *MEN1* (10%). Among HG, *TP53* (51%), *KRAS* (30%), *APC* (27%), *ARID1A* (23%) and *RB1* (11%). Immune-related biomarkers showed lower prevalence in LG tumors compared to HG: TML-high 1% vs 7% (P = .05), MSI-H 0% vs 4% (P = .04), PD-L1 overexpression 1% vs 6% (P = .03). Compared to LG, HG NETs showed a higher mean TML (9.5mut/MB v 5.1, P < .0001), higher mutation rate in *BRAF* (5.4% v 0%, P < .0001), *KRAS* (29.4% v 2.6%, P < .0001) and *PI3KCA* (7% v 0.3%, P < .0001). When compared to GI, PNET carried significantly higher frequency of *MEN1* (25.9% v 0.0%, P < .0001), *FOXO3* (8.6% v 0.8%, P = .005), *ATRX* (20.6% v 2.0%, P = .007), and *TSC2* (6.3% vs 0.0%, P = .007), but lower frequency of mutations in *APC* (1.0% v 13.8%, P < .0001). Comparison between LG GI vs LG PNET is reported in the table. **Conclusions:** Significant molecular differences were observed in GEP-NETs by tumor location and grade, indicating differences in carcinogenic pathways and biology, as well as response to therapy. HG tumors may benefit more from immunotherapy than LG tumors. Mutations in several targetable genes may provide novel therapeutic options and suggests the utility of genomic profiling in this tumor type.

Gene	Platform	LG GI	LG PNET	P-values
MEN1	NGS	0%	24%	< 0.001
ATRX	NGS	0%	33%	0.001

4099 Poster Session (Board #288), Sun, 8:00 AM-11:30 AM

First update on overall survival, progression-free survival, and health-related time-to-deterioration quality of life from the NETTER-1 study: 177Lu-Dotatate vs. high dose octreotide in progressive midgut neuroendocrine tumors. *First Author: Jonathan R. Strosberg, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

Background: The final per-protocol statistical analysis (cut–off date 24 July 2015) of PFS, the primary endpoint of the NETTER-1 study, showed a significant difference ($p < 0.0001$) between the treatment arms. Supplemental updated analysis was requested by regulatory authorities for registration purposes. Quality of life (QoL) was analysed one year later, with a cut-off date of 30 June 2016 for time to clinically relevant deterioration (TTD) in health-related QoL (HRQoL). **Methods:** Overall survival (OS) and PFS were evaluated using Kaplan Meier methodology. HRQoL analysis was based on EORTC QLQC-30 and G.I.NET-21 questionnaires, completed at baseline and every 12 weeks thereafter. TTD was defined as the time from randomization to the first QoL deterioration ≥10 points for each patient in the corresponding domain scale. First OS regulatory update cut-off date was 30 June 2016. **Results:** At this first update, median OS was 27.4 months in Oct arm and still not reached in Lu arm. PFS at this date showed 30 events in the Lu arm and 78 in the Oct arm (HR: 0.21 CI: 0.14 0.33; $p < 0.0001$). HRQoL TTD was significantly longer in the Lu arm vs. the Oct arm for global health status (HR 0.406; p = 0.0006), physical functioning (HR 0.518; p = 0.0147), role functioning (HR 0.580; p = 0.0298), fatigue (HR 0.621; p = 0.0297), pain (HR 0.566; p = 0.0247), diarrhea (HR 0.473; p = 0.0107), disease related worries (HR 0.572; p = 0.0176) and body image (HR 0.425; p = 0.0058). **Conclusions:** This supplemental analysis from the NETTER-1 Phase III study confirms the clinically and statistically meaningful PFS benefit, and still suggests a survival benefit with 177Lu-dotatate. It also demonstrates that 177Lu-dotatate provides a significant quality of life benefit for patients compared to high-dose octreotide. Clinical trial information: NCT01578239.

4100 Poster Session (Board #289), Sun, 8:00 AM-11:30 AM

The role of Ki-67 in determining optimal chemotherapy in high grade neuroendocrine tumors. *First Author: Katharine Thomas, Ochsner Health System, New Orleans, LA*

Background: High grade (HG) neuroendocrine tumors (NETs) are rare neoplasms with limited data about optimal treatment. This retrospective analysis was performed to determine the most efficacious chemotherapy regimen in HGNETs. **Methods:** A single center, retrospective review of patients (pts) who received at least one chemotherapy regimen for HGNET between June 1, 2012 and June 1, 2017 was conducted. Data collection included demographics, pathologic characteristics, imaging results and treatment data. Progression free survival (PFS) was defined as date from initial chemotherapy until date of disease progression based on imaging or death. Median overall survival (mOS) was also analyzed. Chemotherapy regimens included combination capecitabine and temozolomide (CAPTEM), platinum-based therapy (cisplatin or carboplatin) or other (fluorouracil, or capecitabine based chemotherapy). Response to treatment was evaluated using RECIST 1.1. Subset analysis was performed based on Ki-67 (< 55% or ≥55%). **Results:** Fifty-five pts received chemotherapy. Median number of treatment for those with a Ki-67 of < 55% and ≥55% was 3 and 1, respectively. MOS was 18 months irrespective of chemotherapy regimen; mOS by Ki-67 was 40 months for Ki-67 < 55% versus 16 months for Ki-67 ≥ 55% (Logrank test p = 0.0016). Among all pts undergoing first line therapy, CAPTEM significantly improved PFS (p = 0.041). In a sub analysis, Ki-67 < 55 had a longer PFS with CAPTEM (12-mo), followed by other (7-mo) and platinum (4-mo). In pts with Ki-67 ≥ 55%, PFS was highest in platinum-based therapy (5-mo), followed by CAPTEM (2-mo) and other (1-mo). Kaplan-Meier 3- and 6-month PFS rates based on chemotherapy regimen for pts with Ki-67 < 55% and Ki-67 ≥55 are shown in the table. **Conclusions:** This study demonstrates optimal first line chemotherapy treatment is dependent on Ki-67. Pts with a Ki-67 < 55 and Ki-67 ≥55 have improved PFS with CAPTEM and platinum-based therapy, respectively. Ki-67 values should be considered when determining first line chemotherapy regimen among pts with HGNET.

			3-mo PFS rate by Ki-67 (%)		6-mo PFS rate by Ki-67 (%)	
1st Line Regimen	N	Median PFS (mo)	< 55%	≥55%	< 55%	≥55%
CAPTEM	15	12	77	50	77	50
Other	5	7	67	50	67	50
Platinum-based	35	4	51	58	25	36
Overall	55	5	65	57	54	38

4101 Poster Session (Board #290), Sun, 8:00 AM-11:30 AM

Peptide receptor radionuclide therapy (PRRT) transcriptomic signature in blood for prediction of ^{177}lu-octreotate efficacy. *First Author: Lisa Bodei, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: PRRT uses somatostatin receptor (SSR) expression on neuroendocrine tumors (NET) to deliver radiotherapy. Pretreatment patient stratification for response remains a key unmet need. NET transcript expression in blood integrated with tumor grade provides a PRRT predictive quotient (PPQ). This study validates the clinical utility for PRRT. **Methods:** Development and validation was undertaken in 3 independent ^{177}Lu-PRRT-cohorts. Specificity and prognostic value was tested in two somatostatin analog-treated and untreated patients. Developmental cohort: lung and gastroenteropancreatic [GEP] NETs (*n*= 72). The majority were GEP (71%), low grade (86% G1-G2). Prospective validation cohorts (*n*= 42-44) were well differentiated, low grade (86-95%) lung and GEP-NETs. SSA Cohort I *n*= 28 (100% low grade, 100% GEP-NET); SSA Cohort II *n*= 51 (98% low grade; 76% GEP-NET) and an untreated cohort *n*= 44 (64% low grade; 91% GEP-NET). NET blood gene transcripts (*n*= 8: growth factor signaling and metabolism) were measured pre-therapy and integrated with tumor Ki67 using a logistic regression model with a binary output: "predicted responder" (PPQ+); "predicted non-responder" (PPQ-). Response was evaluated using RECIST criteria [Responder (stable, partial/complete response) vs Non-Responder)]. All measurements and analyses were blinded. Statistics included Kaplan-Meier survival and test evaluation analyses. **Results:** Developmental cohort, 56% responded to PRRT. The PPQ predicted 100% of responders and 84% of non-responders (accuracy: 93%). In two validation cohorts (response: 64-79%), PPQ was 95% accurate (PPQ+ = 94-97%, PPQ- = 93-100%). Overall, median PFS was not reached in PPQ+ vs PPQ- (10-14 months; HR: 18-77, $p< 0.0001$). In comparator cohorts, the predictor (PPQ) was 47-50% accurate for SSA-treatment and 50% as a prognostic. No differences in PFS were respectively noted (PPQ+: 10-12 months vs. PPQ-: 9-15 months). **Conclusions:** The PPQ derived from circulating NET specific genes and tumor grade prior to the initiation of therapy is a highly specific predictor of the efficacy of PRRT with an accuracy of 95%.

4102 Poster Session (Board #291), Sun, 8:00 AM-11:30 AM

Clinical outcomes in patients with baseline renal dysfunction in the NETTER-1 study: 177Lu-Dotatate vs. high dose octreotide in progressive midgut neuroendocrine tumors. *First Author: Jonathan R. Strosberg, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

Background: Might potential nephrotoxicity be a risk for therapy with 177Lu-Dotatate? Among patients randomised in the NETTER-1 study, nephrotoxicity and treatment efficacy were evaluated in the two study arms (177Lu-Dotatate (177Lu) vs. high-dose octreotide (Oct)) according to renal function categories at baseline (no dysfunction eCrClC-G $\geq$ 60 ml/min vs. mild dysfunction eCrClC-G = 50 – 59.99 ml/min vs. moderate dysfunction eCrClC-G $<$ 50 ml/min). **Methods:** Changes in renal function were assessed in the two arms per the three baseline categories, and analysed via Fisher's exact test. The primary endpoint of the NETTER-1 study, progression-free survival (PFS), was evaluated after classifying the patients according to the baseline renal function categories (impaired vs. normal at baseline). **Results:** There were 93 patients with normal renal function, 11 with mild baseline renal dysfunction and 13 patients with moderate dysfunction in the 177Lu arm. Equivalent numbers were seen in the Oct arm (85 with normal function, 16 with mild and 9 with moderate dysfunction; p = 0.41825 for imbalance between the two study arms). The rates of deterioration of renal function over baseline in the two treatment arms for each of the three categories of baseline renal function, were similar (p = 0.70695; 1.0000; 1.000, respectively). In patients with no renal impairment at baseline, Kaplan-Meier analysis showed a greater PFS (p $<$ 0.0001 log-rank test); HR 0.180 [95% CI: 0.102 – 0.318] within the patients treated with 177Lu vs. those treated Oct. In those with renal impairment at baseline, Kaplan-Meier analysis showed a greater PFS (p $<$ 0.001 log-rank test); HR 0.251 [95% CI: 0.084 – 0.751] among the patients treated with 177Lu (N = 23) compared to those treated with Oct (N = 24). **Conclusions:** The NETTER-1 study did not show any evidence of nephrotoxicity associated with 177Lu treatment, even in patients with mild to moderate baseline impairment in renal function. Long-term analysis of renal function will be performed at time of overall survival analysis. Treatment with 177Lu resulted in a markedly longer PFS regardless of whether baseline renal function was normal or impaired.

4103 Poster Session (Board #292), Sun, 8:00 AM-11:30 AM

Optimal cut points for Ki-67 proliferative index in predicting survival in high grade neuroendocrine tumors. *First Author: Robert A. Ramirez, Louisiana State University Health Sciences Center, New Orleans, LA*

Background: High grade (HG) neuroendocrine tumors (NETs) are rare neoplasms with limited literature regarding their prognostic course. HG-NETs generally demonstrate aggressive behavior. We hypothesized that patients diagnosed with HG-NETs with a Ki-67 proliferative index of $\geq$55% will have a worse prognosis. **Methods:** Records of patients with HG-NETs seen at our clinic between June 1, 2012 and June 1, 2017 were retrospectively reviewed. Demographics, pathologic characteristics, primary site and treatment data were collected. Overall survival (OS) was measured from date of high-grade diagnosis to either the date of death or the study cutoff date (December 31, 2017). Subset analysis was performed based on Ki-67 at initial HG-NET diagnosis ($<$ 55% or $\geq$55%) as well as Ki-67 at initial NET diagnosis ($<$ 20%, $>$ 20-54%, or $\geq$55%). **Results:** Fifty-five patients were included in our study. Eleven patients were initially diagnosed with low/intermediate grade NETs (Ki-67 $<$ 20%) and subsequently transformed to HG-NETs (Ki-67 $>$ 20%) after progression. Median OS for the entire group was 18 months (m). The 6, 12 and 24m survival rate was 89%, 62%, and 40% respectively. A significant survival advantage was shown in patients with Ki-67 $<$ 55% as shown in the table (p $<$ 0.05) Survival did not vary significantly between primary tumor site. Low/intermediate (L/I) grade patients who transformed to HG-NETs had a median OS from HG diagnosis of 43m with 6, 12 and 24m survival rate of 100%, 82% and 64% respectively which was a significant compared to the entire cohort (p $<$ 0.05). **Conclusions:** Using a Ki-67 value of 55% is useful in conferring prognosis in patients with HG-NETs. Interestingly, patients who were initially diagnosed with L/I grade NETs and transformed to HG survived longer than those with an initial HG diagnosis. Treatment options for HG-NETs should take into account Ki-67 values.

Ki-67 Proliferative Index	N	Median OS (months)	6-month OS	12-month OS	24-month OS
Ki67 < 55%	27	35	96%	74%	53%
Ki-67≥55%	28	12	82%	50%	29%

4104 Poster Session (Board #293), Sun, 8:00 AM-11:30 AM

Pembrolizumab (P) monotherapy in patients with previously treated metastatic high grade neuroendocrine neoplasms (HG-NENs). *First Author: Namrata Vijayvergia, Department of Hematology/Oncology, Fox Chase Cancer Center, Philadelphia, PA*

Background: There is currently no standard therapy for metastatic HG-NENs after progression on platinum based therapy and available chemotherapy is of limited benefit. Given the promising activity of checkpoint inhibitors in small cell lung cancer, we initiated a phase II trial of P (PD-1 inhibitor) in pts with previously treated metastatic HG-NENs. **Methods:** A prospective, open-label, phase 2 trial, for which pts with metastatic, histologically confirmed HG-NENs (Ki67 $>$ 20%), excluding lung/thymus origin, were eligible after prior platinum based therapy. Other eligibility criteria included ECOG PS 0–1, adequate hematological, hepatic, and renal function. Pt selection was not based on PD-L1 expression but archival tissue was mandated for correlative testing of immunophenotype. P was administered at a dose of 200 mg every 3 weeks intravenously with and radiographic evaluation was conducted every 9 weeks. The primary endpoint was overall response rate. **Results:** Between 11/ 2016 and 1/ 2018, 21 pts (11 males/ 10 females) were enrolled from two institutions and received at least one dose of P, thus completing accrual. Grade 3 toxicities were observed in 6 pts (28%) with 4 (19%) at least possibly related to P (elevated liver enzymes, fatigue, hypercalcemia and hyperkalemia). Other common grade 1-2 toxicities observed include fatigue (32%), diarrhea (26%) and nausea/vomiting (37%). Efficacy analyses and correlative studies are underway and will be presented at the meeting. **Conclusions:** P as a single agent can be safely administered to pts with advanced HG-NENs with similar toxicity profile as described previously for this agent. Efficacy data and correlative analysis will be presented at the annual meeting. Clinical trial information: NCT02939651.

4105 Poster Session (Board #294), Sun, 8:00 AM-11:30 AM

Multicenter phase 2 study of nintedanib in patients (pts) with advanced progressing carcinoid tumors. *First Author: Renuka V. Iyer, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: Serotonin is the cause of carcinoid symptoms and can signal the formation of fibroblasts via fibroblast growth receptors (FGFR). Nintedanib is an oral inhibitor of the FGFR pathway and several angiogenic signaling pathways thought to drive carcinoid tumor progression. We hypothesized that nintedanib may slow tumor progression in pts with progressing carcinoids in a phase 2 study. **Methods:** Thirty pts with unresectable/metastatic carcinoids on stable dose of somatostatin analogue for $\geq$3 months were included from two sites (NCT02399215). *Primary Endpoint*: progression free survival (PFS) rate at 16 wks. *Secondary Endpoints*: Objective response (complete + partial responses) using standard RECISTv1.1 criteria; overall survival (OS); change in QOL throughout treatment using EORTC QLQ–GI.NET21 questionnaire for carcinoid pts; and toxicity (graded using the NCI CTCAE version 4.0). **Results:** Baseline characteristics: M/F: 15/15), ECOG PS: 0/1/2: 11/17/2; Median age (years): 64.9 (45.1-77.2); site of origin: small bowel (13), colon (7), lung (4), gastric (1), unknown primary (5); PD on prior everolimus: 10/30 (30%). PFS rate at 16 wks was 86.7%; 95%CI: 72-95.3% (26 pts). The study was designed to compare to a historic PFS rate of 0.30 with everolimus. Kaplan Meier median PFS and OS estimates were 11 and 27.6 months, respectively, with 6 pts currently on active treatment. RECIST response: PR 1(4%), SD 20 (83%), PD 2(8%), NE 1(4%). Reasons for coming off therapy: progression 14 (58%), toxicity 5(21%), other (17%), death due to disease 1(4%). QOL was maintained or improved in at least 50% of subjects while on therapy. Treatment was held in 7 pts (23%) due to AEs. Highest grade AEs: gr2 in 14(47%) and gr3 in 8(27%) pts. The most common gr 2 were GI (9), heme (8) and gr 3 were hypertension (6) and decreased appetite (2). From individual Bayesian analysis using the nintedanib pop PK model developed, correlation between actual and predicted exposures, with 61% variability in the absorption rate between pts was seen. **Conclusions:** Nintedanib is active and well tolerated in pts with advanced carcinoids. PFS data are encouraging and expected to mature. Ongoing biomarker studies may allow optimal pt selection. Clinical trial information: NCT02399215.

4106 Poster Session (Board #295), Sun, 8:00 AM-11:30 AM

Clinicopathological, genomic and immunological features of hyperprogressive disease during PD-1 blockade in gastric cancer patients. *First Author: Yosuke Togashi, Division of Cancer Immunology, Exploratory Oncology Research and Clinical Trial Center, National Cancer Center Hospital East, Kashiwa, Japan*

Background: Hyperprogressive disease (HPD) during PD-1 blockade reported in several cancer types is a big hurdle for applying cancer immunotherapy, whereas there is no report in gastric cancer (GC) and the detailed clinicopathological, genomic, and immunological features remain to be determined. **Methods:** To clarify clinicopathological, genomic, and immunological features of hyperprogressive disease during PD-1 blockade in patients with advanced GC, 36 patients with advanced GC who received nivolumab from October 2017 to December 2017 and underwent at least one imaging evaluation of their clinical responses were enrolled in this study. Tumor DNA/RNA samples and tumor-infiltrating lymphocyte (TIL) were also analyzed using next-generation sequencing and flow-cytometry assay, respectively. **Results:** Among 36 patients, four patients (11.1%) experienced hyperprogressive disease, and their prognosis was very poor with three of four patients died within very short period after the initial administration of nivolumab (range 20 to 65 days). Three and two among four patients were subjected to genome analyses and TIL analyses, respectively. One patient had an MDM2 gene amplification as was previously reported, whereas the other patients did not have any MDM2 gene family alterations. Immunological analyses in two patients revealed that effector regulatory T (eTreg) cells with proliferative capacity ($Ki67^{+}CD45RA^{-}FOXP3^{high}CD4^{+}$ T cells) were markedly increased in TILs from pre-treatment to hyperprogressive disease state, whereas those in non-hyperprogressive disease patients showed significant reduction. Especially, one patient without MDM2 gene amplification contained enormously high frequency of $Ki67^{+}$eTreg cell-infiltration in the tumor at HPD state. **Conclusions:** HPD during PD-1 blockade is observed in gastric cancer as well as other cancer types and the prognosis is very poor. High regulatory T cell-infiltration and MDM2 family gene alterations might contribute to HPD, which should be taken care during the treatment with anti-PD-1 antibodies.

4107 Poster Session (Board #296), Sun, 8:00 AM-11:30 AM

Gemcitabine plus nab-paclitaxel until progression or given sequentially with 5-fluorouracile plus irinotecan (FOLFIRI.3) for first-line treatment of metastatic pancreatic ductal adenocarcinoma (mPDAC): A randomized phase II study (PRODIGE 37-FIRGEMAX). *First Author: Julien Taieb, Sorbonne Paris Cité, Paris Descartes University, Department of Gastroenterology and Digestive Oncology, Georges Pompidou European Hospital, Paris, France*

Background: Chemotherapy is effective in mPDAC but new approaches are still needed to improve patients (pts) survival and quality of life. We have previously published successful results of a sequential treatment strategy of gemcitabine followed by an intensified FOLFIRI regimen[1] with good efficacy and tolerability results. In the present study, we tested the same sequence with the new gemcitabine + nab-paclitaxel (G+A) first-line standard therapy[2]. **Methods:** We randomized chemotherapy-naive pts with proven mPDAC, bilirubin levels ≤1.5 ULN and performance status (PS) 0-2 to receive in alternance G+A (MPACT regimen)[2] (2 months [mo]) and FOLFIRI.3 (FIRGEM regimen)[1] (2 mo; arm A), or G+A alone (arm B). The primary objective was to increase the 6-mo progression-free survival (PFS) rate from 40% (H0) to 60% (H1; binomial exact method; required 124 pts). Analyses were done in preplanned modified intent-to-treat (mITT, pts who received at least one dose of treatment) and per-protocol (PP, pts reaching the 2 mo treatment switch) populations. **Results:** Between Nov 2015 and Nov 2016, 127 pts were enrolled. Mean age was 64 years (range: 38-76), PS was 0/1/2 in 37/51/12%, no major imbalance for baseline characteristics was noted between arms. Main grade 3-4 toxicities per pt (%) were (arms A/B): diarrhea (13/2), nausea/vomiting (9/2), neutropenia (42/31), febrile neutropenia (2/0), skin toxicity (5/14), and peripheral neuropathy (13/20). No toxic deaths occurred. Best objective response rates (mITT) were A: 40% (95%CI, 28-54) and B: 25% (95%CI, 15-38). 6-mo PFS rates were A: 45% and B: 23% in mITT (n = 122; HR: 0.70; 95%CI, 0.48-1.03) and A: 60% and B: 30% in PP (n = 90; HR: 0.57; 95%CI, 0.36-0.90). Median OS (PP) was A: 15.8 and B: 12.4 mo (HR: 0.66. 95%CI, 0.37-1.16). **Conclusions:** The FIRGEMAX strategy with G+A followed by FOLFIRI.3 every 2 mo, appears to be feasible and effective, with manageable toxicities and decreased neurotoxicity, in patients with mPDAC able to reach > 2mo of treatment for their disease. *1-Trouilloud EJC 2014 2-Von Hoff NEJM 2013* Clinical trial information: NCT02827201.

4108 Poster Session (Board #297), Sun, 8:00 AM-11:30 AM

Targeting advanced pancreatic cancer with activated t cells armed with anti-CD3 x anti-EGFR bispecific antibody. *First Author: Lawrence G. Lum, Emily Couric Cancer Center, Charlottesville, VA*

Background: Conventional chemotherapy (CT) for advanced pancreatic cancer (PC) is associated with dismal response rates and poor survival. Arming anti-CD3 activated T cells (ATC) with anti-CD3 x anti-EGFR bispecific antibody (EGFRBi) makes every ATC into a non-MHC-restricted EGFR-specific cytotoxic T lymphocyte. Engagement of CD3 on T cells and EGFR on PC cell lines leads to cytokine secretion, proliferation, cytotoxicity by ATC, and inhibition of tumor growth. **Methods:** We report on 9 LAPC and MPC patients (pts) (5 phase I and 4 phase I/II pts). In our phase I study at Karmanos Cancer Institute (KCI) on NCT0140874, EGFRBi-armed T cells (EGFR BATs) were used to target EGFR in 5 pts with unresectable or metastatic PC in a phase I dose escalation involving 3 weekly infusions of 10, 20, and 40 x 10^9 BATs per infusion followed by a booster infusion 3 months later for up to 80 x 10^9 BATs if they were stable or better. In a phase II study performed at KCI on NCT02620865 and continued at the University of Virginia (UVA) on NCT03269526, 4 pts received two infusions per week of 10^{10} EGFRBi BATs for 4 weeks for a total of 8 x 10^{10}. **Results:** Following the BATs infusions in the phase I study at KCI, one pt was stable for 6.5 months and 2 pts who progressed after the infusions developed complete responses (CRs) to subsequent CT. Remarkably, pt IT20104 who was stable for 1 year on capecitabine had a "flare" or "pseudoprogression" after 3 BATs infusions, but subsequently achieved a CR to capecitabine and has been off therapy for 1 year (40.8 months after enrollment). The median overall survival (OS) in 5 pts was 31.0 months [13.6, 14.5, 31.0, 40.8 (CR) and 42.5 months after enrollment] with the median time to progression (TTP) of 7.0 months. In summary, 5 of 5 pts in the phase I survived > 1 year. In the phase II study, two pts have stable disease at 2.3 and 21.5 months, respectively. The median OS is 31.0 months for all 9 patients. **Conclusions:** While these patients are selected, these results are promising. Targeting PC with EGFR BATs may have improved OS in a small series of pts. The series provides evidence for anti-tumor activity of EGFR BATs, and, in addition, the BATs infusions may enhance tumor responses to subsequent CT. Clinical trial information: NCT01420874.

4109 Poster Session (Board #298), Sun, 8:00 AM-11:30 AM

Sequential treatment with Nab-paclitaxel plus Gemcitabine and Folfirinox in metastatic pancreatic adenocarcinoma: GABRINOX phase II results. *First Author: Eric Assenat, Institut du Cancer de Montpellier (ICM), Univ Montpellier, Montpellier, France*

Background: Folfirinox (FFX) and Nab-paclitaxel/Gemcitabine (AG) showed significant efficacy improvement compared to Gemcitabine alone in metastatic pancreatic cancer (mPC). Alternating AG and FFX may overcome resistance and delay tumor progression. We designed a multicenter phase I-II trial to evaluate a sequential treatment with AG followed by FFX in 1st-line. Phase I established the recommended doses and confirmed the feasibility in a 12-patient expansion cohort (Assenat et al, ESMO 2016). Phase II assessed the efficacy of the recommended doses. **Methods:** During phase II, AG and FFX were administered sequentially, each AG cycle followed by 2 FFX cycles. All chemotherapeutic agents were administered according to standard practice. The primary endpoint was the objective response rate (ORR). **Results:** 58 patients were included in 3 centers, between 2014 and 2016. Patients were 50% male, median age 60 years (34-72), ECOG PS 0 (37.9%) or 1 (62.1%). A median of 4 (1-9) cycles were administered, during 34.2 weeks (2.1-79.4). Neurotoxicity rate was low (gr3: 5.2%). Main grade 3/4 toxicities were thrombosis (17.2%/0%), thombopenia (31%/1.7%), neutropenia (34.5%/22.4%), febrile neutropenia (1.7%/1.7%), nausea (17.2%/0%), diarrhea (25.9%/1.7%), weight loss (1.7%/0%) and asthenia (31%/0%). No toxic death was reported. Efficacy analysis included 57 patients. Response was complete in 3.5% patients; partial in 59.7%; disease was stable in 21% patients, progressive in 15.8%. The primary objective was met with an ORR of 63.2% (95% CI: 49.3-75.5). After a median follow-up of 18.6 months (95% CI: 14.5-25.6), the median progression-free and overall survival were 9.6 months (95% CI: 6.0-12.3) and 17.8 (95% CI: 11.7-21.3) months. **Conclusions:** This phase II study confirmed the phase I data with an acceptable toxicity and a high response rate for this alternating AG and FFX treatment. Survival results are promising and justify considering further randomized trials in these setting. Clinical trial information: NCT01964287.

Time (months)	PFS rate (%)	95% CI	OS rate (%)	95% CI
9	51.6	[37.8-63.8]	70.3	[56.6-80.4]
12	41.2	[27.3-54.7]	61.5	[47.6-72.7]
15 (PFS) / 18 (OS)	29.2	[16.2-43.4]	47.9	[33.3-61.0]

4110 Poster Session (Board #299), Sun, 8:00 AM-11:30 AM

Phase 1b/2 trial of cancer stemness inhibitor napabucasin (NAPA) + nab-paclitaxel (nPTX) and gemcitabine (Gem) in metastatic pancreatic adenocarcinoma (mPDAC). *First Author: Tanios S. Bekaii-Saab, Mayo Clinic, Phoenix, AZ*

Background: NAPA is an oral investigational agent, hypothesized to inhibit cancer stemness pathways, including STAT3 pathway implicated in cancer stem-cell viability. We report updated data in a study of mPDAC patients (pts) (NCT02231723) treated with NAPA + nPTX + Gem, including a subgroup of pts eligible for enrollment in the ongoing phase 3 study (NCT02993731, CanStem111P). **Methods:** A phase 1b/2 multicenter study in mPDAC pts was done to assess the recommended phase 2 dose, PK profile, and signals of anticancer activity of NAPA + nPTX + Gem. Pts received NAPA 240 mg BID + weekly nPTX 125 mg/m^2 + Gem 1000 mg/m^2 for 3 of every 4 weeks until disease progression or other discontinuation criteria. **Results:** Of 59 study pts, 47 (79.7%) were treatment-naïve, and 12 (20.3%) had prior adjuvant treatment. There were no notable PK interactions or dose-limiting toxicities. The most common adverse events included grade 1 diarrhea, neuropathy, pyrexia, and grades 1/2 nausea and fatigue. Among all 59 pts, disease control rate (DCR) was observed in 46 (78.0%) with 2 complete responses (CR) (3.4%) and 26 partial responses (PR) (44.1%) with maturing median progression-free survival (mPFS) and overall survival (mOS) of 7.06 and 9.59 mo, respectively. Among the 50 evaluable pts by RECIST, DCR was 92.0%, with 2 CR (4.0%) and 26 PR (52.0%). Of 9 nonevaluable pts, treatment stopped due to disease progression (3), death (1), noncompliance (2), pt withdrawal (2), and insurance coverage loss (1). In 29 pts eligible for CanStem111P trial, mPFS and mOS is 7.10 and 12.62 mo, respectively. Clinical trial information: NCT02231723. ORR, objective response rate; N/A, not yet reached [1]Evaluable: received ≥1 dose of study drug and had ≥1 on-study RECIST evaluation **Conclusions:** NAPA was well tolerated when combined with nPTX + Gem, with encouraging signs of activity in mPDAC, which are now being further investigated in an ongoing phase 3 study.

	DCR %		ORR %

4111 Poster Session (Board #300), Sun, 8:00 AM-11:30 AM

A phase 1/2, open-label dose-escalation study of liposomal irinotecan (nal-IRI) plus 5- fluorouracil/leucovorin (5-FU/LV) and oxaliplatin (OX) in patients with previously untreated metastatic pancreatic cancer (mPAC). *First Author: Andrew Peter Dean, St. John of God Hospital, Subiaco, Australia*

Background: nal-IRI+5-FU/LV is effective for patients with mPAC after disease progression following gemcitabine-based therapy. The current study (NCT02551991) is a phase 1/2, open-label trial to assess the safety, tolerability, and dose-limiting toxicities (DLT) of nal-IRI+5-FU/LV+OX (NAPOX) for the first-line treatment of patients with mPAC and to determine Phase 3 dosing. **Methods:** NAPOX is being evaluated in patients ≥18 yrs with previously untreated mPAC, with an ECOG performance status ≤1 and adequate organ function. Three of 4 dose-escalation cohorts of NAPOX, dosed on day 1 and 15, have been initiated. Safety and tolerability are the primary endpoints of this study, with assessment of exploratory efficacy signals. **Results:** As of 10 Nov 2017, 24 patients (Cohort A: n = 7; Cohort B: n = 7; Cohort C: n = 10) have received ≥1 dose of NAPOX (median age: 66.0 yrs, range: 44–78 yrs). Five patients reported ≥1 DLT (Cohort A: n = 2/7; Cohort B: n = 1/7; Cohort C: n = 2/10). The most frequent treatment-emergent adverse events (TEAEs) were gastrointestinal (GI) disorders (Cohort A: 71%; Cohort B: 71%; Cohort C: 60%). Grade 3 or 4 TEAEs were GI disorders (Cohort A; 43%; Cohort B: 14%; Cohort C: 50%) and neutropenia (Cohort A: 43%; Cohort B: 29%; Cohort C: 40%). The best overall response was partial response (PR) in 6/24 patients (Cohort B: n = 3/7; Cohort C: n = 3/10). In Cohort B (the lowest and most tolerable cohort), n = 5/7 patients reached disease control (PR or stable disease > 16 weeks), with n = 4/7 patients were treated for ≥24 weeks. **Conclusions:** Initial analysis suggests a well-tolerated dose and promising antitumor clinical activity of NAPOX. Dose escalation and expansion is ongoing. Clinical trial information: NCT02551991.

4112 Poster Session (Board #301), Sun, 8:00 AM-11:30 AM

A phase II study of pre- and post-operative gemcitabine and erlotinib plus pancreaticoduodenectomy (PD) for patients with resectable pancreatic ductal adenocarcinoma (PDAC): ACOSOG Z5041 trial (Alliance). *First Author: Alice Chia-chi Wei, University of Toronto, Toronto, ON, Canada*

Background: For resectable PDAC (without vascular involvement) post-operative adjuvant therapy remains the standard, though there is considerable interest in a neoadjuvant approach. This study evaluates overall survival (OS) with perioperative gemcitabine + erlotinib (G+E) combined with PD for resectable PDAC. **Methods:** ACOSOG Z5041 was a prospective, multicenter, single-arm phase II trial of pre- and postoperative G+E for resectable PDAC. Key eligibility requirements were localized biopsy-confirmed PDAC in the pancreatic head, resectable without evidence of tumor involvement of major mesenteric vessels. Patients (pts) received standard G+E (100 mg days 1-43) prior to and following surgery. The primary endpoint was 2-year overall survival (OS); secondary endpoints included toxicity profile, response rate, resection rate and time to progression. The study was closed early due to slow accrual; no formal hypothesis testing was performed. **Results:** 116 meeting eligibility requirements were enrolled; 114 who initiated treatment were evaluable. By central radiologic review, 97 pts met protocol resectability criteria, 17 pts were beyond. Median age was 66 years (39-88); 55 females (48%). Grade 3+ toxicity was reported in 68 (60%) and 90 (79%) pts during the neoadjuvant phase and overall. 22 (19%) pts did not proceed to surgery. 92 (81%) pts had surgery; 83 (73%) were resected with PD, 9 (8%) were unresectable. R0 and R1 margins were 67 (81%) and 15 (18%) of resected pts, respectively. 54 received post-operative G+E (65% resected, 47% evaluable). 2-year OS for evaluable pts was 40% (95%CI 31-49%) with median OS 21.3 (95%CI 17-26) months. 2-year OS for resected pts was 52% (95%CI 37-59%) with median OS 25.4 (95%CI 22-30) months. **Conclusions:** For resectable PDAC, neoadjuvant therapy provides 2-year OS similar to pts able to receive standard adjuvant therapy. Importantly, futile PD was avoided in 27% pts. Further evaluation of neoadjuvant therapy in resectable PDAC is warranted as more active chemotherapy regimens emerge. Support: U10CA180821, U10CA180882; Clinical trial information: NCT00733746.

4114 Poster Session (Board #303), Sun, 8:00 AM-11:30 AM

Comprehensive molecular profiling of paired patient samples of primary and metastatic (met) pancreatic ductal adenocarcinoma (PDAC). *First Author: Neel Trivedi, Medstar Georgetown University Hospital, Washington, DC*

Background: Pancreatic cancer is the third leading cause of cancer-related death in the U.S. The vast majority of pancreatic cancer is PDAC (90%). Most patients with PDAC die from complications from met disease, thus it is vital to better understand the molecular changes that promote met spread. Prior studies have shown few molecular changes between primary and met PDAC in unpaired analyses, but limited data exist on large-scale comparisons between paired samples from the same patient. **Methods:** We analyzed next-generation sequencing (NGS) and immunohistochemistry (IHC) data from 123 patients with multiple PDAC tumors profiled by Caris Life Sciences and compared paired primary and met samples from the same patient. After patients with unrelated second primary cancers were excluded, 113 pairs were used for analysis. McNemar's test was used to compare primary and met tumor pairs. **Results:** The most common sites of mets were liver (33%), lung (19%), and peritoneum (18%). The average time between samples was 21.3 months (range 1-92). *KRAS* status changed in 13.2% of pairs (5.7% gained, 7.5% lost, n = 53, P = 0.710), *TP53* status changed in 16.1% (16.1% gained, 0% lost, n = 31, P = 0.025), and *SMAD4* status changed in 14.8% (7.4% gained, 7.4% lost, n = 27, P = 1.000). Mets gained expression of TOPO1 (37.5%, n = 80, P = 0.003), TOP2A (42.6%, n = 47, P = 0.003), PTEN (27.3%, n = 66, P = 0.050), and PD-L1 (11.1%, n = 36, P = 0.180). Tumor mutational burden (TMB) increased in mets in 11 of 12 pairs with TMB data (mean 6.67 v. 4.42 mutations per megabase, P = 0.0015 by Wilcoxon signed-rank test). **Conclusions:** *KRAS* mutational status between primary and met PDAC pairs was usually concordant but changed more often than previously reported. TOPO1, TOP2A, and PTEN expression were significantly discordant. The rate of discordance and increase in TMB support profiling of PDAC mets. Continued research into which mutations play key roles in PDAC mets could yield new targets for future therapies.

4115 Poster Session (Board #304), Sun, 8:00 AM-11:30 AM

Geographic and ethnic heterogeneity in the *BRCA1/2* pre-screening population for the randomized phase III POLO study of olaparib maintenance in metastatic pancreatic cancer (mPC). *First Author: Talia Golan, Institute of Oncology, Sheba Medical Center, Ramat Gan, Israel*

Background: Germ-line mutations in *BRCA1/2* (g*BRCA*m) can cause defective repair of double-strand DNA breaks and are a risk factor for mPC. The poly(ADP-ribose) polymerase (PARP) inhibitor olaparib exploits homologous recombination repair deficiency in *BRCA*m tumors to produce synthetic lethality. Its efficacy is being evaluated in the POLO trial (NCT02184195). It is unknown how geography and ethnicity impact uptake of *gBRCAm* pre-screening in mPC. **Methods:** POLO is an international, ongoing, placebo-controlled trial to determine efficacy of olaparib (tablet formulation) maintenance monotherapy in *gBRCAm* pts with mPC. Mandatory pre-screening involves *gBRCA* testing by Integrated BRACAnalysis (Myriad Genetic Laboratories/MGL). The current analysis includes pts with *gBRCA*m previously identified by MGL or via pre-screening. Demographic/clinical history data were collected at enrollment. **Results:** 2206 pts from 12 countries were tested between 10/14 and 12/17. Pre-screening identified 130/2179 (6.0%) with a new *gBRCAm*; 27 additional pts had a previously known *gBRCAm* that were confirmed by Myriad testing; total 159/2206 (7.2%). Pre-screened pts were 57.2% male; 21% had early-onset mPC (Age in yrs: < 33: 0.6%; 33-49: 20.3%; 50-64: 49.4%; 65-88: 29.7%). *gBRCAm* pts were younger (57.9 vs. 61.1 yrs).The countries with the highest rates of new gBRCAm by pre-screening were: USA 37/288 (12.8%), Israel 26/230 (11.3%), France 24/293 (8.1%), Germany 17/262 (6.4%), Italy 15/250 (6%), Spain 14/344 (4%), and Korea 10/196 (5.1%). Outside US and Israel (populations enriched in Ashkenazi Jews), *gBRCAm* was newly identified in 96/1668 (5.75%). All pts with a known *gBRCAm* were White; all *gBRCAm* in African American/Asian/Hispanic pts (n = 19) were first identified by pre-screening. **Conclusions:** 6-7% unselected mPC have *gBRCAm*, with substantial geographic variability. Pts with *gBRCAm* were diagnosed at younger ages. Non-White pts were universally unaware of familial *gBRCAm* before pre-screening, highlighting potential disparities in uptake of genetic testing in minority populations and emphasizing the need to improve access to testing. Clinical trial information: NCT02184195.

4116 Poster Session (Board #305), Sun, 8:00 AM-11:30 AM

Potentially curative combination of TGF-b1 inhibitor losartan and FOLFIRINOX (FFX) for locally advanced pancreatic cancer (LAPC): R0 resection rates and preliminary survival data from a prospective phase II study. *First Author: Janet E. Murphy, Massachusetts General Hospital, Boston, MA*

Background: FFX is under study in LAPC for its potential for curative resection, but the downstaging rate remains low. Preclinical data suggest that inhibition of the renin-angiotensin system with losartan reduces TGF-b1 activity, enhancing intratumoral penetration of chemotherapy by remodeling desmoplasia and improving perfusion. This study investigated the R0 resection rate of FFX/losartan in LAPC. **Methods:** LAPC pts (per NCCN criteria), ECOG PS 0-1 were enrolled in a single institution NCI-sponsored phase II study (NCT01821729). Pts received 8 cycles FFX/losartan. If the tumor was radiographically resectable after chemotherapy, pts received short-course chemoradiation (CRT) in 5 fractions (protons 25 GyE, capecitabine 825 mg/m2 bid). If the tumor still abutted vasculature, pts received CRT to 50.4 Gy with a vascular boost to 58.8 Gy. Primary endpoint was R0 resection rate. Secondary endpoints were mPFS, mOS and circulating biomarkers of losartan activity. **Results:** 50 pts enrolled from 8/2013 to 7/2017. One pt withdrew consent, and 49 pts were evaluable for this analysis. Median age was 63y (42-78), tumor size was 41mm (18-68). Tumor was in the pancreatic head in 31 (63%) of pts. 39 pts received 8 cycles of FFX/losartan, while 10 had fewer than 8 cycles due to progression (4), losartan intolerance (3), and toxicity (3). Grade 3 or greater toxicity occurred in 25 (51%) pts, including diarrhea , thrombocytopenia, nausea, and neutropenia/febrile neutropenia. No single grade 3+ toxicity occurred in more than 14% of pts. 46 pts recieved CRT: 7 pts (14%) had short-course, while 39 pts (80%) had long-course CRT. 39 pts underwent attempted surgery, with 34 pts resected. R0 resection was achieved in 30 pts (61% of evaluable pts, 88% of resected pts), with R1 resection in 4 pts. Overall mPFS was 17.5 months and mOS 31.4 months. Among resected pts, mPFS was 21.3 months and mOS was 33.0 months. Biomarker analysis showed superior OS in pts with lower plasma levels of HGF at baseline. **Conclusions:** FFX/losartan achieved a remarkably high (61%) R0 resection rate in LAPC pts. A multi-center randomized Phase II trial is planned. Clinical trial information: NCT01821729.

4117 Poster Session (Board #306), Sun, 8:00 AM-11:30 AM

Nab-paclitaxel plus S-1 followed by S-1 maintenance therapy as a first-line strategy for advanced pancreatic adenocarcinoma. *First Author: Yan Shi, Chinese PLA General Hospital, Beijing, China*

Background: Growing evidence support maintenance therapy (MT) offer clinical benefit in pancreatic, colorectal and lung cancers. In our phase II trial, nab-paclitaxel plus S-1 (NPS) showed encouraging objective response rate (ORR) as first-line treatment in advanced pancreatic adenocarcinoma (APAC), in which S-1 was an option as MT after NPS. Our observational study aims to evaluate the effectiveness and tolerability of strategically using S-1 as MT after NPS in APAC. **Methods:** Between Jan 2014 and Oct 2017, 122 patients with APAC treated with NPS were included in this observational study. In patients without progression after at least 4-cycle of NPS (nab-paclitaxel, 240mg/m^2 every 3-week; S-1, 80-120 mg/d per body surface area on day 1-14 of each 21-day cycle) or treatment discontinued due to any reasons, S-1 monotherapy was allowed to be given as MT at physician's discretion according to patients' desire and ECOG performance status. Patients were followed up every 2 months until death. ORR, progression-free survival (PFS), overall survival (OS) and safety were measured. **Results:** In 8 locally advanced and 114 metastatic APACs, ORR, median PFS and OS were 49.2%, 7.5 (95%CI 6.0 to 9.0m) and 10.7 months (95%CI 8.6 to 12.8m), respectively. Total 84 patients had no progression after a median of 4 cycles of NPS (2 to 8 cycles), in which 49 had a median of 4-cycle S-1 MT (1 to 32 cycles). Median PFS and OS in patients with S-1 MT were 10.4 months (95% CI 7.9 to 12.9m) and 16.7 months (95%CI 14.5 to 18.9m) compared to 5.1 months (95%CI 4.7 to 5.5m) and 8.1 months (95%CI 6.4 to 9.8m) without S-1 MT ($P < 0.001$). In patients with stable disease (n = 31), mPFS and mOS in S-1 MT group were 10.4 (95%CI 6.9 to 13.9m) and 16.4 months (95%CI 13.8 to 19m) compared to 5.2 (95%CI 4.3 to 6.1m) and 8.1 (95%CI 6.7 to 9.5m) without S-1 MT ($P < 0.05$). Survival rates were 79.1% and 65.7% at 1 year, 61.9% and 33.4% at 2 years in patients with or without S-1 MT, respectively. S-1 MT group had a higher incidence of grade 3 or 4 leukopenia/neutropenia (20.4%) compared to 12.8% in the group without MT. **Conclusions:** Maintenance with S-1 after NPS was effective and well tolerated in APAC, which offered a new first-line strategy for APAC with a promising OS and PFS.

4118 Poster Session (Board #307), Sun, 8:00 AM-11:30 AM

Prospective trial of preoperative FOLFIRINOX in patients with resectable pancreatic ductal adenocarcinoma (PDAC): Report of early endpoints. *First Author: Safi Shahda, Indiana University Melvin and Bren Simon Cancer Center, Indianapolis, IN*

Background: Chemotherapy and surgical resection improve survival in patients with PDAC. Neoadjuvant therapy (NAT) may allow better selection for resection and provides early treatment of micrometastases. We aimed to assess pathologic response, percent of patients who undergo resection, toxicity, perioperative mortality and survival after NAT in patients with resectable PDAC **Methods:** Patients with radiographically resectable PDAC were enrolled on this single-arm clinical trial. Patients received FOLFIRINOX (5FU bolus 400 mg/m^2, leucovorin 400 mg/m^2, 5FU infusion 2400 mg/m^2, oxaliplatin 85 mg/m^2, and irinotecan 180 mg/m^2) on days 1 and 15 of every 28-day cycle. NAT with 2 cycles was followed by restaging imaging prior to surgical exploration and resection. Pathologic response was graded as G1: < 10%, G2: 10-90% and G3 > 90% viable tumor. This study was IRB approved **Results:** Between 6/2014-10/2017, 51 patients consented and 48 enrolled. Demographics: 30 male and 18 female; median age was 65 years (36-76) and race: 43 W, 3 AA, and 2 other. At the data cutoff (12/31/17), 3 patients have not yet had surgical evaluation. Of 45 patients, 36 have completed all planned preoperative chemotherapy. Thirty-five patients have undergone resection with the following features; R0 margin status: 88%, AJCC7 stage IB: 3%, IIA: 22% and IIB: 74%. Pathologic responses were G1: 6%, G2: 31% and G3: 63% without pathologic CR. Four patients (9%) progressed while on NAT, 3 (7%) were found to have metastatic disease during surgery, and none with local progression prohibiting surgical resection. Two patients died on study; one with complications related to NAT. 30-day postoperative mortality was not observed. **Conclusions:** NAT is feasible in patients with resectable PDAC and may select out patients with aggressive biology who would not benefit from resection. Pathologic responses were observed without pCR. Survival data are maturing. Clinical trial information: NCT02178709.

4119 Poster Session (Board #308), Sun, 8:00 AM-11:30 AM

Overall survival of PEGylated pegilodecakin with 5-FU/LV and oxaliplatin (FOLFOX) in metastatic pancreatic adenocarcinoma (PDAC). *First Author: J. Randolph Hecht, David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, CA*

Background: The therapeutic options for 2nd line therapy PDAC remain unsatisfying with 5-FU/LV plus oxaliplatin or nal-irinotecan resulting in a mOS of 5-6 mo. PDAC has been largely refractory to immune-oncology approaches and CD8+ T cells are rare in most PDAC. AM0010 stimulates survival, expansion and cytotoxicity of intratumoral CD8+ T cells. Immune activation, durable stable disease and a 1yr survival of 22.5% was seen in salvage PDAC patients (pts) receiving AM0010 alone. AM0010 has synergistic anti-tumor activity with 5-FU/LV or oxaliplatin in preclinical models. Here we report on the safety, efficacy and overall survival of AM0010 + FOLFOX as 2nd and later line treatment in PDAC pts. **Methods:** PDAC pts progressing on a median of 2 prior therapies (range 1-5) were treated with AM0010 (5ug/kg SQ, qd) + FOLFOX (n = 21). The safety population (n = 25) included also 4 pts with prior oxaliplatin / 5-FU. Tumor responses were assessed with irRC. The survival population included all patients without prior platinum containing regimen. Biomarkers included the sequence analysis of blood derived T cells for T cell clonality. **Results:** AM0010 + FOLFOX, was generally well tolerated. G3/4 TrAEs included thrombocytopenia (56%), anemia (44%), neutropenia (36%) and fatigue (12%). Most cytopenias had a short duration and reaching retreatment criteria within 2-5 days after dose interruption. Dosing AM0010 for 5 days followed by a 2 days dose holiday has avoided G3/4 cytopenias. Grade1/2 but no higher grade neuropathy was observed in 16% of patients. Of 19 evaluable pts, 2 had an irCR, 1 had irPR with 100% reduction in tumor burden, ORR is 15.8%, DCR is 78.9%. With median follow-up of 23.4 months (range 18.9 - 28.9), mPFS was 2.6 mo, mOS was 10.2 mo and 1-year and 2-year survival was 43% and 28.8%, respectively. The expansion of previously non-detected T cell clones correlated with OS $>$ 8 months. **Conclusions:** AM0010 in combination with FOLFOX is well tolerated in patients with metastatic PDAC, and has a reduced incidence of FOLFOX related neuropathy. Immune activation and overall survival are encouraging in this advanced PDAC population. This regimen is currently being studied in a phase 3 trial. Clinical trial information: NCT02009449.

4120 Poster Session (Board #309), Sun, 8:00 AM-11:30 AM

Prognosis of resectable pancreatic cancer based on systemic therapy sequence and regimen: An NCDB analysis. *First Author: Aileen Deng, Thomas Jefferson University Hospital, Philadelphia, PA*

Background: While surgical resection can cure pancreatic cancer (PC), the majority of patients who undergo resection recur. As newer multi-agent chemotherapy regimens have evolved for metastatic PC, there has been increased interest in its use in the neoadjuvant (NAT) setting. However, U.S. clinical practice patterns vary widely. We evaluated the effect of systemic therapy sequence and regimen on prognosis in resected PC. **Methods:** Adult patients with resected, clinical stage I or II PC were identified in the NCDB from 2010-2015. Patients who received NAT followed by resection were matched by a minimum distance approach with those who underwent upfront resection (UR) with or without adjuvant therapy (AT) based upon demographics and disease-specific variables. OS was compared with Kaplan-Meier curves in matched cohorts. The effects of single-agent (SA) versus multi-agent (MA) chemotherapy (CT) on OS was evaluated using multivariate Cox proportional hazards regression model. **Results:** We identified 23,576 patients with clinical stage I or II resected PC. 3,446 patients who received NAT were matched with 3,446 patients who underwent UR. Those who received NAT had improved OS compared to those who underwent UR with or without AT (median survival time [MST] 27.9 versus 23.3 months, respectively; log-rank $p < 0.0001$). Among different treatment sequences, patients who received both NAT and AT had the longest OS compared to those who received either NAT or AT alone (MST 31.3 versus 26.2 versus 26.5 months, respectively; log-rank $p < 0.0001$). In patients treated with NAT alone, those who received MA CT had an improved OS compared to those who received SA CT (adjusted HR 0.72, 95% CI 0.64-0.81). In patients who received MA chemotherapy, MA NAT was associated with an 18% reduction in risk of death compared to those treated with MA AT (adjusted HR 0.82, 95% CI 0.73-0.93). **Conclusions:** In resectable PC, patients who received both NAT and AT had improved survival compared to those who receive NAT or AT alone. This supports future evaluation of maintenance therapy in the adjuvant setting. MA NAT was associated with improved survival compared to SA NAT. This supports current clinical practice and ongoing clinical trials.

4121 Poster Session (Board #310), Sun, 8:00 AM-11:30 AM

A phase II trial of neoadjuvant gemcitabine/nab-paclitaxel and SBRT for potentially resectable pancreas cancer: An evaluation of acute toxicity. *First Author: Manisha Palta, Duke University Medical Center, Durham, NC*

Background: The optimal management of potentially resectable pancreas cancer is unknown. The high rates of local and distant failures following surgical resection highlights the need for improvement in both local and systemic therapies. The combination of newer systemic therapies with ablative radiotherapy could be better tolerated and associated with improved treatment outcomes. **Methods:** Patients with newly diagnosed, previously untreated, non-metastatic pancreatic cancer who were candidates for resection were prospectively enrolled in this single arm study. Patients received a neoadjuvant regimen of 2 cycles of gemcitabine (1000mg/m^2)/ nab-paclitaxel (125mg/m^2) and SBRT (25Gy in 5 fractions). After neoadjuvant treatment patients were restaged and considered for resection. The primary study endpoint was acute toxicity as assessed by CTCAE V 4.0. The primary study hypothesis was that this neoadjuvant regimen would result in Grade 3+ non-hematologic acute toxicity of $<$ 50% (as per RTOG 97-04). **Results:** Twenty-five patients were accrued to this study. 28% had resectable and 72% had borderline resectable disease (per NCCN criteria). 96% of patients received both cycles of systemic therapy and all 25 patients went on to SBRT and completed the planned radiotherapy course. The rate of acute non-hematologic Grade 3+ toxicity with the neoadjuvant regimen was 20% (5/25). The rate of overall Grade 3+ toxicity with neoadjuvant gemcitabine/ nab-paclitaxel was 52% and Grade 3+ non-hematologic toxicity was 17%; exact 80% CI of (8%, 32%). No Grade 3+ acute toxicity was seen with neoadjuvant SBRT and 28% experienced Grade 2 toxicity. 17/25 (68%) patients went on to surgical resection and 93% achieved an R0 resection. Actuarial local control is 77% and medial overall survival is 24 months. **Conclusions:** A neoadjuvant approach of gemcitabine and nab-paclitaxel followed by SBRT in patients with potentially resectable pancreatic cancer was well tolerated. Given robust patient accrual, the initial enrollment was expanded to 40 patients and accrual is ongoing. Prospective evaluation of this treatment regimen in a randomized fashion is warranted. Clinical trial information: NCT02318095.

4122 Poster Session (Board #311), Sun, 8:00 AM-11:30 AM

Quantitative multiplex immune fluorescence to reveal the impact of chemoradiation therapy on modulation of the immune micro-environment of pancreatic ductal adenocarcinoma. *First Author: Thomas Enzler, New York Presbyterian - Columbia, New York, NY*

Background: Patients with advanced pancreatic ductal adenocarcinoma (PDA) continue to have median survival under one year and to date immunotherapy has largely been unsuccessful. Radiation or chemoradiation can cause the release of tumor antigens and pro-inflammatory cytokines leading to stimulation of anti-tumor immunity. We sought to quantify this effect by comparing immune cell infiltrations of PDAs treated with chemoradiation or not treated prior to surgical resection. **Methods:** Slides obtained from surgical specimens were stained using opal fluorophores for CD3, CD8, CD4, FOXP3, CD68, Ki-67, and DAPI for nuclear staining. This method allowed simultaneous evaluation of different markers using quantitative multiplex immunofluorescence (qmIF). Images were taken with automated imaging system VECTRA and analyzed for cell densities in tumor and stromal compartments. We included 20 patients who underwent chemoradiation and 12 patients without neoadjuvant treatment. **Results:** When comparing treated vs. non-treated tumors, total CD3+ densities were significantly higher in stromal tissue of treated tumors (P = 0.0002). There was also a significant increase in CD3+CD8+ T cell densities (P = 0.0006) and CD3+CD4+FOXP3- T cell densities (P = 0.0037) in the stromal tissue of treated tumors. Conversely, CD4+FOXP3+ T cells were significantly increased in the tumor microenvironment (TME) of non-treated tumors when compared to treated tumors (P = 0.0003). No clear differences in infiltrating CD68+ macrophages were observed between the groups. **Conclusions:** To our knowledge this is the first time that immune cell infiltrates of PDA either treated with neoadjuvant chemoradiation or not treated were compared using qmIF. The higher counts of T helper cells and cytotoxic T cells found in treated tumors can be explained by the increased immunogenicity caused by chemoradiation-therapy. The higher densities of CD4+FOXP3+ cells in non-treated tumors likely reflect the immunosuppressive TME. We will try to identify biomarkers predictive of outcome and, hopefully, our findings will provide rationale for the development of new treatment strategies.

4123 Poster Session (Board #312), Sun, 8:00 AM-11:30 AM

Safety, efficacy and pharmacodynamics (PD) of MEDI9447 (oleclumab) alone or in combination with durvalumab in advanced colorectal cancer (CRC) or pancreatic cancer (panc). *First Author: Michael J. Overman, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Oleclumab is a human mAb that binds to CD73 and inhibits production of immunosuppressive adenosine. This is a first-in-human study to investigate the safety, efficacy, and pharmacodynamics of oleclumab alone or in combination with durvalumab in patients (pts) with advanced panc or MSS-CRC. **Methods:** A 3+3 dose-escalation design was followed in which pts received one of 4 escalating doses of oleclumab IV with or without durvalumab 10 mg/kg IV Q2W until disease progression, followed by study expansion with high dose of oleclumab plus durvalumab 10 mg/kg Q2W. AEs and tumor response (RECIST v1.1) were assessed. Free soluble CD73 and cell surface CD73 on lymphocytes were measured by ELISA and flow cytometry, respectively. Tumoral CD73 was centrally assessed by an *in situ* enzyme assay and IHC. **Results:** The initial dose-escalation and PD exploration enrolled 42 monotherapy and 24 combination pts with no reported DLTs. The minimum target serum concentration was exceeded at the top 2 doses. Sustained decrease in free soluble CD73 and CD73 on peripheral T cells was demonstrated across all doses and pts. Decreased CD73 enzymatic activity was observed in all evaluable frozen tumor biopsy samples (n = 4) 20 days after treatment with the top 2 doses of oleclumab. Treatment with oleclumab alone decreased tumoral CD73 expression (5/9) while increasing CD8+ TILs in all 5 samples. Subsequently, durva + oleclumab highest dose was selected for expansion in 2-5L CRC (21 pts) and 2-3L panc (20 pts). The most commonly reported TRAEs in combo expansion were diarrhea (8.7%), pyrexia (8.7%), fatigue (6.5%), and increases in ALT (6.5%), AST (6.5%), and ALP (6.5%). PR was observed for 1/21 CRC (5L) and 2/20 panc (2 and 3L) pts; SD was observed in 2/21 CRC and 3/20 panc pts. Duration of treatment for subjects with disease control was 84-322 days (CRC) and 28-232 days (panc). Treatment is ongoing for 1 CRC (322 days) and 2 panc pts (140 and 182 days). **Conclusions:** Treatment with oleclumab and durvalumab had a manageable safety profile and PD consistent with mechanism of action. Combination therapy has encouraging clinical activity in panc and potentially in CRC pts. Clinical trial information: 02503774.

4124 Poster Session (Board #313), Sun, 8:00 AM-11:30 AM

Final results from a phase II study of 5-fluorouracil, oxaliplatin, and dasatinib (FOLFOX-D) in previously untreated metastatic pancreatic adenocarcinoma. *First Author: Thomas J. George, University of Florida, Health Cancer Center, Gainesville, FL*

Background: Systemic chemotherapy for pancreatic adenocarcinoma (PCa) improves survival but most targeted agents have consistently failed to demonstrate clinical benefits. Src is overexpressed in PCa and promotes an aggressive cancer phenotype. Dasatinib (D) is an oral multi-tyrosine kinase inhibitor (TKI) affecting tumor proliferation through inhibition of Src, Bcr-Abl, CKit and other pathways. Inhibition of Src is associated with biologic modifications favorably modifying the PCa phenotype and has synergy with restoring inherent chemosensitivity. Src inhibition can also increase oxaliplatin activity and modulate Tcell responses. The addition of D to the well-established backbone of FOLFOX represents a multifaceted line of scientific investigation. **Methods:** This phase II trial is to determine activity and toxicity of FOLFOX + D in previously untreated metastatic PCa. Pts must have at least 1 RECIST measurable target lesion, ECOG PS 0-2, normal QTc and adequate organ function. Treatment is standard q14d cycles of mFOLFOX6 with continuous D (150mg PO daily). Tumor assessments occur q8w. Endpoints are PFS (primary), objective and biochemical response rates, clinical benefit rate, freedom from metastases, overall survival (OS), toxicity, and quality of life. Exploratory tissue, CTC and serum analyses to identify predictors of response are planned. Sample size is based on a 50% improved median PFS from 4 (historical) to 6 mo. **Results:** 42 of 44 enrolled pts are evaluable. Baseline demographics are in Table 1. Median PFS was 4.0 mo (95% CI 2.3-8.5; range 0.1-43.3) and OS was 10.6 mo (95% CI 6.9-12.7; range 0.1-47.9). RR was 24% with clinical benefit rate (CR + PR + SD) of 60%. 10 pts (24%) were on active therapy more than a year with a few long term exceptional responders. Toxicity has been previously reported. Molecular profiling of Src expression and circulating biomarkers is ongoing. **Conclusion:** Addition of D to FOLFOX failed to significantly improve PFS in an unselected cohort of PCa pts. Toxicity was manageable. Analysis of Src expression in exceptional responders is ongoing. Clinical trial information: NCT01652976.

Baseline patient demographics

Variable	Median value (%)
Age	65 (range 29-81)
Race	Caucasian n = 37 (88)
Gender	Male n = 28 (67)
Prior adjuvant therapy	7 (17); gemcitabine-based
History of diabetes	11 (26)
Current or Former smoker	20 (48)
Serum CA19-9	3011 (range 1- > 10000) U/mL
ECOG PS	0 (n = 22); 1 (n = 17); 2 (n = 3)

4125 Poster Session (Board #314), Sun, 8:00 AM-11:30 AM

Adjuvant treatment for resected sub-centimeter T1 pancreatic cancer. *First Author: Walid Labib Shaib, Winship Cancer Institute of Emory University, Atlanta, GA*

Background: The standard of care for pancreatic cancer (PC) patients with resected stage I to III is adjuvant chemotherapy. The role of adjuvant treatment for sub-centimeter T1 stage is unknown. This study evaluated treatment patterns and survival outcomes in T1 stage PC using National Cancer Database (NCDB). **Methods:** Retrospective review of the NCDB was conducted for T1 (tumor confined to the pancreas and 2 cm across or smaller), lymph node negative, surgically resected PC and no prior therapy. Patient demographics, tumor histology, treatment modalities, and survival trends were examined between 2004 and 2013. Adjuvant treatments were analyzed. Kaplan-Meier analysis and the log-rank tests were performed to determine the unadjusted association between overall survival (OS), size and treatment. **Results:** A total of 964 patients met criteria for inclusion. The median age was 66 (32-90). Majority were Caucasian (N = 807, 83.7%); 53.5% were female (N = 515), and moderately differentiated (N = 447, 46.4%). Tumors of 1-2cm constituted 71.2% (N = 686); 28.8% < 1cm (N = 178). Majority had negative surgical margins (N = 887, 93.3%). Patients who received surgery alone were 48.3% (N = 466); 27.5% received adjuvant chemotherapy (N = 265), and 22.6% had adjuvant chemotherapy and radiation (N = 218). Patients with < 1cm tumors who received adjuvant therapy had a median OS that was not reached v. 85.3 mo who received surgery alone (P = 0.41). In patients with 1-2 cm tumors, the median OS for patients who received adjuvant treatment was 70.7 mo v. 30.8 mo for patients who received surgery alone (P < 0.0001). The 12-mo, 24-mo, and 60-mo survival was 93.2%, 75.6% and 53.6% respectively, v. 72.5%, 61.0%, and 31.0%, respectively, for patients who received surgery alone. These results of adjuvant therapy for tumors < 1 cm v. 1-2 cm are paralleled for patients who received adjuvant chemotherapy (P = 0.08), and any adjuvant radiation (P = 0.15). **Conclusions:** This is the first report of adjuvant treatment analysis for resected PC patients with sub-centimeter stage I disease. Adjuvant treatment does not appear to improve survival in sub-centimeter T1, stage I PC.

4126 Poster Session (Board #315), Sun, 8:00 AM-11:30 AM

Precision medicine for pancreatic cancer patients:preliminary results from the know your tumor program. *First Author: Emanuel Petricoin, George Mason University, Manassas, VA*

Background: To democratize the implementation of precision medicine (PM) in the care of pancreatic cancer patients, the Know Your Tumor (KYT) program was initiated US-wide using a turn-key PM operating system that produces a treatment decision support tool/report. **Methods:** Tumor samples were obtained for 640 patients from 287 high-volume academic and local community practices covering 44 states. Our system provides a standardized workflow within an IRB-approved registry protocol from patient intake through multi-omic molecular profiling, integration of treatment history followed by computational analysis to produce a treatment decision support tool of patient-tailored therapeutic options. Longitudinal outcome is collected on every patient along with treatment decisions, and patient experience. **Results:** Tumor samples were adequate for next-generation sequencing in 96% and immunohistochemistry in 91% of patients. *KRAS* mutations were identified in 92% of pancreatic ductal adenocarcinomas. A tumor board reviewed the results for every patient and found actionable genomic alterations in 50% of patients (with 27% highly actionable) and actionable proteomic alterations (excluding chemopredictive markers) in 5%. Actionable alterations commonly found were in DNA repair genes (*BRCA1/2* or *ATM* mutations, 8.4%) and cell cycle genes (*CCND1/2/3* or *CDK4/6* alterations, 8.1%). A subset of samples was assessed for actionable phosphoprotein markers. To date, 126 (19.7%) patients have utilized a molecularly matched therapy. Patients with highly actionable biomarkers who received matched therapy (n = 17) had a median progression-free survival (PFS) of 4.1 months, significantly longer than patients without highly actionable biomarkers (n = 72; PFS = 2.8 months; adjusted *P*-value = 0.03). **Conclusions:** A comprehensive PM system can be implemented in community and academic settings, with highly actionable findings observed in ~25% of pancreatic cancers. Patients whose tumors have highly actionable molecular alterations and who receive matched therapy demonstrated significantly increased PFS. Our findings support expansion and further prospective evaluation of precision oncology in pancreatic cancer.

4127 Poster Session (Board #316), Sun, 8:00 AM-11:30 AM

Chemotherapy and radiotherapy application for pancreatic cancer in Europe and USA: An international population-based study. *First Author: Lei Huang, German Cancer Research Center (DKFZ), Heidelberg, Germany*

Background: The role of chemotherapy in the treatment of pancreatic cancer (PaC) has been well-established, while radiation plays ambiguous roles. This large-scale international population-based study aimed to investigate the trends and variations in the application of chemotherapy and radiotherapy for PaC in Europe and the US and to explore the application determinants. **Methods:** Population-based data from multiple European national cancer registries and the US Surveillance, Epidemiology, and End Results (SEER)-18 database during 2003-2014 were analyzed. Temporal trends and geographical variations in the application of chemotherapy and radiotherapy were quantified using age standardization. Associations between treatment and demographic and clinical characteristics were assessed using multivariable logistic regression. **Results:** A total of 141,533 PaC patients were analyzed. From 2003-2005 to 2012-2014, chemotherapy application rates increased in most countries and more strongly among resected cancers, while radiation rates were generally low with a slight decline or no obvious trend. In 2012-2014, 13.1% (Estonia) to 64.4% (Belgium) of patients with resected PaC and 18.1% (Slovenia) to 60.0% (Belgium) of those with unresected cancer underwent chemotherapy. Radiation was administered in 2.6% (the Netherlands) to 26.7% (the US) of resected and 0.7% (the US) to 6.2% (Belgium) of unresected tumors. Strong temporal and geographical variations were observed. Patterns and strengths of the associations between treatment administration and demographic and clinical factors including age, tumor TNM stage, and location differed substantially between resected and unresected diseases and varied greatly across countries. **Conclusions:** Administration of chemotherapy but not radiotherapy for PaC increased during the last decade in Europe and the US. The evidence from randomized trials majorly supporting chemotherapy does not seem to have been implemented into the wider clinical practice in many countries. The uptake strongly varied between countries, highlighting the need for standardization in PaC treatment to improve patient care.

4128 Poster Session (Board #317), Sun, 8:00 AM-11:30 AM

DNA repair deficiency, genomic instability and immune profiling in a phase 1 study of locally advanced pancreatic cancer patients treated with veliparib, gemcitabine and radiotherapy. *First Author: Richard Tuli, Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Medical Center, Los Angeles, CA*

Background: A phase I trial of veliparib (V), gemcitabine (G) and radiotherapy (RT) was conducted to determine the maximum tolerated dose (MTD) and clinical activity in patients with and without DNA damage repair (DDR) defects. **Methods:** LA patients were treated with weekly G (1000 mg/m2), daily RT (36 Gy/15 fractions) and daily V 20 mg BID for 3 weeks escalated per Bayesian method followed by standard chemotherapy. DAVID was used to interpret differential gene expression. Cox regression model was used to identify DDR pathways associated with survival. Next generation sequencing (NGS) identified genetic mutations involved in DDR, tumor mutation burden (TMB) and microsatellite instability (MSI) status. Blood samples were interrogated for PAR protein and cytokines using an ELISA and electrochemiluminescent array, respectively. The log-rank test was used to evaluate differences in PFS and OS. **Results:** 34 patients were enrolled from 2013 to 2016. MTD of veliparib was 40 mg BID with gemcitabine 400 mg/m2 and RT (36 Gy/15). 12 patients experienced DLT (83.3% lymphopenia, 8.3% neutropenia). Median PFS and OS were 10 and 15 months, respectively. Gene expression analysis identified DDR defects in 50% of patients. Median PFS and OS were significantly higher for these biomarker positive patients (17 vs. 8 mos, $p < .01$; 22 vs. 12 mos, $p < .001$, respectively). NGS identified 10 DDR mutations which were not prognostic of outcome. median TMB was 1.8 mut/Mb. A single MSI high patient was identified who was also TMB high (> 20 mut/MB) and harbored DDR deficiency by NGS. Lower PAR levels were associated with borderline statistically significant improvements in both PFS and OS ($p < .06$). Higher levels of IL2 and IL12 and lower levels of FLT1 were associated with improved PFS and OS ($p < .05$). **Conclusions:** The combination of V, G and RT was well tolerated. DDR alterations were identified in a large proportion of patients and were associated with improved PFS and OS. Whereas most patients were MSS and had low TMB, those with higher levels of pro-inflammatory cytokines were likely to harbor DDR alterations which were associated with improved outcomes. Clinical trial information: NCT03245541.

4129 Poster Session (Board #318), Sun, 8:00 AM-11:30 AM

High prevalence of hereditary cancer syndromes and outcomes in adults with early-onset pancreatic cancer. *First Author: Maria Fernanda Montiel, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Most patients with Pancreatic Ductal Adenocarcinoma (PDAC) are diagnosed over the age of 65. Individuals diagnosed under the age of 60 are considered to be early-onset and potentially at high risk for a genetic predisposition. We aimed to determine the prevalence of germline mutations among early-onset PDAC, as well as their influence in prognosis. **Methods:** A High Risk Cohort (HRC) and a General Cohort (GC) were included in this study. The HRC patients were patients with PDAC who met referral criteria for genetic counseling and were seen at The University of Texas MD Anderson Cancer Center (MDACC) from 2005-2016. The GC patients had metastatic PDAC and were seen at MDACC between 2010-2016. Either gene-specific (targeted) or panel DNA germline sequencing for the 13 most common genes associated with pancreatic cancer (*ATM*, *APC*, *BRCA1*, *BRCA2*, *CDKN2A*, *MLH1*, *MSH2*, *MSH6*, *PMS2*, *PALB2*, *STK11*, *EPCAM, PMS2)* was performed. Survival outcomes were analyzed with respect to germline mutational status and age by using Kaplan-Meier curves. **Results:** A total of 409 patients underwent genetic testing (277 from High Risk and 132 from General Cohort). As expected, the HRC had higher prevalence of germline mutations compared to the general cohort: 17.3% vs 6.81%. The most common mutations in both cohorts were in BRCA1/2 and MMR genes. Patients younger than 60 years old had significantly higher prevalence of germline mutations in both the HRC (OR: 1.93 +/-1.03-3.70, P: 0.039) and GC (4.78 +/-1.10-32.95, P: 0.036). With respect to clinical outcomes, the GC patients with germline mutations had significant higher median survival as compared to patients without mutations, 18.2 months vs 9.2 months respectively (HR: 0.44, 95% CI of HR: 0.25-0.76, *P*= 0.030). In the HRC, only patients older than 60 years old with mutations had better overall survival compared to the group without mutations (HR: 0.40, 95% CI of HR: 0.20-0.80, *P*= 0.038). **Conclusions:** Germline mutations are highly prevalent in patients with PDAC of early-onset and can be predictive of better outcomes. Considering emerging screening strategies for relatives carrying susceptibility genes as well as impact on therapy choices, genetic counseling and testing should be encouraged in young onset PDAC.

4130 Poster Session (Board #319), Sun, 8:00 AM-11:30 AM

Outcome driven persona-typing for precision oncology: Beyond a genomics centered view of individualized therapy. *First Author: Emanuel Petricoin, George Mason University, Manassas, VA*

Background: Precision oncology is currently being defined mainly by a genomics-oriented view to tumor biology. However, a multi-omic view to tumor biology and more accurate outcome prediction is emerging. Combining this with treatment history, clinical-epidemiological data, and outcomes data may provide patient-specific descriptors that in N-dimensional space constitute population based "personas" that share common outcome destinies and identify response predictors to any given therapy. **Methods:** We utilized our database from 919 pancreatic adenocarcinoma patients within our ongoing registry study as a feasibility study. Commercial exome (315 genes by NGS) and proteomic data (24 proteins by IHC) as well as previous and current treatment history, epidemiological data and outcomes data were collected on every patient. Overall Survival (OS) was calculated and 10 individual outcome "personas" were created that spanned short-term survival (< 6 months) to long term survival (32-110 months). Statistical analysis of individualized gene, protein, specific treatment type, disease stage, location, age, gender, ethnicity, was used to determine key principal components that significantly ($p < 0.05$) described each outcome persona to create a unique persona-type identifier. **Results:** Proteomic information was significantly associated with outcomes more frequently then genomic information ($p = 0.02$). Longest term outcome personas (OS > 32 months) were characterized by increased PD1 and decreased TS protein levels along with increased frequency of BRCA2 genomic alterations and treatment with off-label targeted therapy. Shorter term personas (OS < 6 months) were described by high TS protein levels along with genetic alterations in MYCL1, MYST3, VEGFA, ZNF703 and KEL. **Conclusions:** Persona-typing can be used to define and map key characteristics that associate with outcome and specific treatment. In the future, individual patients can be mapped to predefined personas that could more accurately describe outcome destiny and optimized/personalized therapy options.

TPS4131 Poster Session (Board #320a), Sun, 8:00 AM-11:30 AM

An investigator initiated multicenter phase I/II study of paclitaxel, ramucirumab with nivolumab as the second-line treatment in patients with metastatic gastric cancer. *First Author: Tomohiro Nishina, Shikoku Cancer Center, Matsuyama, Japan*

Background: Paclitaxel (PTX) and ramucirumab (RAM) is a standard regimen as the second-line treatment for metastatic gastric cancer (mGC). In the phase III ATTRACTION-2 trial, nivolumab (NIVO) significantly improved overall survival (OS) over placebo for metastatic gastric cancer (mGC) patients (pts) refractory to standard therapies. In preclinical models, anti-angiogenesis agents with immune-checkpoint inhibitors demonstrated enhanced activity against cancer cells compared with either drug alone. **Methods:** We are conducting a phase I/II study to determine the recommended phase II dose (RP2D) and evaluate the efficacy, safety and biomarkers of the combination regimen of PTX, RAM with NIVO in pts with mGC as the second-line treatment. Key eligibility criteria are: mGC pts who were refractory or intolerant to fluoropyrimidine and platinum in the first-line treatment, and had no prior immunotherapy; an age of 20 years or older; ECOG performance status of 0-1; and controllable hypertension. Phase I is designed to determine RP2D in the dose de-escalation design of NIVO (q4w, 3 mg/kg on days 1 and 15 for level 1 and 1 mg/kg for level −1) with fixed doses of PTX and RAM (q4w, 80 mg/m^2 on days 1,8 and 15 and 8 mg/kg on days 1 and 15, respectively). Primary endpoint is progression-free survival (PFS) rate at 6 months in pts treated with RP2D. Using a single stage binomial design, this study requires 43 pts, with a PFS rate at 6 months of 50% deemed promising and 35% unacceptable (one-sided alpha = 0.1; beta = 0.25). 35 patients have been enrolled since Feb 2017. Clinical trial information: UMIN000025947.

TPS4132 Poster Session (Board #320b), Sun, 8:00 AM-11:30 AM

FOLFIRI plus ramucirumab versus paclitaxel plus ramucirumab for patients with advanced or metastatic adenocarcinoma of the stomach or gastroesophageal junction as second-line therapy: The RAMIRIS study. *First Author: Sylvie Lorenzen, Third Department of Internal Medicine (Hematology/Medical Oncology), Klinikum rechts der Isar, Technische Universitat Munchen, Munich, Germany*

Background: The majority of patients with gastroesophageal cancer present with inoperable or metastatic disease. After failure of first-line chemotherapy, ramucirumab is a proven option as monotherapy and in combination with paclitaxel as second line treatment in advanced gastric cancer. Irinotecan has shown significant improvement of overall survival compared to best supportive care (BSC) in the second line setting and is an accepted safe and efficient standard chemotherapeutic treatment for patients with refractory gastroesophageal cancer. More and more patients get treated with taxanes in the perioperative or 1st line metastatic setting. For those patients the benefit of a combination of ramucirumab and paclitaxel is unclear, and many physicians would choose an irinotecan based regimen as second line treatment. This provides a rationale for the evaluation of FOLFIRI + ramucirumab. **Methods:** This is a prospective, multicenter, randomized, investigator initiated phase II trial. Patients with advanced gastric or esophagogastric junction cancer will be randomized 2:1 to FOLFIRI (irinotecan 180 mg/m^2; 5-FU 400 mg/m^2; leucovorin 400 mg/m^2; 5-FU 2400 mg/m^2 on day 1 and 15 of a 28-day cycle) plus ramucirumab 8mg/kg every two weeks (Arm A) or paclitaxel 80 mg/m^2 (days 1, 8, 15 of a 28-day cycle) plus ramucirumab 8mg/kg every two weeks (Arm B). Primary endpoint of the trial is OS rate after 6 months, based on the ITT population. The experimental therapy (FOLFIRI + Ramucirumab; n = 67) is considered to be a highly promising candidate for further development (e.g. in a phase III trial), if the true OS rate amounts to 65% or more, as this corresponds to the efficacy of the standard ramucirumab-paclitaxel regimen according to the RAINBOW study in the western population. Secondary endpoints are progression-free survival, response rate, safety and tolerability. Currently (Jan 2017) 40 of planned 111 patients are randomized. Clinical trial information: NCT03081143.

TPS4133 Poster Session (Board #321a), Sun, 8:00 AM-11:30 AM

A randomized phase 2, multicenter, open-label study of trastuzumab deruxtecan (DS-8201a) in subjects with HER2-expressing gastric cancer. *First Author: Kensei Yamaguchi, The Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo, Japan*

Background: There is no HER2-targeted therapy for patients with HER2-positive gastric cancer who progressed on trastuzumab-based therapy. DS-8201a is a novel HER2-targeted antibody-drug conjugate with a humanized HER2 antibody attached to a topoisomerase I inhibitor payload by a cleavable peptide-based linker (deruxtecan), and with a high drug-to-antibody ratio of 7 to 8. In the ongoing phase 1 DS8201-A-J101 trial, DS-8201a showed a manageable safety profile and promising antitumor activity in salvage-line subjects with gastric cancer who previously received trastuzumab (confirmed objective response rate [ORR] of 45.5% at Oct 16, 2017 data cutoff) (Iwasa et al, ASCO-GI 2018). **Methods:** The randomized, phase 2, multicenter, open-label, DESTINY-Gastric01 study will assess the efficacy and safety of DS-8201a in HER2-expressing gastric cancer subjects. The primary cohort, HER2-positive (IHC 3+ or IHC 2+/ISH+) subjects who progressed after ≥2 prior regimens and previously received trastuzumab, will be randomized (2:1) to DS-8201a (6.4 mg/kg dose; once every 3 weeks) or physician's choice (irinotecan or paclitaxel). Two nonrandomized exploratory cohorts will assess the efficacy and safety of DS-8201a in subjects with HER2-low gastric cancer (IHC 2+/ISH- and IHC 1+, respectively) who are treatment-naïve to HER2-targeted therapies. The primary endpoint is ORR assessed by an independent central review; secondary endpoints include overall survival (OS), progression-free survival, duration of response, disease control rate, pharmacokinetics, and safety (as shown in ClinicalTrials.gov). The primary analyses for ORR and interim OS analysis will occur after all subjects complete tumor assessments on week 18 and when approximately 108 OS events are observed, whichever comes later. The primary cohort will enroll 180 subjects; providing 92.9% power to detect a difference between the ORR of 40% for DS-8201a vs 15% for physician's choice. Each exploratory cohort will enroll a maximum of 20 subjects. Enrollment began in October 2017. As of Feb 13, 2018, 12 of 180 subjects have been enrolled. Clinical trial information: NCT03329690.

TPS4134 Poster Session (Board #321b), Sun, 8:00 AM-11:30 AM

MORPHEUS: A phase Ib/II trial platform evaluating the safety and efficacy of multiple cancer immunotherapy (CIT) combinations in patients (pts) with gastric or pancreatic cancer. *First Author: Do-Youn Oh, Department of Internal Medicine, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, Republic of (South), Korea*

Background: Multiple cancers have been treated successfully with CIT; nonetheless, only subsets of pts experience durable response with CIT monotherapy. CIT combinations may therefore be needed to simultaneously address multiple mechanisms of cancer immune evasion. The MORPHEUS platform consists of multiple, global, open-label, randomized Phase Ib/II trials designed to investigate CIT combinations in pts with different tumor types. Using a randomized trial design, multiple CIT combination arms will be compared with a single control arm. Furthermore, the design of the trials will aid in the development of CIT combinations by identifying early signals and offers the flexibility to open new treatment arms with novel CIT combinations and to close arms that show minimal clinical activity or unacceptable toxicity. Various CIT combinations that simultaneously enhance immune cell priming and activation, tumor infiltration and/or recognition of tumor cells for elimination will be evaluated. Here, we describe MORPHEUS Phase Ib/II trials in pts with gastric or gastroesophageal junction cancer (GC) or metastatic pancreatic ductal adenocarcinoma (mPDAC), both representing major unmet medical needs. **Methods:** MORPHEUS-GC (NCT03281369) will enroll 2 cohorts, including pts with advanced unresectable or metastatic GC who are chemotherapy naive or have progressed on platinum- or fluoropyrimidine-based chemotherapy. MORPHEUS-PDAC (NCT03193190) will enroll pts with mPDAC who have progressed on 1 line of prior chemotherapy. Additional eligibility criteria include measurable disease per RECIST v1.1 and accessibility of the tumor for biopsy. Pts in both trials will be randomized to one of the CIT combination arms or a control arm (up to 8 arms across 2 cohorts in GC; 4 arms in PDAC). In the setting of unequivocal disease progression/toxicity, pts may be eligible to switch to a different CIT combination arm. Safety measures and investigator-assessed ORR per RECIST v1.1 are primary endpoints. PFS, OS, DCR and DOR are among the secondary endpoints. Exploratory biomarkers will also be examined. Clinical trial information: NCT03281369 and NCT03193190.

TPS4135 Poster Session (Board #322a), Sun, 8:00 AM-11:30 AM

FIGHT: A phase 3 randomized, double-blind, placebo controlled study evaluating (bemarituzumab) FPA144 and modified FOLFOX6 (mFOLFOX6) in patients with previously untreated advanced gastric and gastroesophageal cancer with a dose finding phase 1 lead-in. *First Author: Daniel V.T. Catenacci, University of Chicago Pritzker School of Medicine, Chicago, IL*

Background: FGFR2b overexpression and *FGFR2* gene amplification occurs in approximately 10% of patients with gastric cancer (GC) and is associated with a poor prognosis and the presence of metastases. Bemarituzumab, a first-in-class afucosylated, humanized IgG1 monoclonal antibody, selectively binds to FGFR2b, inhibiting ligand binding and blocking receptor activation and downstream signaling. Bemarituzumab is glycoengineered to enhance antibody-dependent cell-mediated cytotoxicity (ADCC). A phase 1 study of bemarituzumab monotherapy in solid tumors (Catenacci D, Rha S, Bang YJ, et.al. ASCO 2017) identified no dose-limiting toxicities. The reported response rate was 19% (4/21) with median duration of response of 15.4 weeks in patients with late-line GC and high FGFR2b overexpression. Based on the safety and activity profile of bemarituzumab monotherapy in GC, we designed a phase 3 trial with safety run-in of bemarituzumab in combination with mFOLFOX6. **Methods:** The FIGHT study (FPA144-004; NCT03343301) is a global, randomized, double-blind, placebo-controlled phase 3 trial evaluating bemarituzumab and mFOLFOX6 in first-line patients with advanced GC. Patients with unresectable locally advanced, or metastatic GC are eligible if tumors have *FGFR2* amplification by circulating tumor DNA (ctDNA) or FGFR2b overexpression by immunohistochemistry (IHC). Eligible patients are randomized 1:1 to bemarituzumab + mFOLFOX6 versus placebo + mFOLFOX6. Bemarituzumab or placebo dosing will continue every 2 weeks until radiographic or clinical disease progression, or intolerable toxicity. The primary endpoint is overall survival (OS) and key secondary endpoints include investigator-assessed progression-free survival (PFS) and objective response rate (ORR). The primary analyses will be event-based. The FIGHT Phase 3 trial is preceded by a Phase 1 safety evaluation in gastro-intestinal tumors without selection for FGFR2b. This portion of the trial initiated in December 2017 and is currently in progress with accrual to phase 3 expected in mid-2018. Clinical trial information: NCT03343301.

TPS4136 Poster Session (Board #322b), Sun, 8:00 AM-11:30 AM

KEYNOTE-585: Phase 3 study of chemotherapy (chemo) + pembrolizumab (pembro) vs chemo + placebo as neoadjuvant/adjuvant treatment for patients (pts) with gastric or gastroesophageal junction (G/GEJ) cancer. *First Author: Yung-Jue Bang, Seoul National University College of Medicine, Seoul National University Hospital, Seoul, Republic of (South), Korea*

Background: The FDA approved pembro for treating pts with recurrent locally advanced or metastatic G/GEJ adenocarcinoma whose disease has progressed on or after ≥2 prior therapies and whose tumors express PD-L1 (combined positive score ≥1). Combining chemo with pembro in the neoadjuvant/adjuvant setting may be beneficial for pts with locally advanced, resectable G/GEJ cancer. KEYNOTE-585 is a phase 3, randomized, double-blind study of chemo + pembro versus chemo + placebo as neoadjuvant/adjuvant treatment for locally advanced resectable G/GEJ cancer. **Methods:** Key eligibility criteria are age ≥18 years; previously untreated G/GEJ adenocarcinoma (Siewert type 2 or 3 tumor; Siewert type 1 tumor eligibility limited to those for whom planned treatment is perioperative chemo and resection), with no evidence of metastatic disease; planned surgery after preoperative chemo; ECOG performance status 0-1; adequate organ function; no active autoimmune disease. Pts will be randomly assigned 1:1 to receive chemo + pembro (arm 1) or chemo + placebo (arm 2). Pts will receive neoadjuvant (preoperative) chemo + pembro every 3 weeks (Q3W) for 3 cycles or chemo + placebo Q3W for 3 cycles followed by surgery, then adjuvant chemo + pembro Q3W for 3 cycles or chemo + placebo Q3W for 3 cycles, then monotherapy with pembro or placebo Q3W for 11 cycles; treatment will occur for up to 17 cycles. Chemo is cisplatin 80 mg/m^2 IV + either capecitabine 1000 mg/m^2 orally twice daily or 5-fluorouracil (5-FU) 800 mg/m^2 IV (investigator s choice). Pembro 200 mg was administered by IV. Adjuvant monotherapy is pembro (arm 1) or placebo (arm 2). In a separate safety cohort, 5-FU 2600 mg/m^2 IV + docetaxel 50 mg/m^2 IV + oxaliplatin 85 mg/m^2 IV + leucovorin 200 mg/m^2 IV (FLOT) is being evaluated as a potential chemo option. Primary end points are overall survival, event-free survival per central review, and pathologic complete response (no invasive disease and histologically negative nodes) rate. Adverse events are graded per NCI CTCAE v4.0 and will be monitored for 30 or 90 days after treatment. Pts will be followed for survival. Planned enrollment is 800 pts. Clinical trial information: NCT03221426.

TPS4137 Poster Session (Board #323a), Sun, 8:00 AM-11:30 AM

NCI 10066: A phase 1 / 2 study of olaparib in combination with ramucirumab in metastatic gastric and gastroesophageal junction (GEJ) adenocarcinoma. *First Author: Michael Cecchini, Yale University, New Haven, CT*

Background: Gastric cancer remains a significant health problem in the US and globally with more than 951,600 annual cases worldwide. Moreover, the incidence of GEJ-centered adenocarcinoma is increasing dramatically in Western countries. First line chemotherapy has a < 12month median survival. In 2nd line, ramucirumab, a monoclonal antibody against VEGFR2 is approved as single agent or with paclitaxel. Hypoxia mimetic agents such as ramucirumab down-regulate homologous recombination and sensitize tumors to Poly ADP ribose polymerase inhibition (PARPi). Gastric cancer is also known to have a homologous recombination deficiency (HRD) subtype. We therefore proposed combining the PARPi olaparib with ramucirumab in metastatic gastric and GEJ adenocarcinoma. **Methods:** The study is sponsored by the Clinical Therapy Evaluation Program and is active throughout the Extended Therapeutics Clinical Trials Network. A phase 1 3+3 dose escalation is followed by an open-label single arm phase 2. The primary objective of phase 1 is to establish the safe dose of olaparib with ramucirumab. The phase 2 primary objective is to measure efficacy by the objective response rate (ORR). Eligible patient received ≥ 1 line of prior chemotherapy, no prior angiogenesis inhibitors or PARPi, have measurable disease, usual laboratory parameters, and ECOG PS 0-1. Phase 1 will enroll 9-18 patients depending on DLT. In phase 2, the BROCA-HR gene panel is an integrated biomarker. This panel includes 87 DNA repair genes, 17 of which would be expected to confer HRD when mutated. In gastric cancer these HRD genes are mutated in up to 35% of tumors reported in COSMIC and TCGA. However, given the uncertainty of the biomarker distribution in our study, 40 patients will be enrolled in phase 2 and the ORR will be stratified by biomarker distribution. The H_0 is ORR of < 5% based on the historical control for ramucirumab. The H_1 is 25% ORR for the BROCA-HR positive cohort and 20% for the negative cohort. A pre-treatment biopsy for BROCA-HR testing is required. Other studies include detecting mutational signatures, PAR substrate analysis, and PDX generation. Phase 1 is currently enrolling. Clinical trial information: NCT03008278.

TPS4138 Poster Session (Board #323b), Sun, 8:00 AM-11:30 AM

An intergroup phase III trial of ramucirumab plus irinotecan in third or more line beyond progression after ramucirumab for advanced gastric cancer (RINDBeRG trial). *First Author: Daisuke Sakai, Osaka Gastrointestinal cancer chemotherapy Study Group (OGSG), Osaka, Japan*

Background: Ramucirumab, an anti-VEGFR2 fully human monoclonal IgG1 antibody showed survival benefits in two randomized trials of 2nd line chemotherapy for advanced gastric cancer (AGC), and ramucirumab plus paclitaxel is recognized as 2nd line standard treatment. It has been suggested that sustained VEGF blockade might contribute to long-term disease control in various cancers. **Methods:** This randomized phase III study comparing irinotecan ± ramucirumab recruits patients with AGC from 110 institutions participating in 9 clinical trial groups in Japan. Primary endpoint is overall survival (OS), with the assumed hazard ratio of 0.77 (power of 80% and significance level of one-sided 0.05). Secondary endpoints include progression-free survival, time to treatment failure, response rate, disease control rate, and safety. Major eligibility criteria are: 1) histologically proven gastric or esophagogastric adenocarcinoma, 2) unresectable or recurrent disease, 3) two or more lines of chemotherapy with platinum, fluoropyrimidines, taxanes, and ramucirumab (no prior use of irinotecan), 4) disease progression during prior chemotherapy containing ramucirumab, 5) age ≥ 20years, 6) performance status (PS) 0-1, 7) evaluable disease as defined in the RECIST v1.1, 8) adequate hematologic, renal, hepatic and metabolic function (including urinary protein = 0 or 1+), 9) expected survival ≥ 90 days, 10) written informed consent. Patients are randomly allocated (1:1) to ramucirumab plus irinotecan or irinotecan alone. Irinotecan is administered at a dose of 150 mg/m2, every two weeks, in both arms, and ramucirumab at a dose of 8 mg/kg is added biweekly. Status: Opened to accrual February 2017, at 31 Jan 2018, 87/400 patients have been enrolled. Clinical trial information: UMIN000023065.

TPS4139 Poster Session (Board #324a), Sun, 8:00 AM-11:30 AM

Iconic: Peri-operative immuno-chemotherapy in operable oesophageal and gastric cancer. *First Author: Sonia Mansukhani, The Institute of Cancer Research, London, United Kingdom*

Background: Peri-operative chemotherapy with 5FU, oxaliplatin and docetaxel (FLOT) is a new standard of care in resectable gastro-oesophageal adenocarcinoma (GOA), however with 3y survival rates of only 57% there is a need to further improve outcomes by developing innovative therapeutic combinations. PD1/PDL1 checkpoint inhibitors have shown activity in GOA and we are conducting a single-arm phase II trial to investigate the safety and efficacy of the anti-PDL1 antibody avelumab in combination with FLOT (FLOT-A) as peri-operative therapy in resectable GOA. The combination aims to generate synergy by enhancing progression through the cancer-immunity cycle via the pro-immunogenic effect of FLOT chemotherapy and simultaneous avelumab-induced release of the immune inhibitory effect of the PD1/PDL1 checkpoint. **Methods:** The 2-stage trial design will evaluate the safety and efficacy of avelumab (starting dose: 10mg/kg IV 2 weekly, pre-planned dose reduction to 7mg/kg IV 2 weekly if dose limiting toxicities occur) with standard dose FLOT chemotherapy (5FU 2600mg/m2/24hr, leucovorin 200mg/m2, oxaliplatin 85mg/m2 and docetaxel 50mg/m2) for pts with operable GOA treated on a peri-operative pathway. Stage 1 will establish the safe and maximum tolerated dose of FLOT-A using a 3+3 dose finding design. Stage 2 will assess the efficacy of FLOT-A based on pathological complete response (pCR) rate and peri-op safety. The primary endpoint is pCR. Using an A'hern single stage design to rule out a lower limit of 10% pCR rate and demonstrate an increase to 25% requires the inclusion of 40 pts, to achieve 80% power and a 1-sided 0.05 significance level. An interim analysis will assess safety and Mandard tumour regression grading (TRG) after 15 pts become evaluable. If $\geq$5 pts achieve TRG 1-3 the trial will expand to 40 pts. Secondary endpoints are ORR, PFS and OS. Exploratory objectives will investigate dynamic changes of immune infiltrates in baseline and on-treatment biopsies and correlate neoepitope load, blood lymphocyte activation and faecal microbiome with tumour response. Recruitment commenced in July 2017 and 40 pts will be recruited in 2 years. Clinical trial information: NCT03399071.

TPS4140 Poster Session (Board #324b), Sun, 8:00 AM-11:30 AM

Induction nivolumab or nivolumab/ipilimumab prior to concurrent chemoradiation plus nivolumab in patients with operable stage II/III esophageal/gastroesophageal junction cancer. *First Author: Ronan Joseph Kelly, Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD*

Background: Neoadjuvant chemoradiation (cRT) prior to surgical resection in stage II/III esophageal/gastroesophageal junction (EC/GEJ) cancer results in a complete pathologic response rate of approximately 20-25%, in adenocarcinoma subtypes. The appearance of favorable microenvironment features (enhanced tumor lymphocytes, perivascular lymphocytes and tertiary lymphoid structures) after induction therapy in resected EC suggest tumors may respond favorably to immune based therapy and in particular to PD-1 based checkpoint blockade when combined with cRT prior to surgical resection. In addition, preclinical models suggest that esophageal radiation significantly increases PD-L1 expression. The Phase III Attraction 2 study has demonstrated activity of nivolumab in a subset of heavily pretreated patients with gastroesophageal cancer. This trial proposes to evaluate the safety/efficacy of induction nivolumab or nivolumab plus ipilimumab prior to concurrent chemoradiation plus nivolumab in operable stage II/III EC. **Methods:** This is an open-label, single-arm, multicenter clinical study that will enroll 32 patients. Eligible subjects consist of adults with histologically confirmed, resectable stage II/III EC/GEJ located below the carina. Subjects must be newly diagnosed and cannot have received prior treatment. A pre-treatment biopsy is required prior to two cycles of induction nivolumab (arm A) or one cycle of induction nivolumab/ipilimumab (arm B). A repeat research biopsy is performed after the induction phase and prior to initiation of carboplatin/paclitaxel/RT plus nivolumab. Nivolumab 240mg is administered every 2 weeks for 5 cycles in total (two as induction and three with concurrent cRT). An Ivor-Lewis esophagectomy is performed approximately 6-10 weeks post completion of cRT. The primary endpoint is safety. Secondary endpoints include an assessment of the pathological complete response rate, recurrence free survival, overall survival and immunologic correlates. The study was initiated in July 2017 and is ongoing at Johns Hopkins and at the Allegheny Health Network. Clinical trial information: NCT03044613.

TPS4141 Poster Session (Board #325a), Sun, 8:00 AM-11:30 AM

IMbrave150: A randomized phase III study of 1L atezolizumab plus bevacizumab vs sorafenib in locally advanced or metastatic hepatocellular carcinoma. *First Author: Richard S. Finn, David Geffen School of Medicine at UCLA, Los Angeles, CA*

Background: Hepatocellular carcinoma (HCC) is a lethal disease with the highest mortality-to-incidence ratio of any solid tumor. The current standard of care for 1L treatment of patients (pts) with locally advanced or metastatic HCC is sorafenib (sor), a multikinase inhibitor. Single-agent treatment involving inhibition of PD-L1/PD-1 immune checkpoint or VEGF has shown modest activity in HCC. Evidence from a Phase I study (Stein ASCO 2018, submitted) in HCC supports a strong scientific rationale for combining atezolizumab (atezo; anti–PD-L1) with bevacizumab (bev; anti-VEGF) to achieve greater clinical benefit. In addition to its anti-angiogenic activity, bev may have immunomodulatory effects in the tumor microenvironment (increased DC maturation, enhanced T-cell infiltration, reduced MDSCs and Tregs in tumors) that can potentially increase the efficacy of atezo in inhibiting PD-L1/PD-1 signaling and restoring anti-tumor T-cell activity. **Methods:** IMbrave150 (YO40245) is a Phase III, open-label, multicenter, randomized study to evaluate atezo + bev vs sor in pts with locally advanced or metastatic and/or unresectable HCC. Eligible pts will be naive to prior systemic therapy for HCC, have $\geq$ 1 measurable untreated lesion (per RECIST v1.1), Child-Pugh class A liver function and ECOG PS 0/1. Pts with bleeding or high risk for bleeding with untreated varices will be excluded. Randomization will be stratified by region (Asia [excluding Japan] vs rest of world), macrovascular invasion and/or extrahepatic spread (presence vs absence), baseline α-fetoprotein level ($<$ 400 vs $\geq$ 400 ng/mL) and ECOG PS (0 vs 1). Pts will be randomized 2:1 to receive atezo (1200 mg) plus bev (15 mg/kg) IV Q3W or sor (400 mg) PO BID until loss of clinical benefit or unacceptable toxicity. No crossover will be allowed. Co-primary and secondary efficacy endpoints are listed in Table. $\approx$ 480 pts are planned to be enrolled globally. Clinical trial information: NCT03434379.

Efficacy endpoints.

Co-primary
ORR (investigator [INV]-assessed per RECIST v1.1), OS
Secondary
PFS, DOR, TTP (INV-assessed per RECIST v1.1)
ORR, PFS, DOR, TTP (independent review facility (IRF)-assessed per RECIST v1.1)
ORR, PFS, DOR, TTP (IRF-assessed per HCC mRECIST)

TPS4142 Poster Session (Board #325b), Sun, 8:00 AM-11:30 AM

A multi-center randomized phase II study of nivolumab in combination with gemcitabine/cisplatin or ipilimumab as first line therapy for patients with advanced unresectable biliary tract cancer. *First Author: Vaibhav Sahai, University of Michigan Comprehensive Cancer Center, Ann Arbor, MI*

Background: Patients (pts) with advanced biliary tract cancers (BTC) have poor prognosis with a median overall survival (OS) less than 12 months. This randomized, multi-institutional, phase 2, two-arm study is designed to investigate the role of combinational immunotherapy, using nivolumab with chemotherapy (gemcitabine/cisplatin) or as dual immunotherapy (nivolumab and ipilimumab) in pts with advanced BTC. **Methods:** Key eligibility criteria include histologically confirmed advanced, unresectable biliary adenocarcinoma (intrahepatic or extrahepatic and gallbladder) without prior systemic treatment, measurable disease per RECISTv1.1, ECOG PS 0-1, and absence of autoimmune disease and/or chronic steroid use. Primary objective is to evaluate the progression-free survival (PFS) rate at 6 months. Secondary objectives include evaluation of overall response rate (ORR) per immune related (ir)RECIST, median PFS and OS and safety in this patient population. Exploratory objectives include identification of biomarkers of response and mechanisms of resistance through serial (before, on and post therapy) biopsies and blood collection, including sequential whole exome/transcriptomic analysis and immune cell subset analysis (tissue and blood). Arm A therapy provides gemcitabine 1000 mg/m^2, cisplatin 25 mg/m^2 on days 1, 8 with nivolumab 360 mg on day 1 every 3 weeks for 6 months. In the absence of disease progression, pts may continue single agent nivolumab for up to 2 years. Arm B therapy includes nivolumab 240 mg every 2 weeks and ipilimumab 1 mg/kg every 6 weeks for up to 2 years in absence of disease progression. Accrual goal is 32 evaluable pts per arm. Using a null hypothesis value of 59% median PFS at 6 months, and an 80% alternative hypothesis, this ongoing study has $>$ 80% power, with a one-sided alpha of 0.05 to identify treatment efficacy in one or both study arms. Clinical trial information: NCT03101566.

TPS4143 Poster Session (Board #326a), Sun, 8:00 AM-11:30 AM

TREETOPP: A phase 2/3 study of varlitinib plus capecitabine versus placebo plus capecitabine as second-line treatment in patients with advanced or metastatic biliary tract cancers (BTCs). *First Author: Milind M. Javle, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: BTCs are rare and have a poor prognosis. These cancers are often diagnosed at advanced stage with limited treatment options and poor overall survival (OS). Overexpression of epidermal growth factor receptor (EGFR), HER2, HER3, and HER4 vary from 23-57%, 4-13%, 12-23% and 59-60% of BTCs, respectively. Varlitinib is a small molecular tyrosine kinase inhibitor of EGFR, HER2 and HER4 with potent antitumor effect in preclinical BTC models. Varlitinib also demonstrated tumor shrinkage responses and durable disease stabilization in BTC patients in Phase IB study. **Methods:** A randomized, double-blind, placebo-controlled phase 2 (Part 1)/ 3 (Part 2) study to compare the efficacy of varlitinib (300 mg BID, every day) versus placebo, when combined with capecitabine (1000 mg/m^2, BID for 14 days). The primary endpoints of Part 1 are objective response rate (ORR) and progression-free survival (PFS) and for Part 2 is OS. Eligible patients include those with confirmed advanced or metastatic 2nd line BTC, including intrahepatic or extrahepatic cholangiocarcinoma, gallbladder cancer and carcinoma of ampulla of Vater. Patients must have failed gemcitabine-contained 1st line systemic treatment. The target sample size is 482 patients, and enrollment has started on May 24, 2017. Safety data will be listed and summarized. Co-primary endpoints of Part 1 will be analyzed using data from an Independent Central Review of radiological data. A Hochberg procedure will be used to control the familywise type I error rate for Part 1 at the 10% level (one-sided). For Part 2, the primary endpoint, OS, will be tested at the two-sided 5% significance level. Clinical trial information: NCT03093870.

TPS4144 Poster Session (Board #326b), Sun, 8:00 AM-11:30 AM

A randomized, multicenter phase 3 study of durvalumab (D) and tremelimumab (T) as first-line treatment in patients with unresectable hepatocellular carcinoma (HCC): HIMALAYA study. *First Author: Ghassan K. Abou-Alfa, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Thus far, sorafenib remains the standard of care for first line systemic therapy in patients with advanced HCC but patient prognosis and quality of life (QOL) continues to be poor. HCC may be responsive to immunotherapy due to higher expression of immunosuppressive cells and upregulation of CTLA-4 and PD-1 immune checkpoints (Gao et al 2009, Hato et al 2014, Pardee & Butterfield 2012). Hepatitis B virus (HBV) and hepatitis C virus (HCV) infection are also associated with upregulation of regulatory T cells and PD-L1/PD-1 expression (Miroux et al 2010, Pardee & Butterfield 2012). Blockade of PD-L1/PD-1 or CTLA4 immune checkpoints demonstrated clinical benefit in HCC as monotherapy. In preclinical studies, combination of anti-PD-L1 and anti-CTLA-4 antibodies enhanced antitumour activity compared to monotherapy, indicating that the two pathways are non-redundant (Stewart, et al). Early clinical data from a phase I/II trial combining anti-PD-L1 and CTLA-4 (NCT02519348) demonstrated safety and a durable objective response rate (ORR) of 18%, prompting study expansion. **Methods:** HIMALAYA (NCT03298451) is the first randomized, open-label, multicenter, phase 3 study to assess the efficacy and safety of D+T combination therapy versus sorafenib in the first-line treatment of patients with unresectable, histologically-confirmed HCC. Patients will be randomized to arms evaluating D monotherapy, D+T combination therapy, or sorafenib monotherapy. Patients will be stratified according to macrovascular invasion (yes versus no), etiology of liver disease (HBV versus HCV versus others), and performance status (ECOG 0 vs 1). The primary endpoint for this study is overall survival (OS). Secondary endpoints include ORR, duration of response, disease control rate, progression-free survival, and time to progression according to RECIST v1.1 using investigator assessments. Safety and health-related QoL will also be assessed. Clinical trial information: NCT03298451.

TPS4145 Poster Session (Board #327a), Sun, 8:00 AM-11:30 AM

Liposomal irinotecan (nal-IRI) plus 5-fluorouracil (5-FU) and leucovorin (LV) or gemcitabine plus cisplatin in advanced cholangiocarcinoma: The AIO-NIFE-trial, an open label, randomized, multicenter phase II trial. *First Author: Thomas Jens Ettrich, Ulm University, Ulm, Germany*

Background: Biliary tract cancer (CCC) is associated with a poor prognosis due to mostly advanced stages at diagnosis. Overall survival does not exceed 6 months and the 5-year overall survival rate is less than 5% for patients with advanced or metastatic disease. Advanced CCC shows response to chemotherapy resulting in an improved disease control, improved survival and quality of life (QoL). In the ABC-02 phase III trial, gemcitabine combined with cisplatin compared with gemcitabine alone prolonged PFS (8.0 vs. 5.0 mo) and OS (11.7 vs. 8.1 mo) and is considered as standard of care. So far this regimen has not been compared with other active combination regimen. Irinotecan in combination with 5-FU showed promising results in 1st- and 2nd-line therapy in many GI cancers. In pancreatic adenocarcinomas, the combination of liposomal irinotecan (nal-IRI) plus 5-FU/LV improves survival in a post gemcitabine-based treatment setting. Our research hypothesis is that this regimen compares well with respect to clinical endpoints with the standard of care gemcitabine plus cisplatin in patients with advanced CCC. **Methods:** NIFE is a randomized study for patients (to be enrolled n = 92) with locally advanced or metastatic, non-resectable, intra- or extrahepatic cholangiocarcinoma): Arm A (experimental): Nal-IRI 80 mg/m2, leucovorin 400 mg/m2, 5-FU 2400 mg/m2, on day 1, cycle q2w), Arm B (standard): Cisplatin 25 mg/m2 and Gemcitabine 1000 mg/m2 on day 1 and 8, cycle q3w. NIFE is an open label, non-comparative, multicenter, two-sided phase II study with an unconnected analysis of the results in both arms against a fixed PFS rate ($<$ 40% at 6months). The randomization (1:1) is eminent to achieve two comparable patient groups. Primary objective is PFS at 6 months. Key secondary objectives are 3-year OS, PFS, ORR, DCR and QoL/ TUDD. There will be a retrospective surgical and radiological review. Tissue and blood sample collection will be mandatory for biomarker analyses (microdissection and exome sequencing of tumor tissue, ctDNA exome sequencing, transcriptome, miRNA-arrays). Start was in Q I/2018 in 25 centers in Germany. Clinical trial information: NCT03044587.

TPS4146 Poster Session (Board #327b), Sun, 8:00 AM-11:30 AM

A multicenter pilot study of nivolumab (NIVO) with drug eluting bead transarterial chemoembolization (deb-TACE) in patients (pts) with liver limited hepatocellular carcinoma (HCC). *First Author: James J. Harding, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY*

Background: Emerging preclinical and clinical data indicate that regional therapies impact the immune microenvironment, induce a peripheral immune response, and may augment the effects of immune checkpoint blockade. Given the activity of NIVO in the metastatic setting, we propose to test the safety of NIVO at earlier stages of HCC (BCLC-B) as an adjuvant therapy to TACE. **Methods:** This is a multicenter phase 1 study of the combination of NIVO and deb-TACE in unresectable HCC pts (BCLC Stage B) who are not candidates for curative treatment and have Child Pugh A hepatic function (NCT03143270). The primary objectives are to assess the safety, tolerability, and to define the optimal dosing schedule of the combination. A modified 3 + 3 design will sequentially treat pts with differing schedules of NIVO relative to deb-TACE. For all cohorts, deb-TACE (loaded with 75mg of doxorubicin) is administered on Day 0. NIVO is dosed at 240mg IV every 14 days for 1 year. In Cohort 1, NIVO is administered beginning on day +14 after deb-TACE. In Cohort 2, interrupted NIVO dosing begins at Day -28 but is held on the Day 0 at the time of deb-TACE, then restarted on Day +14. In cohort 3, continuous NIVO dosing begins on Day -28 without interruption during deb-TACE. If limiting toxicities occur in $\leq$33% of each cohort; cohort 3 will be defined as the recommended schedule for this combination. This cohort will then be expanded to a total of 16 pts. Cross-sectional imaging is completed at baseline, 1 month post-embolization, and every 3 months until disease progression, intolerable toxicities, or consent withdrawal. Secondary endpoints include overall response rate by modified Response Evaluation Criteria in Solid Tumors (RECIST) and RECIST v1.1, time to progression, progression-free and overall survival. Correlative objectives include sequential whole blood sampling and biopsies (pretreatment, on-treatment, at progression) to define mechanisms of anti-PD-1 resistance and to explore the effect of different schedules of treatment on the immune environment. Up to 28 pts will enroll at 4 sites over a 2 year period. Cohorts 1 and 2 have completed enrollment as of February 2018. Clinical trial information: NCT03143270.

TPS4147 Poster Session (Board #328a), Sun, 8:00 AM-11:30 AM

Pembrolizumab-based therapy in previously treated high grade extrapulmonary neuroendocrine carcinomas. *First Author: Claire Hooker, University of California, San Francisco, San Francisco, CA*

Background: The efficacy of immune checkpoint inhibitors (CPI) has not been established in extrapulmonary high grade neuroendocrine carcinomas (EP-HGNECs), a disease for which additional treatment options are needed. Pembrolizumab (PEM) has demonstrated safety and preliminary efficacy in small cell lung cancer. This phase 2 study aims to evaluate the efficacy and safety of PEM-based therapy in biomarker unselected EP-HGNECs. **Methods Design:** Open label, adaptive Simon's 2-stage study of PEM alone (Part A) and PEM plus chemotherapy (weekly irinotecan (IRI) or paclitaxel (P); dealers' choice) (Part B). If more than 2 responses out of 14 pts by week 18 (stage 1 part A), then 21 additional patients (pts) will enroll in stage 2 (Part A), which corresponds to H_0 10% vs. H_1 26% at type I error of 0.05 with power 80%. If there is insufficient activity, the study will proceed to Part B, with a safety lead-in of 6-12 pts for IRI/PEM (up to two dose levels, 1 and -1), then 16 additional patients will be accrued for a total of 22 patients treated with PEM plus chemotherapy based on one-side binomial test of H_0 10% vs. H_1 31% at type I error of 0.05 with power 80%. Total N needed to attain 80% power will be either 35 (Part A) or 36-42 (Part A then B) with overall type I error of 0.1. Key eligibility: EP-HGNEC of all sites (excluding Merkel cell carcinoma) with progression during or after first line systemic therapy, no prior CPI, bilirubin and creatinine $\leq$1.5x ULN, ECOG PS 0-1, agreeable to baseline tumor biopsy. Treatment: PEM 200 mg IV Q21days for up to 35 treatments. Primary endpoint (EP): Overall radiographic response rate by RECIST1.1. Secondary EP: Safety, duration of response, overall survival, progression-free survival. Exploratory EP: irRECIST v RECIST1.1, baseline PBMC and tumor immune cell profiles, T cell receptor (TCR) repertoires change from baseline to post treatment time points, tumor mutation profile, Ki67 index, PD-L1 expression. Current enrollment: 5 of planned 14 patients in stage I of Part A (6/2017-present). Clinical trial information: NCT03136055.

TPS4148 Poster Session (Board #328b), Sun, 8:00 AM-11:30 AM

A phase I/II study of fosbretabulin in combination with everolimus in neuroendocrine tumors that have progressed after at least one prior regimen for metastatic disease. *First Author: Aman Chauhan, University of Kentucky, Lexington, KY*

Background: Gastroenteropancreatic neuroendocrine tumors (GEPNETs) are rare tumors. Recent SEER database analysis shows consistent surge in the incidence of GEPNETs. Due to indolent nature of GEPNETs the prevalence of disease far exceeds the incidence. Treatment options for metastatic progressive neuroendocrine tumors are expanding. Fosbretabulin is a synthetic, water-soluble, phosphorylated prodrug of the natural product Combretastatin A4 (CA4P), which was originally isolated from the bark of the South African bush willow, Combretum caffrum. Fosbretabulin is the lead compound in a class of agents termed vascular disrupting agents (VDAs) and has shown activity as single agent in ovarian cancers and GEPNETs. Rationale: The vasoconstrictive effect of fosbretabulin is potent, though short-lived (4-8 hours), with no cumulative adverse effect. Everolimus inhibits angiogenesis, slows tumor growth and has a prolonged half-life (30 hours). Combining these two agents with distinctly different mechanisms of action may improve tumor control without additional toxicities, and has the potential of reducing drug resistance. **Methods:** This is an investigator initiated, single center, open label, phase I/II study involving gastroenteropancreatic neuroendocrine tumors, consisting of a dose escalation Part A followed by an expansion cohort Part B. Primary Objective is to establish the maximum tolerated dose of the combination of everolimus and fosbretabulin in neuroendocrine tumors that have progressed after at least one prior regimen for metastatic disease. Secondary Objectives include evaluation of safety profile of the combination and to observe and record anti-tumor activity. Patients will be treated with daily oral everolimus. Fosbretabulin will be administered IV either q3 weekly or q weekly based on partial order continuous reassessment model (PO CRM). Clinical trial information: NCT03014297.

TPS4150 Poster Session (Board #329b), Sun, 8:00 AM-11:30 AM

A phase I/II study of ribociclib plus everolimus in patients (pts) with metastatic pancreatic adenocarcinoma (mPAC) refractory to chemotherapy. *First Author: Benjamin Adam Weinberg, Georgetown Lombardi Comprehensive Cancer Center, Washington, DC*

Background: mPAC has a poor prognosis, with a 5-year survival rate of 2.3%. CDK4/6 is often deregulated in mPAC due to loss of *CDKN2A* via homozygous deletion or epigenetic silencing, resulting in the loss of the p16INK4a protein that naturally inhibits CDK4/6. CDK4/6 inactivates the retinoblastoma protein (RB), allowing E2F family transcription factors to promote cell cycle progression. Inhibitors of CDK4/6 have been ineffective as single agents in part due to Ras-mediated activation of alternate signaling pathways including the PI3K-mTOR pathway. We have shown that co-inhibition of the CDK4/6 and mTOR pathways suppresses growth in mPAC patient-derived xenografts. We are investigating the activity of the combination of ribociclib (a CDK4/6 inhibitor) and everolimus (an mTOR inhibitor) in pts with mPAC. **Methods:** This is a phase I/II, single-arm, open-label study. Eligible pts are $\geq$ 18 years old, have histologically confirmed mPAC with progression on at least 1 prior 5-FU- and 1 gemcitabine-based regimen, an ECOG performance status of 0-1, normal bone marrow and hepato-renal function, and no concurrent anticancer therapy. Exclusion criteria are use of prior CDK or mTOR inhibitors or known CNS metastases. Pts in the phase I portion will be enrolled in a 3+3 design to find the recommended phase II dose (RP2D) of ribociclib with dose escalation and de-escalation levels. Pts in the phase II portion will receive ribociclib at the RP2D daily for 21 days out of a 28 cycle with everolimus 2.5 mg daily continuously. The phase II portion will use a Simon's Minimax 2-stage design. Disease will be assessed by imaging every 8 weeks. Treatment will continue if it is tolerated and there is no disease progression. The primary endpoint of the phase II portion is progression free survival (PFS) at 8 weeks. Secondary endpoints are median PFS, median overall survival, best overall response rate by RECIST 1.1, and safety. Correlative studies include assessment of the pharmacodynamic effects on the RB pathway using pre- and on-treatment tumor biopsies, tumor sequencing, and analysis of circulating tumor DNA. Enrollment began in Q2 2017 with a goal accrual of 44 pts. Clinical trial information: NCT02985125.

TPS4151 Poster Session (Board #330a), Sun, 8:00 AM-11:30 AM

Entinostat in combination with nivolumab for patients with advanced cholangiocarcinoma and pancreatic adenocarcinoma. *First Author: Marina Baretti, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD*

Background: The use of antibody therapy targeting immune checkpoints has become a major focus of cancer immunotherapy, with the most compelling activity seen in the minority of patients with immunogenic tumors, where T cell infiltration naturally occurs while most pancreatic cancer (PDAC) and cholangiocarcinoma (CC) are not highly immunogenic, due to an immunosuppressive microenvironment and lack of tumor antigen expression and recognition. Our laboratory has explored entinostat, a histone deacetylase inhibitor (HDACi) to alter the function of suppressive myeloid derived suppressor cells (MDSC) in favor of recruiting T cells in murine PDAC models, showing that entinostat improves survival when given with anti-PD1 therapy. Our efforts are focused on producing new treatment options for CC and PDAC patients using epigenetic and immunotherapy combinations. **Methods:** An open-label, two-arm study enrolling patients with histologically confirmed unresectable or metastatic CC or PDAC, who have progressed after at least one line of prior therapy. Eligibility criteria include having measurable disease, performance status $\leq$1, and good end organ function. Exclusion criteria include history of autoimmune disease. Patients have a pre-treatment biopsy followed by 14 days of entinostat at a dose of 5 mg oral once a week followed by a second biopsy. Patients then begin nivolumab 240 mg every two weeks combined with entinostat until disease progression. The study is planned with 27 evaluable subjects per histology based on a Simon's two-stage design that allows early termination for lack of efficacy. The primary objective of the trial is to determine whether the combination of entinostat plus nivolumab yields a clinically compelling antitumor activity measured as objective response rate (ORR, assessed by RECIST 1.1). Secondary objectives will include progression free survival (PFS), overall survival (OS), safety and immunological correlates to evaluate the effect of HDAC inhibition on the TME by interrogating clinical specimens. The clinical study has been activated in November 2017 (NCT03250273) and 10 of planned 54 patients have been enrolled. Clinical trial information: NCT03250273.

TPS4152 Poster Session (Board #330b), Sun, 8:00 AM-11:30 AM

Phase 1b study of gemcitabine, nab-paclitaxel, and ficlatuzumab in patients with advanced pancreatic cancer. *First Author: Kimberly Perez, Dana-Farber Cancer Institute, Boston, RI*

Background: Nearly 80% of patients diagnosed with pancreatic ductal adenocarcinoma(PDAC) present with advanced, unresectable disease at the time of diagnosis, and as a result only about 4% will live 5 years after diagnosis. Paired-related homeodomain transcription factor 1 (Prrx1) isoforms – Prrx1a and 1b - are involved in pancreatic development, pancreatitis, and carcinogenesis. Prrx1a stimulates metastatic outgrowth and mesenchymal-epithelial transition(MET). Prrx1b promotes invasion and epithelial-mesenchymal transition (EMT). HGF is a novel transcriptional target of Prrx1b. Ficlatuzumab is a potent and selective recombinant humanized hepatocyte growth factor (HGF) inhibitory immunoglobulin G subclass 1 monoclonal antibody. It neutralizes HGF/c-Met binding and HGF-induced c-Met phosphorylation thereby inhibiting the c-Met pathway which has been associated with progression from primary to metastatic disease. In preclinical pancreatic adenocarcinoma models, inhibition of Prrx1b-HGF signaling using ficlatuzumab in combination with gemcitabine reduced primary tumor volume and eliminated metastatic disease. **Methods:** Patients with untreated metastatic PDAC will be enrolled in a phase Ib dose escalation study with 3+3 design and three dose cohorts of ficlatuzumab administered with gemcitabine (1000 mg/m^2) and nab-paclitaxel (125 mg/m^2) given 3 weeks on and 1 week off, followed by 18 patient expansion phase at maximally tolerated dose (MTD) for safety evaluation. The primary objective is to identify the MTD of ficlatuzumab when administered in combination with gemcitabine and nab-paclitaxel in patients with previously-untreated advanced pancreatic cancer. Secondary objectives include evaluation of safety, response rate and progression-free survival. Exploratory objectives will be performed to evaluate serum and tumor biomarkers of disease response. This analysis will include evaluation of a BDX004 prognostic proteomic signature detected in patients' pre-treatment blood sample. A pre-treatment biopsy will also be interrogated for HGF and markers of the cMet pathway; by immunohistochemistry, exome and transcriptome sequencing, and organoid development. Clinical trial information: NCT03316599.

TPS4153 Poster Session (Board #331a), Sun, 8:00 AM-11:30 AM

SWOG S1505: A randomized phase II study of perioperative mFOLFIRINOX vs. gemcitabine/nab-paclitaxel as therapy for resectable pancreatic adenocarcinoma. *First Author: Davendra Sohal, Cleveland Clinic, Cleveland, OH*

Background: Clinical outcomes after curative therapy for resectable pancreatic ductal adenocarcinoma (PDA) remain suboptimal. Series show that 70-85% of patients die of systemic recurrence. Improved overall survival (OS) in the metastatic setting with the use of multi-agent chemotherapy regimens (FOLFIRINOX, gemcitabine/nab-paclitaxel) holds the promise of progress in the curative setting as well. However, aggressive systemic therapy is usually not feasible after major pancreatic surgery. Therefore, early control of systemic disease by increased preoperative chemotherapy may improve outcomes. Furthermore, the perioperative platform facilitates early identification of patients with chemotherapy-resistant tumors and allows prospective biomarker studies in the future. **Methods:** This is a randomized phase II study intended to choose the most promising perioperative regimen to test in a larger trial. Eligibility requirements include adult patients with an ECOG PS of 0 or 1, a confirmed histopathologic diagnosis of PDA, and resectable disease as confirmed by central radiology review: no involvement of the celiac, common hepatic, or superior mesenteric arteries (and, if present, variants); no involvement, or $< 180°$ interface between tumor and vessel wall, of the portal or superior mesenteric veins; patent portal vein/splenic vein confluence; no metastases. Treatment includes 12 weeks [either 6 doses of mFOLFIRINOX (5-fluorouracil, irinotecan, oxaliplatin – without bolus 5-FU and leucovorin), or 9 doses of gemcitabine/nab-paclitaxel, on standard schedules] of preoperative chemotherapy, followed by surgical resection and 12 weeks of identical postoperative chemotherapy. Primary outcome is 2-year OS, using a "pick the winner" design with minimum two-year OS of 40% assuming a 58% alternative hypothesis, 88% power, and a 1-sided α of 0.05, providing 90% probability of selecting the better regimen with a total sample size of 150 patients. Correlative studies are planned. The study opened through the National Clinical Trials Network (NCT02562716), and is supported by NIH/NCI/NCTN grants CA180888, CA180819, CA180821, CA180833. Clinical trial information: NCT02562716.

TPS4154 Poster Session (Board #331b), Sun, 8:00 AM-11:30 AM

A SU2C catalyst randomized phase II trial of pembrolizumab with or without paricalcitol in patients with stage IV pancreatic cancer who have been placed in best possible response. *First Author: Vincent M. Chung, City of Hope, Duarte, CA*

Background: Pancreatic cancer remains a deadly disease and despite advances in chemotherapy treatment, survival for most patients is still less than one year. Refractory pancreatic cancer has not been responsive to checkpoint inhibitors and only in the small population of MSI high pancreatic cancers have we seen activity. The microenvironment plays an important role in limiting the immune response and researchers from the Salk Institute demonstrated that vitamin D receptor agonists sensitize both primary and metastatic pancreatic cancer lesions to checkpoint blockade. Our trial evaluates the role of maintenance immunotherapy and paricalcitol after best response to cytotoxic chemotherapy. **Methods:** This SU2C Catalyst trial will be conducted at Honor Health Research Institute, City of Hope National Medical Center and University of California San Diego Moores Cancer Center. Patients with metastatic pancreatic cancer receiving standard first line chemotherapy are eligible to be randomized after achieving best response defined as stable disease or partial response for 2 months with no further shrinkage of $\geq$ 20% on scan and no further decrease of $\geq$ 10% in the tumor markers while on chemotherapy. Patients with a serum vitamin D level $\geq$ 50 ng/mL are excluded. The primary endpoint of this study is to estimate the percentage of patients progressing at 6 months while on maintenance therapy. Secondary objectives evaluate the toxicity of the combination, overall survival and tumor mutational landscape. Twenty-four patients are planned to be randomized 1:1 to either pembrolizumab 200 mg every 3 weeks plus paricalcitol 25 mcg 3 times per week or pembrolizumab plus placebo. Archival tumor tissue is required and optional biopsies are allowed to further explore biomarkers of response to therapy. ClinicalTrials.gov Identifier: NCT03331562 Support: Stand Up To Cancer (SU2C) Catalyst Merck Grant Clinical trial information: NCT03331562.

TPS4155 Poster Session (Board #332a), Sun, 8:00 AM-11:30 AM

A phase I/II study of trifluridine/tipiracil (TAS-102) in combination with nanoliposomal irinotecan (NAL-IRI) in advanced GI cancers. *First Author: Olatunji B. Alese, Winship Cancer Institute, Atlanta, GA*

Background: Trifluridine/tipiracil (FTD/TPI, also known as TAS-102) is a combination of a nucleoside analogue and a thymidine phosphorylase inhibitor. TAS-102 has shown activity in 5FU-resistant colorectal cancer (CRC). Nano liposomal-Irinotecan (Nal-IRI) achieve higher intra-tumor concentrations than irinotecan (142-fold) and its major metabolite, SN-38 (9-fold), resulting in superior anti-tumor activity compared to free irinotecan in multiple tumor xenografts. Clinical trials have established activity of Nal-IRI combined with 5FU in pancreatic cancer. The combination of Nal-IRI with the more potent nucleoside analogue TAS-102 may result in a more effective systemic therapy regimen in CRC and pancreatic cancer. The aim of this study is to define the recommended phase II dose (RP2D) of the combination and evaluate the activity in pancreatic cancer and CRC. **Methods:** Eligible patients for the phase I trial include stage IV or locally advanced unresectable gastrointestinal adenocarcinomas, who have failed at least one prior therapy; age $\geq$18 years, ECOG PS 0-1 and measurable disease per RECIST 1.1. The trial design is standard 3+3. TAS-102 is administered orally in four dose levels of 25, 25, 30, 35mg/m^2 BID on days 1-5, with Nal-IRI at corresponding dose levels of 50, 70, 70, 70mg/m^2 IV on day 1 , in 14-day cycles. After recommended phase II doses are established, an expansion phase will enroll 20 patients with pancreatic adenocarcinoma (Arm A) and 20 patients with colorectal adenocarcinoma (Arm B). These patients must have either locally advanced unresectable or metastatic disease, and have failed at least one prior therapy that must not have included irinotecan. The primary endpoint of the phase II portion is overall response rate. Simon's two-stage design will be used for each arm of the phase II component. In the first stage, 10 patients will be accrued. If there are fewer than 1 responder, the cohort will be stopped. Otherwise, 10 additional patients will be accrued for a total of 20. Enrollment to the escalation phase I part of the study started in February 2018. Clinical trial information: NCT03368963.

TPS4156 Poster Session (Board #332b), Sun, 8:00 AM-11:30 AM

SM-88 in advanced cancers of the pancreas (SMACP). *First Author: Marcus Smith Noel, University of Rochester James P. Wilmot Cancer Institute, Strong Memorial Hospital, Rochester, NY*

Background: Treatment options for recurrent/refractory advanced pancreatic cancer (PC) include largely ineffective toxic therapies or palliation. SM-88 is a combination of dysfunctional tyrosine derivative (TD), mTOR inhibitor, CYP3a4 inducer and oxidative stress catalyst, previously reported to have activity in a variety of cancers and settings, with no drug-related grade 3 or 4 toxicity (J Clin Oncol 36, 2018 (suppl 6S; abstr 175. JCO 35, 2017 (supp e14060) Reduction of circulating tumor cells (CTCs), RECIST responses and prolonged duration of clinical benefit have also been reported with SM-88 in multiple tumor types including PC. (J Clin Oncol 31, 2013 (suppl; abstr e22095). We now describe an ongoing trial of SM-88 in metastatic PC. **Methods:** This is a prospective, multicenter ($>$ 30 sites), North American Phase II trial evaluating SM-88 as a single agent in recurrent PC. Eligible patients must have histologically confirmed metastatic PC, ECOG PS $<$ 3, measurable disease, and have received at least one line of prior therapy. MSI-H tumors must have had targeted therapy. 36 subjects are planned for the 1st stage, randomized 1:1 between the currently utilized clinically active regimen and a 2X dose, with the expansion dose selected based on clinical benefit and toxicity. Using Fleming's two-stage minimax design, based on overall response rate at 16 weeks, with H(0): ORR $<$ 8% vs H(1): ORR $>$ 16% ,99 evaluable will be required, yielding $>$ 95% power to detect an OS of 90% at 6 months compared to historical OS of 55%. Primary endpoints are ORR and OS. Secondary endpoints include PFS ratio, disease control rate duration of response, and time to subsequent treatment. Correlative studies include circulating tumor cells (CTCs) with genomics, tumor markers, EORTC QLQ-C30 and EORTC QLQ-PAN26, pharmacokinetics, pro-insulin, leptin and neutrophil:lymphocyte ratio, A known toxicity of SM-88 is skin hyperpigmentation and this will be investigated as a possible biomarker along with other exploratory endpoints. Clinical trial information: NCT pending

TPS4157 Poster Session (Board #333a), Sun, 8:00 AM-11:30 AM

A phase II trial of cabozantinib and erlotinib for patients with EGFR and c-MET co-expressing metastatic pancreatic adenocarcinoma. *First Author: Olumide B. Gbolahan, Indiana University School of Medicine, Indianapolis, IN*

Background: c-MET over-expression is associated with poor prognosis in pancreatic ductal adenocarcinoma (PDAC)(Kim JH, et al. Oncotarget. 2017; 8(42):73098-104). It activates mitogenic signaling, and this may contribute to the limited clinical activity of erlotinib in metastatic PDAC, given the cross talk between EGFR and c-MET(Dulak AM, et al. Oncogene. 2011; 30(33):3625-35). Preclinical data suggests that the addition of cabozantinib (a c-MET antagonist) to erlotinib improves anti-tumor activity. The combination in our lab resulted in significant tumor shrinkage, and improvement in survival in a *KPC* PDAC mouse model compared to treatment with gemcitabine alone. We designed this study to determine the activity of cabozantinib (Cabo) and erlotinib (Eelo) in a population of metastatic PDAC patients whose tumors co-overexpress EGFR and c-MET. **Methods:** This is an open-label, single arm, Phase II trial of the combination of cabozantinib and erlotinib in metastatic PDAC. Male and female patients $>$ 18years with biopsy proven PDAC and radiologically measurable metastatic disease following progression after first line therapy are eligible. Patients must have tumor tissue available from a surgical resection or archived core biopsy. Only those whose tumors express at least 2+ EGFR and c-MET based on IHC will be allowed on study. ECOG PS2 and above, prior use of Cabo or Erlo, and symptomatic brain metastasis or brain metastasis requiring steroids will exclude patients from this study. Cabo will be administered at 40mg daily dose and Erlo at 100mg daily dose every 28 days without break. The study will be conducted at the Indiana University Simon Cancer Center. The primary objective is to demonstrate at least a 15% radiographic response rate for the combination in the selected population. Secondary objectives include assessment of safety and estimation of PFS, ORR and OS. Based on a Simon two stage design, we will enroll 37 patients in total. If there are no radiologic responses in the 11 patients tested in the first stage, the trial will be closed. The trial opened in November 2017, we have screened 4 patients and enrolled 1. ClinicalTrials.gov Identifier: NCT03213626

TPS4158 Poster Session (Board #333b), Sun, 8:00 AM-11:30 AM

PRIMUS-001: An adaptive phase II study of FOLFOX-A (FOLFOX and *nab*-paclitaxel) versus AG (*nab*-paclitaxel and gemcitabine) in patients with metastatic pancreatic cancer, with integrated biomarker evaluation (ISRCTN75002153) – Part of Precision-Panc. *First Author: Janet Shirley Graham, Beatson West of Scotland Cancer Centre, Glasgow, United Kingdom*

Background: Platinum-containing regimens (e.g. FOLFIRINOX) have shown survival benefit for pancreatic cancer (PC), with some "exceptional responders"; biomarkers (BM) of response are not well defined. Tumors with mutations in *BRCA1/2* and other Fanconi Anemia genes, are preferentially sensitive to DNA-damaging agents (e.g. platinum) through synthetic lethality mechanisms, as they are defective in DNA damage response (DDR). We have shown that DDR deficiency may be present in 20% of PC. PRIMUS-001 aims to exploit defective DDR as a therapeutic vulnerability, with integrated study of BM of DNA-damaging agent response. **Methods:** PRIMUS-001 will enroll patients who are profiled molecularly using Precision-Panc NGS Diagnostic (BM via bespoke clinical grade assay). It is a multicentre, randomized (1:1), open-label, phase II trial comparing FOLFOX-A (*nab*-paclitaxel 150mg/m^2 IV, oxaliplatin 85mg/m^2, folinic acid 350mg flat dose, fluorouracil infusion 2400mg/m^2 continuous IV infusion) vs AG (*nab*-paclitaxel 125mg/m^2, gemcitabine 1000 mg/m^2). Treatment is until progression or unacceptable toxicity. PFS is the primary endpoint alongside assessment of the predictive value of BM (enhanced benefit of FOLFOX-A in BM+ve). The study has 2 interim futility analyses at which recruitment may: stop, continue in all-comers or BM +ve only. The final analysis occurs at 416 PFS events (460 patients recruited). The study determines if a phase III should occur in all-comers (+/- BM testing), be restricted to BM +ve patients or should not occur. The study has 87% power (5% 1-sided level of statistical significance) to detect a an increase in median PFS from 5.5 to 7.3 mnths in all-comers. In BM +ve patients there is 89% power (10% 1-sided) to detect an increase in median PFS from 5.5 to 10 mnths. The main inclusion and exclusion criteria are similar to major efficacy trials. Patients must come from the Precision-Panc Master Protocol with tumor tissue suitable for molecular analysis. Current Enrolment: To date 4 patients have been randomized: 3 to receive FOLFOX-A and 1 to receive AG treatment Clinical trial information: 75002153.

4500 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Pembrolizumab monotherapy as first-line therapy in advanced clear cell renal cell carcinoma (accRCC): Results from cohort A of KEYNOTE-427. *First Author: David F. McDermott, Beth Israel Deaconess Medical Center, Boston, MA*

Background: Programmed death-1 (PD-1) inhibitor–based combination therapy shows clinical benefit in first-line accRCC. However, data are limited on clinical impact of first-line PD-1 inhibitor monotherapy. KEYNOTE-427 (NCT02853344) is a single-arm, open-label, 2-cohort, phase 2 study that evaluates efficacy and safety of the PD-1 inhibitor pembrolizumab (pembro) as first-line monotherapy in accRCC and anccRCC. Results from the accRCC cohort (cohort A) are presented. **Methods:** Patients (pts) with histologically confirmed accRCC who received no prior systemic therapy were eligible. Additional key eligibility criteria included measurable disease (RECIST v1.1, independent central review [ICR]) and Karnofsky performance status ≥70%. Pembro 200 mg was administered intravenously Q3W for 2 y or until confirmed progressive disease, unacceptable toxicity, or pt decision to withdraw. Primary end point: objective response rate (ORR) per RECIST v1.1, ICR. Additional end points included duration of response, safety, and biomarkers associated with response. **Results:** At data cutoff (Oct 6, 2017), median (range) follow-up was 7.2 (0.9-11.7) mo. 110 pts were enrolled; 107 included in the efficacy analysis (opportunity for ≥1 postbaseline assessment). Median age (range) was 64 (29-87); 78% were male. 37.3%, 47.3%, and 15.5% of pts had IMDC risk categories of favorable, intermediate, and poor, respectively. Confirmed ORR by ICR was 33.6% (n = 36; 95% CI, 24.8-43.4) with 1 complete response (0.9%) and 35 (32.7%) partial responses. ORR for pts with favorable, intermediate/poor risk IMDC was 27.5% and 37.3%, respectively. Median duration of response was not reached (range, 1.4+ to 8.2+). 73.6% of pts experienced a treatment-related adverse event (AE); most common (≥10%) were fatigue (23.6%), pruritus (21.8%), diarrhea (16.4%), rash (13.6%), and arthralgia (11.8%). 18.2% experienced a grade 3-5 treatment-related AE; 1 patient had grade 5 pneumonitis. **Conclusions:** Pembro monotherapy demonstrated promising efficacy and acceptable tolerability in pts with accRCC. Potential tissue-based biomarkers associated with response will be presented. Clinical trial information: NCT02853344.

ABSTRACT WITHDRAWN

4502 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

A randomized, open label, multicenter phase 2 study, to evaluate the efficacy of sorafenib (So) in patients (pts) with metastatic renal cell carcinoma (mRCC) after a radical resection of the metastases: RESORT trial. *First Author: Giuseppe Procopio, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: Radical metastasectomy (Mtx) followed by observation (Obs) is a commonly used strategy in selected mRCC pts. RESORT was the largest prospective study that assessed the role of angiogenesis inhibition in mRCC pts after radical Mtx. **Methods:** The main eligibility criteria were a previous nephrectomy, predominant clear cell histology, a radical excision of no more than 3 metastases. All pts were randomized (1:1) within 12 weeks (wks) from surgery to receive SO or Obs for a maximum of 52 wks with stratification according to time from nephrectomy to metastases (more vs less than 12 months-mos), site of disease (lung vs others) and number of lesions (single vs multiple). SO was administered at the standard dose 400 mg twice daily. Radiologic restaging was performed every 12 wks. The primary endpoint was recurrence-free survival (RFS), defined as the time from randomization to disease relapse or death. A blood sample for exploratory analysis was collected at defined timepoints. **Results:** From November 2012 to November 2017, 76 pts were enrolled (32 in SO and 36 in Obs arm); 6 pts were screening failure and 2 pts never started treatment. An interim analysis was performed in the Intention To Treat population (median follow-up 21 mos) included 68 pts with well balanced baseline characteristics between the two arms. Median RFS was 29 mos (95%CI 10-NA) in SO arm versus 35 mos (95% 17-NA) in the Obs arm: 12 and 24 mos RFS was 62% (95% CI 46-84) and 52% (95% CI 35-76) in SO while 74% (95% CI 59-91) and 59% (95% CI 42-82) in Obs arm respectively. No differences in RFS were observed considering the stratification factors. Grade 3 adverse events with SO were 22% vs 3% in the Obs arm. Only 2 pts received the full SO dose, the remaining 30 pts had at least one interruption or dose reduction. Considering the % of administered vs planned dose as a continuous variable in a Cox model, a slight decrease of the recurrence risk was observed when increasing SO dose, however the number of events observed was too small to obtain reliable estimates. **Conclusions:** Sorafenib was safe but did not affect RFS in pts with mRCC after complete Mtx. Clinical trial information: NCT01444807.

4503 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

First results from the primary analysis population of the phase 2 study of erdafitinib (ERDA; JNJ-42756493) in patients (pts) with metastatic or unresectable urothelial carcinoma (mUC) and *FGFR* alterations (FGFRalt). *First Author: Arlene O. Siefker-Radtke, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: ERDA is an FGFR inhibitor with activity in pts with mUC and FGFRalt. FGFRalt occur in 10-20% of mUC and are enriched in immunologically "cold" luminal 1 UC. Two independent published reports showed a 5% investigator-reported response rate to prior immune checkpoint inhibitors (ICI) among pts with select FGFRalt, suggesting a need for new treatment options in this population. Here we report efficacy and safety of ERDA in the global open-label phase 2 study BLC2001 (NCT02365597). **Methods:** Pts had measurable mUC with prespecified FGFRalt, ECOG 0-2, and progression during/following ≥ 1 line of prior chemo or ≤ 12 mos of [neo]adjuvant chemo, or were cisplatin ineligible, chemo naïve. Prior ICI treatment was allowed. The optimal schedule of ERDA determined in the initial part of the study was 8 mg/d continuous ERDA in 28-d cycles with uptitration to 9 mg/d if protocol-defined target serum phosphate level was not reached and if no significant treatment-related adverse events (TRAEs) occurred. Primary end point was ORR, with a null hypothesis of ORR ≤ 25%. **Results:** 96 pts were treated with median 5 cycles of optimized ERDA dose regimen; 10% were chemo naïve, 47% had received ≥ 2 prior lines of therapy, 80% had visceral metastases. There was a 42% confirmed (c) ORR (RECIST 1.1) (3% CR, 39% PR) and 80% disease control rate (CR + PR + SD). There was a 70% cORR among pts with prior ICI (n = 21). AEs were manageable; 10% discontinued due to TRAEs; there were no treatment-related deaths (Table). **Conclusions:** Treatment with ERDA yielded a robust response rate and was tolerable in pts with chemorefractory mUC and FGFRalt, a population with poor prognosis and high unmet need based on low response rate to prior ICI. Final primary analysis results, including OS, PFS, and response duration, will be presented. Phase 3 is ongoing. Clinical trial information: NCT02365597.

4504 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Updated results from the enfortumab vedotin phase 1 (EV-101) study in patients with metastatic urothelial cancer (mUC). *First Author: Jonathan E. Rosenberg, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Patients (pts) with mUC are in need of novel therapies. Enfortumab vedotin (EV) is an antibody–drug conjugate that delivers a microtubule-disrupting agent to tumors expressing Nectin-4, a protein overexpressed in most urothelial cancers. Preliminary results of the EV-101 study (NCT02091999) suggest EV is active and tolerable at the RP2D of 1.25mg/kg; updated results from pts with mUC treated at RP2D are reported. **Methods:** Patients with mUC treated with ≥1 prior chemotherapy or who were ineligible for cisplatin received a 30-min infusion of EV on Day 1, 8, and 15 of each 28-day cycle. The primary objective was tolerability; antitumor activity (per RECIST v1.1), assessed by investigators every 8 wk, was a secondary objective. **Results:** As of 11 Jan 2018, 155 pts with mUC have been enrolled; 112 received EV at RP2D (median age 67 yr [range 24–86]). Bladder was the primary tumor site in 84 pts (75%) and 32 (29%) had liver metastases (LM). Ninety-one pts (81%) received prior platinum chemotherapy; 67 (60%) received ≥2 prior therapies in the metastatic setting, including 84 (75%) who had a checkpoint inhibitor (CPI). Consistent with previous reports, EV was generally well tolerated. Grade ≤2 fatigue (50%) was the most commonly reported treatment-related AE (TRAE). The most common Grade ≥3 AEs, regardless of attribution, were anemia (7%), hyponatremia (6%), urinary tract infection (6%), and hyperglycemia (5%). Four pts experienced a fatal TRAE (respiratory failure, urinary tract obstruction, diabetic ketoacidosis, multiorgan failure). Confirmed CR and PRs were observed in 3 and 34 pts, respectively; ORR = 33% (95% CI 24.7–42.9). Eight unconfirmed PRs were pending assessment. Additionally, ORRs in study subpopulations were 32% (prior CPI, n = 84), 37% (CPI naïve, n = 27), and 26% (LM/prior CPI, n = 23). Overall median DOR was 24.3 wk (95% CI 16.3–47.3) and PFS was 23.1 wk (95% CI 20.1–24.1). Median OS was 12.5 mo (95% CI 8.1–14.8) with 76 pts (68%) censored and OS at 6 mo was 75.1%. However, time-to-event endpoints continue to evolve. **Conclusions:** Enfortumab vedotin has encouraging ORR and PFS in heavily pretreated pts with mUC, including pts with LM and prior CPI treatment. Survival data awaits maturity. Clinical trial information: NCT02091999.

4505 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Cctg BL12: Randomized phase II trial comparing nab-paclitaxel (Nab-P) to paclitaxel (P) in patients (pts) with advanced urothelial cancer progressing on or after a platinum containing regimen (NCT02033993). *First Author: Srikala S. Sridhar, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Nab-P has shown promising activity as second line treatment of advanced urothelial cancer post platinum (Ko YJ, Lancet Oncol 2013) and may be more active and less toxic compared to P. **Methods:** Canadian Cancer Trials Group led a multicentre randomized phase II trial comparing Nab-P 260mg/m2 IV q21 days to P 175mg/m2 IV q21 days in pts with advanced urothelial cancer progressing after one line of platinum-based therapy. The primary endpoint was progression free survival (PFS); secondary endpoints included overall survival (OS), response rate (RR), adverse events (AEs) using CTC AE V4.03 and QOL (EORTC-C15-PAL, FACT-Taxane). A sample size of 199 pts was selected to detect target PFS HR of 0.67 using a 1-sided 5% level test with 81% power. Stratification factors included ECOG, liver mets, LN only mets, Hb level and ≤6mo from last platinum regimen. **Results:** 199 pts from Canada and Australia were enrolled from 2014-2017 with median age 67y, including 72% males, 30% liver mets, 84% ECOG 0/1 and 55% ≤6mo from last platinum therapy. Relative dose intensity ≥90% was 78% for Nab-P vs 67% for P. With median follow up 16.4mo, median PFS for Nab-P was 3.4mo vs 3.0mo for P (HR 0.92, 90%CI 0.68-1.23, p = 0.31); median OS for Nab-P was 7.5mo vs 8.8mo for P (HR 0.95, 90%CI 0.70-1.30, p = 0.40). RR were similar, Nab-P 21% vs P 23% (p = 0.97). Rate of Grade(Gr)3+ all causality AEs was 67% for Nab-P vs 46% for P (p = 0.009); peripheral sensory neuropathy was 74% (Gr3+ 7%) for Nab-P vs 66% (Gr3+ 3%) for P (p = 0.27 (all grades), 0.33(Grd3+)). There were no significant differences in mean scores in any domain of QOL between Nab-P and P. **Conclusions:** Nab-P has similar efficacy and QOL compared to P as second line therapy in advanced urothelial cancer. Gr3+ all causality AEs were higher in the Nab-P arm. Clinical trial information: NCT02033993.

4506 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

A phase II study investigating the safety and efficacy of neoadjuvant atezolizumab in muscle invasive bladder cancer (ABACUS). *First Author: Thomas Powles, Barts Cancer Institute, Queen Mary University of London, London, United Kingdom*

Background: Atezolizumab is a PD-L1 inhibitor which is licenced in metastatic urothelial cancer. This study investigates the efficacy and safety of neoadjuvant atezolizumab given prior to cystectomy in operable muscle invasive transitional cell carcinoma bladder cancer. **Methods:** This single arm phase 2 study investigated 2 cycles of atezolizumab (1200mg Q3) prior to cystectomy in muscle invasive transitional cell cancer (T2-4N0M0). Pathological complete response (pCR) occurring in ≥20% of patients was the primary endpoint. Biomarker analysis on sequential tissue was a co-primary endpoint. Cross sectional imaging was performed at baseline and prior to cystectomy which occurred 4 - 8 weeks after starting atezolizumab. Radiological response was assessed. Adverse events (AEs) and surgical complications were assessed using CTCAE v4.03 and the Clavien-Dindo classification. The IDMC reviewed the first 69 patients (of 85) and supported this interim presentation. **Results:** The median age of the 69 patients was 73 years (range 54-88). At baseline pT2, T3, T4 disease occurred in 77%, 16% and 7% of patients respectively. 14 (20%) patients had only 1 cycle (8 due to AEs). 7 patients did not have cystectomy (1 disease progression, 2 treatment related AE). There was 1 potential treatment related death during treatment/perioperative period (cardiovascular disease). Treatment related grade 3/4 toxicity occurred in 12% of patients. Grade 3 or 4 surgical complications occurred in 31% of pt. The pCR rate was 18/62 (29%) [95%CI: 18% to 42%] (pT0 23%, Tis 6%, T1 10% T2 21% T3 24% T4 16% stage at surgery). 39% of patients were down staged to non-muscle invasive disease. 3/18 (17%) of the pCR patients had pT3/4 disease at baseline. 30 patients had sequential imaging and radiologically measurable disease at baseline. 23% [95%CI, 10% to 42%] and 13% [95%CI, 4% to 31%] of these patients radiologically responded and progressed respectively. Biomarker results including T cell infiltration and PD-L1 status before and after therapy will be presented. **Conclusions:** Neoadjuvant atezolizumab is safe and associated with a meaningful pathological CR rate at this interim stage. Further exploration is justified. Clinical trial information: NCT02662309.

4507 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Preoperative pembrolizumab (pembro) before radical cystectomy (RC) for muscle-invasive urothelial bladder carcinoma (MIUC): Interim clinical and biomarker findings from the phase 2 PURE-01 study. *First Author: Andrea Necchi, Istituto Nazionale dei Tumori, Milan, Italy*

Background: MIUC is an aggressive disease and cisplatin-based neoadjuvant chemotherapy is administered in a minority of pts. Pembro is an EMA and FDA-approved therapy for metastatic UC after platinum failure or for cisplatin-ineligible pts. **Methods:** PURE-01 (NCT02736266) is an open-label, single-arm, phase 2 study. Pts have predominant UC histology and cT≤3bN0 stage. Pts are enrolled regardless of cisplatin eligibility. Disease assessment is made via CT, PET/CT, and multiparametric bladder MRI (mpMRI). Pts receive 3 cycles of pembro 200mg q3w before RC. Pathologic complete response (pT0) in ITT population is the primary endpoint. The H_1 is pT0 ≥25% and H_0 pT0≤15%. 71 pts will be enrolled, with 43 pts at first stage according to MinMax design. ≥7pT0 are required at first stage. Biomarker analyses include: IHC PD-L1 combined positive score (CPS, Dako 22C3) and genomic sequencing with hybrid-capture based comprehensive genomic profiling. Tumor mutational burden (TMB) is determined on 1.1 Mbp of sequenced DNA and reported as mutations (mut) per megabase (Mb) and microsatellite instability is determined on 114 loci. **Results:** From 02/17-02/18, the first stage of 43 pts was completed (36M, 7F). 27 had cT3, 16 cT2; 59% had TMB > 10 mut/mb; 9% TMB > 20 mut/mb. All tumors were microsatellite stable. All pts had evident disease at mpMRI before pembro. One pt (2.3%) had G3 irAE (ALT increase) and suspended pembro; 6 (13.9%) had reversible G2 irAE. At the time of this analysis, 25 pts are evaluable for the primary endpoint. There were 8/25 pT0 (32%, 95%CI: 16.7-47.6) and 3 pTa/is (total pT < 2 rate: 44%). In TURB samples, mean CPS score for pT0 pts was 44.8% vs 17.4% non-pT0 pts ($p < 0.001$), mean TMB was 11.2 mut/mb vs 11.2 mut/mb, respectively. On 9 evaluable pts, substantial differences were found in pre- vs post-pembro genomic alterations (GA). Mean pre-pembro GA/tumor was 8.7; mean post-pembro GA/tumor was 7 (mean 47.5% overlapping GA). **Conclusions:** Pembro is safe and has already exceeded the pT0 responses required at first stage. PD-L1 CPS may be predictive of pT0 response, and full translational findings at first stage will be presented. Clinical trial information: NCT02736266.

4508 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Multicenter randomized phase 2 trial of paclitaxel, ifosfamide, and cisplatin (TIP) versus bleomycin, etoposide, and cisplatin (BEP) for first-line treatment of patients (pts) with intermediate- or poor-risk germ cell tumors (GCT). *First Author: Darren R. Feldman, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: A prior single arm phase 2 trial of TIP in intermediate- and poor-risk GCT found superior rates of response, progression-free survival (PFS), and overall survival (OS) compared to historical controls with BEP (JCO 34:21, 2016) leading to this randomized phase 2 study of TIP vs. BEP conducted across 7 centers. **Methods:** From 7/2013 to 7/2017, pts age ≥18 with untreated, IGCCCG intermediate- (LDH modified to ≥3x upper limit of normal) or poor-risk GCT were randomized to 4 cycles of TIP (paclitaxel 120mg/m^2 days 1-2; ifosfamide 1200mg/m^2 days 1-5; and cisplatin 20mg/m^2 days 1-5) or standard BEP. Prophylactic G-CSF was given to both arms whereas levofloxacin was optional but encouraged for TIP pts. The primary endpoint was the 6-month favorable response rate (CR + PR-negative markers). With alpha of 0.1, a sample size of 88 pts had 80% power to detect a one-sided increase in 6-month favorable response rate from 65% with BEP to 85% with TIP. PFS, OS, and biologic correlates including next generation sequencing (NGS) were secondary endpoints. **Results:** Of 91 eligible pts (n = 45 TIP, n = 46 BEP), 81 had nonseminoma,10 had seminoma; 37 had intermediate-risk and 54 poor-risk. Primary site was testis in 69, mediastinum in 19, and retroperitoneum in 3. 86 pts (TIP: n = 42; BEP; n = 44) were evaluable for 6-month favorable response with no difference between the two arms overall (76% for TIP vs. 73% for BEP) or among intermediate- (100% vs. 88%) or poor-risk (57% vs. 63%) pts. With median follow-up of 1.71 years, estimated 1-year PFS was 72% for both arms (Table). Toxicity and biologic correlate data including NGS will be presented at the meeting. **Conclusions:** First-line TIP did not improve but had a similar 6-month favorable response rate as BEP among pts with intermediate- or poor-risk GCT. TIP could represent an alternative to BEP for pts with a contraindication to bleomycin. Clinical trial information: NCT01873326.

Characteristics and outcomes for evaluable Pts.

4509 Poster Discussion Session; Displayed in Poster Session (Board #335), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

Pegilodecakin with nivolumab (nivo) or pembrolizumab (pembro) in patients (pts) with metastatic renal cell carcinoma (RCC). *First Author: Nizar M. Tannir, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Pegilodecakin (PEGylated hIL-10, AM0010) alone produced 25% partial responses (PR) in heavily pre-treated (median prior therapies 3) RCC pts. IL-10 receptors and PD1 are expressed on activated and exhausted CD8+ T cells. IL-10 stimulates the cytotoxicity and proliferation of CD8+ T cells. This provides a rationale for combining pegilodecakin with anti-PD-1. **Methods:** Between 2/20/2015 and 11/18/16, 38 pts with metastatic RCC (87% clear cell) were enrolled in a phase Ib trial and received pegilodecakin at 10 (n = 6) or 20 ug/kg (n = 32, QD SC) and nivo (n = 29; 3mg/kg, q2wk IV) or pembro (n = 9; 2mg/kg, q3wk IV). Pts had intermediate- or poor-risk disease by IMDC criteria (94%) and a median of 1 prior therapy (range: 1-3), including at least one VEGFR-TKI. **Results:** Pegilodecakin + nivo or pembro was well tolerated. TrAEs were reversible and transient. G3/4 TrAE in pts who received pegilodecakin (20 ug/kg) + nivo or pembro included anemia (10), thrombocytopenia (7), and hypertriglyceridemia (6). Two pts had a reversible cytokine release syndrome with splenomegaly and increased immune mediated red blood cell phagocytosis (HLH) most likely due to T-cell activation, as both pts had PRs. Pts on 10ug/kg pegilodecakin + nivo or pembro did not have G3/4 anemia or thrombocytopenia. As of 1/29/2018, response evaluation by irRC yielded 14 PRs of 34 evaluable pts (41%) including 3 complete response [CRs] (9%); 15 additional pts had stable disease (44%), 8 of whom had a tumor reduction of more than 30%. By RECIST, ORR and disease control rate (DCR) were 53% and 81%. Median progression-free survival (PFS) was 16.7 mos with pegilodecakin + pembro, and was not reached for pegilodecakin + nivo at a median follow up of 13.8 mos (range: 0.5-19.8). The 1y- overall survival for pegilodecakin + anti-PD-1 is 89%. Pegilodecakin strongly expanded previously undetectable T cell clones in the blood, which correlated with tumor response. Nanostring expression profiling separated pts with CR/PR from progressive disease. **Conclusions:** Pegilodecakin with nivo or pembro is well-tolerated in mRCC pts; the recommended phase 2 dose is 10ug/kg. The efficacy and the observed CD8+ T cell activation are very encouraging. Clinical trial information: NCT02009449.

4510 Poster Discussion Session; Displayed in Poster Session (Board #336), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

A phase 1/2 study evaluating the efficacy and safety of the oral CXCR4 inhibitor X4P-001 in combination with axitinib in patients with advanced renal cell carcinoma. *First Author: Ulka N. Vaishampayan, Karmanos Cancer Center, Detroit, MI*

Background: X4P-001 is an oral, selective, allosteric inhibitor of the chemokine receptor CXCR4, which is a promising novel target in renal cell carcinoma (RCC). X4P-001 in combination with the tyrosine kinase inhibitor axitinib demonstrated greater than additive anti-tumor activity in xenograft models mediated by decreased myeloid-derived suppressor cell trafficking and reduced proangiogenic signaling. **Methods:** This is a Phase (Ph) 1/2 trial in patients (pts) with advanced clear cell RCC who have failed at least one prior therapy. The safety, tolerability, and recommended Ph 2 dose (RP2D) of X4P-001 in combination with axitinib was established in Ph 1. Here we report results for preliminary efficacy in both the Ph1 dose escalation cohorts and the Ph 2 expansion cohort of pts treated at the RP2D. **Results:** The Ph 1 portion of the study is completed and established the combination therapy to be safe and tolerable at the RP2D of 400 mg QD X4P-001 + 5 mg BID axitinib. As of 01 January 2018, data are available for 10 pts in Ph 1 and 41 pts in Ph 2 treated at the daily 400 mg dose (either 200 mg BID or 400 mg QD) of X4P-001 + 5 mg BID axitinib. The median age was 64 years (range 41-87). Patients had received a median of 2 prior lines of systemic therapy (1 line: 29%; ≥ 2 lines: 71%). Seven pts (13.7%) were discontinued from the study due to adverse events (AEs) regardless of relationship. Of the 22 clinically evaluable pts, the objective response rate was 31.8% (1 CR; 6 PR) and the disease control rate was 86.4%. Median duration on treatment was 24 weeks (range 2 - 84). The most common (≥ 10%) treatment-related AEs of any grade were diarrhea, fatigue, hypertension, decreased appetite, dysphonia, nausea, blood creatinine increased, dry eye, headache, and vomiting. Hypertension was the only treatment-related AE (≥ Grade 3) to occur in > 5% of pts (9.8%) and the only serious AE to occur in more than one pt (3.9%). **Conclusions:** Preliminary results from the study demonstrate that X4P-001 + axitinib is clinically active in pts with advanced clear cell RCC and well tolerated with a manageable safety profile. Enrollment in the Ph 2 portion is near-completion and updated study results will be reported. Clinical trial information: NCT02667886.

4511 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Patient-reported outcomes (PROs) in IMmotion151: Atezolizumab (atezo) + bevacizumab (bev) vs sunitinib (sun) in treatment (tx) naive metastatic renal cell carcinoma (mRCC). *First Author: Bernard Escudier, U1015 INSERM, Gustave Roussy Cancer Campus, Paris Saclay University, Villejuif, France*

Background: The randomized, open-label Phase III IMmotion151 study met its coprimary endpoint in PD-L1+ patients (pts) with improvement in investigator-assessed PFS for atezo + bev vs sun (HR 0.74; median 11.2 vs 7.7 mo, $P = 0.02$). Encouraging efficacy was also observed in the intent-to-treat (ITT) population (HR 0.83; 11.2 vs 8.4 mo) (Motzer, ASCO-GU 2018). PROs were evaluated as secondary and exploratory endpoints to document pt perspective on overall clinical benefit for each tx. **Methods:** Pts received atezo 1200 mg IV q3w + bev 15 mg/kg IV q3w (n = 454) or sun 50 mg PO QD 4 wk on/2 wk off (n = 461). Pts completed the MD Anderson Symptom Inventory (MDASI) and Functional Assessment of Cancer Therapy-Kidney Symptom Index 19 (FKSI-19) questionnaires on days 1 and 22 of each 6 wk cycle, at end of tx, and during survival follow-up. Prespecified concepts included symptom burden (MDASI symptom severity and symptom interference with daily living) and bother from tx side effects (FKSI-19 GP5 item). Health-related quality of life (HRQoL) was also assessed (FKSI-19 total). Descriptive analyses included summary statistics for scores (effect sizes [ES] ≥ 0.3 suggest clinically meaningful differences), score changes from baseline (BL), and time to deterioration (TTD; first ≥ 2-point score increase in MDASI interference). **Results:** BL completion in ITT pts was > 80% and ≥ 70% until wk 57. At post-BL visits, pts receiving atezo + bev had milder and more stable symptom severity, less interference (differences in mean score ES: mean 0.3; range 0.1 - 0.5), and better HRQoL (differences in mean score ES: mean 0.4; range 0.1 - 0.6) vs pts receiving sun, who more often reported worsened interference. TTD in interference was also delayed (HR 0.56; 95% CI 0.46, 0.68): median for atezo + bev was 11.3 mo vs 4.3 mo for sun. A greater proportion of atezo + bev-treated pts reported no or little bother from tx side effects vs sun-treated pts. **Conclusions:** PRO data suggest atezo + bev maintained day-to-day functioning with minimal symptom interference and delayed TTD vs sun, further supporting positive benefit-risk for the combination regimen in first-line mRCC. Clinical trial information: NCT02420821.

4512 Poster Discussion Session; Displayed in Poster Session (Board #338), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

BMS-986205, an indoleamine 2,3-dioxygenase 1 inhibitor (IDO1i), in combination with nivolumab (NIVO): Updated safety across all tumor cohorts and efficacy in pts with advanced bladder cancer (advBC). *First Author: Josep Tabernero, Vall d'Hebron University Hospital, Barcelona, Spain*

Background: NIVO (anti–PD-1) has shown durable responses and manageable safety (ORR, 19.6%; grade 3–4 treatment-related AEs [TRAEs], 18%) in pts with advBC (Sharma P, et al. *Lancet Oncol* 2017), but prolonging survival in more pts requires additional approaches to overcome tumor evasion mechanisms. IDO1 allows tumor escape through kynurenine (KYN) production, which stimulates development of regulatory T cells and suppresses effector T-cell proliferation. Anti–PD-1 therapy can upregulate IDO1, supporting the rationale for combining NIVO with an IDO1i. BMS-986205 is a selective, potent, once-daily (QD), oral IDO1i that works early in the IDO1 pathway to reduce KYN production. BMS-986205 + NIVO demonstrated a favorable safety profile and antitumor activity in heavily pretreated pts with select solid tumors (Luke J, et al. SITC 2017; NCT02658890). Updated safety across all tumor cohorts and efficacy in the advBC cohort are reported. **Methods:** Dose-escalation methods of this phase 1/2a, open-label study were previously described; during expansion, pts received BMS-986205 100 or 200 mg QD + NIVO 240 mg IV Q2W or 480 mg IV Q4W. Objectives included safety and ORR by RECIST v1.1 (includes unconfirmed [u] responses). Prior IO therapy was permitted in the advBC cohort. **Results:** As of Dec 15, 2017, 434 pts received BMS-986205 + NIVO. TRAEs were reported in 51% of pts (grade 3–4, 12%), the most common being fatigue (13%) and nausea (10%); 16 pts (4%) discontinued due to TRAEs, and 1 pt died due to a TRAE (myocarditis). With a median follow-up of 17 wk (range, 4–53), the ORR among 29 pts with advBC was 34% (1 u CR, 9 PRs [1 u]), and the disease control rate (DCR) was 48%. Of 29 pts, 26 had no prior IO therapy; ORR in these pts was 38% (1 u CR, 9 PR [1 u]), and the DCR was 54%. ORR in pts with tumor PD-L1 $\geq$ 1% (Dako PD-L1 IHC 28-8 pharmDx assay; n = 15) vs $<$ 1% (n = 11) was 47% vs 27%. **Conclusions:** BMS-986205 + NIVO was well tolerated, with a safety profile similar to that of NIVO monotherapy. Preliminary evidence of efficacy was observed in advBC, supporting further evaluation of BMS-986205 + NIVO. Updated data by dose and subgroup in the advBC cohort will be presented. Clinical trial information: NCT02658890.

4513 Poster Discussion Session; Displayed in Poster Session (Board #339), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

Rogaratinib in patients with advanced urothelial carcinomas prescreened for tumor FGFR mRNA expression and effects of mutations in the FGFR signaling pathway. *First Author: Markus Joerger, Cantonal Hospital St. Gallen, St. Gallen, Switzerland*

Background: Activation of FGFR signaling is involved in a variety of malignancies including advanced urothelial cancer (UC). Rogaratinib is an oral pan-FGFR kinase inhibitor. We report here the results from a phase I expansion cohort in UC patients prescreened for FGFR1-3 mRNA expression levels with particular attention to activity in patients (pts) with evidence of activating mutations in potential resistance genes, including PIK3CA and RAS. (NCT01976741) **Methods:** Pts with advanced urothelial carcinomas were selected based on high FGFR1-3 mRNA expression in biopsy specimens. Somatic mutations in FGFR downstream signaling genes were detected by PCR array. Pts were treated with rogaratinib 800mg twice daily until tumor progression, intolerable toxicity, or withdrawal. Tumor response was assessed by RECIST, v1.1. Adverse events were reported using CTCAE v4.03 criteria. **Results:** A total of 219 UC pts were prescreened for FGFR1-3 mRNA expression levels and FGFR3 activating mutations, with 99 samples (45%) found to be FGFR-positive. Of those, 87% of samples were positive for FGFR3 mRNA, 5% for FGFR1 mRNA and 8% were double FGFR mRNA-positive (FGFR1/2, 1/3 or 2/3). Frequency of FGFR3 activating mutations in UC samples was 7%, all of which also had high FGFR3 mRNA. Fifty one pts were evaluable for response. Overall objective response rate (ORR) was 24% (12/51; all PRs) and disease control rate (DCR) was 73% (37/51). Interestingly, 0/12 pts with a PR had a hotspot mutation in either PIK3CA or RAS-encoding genes whereas 7/14 pts with PD revealed such a mutation. ORR in PIK3CA/RAS wild type UC pts is 30.6 %. Ten FGFR-positive UC pts had prior immuno-oncology (I/O) treatment, 9 of whom had progressive disease as best response. For these 10 pts the ORR was 30% and the DCR 80%. **Conclusions:** Selection of pts for treatment with rogaratinib based on FGFR mRNA expression levels was feasible and identified drug-sensitive pts with and without underlying FGFR gene alterations. Rogaratinib had a favorable safety profile and showed promising anti-tumor activity in UC pts, with an ORR of 24%, including pts refractory to prior I/O treatment but not with PIK3CA or RAS mutations. Clinical trial information: NCT01976741.

4514 Poster Discussion Session; Displayed in Poster Session (Board #340), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

VinCaP: A phase II trial of vinflunine chemotherapy in locally-advanced and metastatic carcinoma of the penis (CRUK/12/021). *First Author: Lisa M. Pickering, St. Georges University Hospitals Foundation Trust and The Royal Marsden Foundation Trust, London, United Kingdom*

Background: Platinum-based combination chemotherapy regimens are active in the treatment of penis cancer, but toxicity limits their value for patients with metastatic disease. VinCaP aims to define both the toxicity and the disease control rate for the non-platinum cytotoxic agent Vinflunine. **Methods:** A phase II single-arm trial was conducted. Eligible patients had measurable, histologically-proven squamous cell carcinoma (SCC) of the penis, staged M1; or M0,Tx,N3; or M0,Tx,N2 and deemed inoperable by multidisciplinary team; or M0, T4 any N, ECOG performance status 0-2 and adequate hepatic and renal function. Treatment was 4x21-day cycles of vinflunine (320mg/m^2). In 22 evaluable patients $\geq$7 responses/stabilisations were required to conclude a clinical benefit rate (CBR(CR/PR/SD)) of at least 40% and exclude a rate of $<$ 15% (p0 = 0.15, p1 = 0.40, α = 0.05, β = 0.80, Fleming-A'Hern exact design). Primary endpoint was CBR after 4 cycles of vinflunine. Secondary endpoints included objective response rate (ORR: CR/PR), safety, tolerability, progression-free survival (PFS) and overall survival (OS). **Results:** 25 patients (median age 68 years) were recruited from 8 UK centres between June 2014 and May 2017. 19 patients were M1. Of 22 patients who received treatment: 15 (68%) experienced grade 3/4 adverse events (AE); neutropenia was the most common AE (n = 5, 23%). Recruitment halted in Sep 2016 to investigate 2 treatment-related deaths (1 sepsis, not neutropenic; 1 neutropenic, not septic); re-opened Nov 2016. 10 patients had clinical benefit, CBR = 45.5%, 95%CI: 24.4-67.8, in the evaluable population (n = 22). ORR: 27.3%, (10.7-50.2) in evaluable population; 35.5%, (14.2-61.7) in measurable population (n = 17). Median PFS: 2.9 months, 95%CI: 1.4-6.4; 12 month PFS: 16.7% (4.6-35.3). Median OS: 8.4 months, (3.2-14.1); 12 month OS: 33.7%, (15.4-53.1). **Conclusions:** CBR exceeded the threshold to recommend further research and ORR was comparable to other recent phase II trials in penis cancer. Toxicity profile in keeping with known profile for vinflunine. Vinflunine is an active agent in the treatment of locally advanced and metastatic SCC of the penis. Clinical trial information: NCT02057913.

4515 Poster Discussion Session; Displayed in Poster Session (Board #341), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

Characterizing tumor immune microenvironment (TME) and outcomes for 409 patients (pts) treated on COMPARZ: Distinct clusters emphasize immune infiltration vs. angiogenesis. *First Author: Martin Henner Voss, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Growing evidence highlights the critical role of the TME for RCC biology and response to systemic therapy. We used integrated molecular profiling to characterize immune & stromal TME across a large cohort of pts treated on the phase 3 COMPARZ trial. **Methods:** We performed mRNA expression profiling (Affymetrix GeneChip HTA 2.0) and unsupervised consensus clustering from archival paraffin specimens. Clusters were characterized by gene set enrichment analyses (GSEA); transcriptional deconvolution; a 43 gene angiogenesis expression score; immunohistochemistry (IHC) for PD-L1 expression on tumor cells and macrophages; and mutation status for a defined list of genes. Findings were correlated with clinical outcomes using parametric and non-parametric tests. **Results:** mRNA clustering was done for 409 patients (212 sunitinib, 197 pazopanib treated) and revealed 4 biologically distinct clusters (C1-4) with significant differences in median overall survival (OS; P= 2.00E-4) and progression free survival (PFS; P= 0.03). C4 displayed the worst outcomes and highest rate of IMDC poor risk features (45.7% pts); GSEA showed enrichment for inflammation signatures, e.g. IFN-γ responses. Immune deconvolution demonstrated the most immune-infiltrated TME for C4 with enrichment of many immune subsets, especially macrophages (compared to C1-3, P= 0.0015); C4 also had the highest rate of PD-L1 expression on tumor cells and macrophages (P= 3.50E-7). Pts in C3 had the most favorable outcomes and displayed the highest angiogenesis gene expression levels (P= 2.20E-16). An integrated model of molecular and IMDC variables compared to IMDC risk stratification alone improved the c-index for OS from 0.63 to 0.69 and PFS from 0.60 to 0.65. **Conclusions:** mRNA-based analyses revealed four distinct molecular subgroups of RCC associated with varying outcomes on TKI therapy. These data highlight stromal and immune TME, specifically angiogenesis and macrophage infiltration programs, as powerful determinants of clinical course. Further study of these differences will be critical in advancing the field of advanced RCC towards precision-medicine. Clinical trial information: NCT00720941.

Alterations in key clear cell renal cell carcinoma (RCC) genes to refine patient prognosis. *First Author: Dominick Bossé, Dana-Farber Cancer Institute, Boston, MA*

Background: Genomic alterations (GA) in VHL, PBRM1, BAP1, SETD2, TP53 and KDM5C are frequently present in metastatic RCC (mRCC). We investigated the prognostic value of GA resulting in loss of function (LOF) of these genes in mRCC patients stratified by International mRCC Consortium Database (IMDC) risk group. **Methods:** Patients from 7 US centers and 1 annotated cohort from TCGA who had clear cell mRCC treated with 1st line VEGF tyrosine kinase inhibitor and tumor genomics available were included. Tumors were sequenced using next generation sequencing (institutional and commercial platforms) or whole exome sequencing (TCGA). LOF was defined as presence of pathogenic gene variant or 2 copy deletion. Cox model adjusting for age, IMDC risk group was used to investigate the association between GA and overall survival (OS). The prognostic value of GA was further assessed in IMDC favorable, intermediate and poor risk group. **Results:** In total, 308 patients were analyzed. IMDC risk group distribution was favorable 21%, intermediate 54%, poor 17% and unknown 8%. Patients had GA in VHL 77%, PBRM1 43%, SETD2 29%, BAP1 19%, TP53 11%, KDM5C 11%. GA in BAP1 was associated with worse IMDC risk group (favorable 8%, intermediate 23% and poor 20%, p = 0.023) and worse OS (aHR 1.7; 95%CI 1.1-2.5, p = 0.01). GA in PBRM1 (aHR = 0.6; 95%CI 0.4-0.8, p = 0.001) and KDM5C (aHR = 0.4; 95%CI 0.2-0.8, p = 0.007) was associated with better OS. SETD2, TP53 and VHL were not associated with prognosis (p > 0.4). Co-occurrence of GA in BAP1 and PBRM1 was 3.8%. Patients with tumors PBRM1 wild type and harboring GA in BAP1 had worse OS [37 vs 50 mos, aHR 1.9 (95%CI 1.2-2.8 p = 0.004]. When stratified by IMDC risk group, this tumor genomic profile was prognostic for patients with intermediate risk disease only (Table). **Conclusions:** mRCC tumors which are PBRM1 wild type and with LOF in BAP1 have worse survival. Assessment of GA in these key genes can further prognosticate IMDC intermediate risk patients and be useful to stratify patients in clinical trials.

Prospective phase II multi-center study of individualized axitinib (Axi) titration for metastatic renal cell carcinoma (mRCC) after treatment with PD-1 / PD-L1 inhibitors. *First Author: Moshe Chaim Ornstein, Cleveland Clinic Taussig Cancer Institute, Cleveland, OH*

Background: Standard of care treatment in mRCC after checkpoint inhibitor (CPI) therapy includes VEGFR TKIs, though no prospective data have been published. Axitinib (Axi) is a VEGF-R inhibitor with prior clinical data supporting increased efficacy with dose titration. The existing titration schema of 5mg BID to 7mg BID to 10mg BID every 4 weeks, however, can lead to toxicity due to the magnitude of dose increases. A prospective, multi-center phase II trial of Axi given on an individualized dosing algorithm in mRCC after treatment with CPI was conducted (NCT02579811). **Methods:** Patients (pts) with clear cell mRCC, adequate organ function and measurable disease whose most recent therapy was anti PD-1 / PD-L1 treatment were eligible. Pts were treated with Axi 5mg BID starting dose with upward dose titration in 1mg BID increments (e.g. 5mg BID to 6mg BID, up to 10mg BID max dose) every 14 days if there was no grade (G) 2 Axi-related mucositis, diarrhea, hand-foot-syndrome, or fatigue. If G2 adverse events (AEs) occurred, pts took a 3-day break then resumed the same dose. Recurrent G2 AEs despite treatment breaks or G3/4 AEs resulted in dose reduction in 1mg BID increments. The primary outcome was progression free survival (PFS) with 38 pts needed to improve PFS from 6.5 months (based on retrospective data of TKI post-CPI) to 9.5 months (a = 0.10; power 80%). **Results:** The trial has completed accrual (n = 38): 74% male, median age 64, 89% KPS ≥80%, 16%/66%/19% IMDC favorable/intermediate/poor risk, 94% prior nephrectomy, 71% ≥ 2 prior therapies. Most recent therapy was 89% anti PD-1 (63% nivolumab monotherapy; 17% ipilimumab/nivolumab; 9% other) or 11% anti PD-L1 (6% atezolizumab; 3% bevacizumab/atezolizumab; 3% durvalumab). In evaluable pts, the estimated median is PFS 9.2 months, with 54% of pts still on Axi. The ORR is 38.7% (best response PR 38.7%, SD 48.3%, and PD 12.9%). The median highest dose per pt was 6mg BID (range, 5-9) and 44% of pts required dose reduction to < 5mg BID. There were no unexpected toxicities related to Axi. **Conclusions:** Axitinib on an individualized titration schema resulted in robust clinical efficacy after checkpoint inhibitor therapy. Clinical trial information: NCT02579811.

Correlation of degree of tumor immune infiltration and insertion-and-deletion (indel) burden with outcome on programmed death 1 (PD1) therapy in advanced renal cell cancer (RCC). *First Author: Martin Henner Voss, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Mutation load and neoantigen burden predict benefit from anti-PD1 therapy across several cancers but are generally low in RCC. Pan-cancer comparisons highlight RCC for its enriched tumor immune infiltrate and a high proportion of indels, which may be immunogenic. We investigated these phenomena in anti-PD1 treated patients (pts) with comparison to pts receiving tyrosine kinase inhibitors (TKI). **Methods:** Whole exome sequencing (WES) was done for 77 tumors from 2 anti-PD1 treated pt cohorts; 25 pts provided RNAseq data. Overall mutation burden, indels, and predicted neoantigens were quantified. ESTIMATE and CIBERSORT algorithms were used to infer abundances of immune infiltrate and detailed immunophenotypes from RNAseq. We investigated correlation of molecular features with overall survival (OS) and durable clinical benefit (DCB = progression free survival > 6mo). A cohort of TKI-treated pts with no prior anti-PD1, previously analyzed as part of the TCGA, was used for comparison (35 with WES, 33 with RNAseq). **Results:** Higher overall immune infiltration correlated favorably with DCB in the PD1 cohort (stratified Mann Whitney test; p = 0.05) but not in TKI treated pts (p = 0.84). As the two most abundant infiltrating cell types, M2 macrophages (p < 0.001) but not CD8+ T cells (p = 0.22) associated with DCB from anti-PD1 therapy; neither associated with outcomes in TKI pts (p = 0.15, p = 0.76). Expectedly, mutation counts were low (median 68; inter-quartile range 45-93). While neither mutation nor neoantigen burden impacted on OS with anti-PD1 therapy (stratified Cox Proportional HR 1.02; p = 0.6; HR 1.01; p = 0.69, respectively), association with OS was significant for frameshift indel count (HR 0.85; p = 0.006). Correlation was similar but did not reach significance in TKI pts (HR 0.87; p = 0.07). **Conclusions:** In anti-PD1 treated RCC pts, baseline tumor immune infiltration, particularly by M2 macrophages, associated favorably with outcome. In contrast to other cancers, mutation and neoantigen load did not affect treatment outcomes; yet higher indel counts appeared to confer superior OS. Such associations were not seen for TKI treated pts.

Gut microbiome composition to predict resistance in renal cell carcinoma (RCC) patients on nivolumab. *First Author: Lisa Derosa, U1015 INSERM, Gustave Roussy Cancer Campus, Paris Saclay University, Villejuif, France*

Background: Efforts are ongoing to identify mechanisms driving response/resistance to immune checkpoint inhibitors (ICI) in order to personalize therapy. Recently, we speculated that antibiotics (ATB)-related dysbiosis decreases activity of ICI in cancer pts. We and others reported that outcome with ICI in melanoma and epithelial cancers were influenced by the microbiome composition. Here we evaluated the impact of microbiome in RCC. **Methods:** Within a large cohort of RCC pts (n = 85) treated in the NIVOREN study with nivolumab at Gustave Roussy, we prospectively collected fecal samples (n = 69). Of note, the minority of them received ATB before starting ICI (n = 11). Pts were classified as either primary resistant (PD) or non-PD based on RECIST (outcome, 6 months PFS). Metagenomic (MG) data from whole genome sequencing (WGS) were analyzed by multivariate and pair-wise/fold ratio (FR). Then, ICI-resistant RENCA mice were compensated with fecal microbiota transplantation (FMT) from non-PD pts or with commensals identified by WGS-MG to restore responsiveness to ICI to establish cause-effect relationship between dysbiosis and resistance. **Results:** After a median follow-up of 14 months, 27 (39%) pts were PD and 42 (61%) pts were non-PD, based on best response. Considering pts who received ATB, 8 (73%) were PD and 3 (27%) were non-PD *(p = 0.01)*. The microbiome alfa (intra-sample) and beta (inter-sample) diversity were not significantly different among PD and non-PD RCC pts. However, specific gut MG-fingerprints were related to best responses and/or PFS6. Excluding ATB treated patients, *Akkermansia muciniphila* and *Bacteroides salyersiae* were more abundant in non-PD pts with a FR of 2.65 *(p = 0.01)* and 27.09 *(p = 0.05),* respectively. Finally, we showed that *Bacteroides (B. salyersiae* but not *B. xylanisolvens*) or *A. muciniphila* could restore the efficacy of ICI in "unfavorable/dysbiotic" FMT-recipient tumor bearers, improving by a 43% the prevalence of non-PD. **Conclusions:** This is the largest prospective analysis so far, showing that composition of gut microbiome may predict resistance to anti-PD-1 in RCC pts. Interventions to modulate gut microbiome may represent strategies to improve clinical outcomes with ICI.

4520 Poster Discussion Session; Displayed in Poster Session (Board #346), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

A pilot randomized study evaluating nivolumab (nivo) or nivo + bevacizumab (bev) or nivo + ipilimumab (ipi) in patients with metastatic renal cell carcinoma (MRCC) eligible for cytoreductive nephrectomy (CN), metastasectomy (MS) or post-treatment biopsy (Bx). *First Author: Jianjun Gao, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Since ipi and nivo use distinct mechanisms for T cell activation and bev promotes antigen presentation, we hypothesize that nivo+bev or nivo +ipi would safely lead to measurable immunologic changes and improved clinical activity in MRCC. **Methods:** In this open-label, randomized trial (NCT02210117), adults with MRCC w/o prior immune checkpoint therapy and anti-VEGF therapy were enrolled and randomized 2:3:2 to receive nivo, nivo +bev or nivo+ipi, followed by surgery (CN or MS), or Bx, and subsequent nivo maintenance therapy up to 2 years. Response was assessed at ≥12 weeks. Pre- and post-treatment blood and tumors were obtained for correlative studies. **Results:** One hundred patients have been accrued and 90 are evaluable for responses (table below, W = withdrawal; BOR = Best overall response; BRES = Best Response excluding surgical effect). Clinical trial information: NCT02210117. BOR was 50% complete response (CR) + partial response (PR) nivo, 48% CR+PR nivo+bev, 39% CR+PR nivo+ipi. For patients getting surgery, BOR was: 77% nivo, 93% nivo+bev, and 70% nivo+ipi. Grade 3 or 4 toxicities were 30% for nivo, 45% for nivo+bev (including 18% bev-specific hypertension), and 57% for nivo+ipi. We identified a number of immune signatures in relation to clinical responses. **Conclusions:** Patients able to stay on therapy and receive surgery had BOR ranging from 70%-93%. Combination therapy nivo ± [bev or ipi] plus cytoreductive surgery deserves to be tested in a larger phase 3 trial for MRCC. We will also report correlative biomarker data.

Pembrolizumab (pembro) versus investigator's choice (paclitaxel, docetaxel, or vinflunine) in recurrent, advanced urothelial cancer (UC): 2-year follow-up from the phase 3 KEYNOTE-045 trial. *First Author: Yves Fradet, CHU de Québec - Université Laval, Québec City, QC, Canada*

Background: Based on interim results from the phase 3 KEYNOTE-045 (NCT02256436) study comparing pembro and investigator s choice of chemotherapy (chemo), pembro was approved for the treatment of locally advanced or metastatic UC that has progressed during or after a platinum-containing regimen. Updated results after 2-year follow-up are presented. **Methods:** Eligible patients (histologically or cytologically confirmed UC, progression after platinum, ECOG PS 0-2, measurable disease per RECIST v1.1, ≤2 lines of systemic therapy) were randomly assigned 1:1 to receive pembro 200 mg Q3W or investigator s choice of paclitaxel 175 mg/m^2 Q3W, docetaxel 75 mg/m^2 Q3W, or vinflunine 320 mg/m^2 Q3W. Primary efficacy end points were OS and PFS (RECIST v1.1, blinded central review). ORR (RECIST v1.1, blinded central review) was a secondary end point. **Results:** As of Oct 26, 2017, among 542 enrolled patients (pembro, 270; chemo, 272), median follow-up was 27.7 mo. Median OS was significantly longer with pembro vs chemo (10.3 vs 7.3 mo; HR, 0.70; $P< 0.0002$). OS benefit with pembro vs chemo was seen in all PD-L1 expression subgroups (HR; combined positive score [CPS] < 1, 0.82; CPS ≥1, 0.58; CPS < 10, 0.75; CPS ≥10, 0.56) and was maintained regardless of age, ECOG PS, prior therapy, liver metastases, baseline hemoglobin, time from last chemo, histology, risk factor group, and choice of chemo. PFS was not different between arms (2.1 vs 3.3 mo; HR, 0.96; $P= 0.32$). ORR was higher with pembro vs chemo (21.1% vs 11.0%). Median duration of response was longer with pembro (not reached [1.6+ to 30.3+ mo] vs 4.4 mo [1.4+ to 29.9+ mo]), and a greater proportion of responses lasted ≥12 mo (68% vs 35%) per Kaplan-Meier method. Fewer patients with pembro vs chemo experienced a treatment-related adverse event of any grade (62.0% vs 90.6%) and a grade ≥3 adverse event (16.5% vs 50.2%). **Conclusions:** Results observed over 2-year follow-up, including OS benefit and superior safety with pembro vs chemo, were consistent with the interim analyses that led to the approval of pembro in locally advanced or metastatic UC that progressed during or after platinum-based chemotherapy. Clinical trial information: NCT02256436.

4522 Poster Session (Board #348), Sat, 8:00 AM-11:30 AM

Conservative management following clinical complete response to neoadjuvant chemotherapy for muscle-invasive bladder cancer: Contemporary outcomes of a multi-institutional prospective cohort study. *First Author: Patrick M Mazza, Department of Urology, Columbia University Medical Center, New York, NY*

Background: Neoadjuvant platinum-based chemotherapy (NAC) followed by radical cystectomy (RC) is the gold standard treatment for muscle-invasive bladder cancer (MIBC). High morbidity and mortality associated with RC and favorable survival outcomes seen in patients who exhibit a clinical complete response (cCR) to NAC and forego RC has encouraged interest in conservative management of MIBC. We report the outcomes of patients from two institutions who experienced a cCR to NAC and opted for surveillance only. **Methods:** Prospective enrollment and retrospective review of patients occurred at Columbia University Medical Center (CUMC) and Memorial Sloan Kettering Cancer Center (MSKCC) to produce two distinct, IRB-approved databases of MIBC patients who underwent "radical" TURBT (complete resection down to muscularis propria) followed by NAC, exhibited a cCR, and opted for surveillance only from 2001-2017. A cCR was defined as negative "radical" TURBT, urine cytology, and cross-sectional imaging. Patients were followed at 3-6 month intervals with cystoscopy ± biopsy, urine cytology, and cross-sectional imaging, with databases continually updated. **Results:** The 148 patient cohort included 119 (80%) men and 29 women of median age 62 (32-88) years and follow-up 55 (5-145) months. NAC regimens were 31% MVAC, 63% gemcitabine and cisplatin, and 6% other platinum-based regimens. Of the 148, 71 (48%) recurred in the bladder—16 (11%) with MI disease and 55 with non-muscle invasive (NMI). Salvage RC prevented cancer-specific death in 9 of 12 (75%) patients who accepted RC after MI relapse and 13 of 14 (93%) after NMI relapse. 5-year disease-specific, overall, cystectomy-free, and recurrence-free survival rates for the entire cohort were 90%, 86%, 76%, and 64%. **Conclusions:** The favorable outcomes observed in this large, multi-institutional cohort support the efficacy of surveillance only for carefully selected and closely monitored MIBC patients. Future studies should aim to improve patient selection by identifying biomarkers predictive of invasive relapse and developing novel imaging methods for its detection.

4523 Poster Session (Board #349), Sat, 8:00 AM-11:30 AM

Atezolizumab (atezo) in first-line cisplatin-ineligible or platinum-treated locally advanced or metastatic urothelial cancer (mUC): Long-term efficacy from phase 2 study IMvigor210. *First Author: Arjun Vasant Balar, Laura and Isaac Perlmutter Cancer Center, NYU Langone Medical Center, New York, NY*

Background: Platinum-based chemotherapy is a standard first-line approach for mUC, but many pts are ineligible for cisplatin, and progression is common. Atezo (anti–PD-L1) was approved for first-line cisplatin–ineligible and platinum-treated mUC pts following IMvigor210 results. Here we present more mature DOR and OS data in both populations. **Methods:** Cohort 1 (NCT02951767) pts were treatment naive for mUC, had ECOG PS ≤ 2 and were ineligible for cisplatin by at least one of the following: GFR > 30 and < 60 mL/min, ≥ G2 hearing loss or peripheral neuropathy or ECOG PS 2. Cohort 2 (NCT02108652) pts progressed after platinum and had ECOG PS ≤ 1 and GFR ≥ 30 mL/min. Atezo 1200 mg IV q3w was given until PD (Cohort 1) or loss of clinical benefit (Cohort 2). We evaluated the following efficacy endpoints: RECIST v1.1 ORR by central review (primary), DOR, OS. **Results:** 119 Cohort 1 pts (median follow-up, 29 mo) and 310 Cohort 2 pts (median follow-up, 33 mo) were evaluable as of July 12, 2017. In Cohort 1, ORR was 24% (95% CI: 16, 32), CR rate was 8%, and median DOR was not reached (95% CI: 30.4 mo to not estimable; 19 of 28 responses ongoing); in elderly pts (≥ 80 y; Cohort 1, n = 25), ORR was 28% (95% CI: 12, 49), and CR rate was 12%. Further characterization of outcomes in pts ≥ 80 y and subgroups with poor prognostic factors will be presented. In Cohort 2, ORR was 16% (95% CI: 13, 21), CR rate was 7%, and median DOR was 24.8 mo (95% CI: 13.8, 30.4). In both cohorts, sustained responses occurred among pts who discontinued atezo for reasons besides PD. In Cohort 1, median OS was 16.3 mo (95% CI: 10.4, 24.5), with 1-y OS of 58% (95% CI: 49, 67) and 2-y OS of 41% (95% CI: 32, 50); in Cohort 2, median OS was 7.9 mo (95% CI: 6.7, 9.3), with 1-y OS of 37% (95% CI: 31, 42) and 2-y OS of 23% (95% CI: 19, 28). **Conclusions:** With > 2 y median follow-up, responses to first-line atezo in cisplatin-ineligible mUC pts, including pts ≥ 80 y, appeared durable, resulting in continued improvement in OS since the primary analysis. For pre-treated pts, ORR and OS were in line with prior data, and taken together with DOR, data were consistent with Ph 3 results (IMvigor211, NCT02302807). Clinical trial information: NCT02951767 and NCT02108652.

4524 Poster Session (Board #350), Sat, 8:00 AM-11:30 AM

Updated efficacy and safety of KEYNOTE-052: A single-arm phase 2 study investigating first-line pembrolizumab (pembro) in cisplatin-ineligible advanced urothelial cancer (UC). *First Author: Jacqueline Vuky, Oregon Health & Science University, Portland, OR*

Background: Based on initial results from the phase 2 KEYNOTE-052 study (NCT02335424), pembro was approved for the treatment of cisplatin-ineligible patients with advanced UC. The results of the long-term follow-up analysis of KEYNOTE-052 are presented. **Methods:** Eligible patients were cisplatin ineligible (ECOG PS 2, CrCl ≥30 to <60 mL/min, grade ≥2 neuropathy/hearing loss, NYHA Class 3 heart failure), had advanced UC, and had received no prior chemotherapy for metastatic disease. Patients received pembro 200 mg IV Q3W for up to 24 months. Imaging was performed at wk 9, then Q6W for 12 months, and Q12W thereafter. The primary end point was confirmed ORR (RECIST v1.1, independent central review). **Results:** Efficacy and safety were assessed in 370 patients. Median age was 74 years; 10.8% of patients were ≥85 years old; 42.2% were ECOG PS 2; and 85.1% had visceral disease. As of the Nov 30, 2017, data cutoff, median (range) follow-up was 11.5 (0.1-31.3) mo. Confirmed ORR was 28.9% (95% CI, 24.3-33.8); 30 (8.1%) and 77 (20.8%) patients had complete response and partial response, respectively. Median duration of response was not reached (NR) (95% CI, 21.4 mo to NR); 82% and 68% of patients had a response of ≥6 and ≥12 mo, respectively. Median OS was 11.5 (95% CI, 10.0-13.3) mo; 6-and 12-mo OS rates were 67.2% and 47.5%, respectively. In patients with a PD-L1 expression combined positive score of ≥10 (n=110), ORR was 47.3% (95% CI, 37.7-57.0) and median OS was 18.5 mo (95% CI, 12.2 mo to NR). Median OS was NR (12.4 mo to NR) in patients with lymph node–only disease (n=51) and was 13.1 (95% CI, 11.0-16.8) mo in patients with ECOG PS 0/1 (n=214) and 9.7 (95% CI, 5.7-11.6) mo in patients with ECOG PS 2 (n=156). Treatment-related adverse events (AEs) occurred in 67.6% of patients; most common (≥15%) were fatigue (18.1%) and pruritus (17.8%). Grade ≥3 treatment-related AEs occurred in 20.3% of patients. Immune-mediated AEs occurred in 24.6% of patients. **Conclusions:** Pembro continues to be well tolerated and elicits clinically meaningful, durable antitumor activity in a broad spectrum of cisplatin-ineligible patients with advanced UC. Clinical trial information: NCT02335424.

4525 Poster Session (Board #351), Sat, 8:00 AM-11:30 AM

Upper tract urothelial carcinoma is non-basal and T-cell depleted. *First Author: Panagiotis J. Vlachostergios, Division of Hematology & Medical Oncology, Weill Cornell Medical College & New York-Presbyterian Hospital, New York, NY*

Background: Urothelial cancer (UC) of the upper urinary tract (UTUC) accounts for 5-10% of UC. Despite sharing a common histology with bladder UC (UCB), staging and prognosis differences have been reported. **Methods:** To dissect the central biological features of UTUC driving its phenotype, we performed an integrated analysis of UTUC tumors using whole-exome (WES) and RNA sequencing (RNAseq). We compared the exome and transcriptome of UTUC to the TCGA UCB and an independent UTUC validation dataset (VALD). **Results:** We performed an integrated analysis of WES (n = 16) and RNAseq (n = 19) from biobanked nephroureterectomy archival specimens of 19 chemotherapy-naïve patients with UTUC. Patients' demographics are as follows: median age 71 (range 46-87); 11 men, 8 women; 11 former/current smokers; 13 renal pelvis, 6 ureteral; 17 high-grade, 2 low-grade; 8 low stage (< pT2), 11 high stage (≥ pT2). Our analyses revealed several insights: 1) UTUC has a significantly lower frequency of TP53 mutations (3/16, 18.7%) compared to UCB patients (198/412, 48%) (p = 0.03) but similar frequency of mutations in chromatin modifying (KMT2C, KMT2D, KDM6A), transcription activation (CREBBP), receptor tyrosine kinase (FGFR3, PIK3CA, ERBB2, KRAS), and cell cycle regulation (RB1) genes. 2) UTUC is characterized by downregulation of the DNA mismatch repair genes (p ≤ 0.05) and APOBEC3A, APOBEC3B genes (p < 0.01) and a lower total mutational burden compared to UCB (2 vs 5 mutations per Mb, p = 0.01). 3) UTUC is intrinsically non-basal. UTUC is predominantly luminal by UNC (18/19, 95%) and the MD Anderson (MDA) (17/19, 89%) criteria, and luminal-papillary (16/19, 84%) by the TCGA criteria. All VALD UTUC tumors (n = 10) clustered with the luminal-papillary subtype. 4) UTUC tumors exhibit a T-cell depleted phenotype (17/19, 89%). 5) FGFR3 expression is a dominant transcriptional outlier in UTUC (7/19, 37%) and is associated with a T-cell depleted phenotype (p < 0.01). **Conclusions:** Our study demonstrates that UTUC is predominantly and intrinsically non-basal. We show that UTUC is characterized by a T-cell-depleted phenotype associated with FGFR3 overexpression. By dissecting the biology of UTUC, we provide the biological rationale for future UTUC-specific therapeutic strategies.

4526 Poster Session (Board #352), Sat, 8:00 AM-11:30 AM

Ramucirumab (RAM) exposure-response (ER) relationship in RANGE, a randomized phase III trial of docetaxel (DOC) with or without RAM in advanced urothelial carcinoma (UC) patients (pts) who progressed on or after platinum therapy. *First Author: Ronald De Wit, Erasmus MC Cancer Institute, Rotterdam, Netherlands*

Background: RAM+DOC improved PFS & had acceptable safety in UC (Petrylak, et al *Lancet*, 2017). RAM ER relationships are reported. **Methods:** Pts received RAM (10 mg/kg) + DOC (75 mg/m^2) or placebo (P) + DOC (Day 1 of a 21 day cycle) until discontinuation criteria were met. Evaluable pts (n = 161) were classed into high *v* low groups at the median observed RAM $C_{min\text{-}1}$ (minimum concentration after first dose) or $C_{min\text{-}1}$ quartiles (Q1 = lowest). Matched case controls (MCC) were based on UC prognostic factors. Cox regression was performed. Exposure (E)-safety data are descriptive. **Results:** Subgrouping by baseline prognostic factors indicated pts with 2-4 Bellmunt risk factors, ≥3 metastatic sites, < 10g/dL hgb or < 3.5g/dL albumin often achieved low $C_{min\text{-}1}$. PFS did not differ between low $C_{min\text{-}1}$ & P+DOC pts. High $C_{min\text{-}1}$ pts had ↑ PFS *v* P+DOC pts in 5 (Table) of the 10 subgroups. From $C_{min\text{-}1}$ Q1-4, ORRs were 10.9%%, 38.3%, 34.8% & 37.5%. In a MCC analysis, pts achieving higher E had ↑ PFS & ↓ HR (Table). From Q1-4, grade ≥3 neutropenia increased, but no clear trends were seen for the other grade ≥3 events- fatigue, hypertension and febrile neutropenia. **Conclusions:** Q1 pts had lower mPFS & ORR *v* Q2-4. The potential association between baseline risk factors & E achieved may confound ER analysis & warrants further exploration. Safety appears manageable across RAM E levels. Clinical trial information: NCT02426125.

Comprehensive genomic characterization of urothelial carcinomas. *First Author: Amin Nassar, Brigham and Women's Hospital, Boston, MA*

Background: While the genetic characteristics of muscle-invasive bladder cancer have been studied in detail, there are few reports using the same genetic analysis platform to investigate differences and similarities among urothelial carcinoma (UC) derived from different sites and with differing degrees of invasion. **Methods:** We used targeted exome sequencing with Oncopanel to study 82 low-grade (LG) non-muscle invasive bladder cancer tumors (LG-NMIBC), 127 high-grade (HG) NMIBC, 199 muscle-invasive bladder cancer tumors (MIBC), and 55 HG invasive upper tract urothelial carcinoma (UTUC) tissue samples. Oncopanel assesses 275-447 cancer genes for somatic mutations and copy number alterations without a paired normal. All single nucleotide variants (SNVs) that were considered likely germline were excluded. Clinico-pathological characteristics, mutation frequencies for 238, and tumor mutation burden (TMB) were determined for the 4 types of UC, and were compared using the χ^2 test and Kruskall Wallis Test. Nominal p values were obtained, and the Benjamini-Hochberg fdr correction was employed to determine statistical significance (q < 0.1). **Results:** Key results are shown in the Table. **Conclusions:** In this series of uniformly analyzed UC samples of different kinds, we found that: 1) FGFR3, STAG2 and KDM6A mutations are highly enriched in LG-NMIBC; 2) HG-NMIBC, MIBC, and UTUC all have similar genetic alterations; and 3) TP53 and RB1 mutations are associated with all of the latter 3 types of UC in contrast to LG-NMIBC.

4528 Poster Session (Board #354), Sat, 8:00 AM-11:30 AM

Clinical efficacy of cabozantinib plus nivolumab (CaboNivo) and CaboNivo plus ipilimumab (CaboNivoIpi) in patients (pts) with chemotherapy-refractory metastatic urothelial carcinoma (mUC) either naïve (n) or refractory (r) to checkpoint inhibitor (CPI). *First Author: Rosa Nadal, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: Preliminaryclinical activity of CaboNivo and CaboNivoIpi has been previously reported for mUC pts and other genitourinary tumors. Here, we report longer follow-up data of CaboNivo and CaboNivoIpi in pts with mUC nCPI and safety and preliminary clinical activity of CaboNivo in mUC rCPI **Methods:** This phase 1 dose + expansion cohorts study enrolled mUC nCPI (escalating doses of CaboNivo n = 15 and CaboNivoIpi n = 8) and mUC rCPI (Cabo40-Nivo3mg/kg n = 7) pts until progression/unacceptable toxicity. Objectives: Safety, ORR, DOR, PFS and OS. Tumors were assessed for response q8wks (RECIST 1.1). Adverse events (AEs) were graded (G) by NCI-CTCAE v4.0. **Results:** 30 mUC pts enrolled. Median follow-up: whole cohort: 11.9 months; mUC rCPI: 5.6 months. All G clinical AEs in ≥20% (n = 29): fatigue (83%), diarrhea (72%) and anorexia (62%); laboratory AEs: ALT elevation (55%), AST elevation (48%) and hyponatremia (48%). Common ≥G3 clinical AEs: fatigue (17%), HTN (14%), thromboembolic events (14%); laboratory AEs: lipase elevation (31%), hypophosphatemia (17%), hyponatremia (10%). Immune-related AEs 14% (n = 4): mUC nCPI: CaboNivo: G3 meningitis; G3 pneumonitis; CaboNivoIpi: G3 colitis; mUC rCPI: G2 adrenal insufficiency. For mUC nCPI CaboNivo ORR: 50% (6/12), mDOR: 24.1months(mo) [95% CI: 7.8 mo-not reached (NR)]; mPFS 24.1mo [95% CI:1.6mo-NR] & mOS: NR. For mUC nCPI CaboNivoIpi: ORR: 33% (2/6), mDOR: NR; mPFS 10.1mo [95% CI:1.6 mo-NR] & mOS: NR. For mUC rCPI CaboNivo, ORR: 28% (2/7), SD 57% (4/7) and DOR: 100% at 5mo. **Conclusions:** Both CaboNivo and CaboNivoIpi are safe and active in mUC nCPI pts, CaboNivo is also active in mUC pts previously treated with immunotherapy, suggesting the addition of Cabo to Nivo may aid in overcoming CPI resistance. Clinical trial information: NCT02496208.

4529 Poster Session (Board #355), Sat, 8:00 AM-11:30 AM

Atezolizumab (atezo) in special populations: Analyses from an expanded access program (EAP) in platinum-treated locally advanced or metastatic urothelial carcinoma (mUC). *First Author: Jean H. Hoffman-Censits, John Hopkins University Sidney Kimmel Cancer Center, Baltimore, MD*

Background: Prior to FDA approval of atezo (anti–PD-L1) for platinum-treated mUC (and later cisplatin-ineligible mUC), a US EAP granted mUC pts access to atezo. The EAP (Bellmunt ASCO 2017) included special populations previously ineligible for Ph II study IMvigor210 (Rosenberg *Lancet* 2016). Here, we evaluate outcomes in pts with impaired baseline renal function or variant histology. **Methods:** This study (NCT02589717) enrolled mUC pts who progressed during or following platinum and had ECOG PS ≤ 2. Pts had predominant TCC histology but no restrictions on CrCl levels. Pts received atezo 1200 mg IV q3w until loss of clinical benefit. ORR (per investigator), DCR (CR+PR+SD) and safety were assessed by CrCl or primary tumor histology. **Results:** 114 pts were response evaluable; responses occurred in most subgroups (Table). All-grade treatment-related AEs (TRAEs) occurred in 46% of 214 safety-evaluable pts. In renal function subgroups, TRAE rates ranged from 35% (CrCl 30-45 mL/min) to 54% (CrCl 45-60 mL/min); no TRAE rate differences by histology were seen (46% each). Similar trends occurred for AEs of special interest. TRAEs leading to discontinuation were uncommon (< 3% across subgroups). Two serious TRAEs (15%) occurred in CrCl < 30 mL/min subgroup (< 8% in other subgroups). **Conclusions:** Responses or SD with atezo were seen in pts with mixed histology or compromised renal function (notably in pts with CrCl 30-45 mL/min), and safety was comparable across subgroups. These results suggest that atezo provides clinical benefit in a broad range of platinum-treated mUC pts. Clinical trial information: NCT02589717.

RECIST v1.1 response by baseline characteristic.

	n	ORR, %	95% CI, %	CR, %	DCR, %	95% CI, %
All	114	15	9, 23	3	49	40, 59
CrCl, < 30 mL/min	6	0	0, 46	0	50	12, 88
30-45	19	21	6, 46	5	63	38, 84
45-60	27	4	0, 19	0	30	14, 50
≥ 60	62	19	10, 31	3	53	40, 66
TCC histology only	102	13	7, 21	2	48	38, 58
TCC with mixed histology[a]	12	33	10, 65	8	58	28, 85

Median follow-up (N = 214): 2.3 mo (range 1.6-3.4).
[a] 1 PR was seen among 2 pts with an adenocarcinoma component and 1 CR + 2 PR among 5 pts with "other" subtype. No responses occurred in 1 pt with sarcomatoid or 4 pts with squamous components; 2 pts with squamous histology and 1 with "other" histology had SD.

4530 Poster Session (Board #356), Sat, 8:00 AM-11:30 AM

Optimization of PD-L1 algorithm for predicting overall survival (OS) in patients with urothelial cancer (UC) treated with durvalumab monotherapy. *First Author: Magda Zajac, AstraZeneca, Cambridge, United Kingdom*

Background: PD-L1 expression is a useful biomarker in predicting response to PD-1 and PD-L1 directed immunotherapies in a variety of tumor types. In UC, studies have implicated PD-L1 expression in tumor cells (TC) and tumor-infiltrating immune cells (IC) as having clinical utility, but the relative importance of each cellular compartment and the most predictive algorithm and PD-L1 expression cutoff remain unclear. **Methods:** PD-L1 expression data (SP263 assay) from 188 patients in the UC cohort from single arm (durvalumab monotherapy) Phase 1/2 Study CD-ON-MEDI4736-1108 (NCT01693562; Oct. 2017 data cutoff) were assessed. Regression models were used to evaluate the impact of PD-L1 expression in TC or IC on OS, progression-free survival (PFS), objective response rate (ORR), best percentage tumor change and tumor shrinkage 15 months after last subject randomization. Kaplan–Meier plots were generated to explore the impact of single biomarker and combined (TC or IC [% PD-L1 positive ICs within IC area]) algorithms on OS. **Results:** Both IC and TC PD-L1 were linked to higher ORR, and IC PD-L1 was associated with better survival in patients treated with durvalumab. IC PD-L1 had a higher impact on response to durvalumab than TC PD-L1, showing significant ($P < 0.05$) association with OS, PFS, ORR, and tumor shrinkage. The best outcomes were obtained when TC and IC algorithms were combined, with TC25%/IC25% proving optimal (Table). **Conclusions:** In UC, the TC25%/IC25% algorithm appears to provide optimal predictive value based on efficacy and prevalence of the biomarker. Additional data from randomized trials are needed to confirm these findings. Clinical trial information: NCT01693562.

4531 Poster Session (Board #357), Sat, 8:00 AM-11:30 AM

***FGFR3* Driven Metastatic Urothelial Carcinoma of the Urinary Bladder (mUCB): A Comprehensive Genomic Profiling Study.** *First Author: Jeffrey S. Ross, SUNY Upstate Medical University, Syracuse, NY*

Background: Using comprehensive genomic profiling (CGP), we queried whether *FGFR3*-driven mUCB could be further defined by additional genomic alterations (GA) and biomarkers of response to immunotherapies. **Methods:** DNA from FFPE tissues of 1,576 mUCB underwent hybrid-capture based CGP to evaluate all classes of genomic alterations. Tumor mutational burden (TMB) was determined on 1.1 Mbp of sequenced DNA and microsatellite instability (MSI) was determined by principal components analysis of optimal homopolymer loci. **Results:** 385 (24%) of the 1,576 UCB featured GA affecting *FGFR1-4*. Of the *FGFR3* GA identified in mUBC (*FGFR3*mut), 77% were SV, 2% were amplifications, 18% were fusions/rearrangements, and 4% had more than 1 GA type. When compared with a cohort of 1,275 *FGFR3* WT mUCB, the GA/tumor and frequency of *TERT* GA were similar. GA in *TP53* and *RB1* were more common in *FGFR3* WT than *FGFR*mut, whereas cell cycle GA (e.g., *CDKN2A)* were more common in *FGFR3*mut tumors. Genes associated with DNA repair were altered in both groups, with *ARID1A* GA more frequent in *FGFR3* WT, *KDM6A* GA more frequent in *FGFR3*mut, and *BRCA1/2* GA less frequent overall and similar in both groups. Targetable *ERBB2* GA were significantly more common in *FGFR3* WT cases. Targets in the MTOR pathway, including GA in *PIK3CA* and *TSC1,* were also more common in *FGFR3*mut mUBC. MSI-High status was extremely rare in both groups. The median TMB was higher in *FGFR3* WT, and samples more often had TMB of ≥10 mut/Mb or ≥20 mut/Mb. **Conclusions:** CGP reveals both similarities and differences in the genomic landscapes of *FGFR3*mut and *FGFR3* WT mUBC. In the 2% of mUBC with *FGFR3* driver GA, other targetable GA affecting kinases or the MTOR pathway are present. As evidenced by TMB, the opportunity for immunotherapies remains significant.

Patient-reported outcomes (PROs) in patients with urothelial carcinoma (UC) treated with durvalumab (second-line or above) in phase 1/2 dose-escalation study 1108. *First Author: Peter H. O'Donnell, University of Chicago Comprehensive Cancer Center, Chicago, IL*

Background: In Study 1108, durvalumab showed meaningful clinical activity in patients with UC, with an objective response rate (ORR) of 17.8% (PD-L1–positive patients: 27.6%) [Powles 2017, *JAMA Oncol*]. We report PRO results. **Methods:** Phase 1/2, open-label, dose escalation study 1108 (NCT01693562) enrolled patients with locally advanced/metastatic UC and prior platinum-based treatment. Patients received durvalumab 10 mg/kg Q2W for 12 months, and were asked to complete Functional Assessment of Cancer Therapy-Bladder Cancer (FACT-BL), European Organisation for Research and Treatment of Cancer Quality of Life (QoL) Questionnaire (EORTC QLQ-C30) and a pain questionnaire at baseline (D1) and days 29, 43, 57, 85 and 113 (D113). Changes in PROs were analyzed descriptively. Improvement/deterioration from D1 was based on minimum important difference: $^1/_2$ baseline standard deviation (SD) for FACT-BL (range 0–156), 10-point difference for EORTC QLQ-C30 (total range 0–100). **Results:** In the full analysis set (n = 182), overall questionnaire completion rate at baseline was 99% and 81% at D113. Pain total mean (SD) score (range 0–10) tended to decrease over time, from 3.4 (2.8) on D1 to 1.9 (2.4) at D113. Mean (SD) FACT-BL total scores improved over time, from 107.5 (23.0) on D1 to 115.4 (22.6) on D113, with similar increases in bladder cancer subscale (BLCS) and trial outcome index (TOI) mean scores. FACT-BL total score improved over time in 32.6% of patients (48.8% no change, 18.6% deterioration); 34.9% showed an improvement in FACT-BLCS, and 32.6% in FACT-TOI. EORTC QoL mean (SD) score improved from 57.1 (24.8) on D1 to 69.0 (21.4) at D113. Improvements in EORTC QLQ-C30 functional domains were seen in 26.3–37.8% of patients, while 57.6–73.1% showed improvements in symptom domains, with largest responses in pain, fatigue, physical and role domains (improvement: 73.1, 57.6, 37.8 and 32.4%; no change: 0.0, 27.3, 46.0 and 41.2%; deterioration: 26.9, 15.2, 16.2 and 26.5%, respectively). **Conclusions:** Overall, the mean scores (domain or total) for pain, FACT-BL and EORTC QLQ-C30 improved over time in patients with UC treated with durvalumab in the phase 1/2 study 1108. Clinical trial information: NCT01693562.

4533 Poster Session (Board #359), Sat, 8:00 AM-11:30 AM

Immune profiling in a randomized phase II trial of acalabrutinib and pembrolizumab (PA) versus pembrolizumab (P) for patients with metastatic urothelial cancer (mUC). *First Author: Tian Zhang, Duke University Medical Center, Durham, NC*

Background: Response rates for checkpoint inhibitors (CPIs) in cisplatin refractory mUC range from 15% to 21%. Thus, biomarkers are needed to predict for treatment responses. We conducted a Ph2 clinical trial in patients with mUC, randomized to P or PA (NCT02351739). From this trial, we performed the first correlation analysis of circulating immune cells with clinical outcomes in mUC patients receiving CPI therapy. **Methods:** 75 patients with cisplatin refractory mUC were treated with P or PA. Pre- and on-study flow cytometry was performed on peripheral blood mononuclear cells for these markers: CD3, CD4, CD8, PD-1, PD-L1, PD-L2, B7-H3, CTLA-4, ICOS, LAG3, TIM3, Ki-67, CD45RA, CCR7, CD38, CD14, HLA-DR, CD16/CD56, CD19/CD20, CD25, CD127, CD39, and CCR4. Single and selected double marker positivity was analyzed on CD4 and CD8 T-cells and monocytes (M). Mean ($\pm$ SD) of relative cell subset frequency (RCSF) was calculated and associated with clinical responses (best radiographic response as defined per RECIST 1.1 criteria). Unadjusted p-values were derived from Kruskal-Wallis testing, with responses as outcomes and RCSF or delta RCSF as correlatives. **Results:** Clinical responses (PR+CR) did not differ between treatments (P = 25% vs. PA = 20%); therefore, pooled results from all treated patients were used for analysis. Baseline RCSF (n = 57) or changes in RCSF from baseline to week 4 (n = 51) were correlated with responses. Patients who had CR had lower expression of LAG3, PDL2, CTLA4 and B7H3 on M at baseline. Among T-cells, lower levels of CTLA4+, PD1+, and ICOS+ CD4 T-cells; and higher CD28-/TIM3- CD8 cells were also associated with CR. Changes from baseline to week 4 were observed for actively proliferating CD4 or CD8 T-cells, CD8 T-cells that co-express TIM3 with CD28 or PD-1, and for TIM3-expressing M subsets, suggesting that early increases in immune cell activation (Ki-67, CD28, PD-1) and interferon response (TIM3) are associated with clinical responses. **Conclusions:** Immune profiling in patients with mUC showed activation and interferon response markers on subsets of T-cells and monocytes that were associated with treatment responses to CPI therapy.

4534 Poster Session (Board #360), Sat, 8:00 AM-11:30 AM

FIERCE-21: Phase 1b/2 study of docetaxel + b-701, a selective inhibitor of FGFR3, in relapsed or refractory (R/R) metastatic urothelial carcinoma (mUCC). *First Author: Joaquim Bellmunt, Dana-Farber Cancer Institute, Boston, MA*

Background: Patients with locally advanced or metastatic urothelial carcinoma (mUCC) have a poor prognosis. FGFR3 is frequently overexpressed in UCC and 15-20% of patients with mUCC have FGFR3 gene mutations or fusions (M/F). B-701 is a fully human monoclonal antibody against FGFR3 that blocks activation of the wildtype and genetically activated receptor. FIERCE-21 is a Phase 1b/2 study designed to evaluate B-701 alone or in combination with docetaxel (D). **Methods:** The study consists of a Phase 1b lead-in (P1b) followed by Phase 2 (P2) expansion and a randomized phase. Eligible patients P1b: the study enrolled mUCC R/R excluding prior taxane treatment, and ECOG >1. Treatment: B-701 at 25 mg/kg and D at 75 mg/m^2 q3w. Efficacy was assessed by investigators (RECIST 1.1). Primary objective: Determine P2 dose and evaluate safety and efficacy. **Results:** 19 patients were enrolled in P1b: median age 66 yrs, ECOG 1 = 58%, Hgb <10 gm/dL 5%, liver metastases 26%, ≥ 2 prior regimens 63%, best response to prior therapy PD 52%. Six patients were positive for FGFR3 M/F. Grade ≥ 3 AEs occurring in ≥ 2 patients were typical of D at this dose and schedule [decreased neutrophil count (26.3%), neutropenia (10.5%), decreased WBC (10.5%)]. Two patients had D dose reductions and no subjects had dose reductions of B-701 or discontinued treatment due to AE. Two patients died, 1 with PD and bleeding, and 1 with MAHA associated with infection and recurrent thrombosis. Four subjects are alive (3 M/F). Median OS has not been reached in M/F vs 5.3 months in WT. **Conclusions:** B-701 combined with standard dose D in an every 3 week schedule in patients with mUCC was well-tolerated with expected myelosuppression. Enhanced activity was seen in the FGFR3 M/F compared to WT patients. Phase 2 expansion is currently enrolling FGFR3 M/F patients (B-701 monotherapy vs. combination B-701+D). Clinical trial information: NCT02401542.

4535 Poster Session (Board #361), Sat, 8:00 AM-11:30 AM

Relapse-free survival (RFS) of clinical T2-4N0 urothelial bladder carcinoma (UBC) after radical cystectomy (RC), with or without perioperative chemotherapy (POC): Endpoints for clinical trial design. *First Author: Marco Bandini, Vita-Salute San Raffaele University, Milan, Italy*

Background: Recent data suggests that the full benefit of neoadjuvant therapy may not be captured via pathologic complete response rates. Improved relapse-free survival (RFS) may identify active agents acting though novel mechanisms. **Methods:** Within RISC and San Raffaele databases (1990-2016), we identified 973 cT2-4N0 UBC patients (pts), from 27 centers in the U.S., Europe, Israel, and Canada. A Cox-based nomogram predicting 12-m RFS was built including pt (gender, race), tumor characteristics (histology, pT, pN and surgical margin status [SMS]), and administration of neoadjuvant or adjuvant chemotherapy (CT). Multiple imputation was performed to handle missing data. Validation (2000 bootstrap resamples) was internally tested. Calibration and prognostic ability was assessed comparing estimated versus observed 12-m RFS. **Results:** Overall, 577 (59.3%) and 236 (24.3%) pts had cT2 and cT3-T4, respectively (T unknown and imputated in 160, 16.4%). 125 (12.8%) had mixed UC+other histologies. 275 pts (28.3%) received neoadjuvant CT, 165 (17%) adjuvant CT. On multivariable analyses, pT ($p<0.002$), pN ($p<0.001$) and SMS ($p=0.005$) were associated with higher rate of recurrence. Conversely, use of adjuvant CT (HR = 0.63, $p<0.001$) was associated with lower rate of recurrence. Results were confirmed in sensitivity analyses after removing 61 (6.2%) non-cisplatin POC. Overall, 405 (41.6%) pts relapsed and 375 (38.5%) died. Median RFS and overall survival were 44 months (95%CI, 36-65) and 57 months (95%CI, 50-90), respectively. In POC-treated pts, nomogram-predicted 12-m RFS rates were 91.6% (95%CI, 87-96), 79.7% (95%CI, 73-88) and 53.0% (95%CI, 44-63), across the nomogram-derived tertiles. In pts who did not receive POC, these estimates were 89.8%, 74.8%, and 47.0%, respectively. The bootstrapped c-index of the nomogram was 78% (95%CI: 74-81). **Conclusions:** Nomogram-predicted 12-m RFS may provide data to base future clinical trial designs of novel agents in the perioperative setting.

4536 Poster Session (Board #362), Sat, 8:00 AM-11:30 AM

Prognostic value of genomic alterations of DNA repair genes in advanced bladder cancer (ABC). *First Author: Ming Yin, The Ohio State University Comprehensive Cancer Center, Columbus, OH*

Background: DNA repair defect plays an important role in tumorigenesis, progression, treatment response and outcomes of BC. There is conflicting data on the prognostic & predictive role of DDR gene alterations in ABC patients (pts) treated with platinum-based chemotherapy (Teo *et al.* ASCO 2017; Mendiratta *et al.* GU ASCO 2018). Thus, further validation is needed to understand prognostic implications of DDR genomic alterations in ABC. **Methods:** Exome sequencing data were obtained from 81 ABC pts who received comprehensive genomic sequencing using FoundationOne (315 cancer-related genes). Overall survival (OS) was measured from time of initial diagnosis and metastasis-related survival (MRS) was measured from time of metastatic diagnosis to death or last follow-up. Cox proportional hazard regression analysis was performed to calculate the hazard ratio (HR) and 95% confidence interval (CI). **Results:** In a panel of 28 DDR genes, mutations were present in 74.1% pts (60/81) with18.5% pts carrying mutations in ≥3 DDR genes. Overall, mutations of DDR genes were not significantly associated with OS (HR = 0.76, 95% CI 0.41–1.43, p = 0.397) or MRS (HR = 0.57, 95% CI 0.30–1.08, p = 0.084). Further evaluation showed that most DDR mutations (excluding ATM/RB1) were associated with longer OS (HR = 0.49, 95% CI 0.27–0.87, p = 0.015) and longer MRS (HR = 0.39, 95% CI 0.21–0.70, p = 0.002), while mutations of ATM/RB1 genes were associated with shorter OS (HR 1.87, 95% CI 0.97–3.59, p = 0.06) but not MRS. There was a trend for longer OS and MRS with increased number of DDR mutations in individual pts. Pts carrying ≥3 DDR mutations (excluding ATM/RB1) seemed to have the best prognosis in our cohort (OS: HR 0.36, 95% CI 0.14–0.92, p = 0.03; MRS: HR 0.20, 95% CI 0.07–0.56, p = 0.002). **Conclusions:** Most DDR mutations correlated with improved clinical outcomes in ABC pts. However, ATM/RB1 mutations correlated with poor prognosis. Pts carrying ≥3 DDR (excluding ATM/RB1) mutations had the best prognosis. Further exploration of the deleterious nature and impact of alterations as well as further external validation are critical. Clinical trials evaluating synthetic lethality with DDR inhibitors are ongoing.

4537 Poster Session (Board #363), Sat, 8:00 AM-11:30 AM

A novel, robust multiplex urine-based immunoassay for bladder cancer detection. *First Author: Hideki Furuya, University of Hawaii Cancer Center, Honolulu, HI*

Background: Bladder cancer (BCa) is among the most commonly diagnosed malignancies worldwide, and due the high rate of post-operative disease recurrence, it is one of the most prevalent in many countries. The development of non-invasive molecular assays that can accurately detect and monitor BCa would be a major advance, benefiting both patients and healthcare systems. We have previously identified a urinary protein biomarker panel that is being developed for application in at-risk patient cohorts. Here, we investigated the potential utility of the multiplex assay in a prospective study. **Methods:** The study cohort collected from urology clinics at two institutions was comprised of a total of 145 subjects. The protein biomarker panel (IL8, MMP9, MMP10, ANG, APOE, SDC1, A1AT, PAI1, CA9, VEGFA) was monitored in voided urine samples collected prior to cystoscopy using a custom multiplex ELISA assay. The diagnostic performance of the biomarker panel was assessed using receiver operator curves (ROC), predictive modeling and descriptive statistics. **Results:** Urinary biomarker concentrations were significantly elevated in cases versus controls, and in cases with high-grade and muscle-invasive tumors. The AUC for the 10-biomarker assay was 0.901 (95% confidence interval, 0.850–0.934), with an overall diagnostic sensitivity specificity of 0.90 and 0.91, respectively. **Conclusions:** Urinary levels of a 10-biomarker panel enabled discrimination of patients with BCa. The multiplex urinary diagnostic assay will continue in prospective study. Clinical trial information: NCT03193528.

4538 Poster Session (Board #364), Sat, 8:00 AM-11:30 AM

Bladder cancer gene expression subtypes (60 gene signature) to define prognosis, differential immune response, and biomarker associations. *First Author: Gregory M. Mayhew, GeneCentric, Research Triangle Park, NC*

Background: Gene expression subtypes provide valuable insight into tumor biology and potential therapeutic response. Differential expression of immune infiltrating cells and biomarkers, tumor mutation burden, therapeutic targets, and overall survival were examined in Muscle Invasive Bladder Cancer (MIBC) subtypes, luminal, luminal infiltrated, basal, and neuronal. **Methods:** Multiple MIBC datasets were assembled including TCGA (n = 408) and 2 other gene expression datasets (n = 305, n = 93). A reduced 60-gene subtyping signature was developed and subtype calls were compared to TCGA clustering. Signatures of multiple immune cells, single immune-biomarkers, drug target genes, proliferation, and mutation burden were examined for differential expression using the Kruskal-Wallis test. Differences in gene mutation distributions were evaluated using Fisher's exact test. Survival differences were assessed using stratified cox models and Kaplan Meier plots. **Results:** Immune cell expression was significantly different across the subtypes in multiple datasets (T cells $p < 0.001$ and *CD274*(PD-L1) $p < 0.002$). The luminal subtype as compared to other subtypes showed lower immune expression for most markers. In the TCGA dataset, drug target genes were differentially expressed (*FGFR2*, *FGFR3*, and *ERBB2* $p < 1e\text{-}05$), as was proliferation ($p < 1e\text{-}20$), and patterns were reproducible across datasets, with luminal and luminal-infiltrated subtypes showing higher expression of *FGFR2*, *FGFR3*, and *ERBB2* and lower proliferation. Mutation frequencies of *FGFR3* and *RB1* varied across subtypes (p = 1e-05 and p = 0.0005), whereas mutation burden did not (p = 0.16), despite marked differences in immune infiltration. In the TCGA dataset, significant differences in survival were observed (p = 0.0385 adjusting for stage), with luminal and luminal-infiltrated, as defined by the 60 gene signature, showing better survival and basal worse survival. **Conclusions:** Biologic gene expression subtypes of MIBC using a reduced 60-gene signature reveal key differences in prognosis, immune cell expression, and drug targets. Subtypes provide potential biomarkers for targeted and immunotherapy response.

4539 Poster Session (Board #365), Sat, 8:00 AM-11:30 AM

Model combining genomic and clinical factors to predict clinical benefit from PD1/PD-L1 inhibitors for advanced UC. *First Author: Amin Nassar, Brigham and Women's Hospital, Boston, MA*

Background: Tumor mutational burden is associated with response to PD1/PD-L1 inhibitors in advanced UC. We explored the ability of copy-number variants (CNVs) and specific genomic alterations to complement single-nucleotide variants (SNVs) to predict clinical benefit in patients (pts) with advanced UC receiving PD1/PD-L1 inhibitors. **Methods:** Targeted exome sequencing (238 genes) was performed on archival tumors from metastatic UC pts treated with PD1/PD-L1 inhibitors at our institution. Clinical Benefit (CB) was defined as any objective reduction in tumor size, and no clinical benefit (NCB) was defined as any objective increase in tumor size by RECIST 1.1. Associations between clinical and genomic features and clinical benefit were assessed using univariate and multivariate logistic regression modeling. **Results:** 61 pts were evaluable, with CB in 24 pts and NCB in 37 pts. The prognostic factors associated with NCB on univariate analysis were neutrophil/lymphocyte ratio (NLR) ≥5, ECOG-PS ≥1, hemoglobin (Hb) < 10 gm/dl, liver metastasis, CDKN2B homozygous deletion, high CNV count and low SNV count. On multivariate analysis, a low SNV count and a high CNV count were associated with NCB. There was a strong trend for association of NCB with liver metastasis and NLR ≥5 (Table). **Conclusions:** A new model combining 2 genomic factors, low SNV and high CNV counts, and 2 clinical factors, high NLR and liver metastasis, appeared associated with NCB in pts with advanced UC receiving PD1/PD-L1 inhibitors. Validation of these hypothesis-generating results is warranted.

Risk factors	Adjusted OR	*p* value
Liver metastasis	7.78 (0.84–71.85)	0.070
CDKN2B homozygous deletion	4.61 (0.24–90.06)	0.314
NLR ≥ 5	9.17 (1.00–84.33)	0.050
ECOG-PS ≥ 1	0.76 (0.12–4.92)	0.775
Hb < 10 gm/dl	7.60 (0.22–258.88)	0.260
CNV count ≥ 1 (median)	8.80 (1.02–76.39)	0.049
SNV count < 8 (median)	12.39 (1.65–92.85)	0.014

4540 Poster Session (Board #366), Sat, 8:00 AM-11:30 AM

Association of circulating tumor (ct)-DNA genomic alterations (GA) with outcomes in metastatic urothelial carcinoma (mUC). *First Author: Petros Grivas, University of Washington, Seattle, WA*

Background: Cell-free ctDNA profiling enables noninvasive identification of GA in mUC. We hypothesized that ctDNA GA correlate with outcomes and signify therapy targets. **Methods:** 477 patients (pts) with UC who underwent ctDNA analysis for potentially actionable GA via Guardant360 were identified. A 73-gene ctDNA next generation sequencing (NGS) panel from CLIA-licensed, CAP-accredited laboratory (Guardant Health, Inc.) offers complete exon sequencing in 19 cancer genes, critical exons in 54 genes, amplifications (18 genes), fusions (6 genes) & indels (23 genes) from 10 mL of peripheral blood. KM method was used to estimate overall survival (OS) and failure-free-survival (FFS) since therapy initiation. Cox proportional hazards regression was used to assess the association of ctDNA GA present in $>10\%$ of pts and clinical factors with OS and FFS in univariable analyses. All tests were 2-sided, $p \leq 0.05$ was significant. We also evaluated GA in serial samples to assess genomic evolution. **Results:** 124 pts had available clinical data, of whom 65 had received prior platinum, 21 prior taxane and 10 prior PD1/PD-L1 inhibitor; ≥ 1 GA was detected in 112 pts. Median age at time of ctDNA collection was 72 and median (range) number of GA per sample was 4 (0-80); 110 pts had ≥ 1 SNV & 39 pts ≥ 1 CNV. Most commonly altered genes were TP53 (55%), PIK3CA (24%) and ARID1A (23%). 1-year OS and FFS were 69% and 35%, respectively. ARID1A (HR 0.49, $p = 0.052$) & BRAF (HR 0.24, $p = 0.048$) GA were associated with longer FFS, while BRCA1 (HR: 2.36, $p = 0.016$) GA with shorter FFS; no GA were significantly associated with OS. After ctDNA collection, 32 pts received platinum, 43 anti-PD1/PDL1, 24 other and 25 no therapy. There was no significant effect of post-ctDNA therapy on OS ($p = 0.91$) or FFS ($p = 0.29$); post-ctDNA therapy did not interact with clinical factors. Serial samples showed new and resolution of some GA. **Conclusions:** ctDNA GA were detected in most pts with mUC and appeared similar to those from prior tumor tissue NGS studies. BRAF & ARID1A GA correlated with longer and BRCA1 GA with shorter FFS suggesting that synthetic lethality with DNA damage repair inhibitors may be clinically useful. Serial sample analysis revealed genomic evolution.

4541 Poster Session (Board #367), Sat, 8:00 AM-11:30 AM

Combined checkpoint immunotherapy and cytotoxic chemotherapy: Further results from a phase Ib/II trial of pembrolizumab and docetaxel or gemcitabine in patients with advanced or metastatic urothelial cancer. *First Author: Mamta Parikh, University of California Davis Comprehensive Cancer Center, Sacramento, CA*

Background: We previously reported tolerability of pembrolizumab plus either docetaxel or gemcitabine in platinum-treated metastatic urothelial cancer patients (pts), given the hypothesis that chemotherapy might enhance tumoral neoantigen expression and modulate immunogenicity of tumor cells, potentially enhancing the response to anti-PD-1 therapy. Herein we report further results from an expansion cohort. **Methods:** Eligible pts had Zubrod PS 0-1, adequate end-organ function, with progression following up to 2 prior lines of chemotherapy (at least one platinum based). Patients were treated with pembrolizumab 200 mg IV on D1 q3weeks plus either docetaxel 75 mg/m2 IV on D1 (Arm A) or gemcitabine 1000 mg/m2 IV on D1 & D8 (Arm B). Primary endpoint was safety; secondary endpoints were overall response rate (RR) and progression free-survival (PFS). **Results:** A total of 20 pts have enrolled, 9 in Arm A, 11 in Arm B. Mean age was 66 (range 31-84). Most common AEs $\geq$ Grade 3 were hyponatremia (8/20), anemia (5/20), fatigue (5/20), neutropenia (4/20), leukopenia (4/20) acute kidney injury (3/20), hypophosphatemia (3/20). There were no treatment-related deaths; 13 died from disease progression. In total, 1 pt had complete response (CR), 5 pts had partial responses (PR), 3 pts had minor responses (MR), 4 had stable disease (SD), and 7 progressed; overall RR was 45% and Disease Control Rate (DCR) was 65%. Arm A had overall RR of 44%, DCR 56%. Arm B had overall RR of 45%, DCR 73%. Median PFS (overall, Arm A & Arm B) were 7, 13.3, and 5.9 months. **Conclusions:** The combination of pembrolizumab with either docetaxel or gemcitabine is tolerated with no unexpected adverse effects, with evidence of efficacy. Expanded cohorts continue to enroll. Clinical trial information: NCT02437370.

4542 Poster Session (Board #368), Sat, 8:00 AM-11:30 AM

A subgroup analysis of the East Asia population in RANGE: A randomized phase 3 study of docetaxel (DOC) with or without ramucirumab (RAM) in platinum-refractory advanced or metastatic urothelial carcinoma (UC). *First Author: Nobuaki Matsubara, National Cancer Center Hospital East, Chiba, Japan*

Background: RANGE (NCT02426125) is a global, randomized, double-blind, placebo-controlled, phase 3 study to evaluate the efficacy and safety of RAM in combination with DOC in patients (pts) with platinum-refractory advanced or metastatic UC. Here we report the results of RAM in combination with DOC in the East Asia population (EA). **Methods:** 530 pts were randomized (1:1) to DOC with either RAM 10 mg/kg or placebo (PL) on day 1 of a 21-day cycle (RAM/DOC or PL/DOC). EA pts (n = 110) received DOC 60 mg/m^2; other pts received DOC 75 mg/m^2. Primary endpoint was investigator-assessed progression free survival (PFS). Secondary endpoints included objective response rate (ORR), overall survival, safety, quality of life (QOL), and pharmacokinetics (PK). **Results:** PFS outcomes (investigator-assessed and blinded centrally reviewed) among EA remained consistent with the intention-to-treat population (ITT) (Table). Improvements in ORR and 6/12 month PFS rates for EA were in line with those for ITT. The most common grade ≥ 3 adverse events in EA, neutropenia and leukopenia, were observed at a similar frequency in both arms. Mean scores for global QOL in EA stayed largely stable over time without a clear difference between arms. Plasma concentrations of DOC for pts in the 60 mg/m^2 group were similar to those for pts in the 75 mg/m^2 group. **Conclusions:** The DOC PK profile for EA pts receiving 60 mg/m^2 was consistent with non-EA pts receiving 75 mg/m^2. Results in EA were consistent with the improved clinical outcomes and manageable safety profile observed with RAM/DOC in ITT. Clinical trial information: NCT02426125.

	ITT (first 437 pts)			EA**		
	RAM/DOC (N = 216)	PL/DOC (N = 221)	HR (95% CI)*	RAM/DOC (N = 53)	PL/DOC (N = 57)	HR (95% CI)*
Median PFS (month) (Investigator assessed)	4.07	2.76	0.757 (0.607-0.943)	3.02	2.99	0.928 (0.597-1.444)

4543 Poster Session (Board #369), Sat, 8:00 AM-11:30 AM

Preliminary results from an ongoing phase 2a study of RX-3117, an oral nucleoside analogue to treat advanced urothelial cancer (aUC). *First Author: Jacob Adashek, Western University of Health Sciences, Los Angeles, CA*

Background: RX-3117 is an oral small molecule nucleoside analogue (cyclopentyl pyrimidyl nucleoside) that is activated by uridine cytidine kinase 2. RX-3117 shows efficacy in various xenograft models, including those of gemcitabine resistant bladder cancer. Preliminary data from Stage 2 of a Phase 2a clinical study of RX-3117 as a single agent in subjects with advanced urothelial cancer (aUC) is described below. **Methods:** The efficacy of oral RX-3117 was evaluated in eligible patients (aged $\geq$ 18 years) with refractory aUC in a Phase 2a study. Primary objectives include safety and efficacy of 700 mg of administered orally RX-3117 for 5 consecutive days followed by 2 days off per week in each 4-week cycle for 4 continuous weeks. The primary endpoint is a $\geq$ 20% rate of progression free survival (PFS) benefit (i.e., proportion of subjects with stable disease for at least 4 months) and/or 10% of evaluable patients with a partial or better response by RECIST criteria. **Results:** As of February 2018, 27 patients (19 males, 8 females) with aUC were treated with RX-3117. The median age was 67 years and ECOG performance status was $\leq$ 1. Prior treatment with gemcitabine or immunotherapy was 85% or 67% of patients, respectively. Five patients achieved stable disease for 4 cycles of RX-3117 treatment; one patient received treatment for 315 days and another patient continues treatment beyond 4 months. One patient achieved a partial response after 2 cycles. Four patients have shown a tumor reduction ranging from 13.9 to 20% as measured by RECIST. All reductions occurred after 1 cycle of RX-3117 treatment, except for one patient's reduction, which occurred after 4 cycles. The most frequent related adverse events were G1/2 diarrhea (14%), fatigue (9%), nausea (9%), vomiting (9%), G1/G2 anemia (7%), and G3 thrombocytopenia (7%). **Conclusions:** RX-3117 is safe and well tolerated and shows preliminary evidence of anti-tumor activity in heavily pretreated patients. The study continues to enroll subjects with aUC in Stage 2. Clinical trial information: NCT02030067.

4544 Poster Session (Board #370), Sat, 8:00 AM-11:30 AM

SPEAR-bladder (study informing treatment pathway decision in bladder cancer): First- through third-line time to treatment failure in the US. *First Author: Gurjyot K. Doshi, US Oncology Network, McKesson Specialty Health, Houston, TX*

Background: Immune-oncology (IO) regimens have improved the clinical outlook for patients with locally advanced or metastatic urothelial carcinoma (mUC). This analysis aimed to assess time to treatment failure (TTF) among patients with mUC treated with systemic chemotherapy and IO regimens in the US community oncology setting. **Methods:** This is a retrospective study of patients with mUC receiving treatment from January 2015 to April 2017, with follow-up through June 2017 using the US Oncology Network electronic health records database. TTF was defined as the interval between treatment initiation in the first (1L), second (2L), or third line (3L) and discontinuation for any reason. TTF was compared between the chemo and IO cohorts using Kaplan-Meier and Cox proportional hazard modeling. **Results:** 523 patients initiated 1L treatment (median age, 72 years; 76.5% male), 241 2L (median age, 69 years; 75.9% male) and 50 3L (median age, 67 years; 74.0% male). Of patients receiving 1L platinum-based combinations (n = 497, 95%), 27.7% were treated with carboplatin/gemcitabine, followed by 26.0% with cisplatin/gemcitabine, and 7.3% with carboplatin/paclitaxel. IO regimens were received by 56.8% of patients in 2L and 68.0% in 3L. In the 2L setting, patients treated with IO regimens had a significantly longer TTF than those treated with systemic chemotherapies ($P < 0.0001$) (Table). **Conclusions:** These findings provide important insights into patterns of care and outcomes among patients with mUC in the community oncology setting. Comparisons between the chemo and IO cohorts were limited due to utilization of heterogenous chemotherapy regimens and small sample sizes. Patients in the IO cohort stayed on therapy for longer periods than chemotherapy-treated patients. Future real-world research may determine generalizability of the results seen in this study.

TTF

Line of Therapy	Chemo, median, weeks	IO, median, weeks	Hazard Ratio (95% CI)	*P*-Value
1L	n = 497 11.3	n = 26 15.1	0.570 (0.346-0.939)	0.0274
2L	n = 104 9.1	n = 137 12.1	0.552 (0.406-0.749)	< 0.0001
3L	n = 16 9.9	n = 34 22.9	0.461 (0.213-0.997)	0.0490

4545 Poster Session (Board #371), Sat, 8:00 AM-11:30 AM

Efficacy of split schedule (SS) vs conventional schedule (CS) neoadjuvant cisplatin-based chemotherapy for muscle-invasive bladder cancer (MIBC). *First Author: Chelsea K. Osterman, University of Pennsylvania, Philadelphia, PA*

Background: Neoadjuvant cisplatin (70mg/m2) based chemotherapy (NAC) prior to cystectomy is standard of care for MIBC. Many patients (pts) cannot receive cisplatin due to impaired renal function. In pts with borderline renal function (eGFR 40-60mL/min), administration of cisplatin 35mg/m2 day 1+8 or 1+2 (i.e., split schedule) is a commonly used alternative. No prior studies have directly compared the effectiveness of SS to CS cisplatin in NAC for MIBC. **Methods:** We conducted a retrospective multi-institutional matched cohort study of MIBC pts receiving either SS or CS cisplatin containing NAC from 2013 -2017. Pts were matched 1:1 on chemotherapy regimen (GC or AMVAC), number of cycles, tumor histology, and clinical stage. All pts had confirmed MIBC, cT2-T4a, with eGFR ^{3} 40mL/min. Primary outcomes included complete (pT0) and partial (< pT2) pathologic response. Comparisons of matched pairs (SS vs. CS pts) were made using the McNemar test and conditional logistic regression. **Results:** 80 matched pts were identified (Table 1). pT0 rates were 17.5% (95% CI, 7 - 33%) and 32.5% (95% CI, 19 - 49%) in SS and CS cisplatin pts, respectively (p = .21),corresponding to an odds ratio for pT0 of 0.45 (95% CI, 0.16 – 1.31). Similarly, rates of < pT2 were 27.5% (95% CI, 15 - 44%) in SS and 45% (95% CI, 29 - 62%) in CS pts (p = 0.21). **Conclusions:** Split schedule cisplatin was associated with numerically but not statistically significant lower pathologic response rates relative to full dose. Limitations of the study include small sample size and treatment selection bias. Although split scheduling of cisplatin is a reasonable alternative to the conventional schedule, larger studies with greater statistical power are required to detect whether true differences exist between these alternative strategies.

Baseline pt characteristics.

	CS (n = 40)	SS (n = 40)	p value
Median age	65.5	71	0.007

4546 Poster Session (Board #372), Sat, 8:00 AM-11:30 AM

Correlation between gene expression and prognostic biomarkers in small cell bladder cancer (SCBC). *First Author: Vadim S. Koshkin, Cleveland Clinic Taussig Cancer Insitute, Cleveland, OH*

Background: SCBC is a rare malignancy with poorly understood biology. TCGA data in BC underscores the presence of a neuronal subtype possibly misclassified by conventional histopathology. Increased small cell component (SC%) and protein expression (expr) of DLL3 and CD56 were previously shown to correlate with worse outcomes in SCBC. The association of gene expr data with available biomarkers has potential to improve risk stratification and inform treatment decisions. **Methods:** 63 patients (pts) at Cleveland Clinic diagnosed between 1993 and 2015 had SCBC histology independently reconfirmed. All pts had SC % quantified and 52 pts had immunohistochemistry (IHC) for DLL3 and CD56. A further subset of 39 pts had gene expr analysis using HTG EdgeSeq OBP. Expr of genes relevant in neuroendocrine tumors was evaluated with a panel including CHGA, DLL1, DLL3, DLL4, ENO1, HES1, HES5, HEY1, NCAM1, NOTCH1, NOTCH2, NOTCH4, RB1, SYP, and TP53. Associations between DLL3 and CD56 protein expr, SC%, and expr of relevant genes were assessed to identify biomarkers pertinent to molecular diagnostics (Spearman correlation, $p < 0.05$). Using these as seed-genes in a network-based approach we sought to develop a prognostic gene expression signature in SCBC. **Results:** Among 52 pts with IHC data, 79% had SC% > 50%, and protein expr of DLL3 and CD56 (> 1% of tumor cells) was 68% and 81%, respectively. DLL3 protein expr correlated positively with mRNA expr of DLL3 (r = 0.70), CHGA (r = 0.55), DLL4 (r = 0.45), and negatively with NOTCH1 (r = -0.47), RB1 (r = -0.48) and ENO1 (r = -0.34). CD56 protein expr correlated positively with mRNA expr of NCAM1 (r = 0.61), DLL4 (r = 0.38), HEY1 (r = 0.42) and SYP (r = 0.34) and negatively with NOTCH1 (r = -0.34) and HES5 (r = -0.35). SC% correlated positively with DLL3 (r = 0.38) and NCAM1 (r = 0.41) and negatively with HES1 (r = -0.34). **Conclusions:** Expression of genes implicated in the pathophysiology of SC tumors correlated with protein expr of DLL3, CD56 and SC%, which were previously shown to be prognostic in SCBC. This supports a prognostic role for a novel gene expr signature in SCBC. Multi-institutional validation of this signature in external BC cohorts as well as comparison with BC TCGA and SC lung cancer datasets are ongoing.

4547 Poster Session (Board #373), Sat, 8:00 AM-11:30 AM

Apache: An open label, randomized, phase 2 study of durvalumab (Durva), alone or in combination with tremelimumab (Treme), in patients (pts) with advanced germ cell tumors (GCT): Results at the end of first stage. *First Author: Daniele Raggi, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: The prognosis of chemorefractory GCT pts is dismal. Durva is an anti-PD-L1 monoclonal antibody (mAb). Treme is anti-CTLA4 mAb. We aimed to investigate the activity of Durva, alone or with Treme, in these pts. **Methods:** Apache (NCT03081923) is an open-label, randomized, 3-stage, phase 2 study. Pts who have failed ≥2 chemotherapy (CT) regimens receive Durva, 1.5 gr q4w, x 13 cycles (arm A) or Durva plus with Treme, 75 mg q4w, x 4 cycles, followed by Durva alone x total 13 cycles (arm B). Serum tumor markers (STM), and radiologic assessments are repeated q8 weeks. The primary endpoint is the modified objective response-rate (mORR = RECIST 1.1 complete or partial response [PR] or stable disease [SD]+STM reduction > 10%). H0: mORR rate ≤10%, H1: mORR ≥25%, type I and II error rates at 10%. The total sample size of 120 pts is split into 3 stages: in stage 1, according to Gehan's rule, each arm is terminated whenever no response is observed. Biomarker analyses include: IHC PD-L1 expression on immune cells (Ventana SP142) and genomic sequencing with FoundationOne assay (Foundation Medicine Inc., Cambridge, MA, USA). Results of first stage are presented. **Results:** From 02/17-11/17, 18 pts were enrolled (17M, 1F), 9 per arm. 14 had gonadal and 4 extragonadal GCT, 15 had received ≥3 prior CT regimens. Median tumor mutational burden (TMB) was 4 mutations (mut)/mb. One pt (5.6%) had reversible G3 irAE (pneumonitis) in arm B. In arm A, 100% of pts had disease progression (PD), all with features of hyperprogression (hyper-PD): 4 had clinical PD and death before restaging, median increase in sum of tumor diameters (RECIST 1.1) was 146%, median increase in the elevated STM was 462%. In arm B, 2 responses (22.2%, 1 RECIST-PR in seminoma and 1 SD with STM reduction in nonseminoma) were observed. PD features were similar to arm A. PD occurred in both arms regardless of PD-L1 expression and TMB (PR case: PD-L1 negative and 4 mut/mb). **Conclusions:** Single-agent durvalumab should not be pursued further in GCT; conversely, combination immunotherapy showed signals of activity and will be expanded to 2nd stage. Response biomarkers are urgently required. Clinical trial information: NCT03081923.

4548 Poster Session (Board #374), Sat, 8:00 AM-11:30 AM

Use of 18F-FDG PET/CT to select candidates for active surveillance: Results of the SEMITEP trial of PET-directed strategy for stage 1 seminoma. *First Author: Yohann Loriot, Institut Gustave Roussy, Villejuif Cedex, France*

Background: Stage I seminoma patients (pts) run a relapse risk of 15-20% without further adjuvant treatment. Pts are usually offered active surveillance or an adjuvant treatment with a risk of overtreatment of about 80%. There is no robust prognostic factor associated with the risk of relapse. 18F-FDG PET/CT (PET) demonstrates high diagnostic accuracy for restaging pts with metastatic seminoma. Our hypothesis was that PET scanning accurately detects micro-metastasis and may help better select patient for therapy. **Methods:** In the SEMITEP trial (NCT01887340), pts with newly diagnosed stage 1 seminoma underwent PET scanning before any decision for adjuvant treatment. PET scans were assessed by a local nuclear physician but were centrally retrospectively reviewed. A PET was interpreted as positive if any non-physiological 18F-FDG uptake was observed. Pts with negative PET findings were assigned to a surveillance protocol with no further adjuvant treatment and alleged surveillance work-up; pts with positive PET findings were recommended to receive immediate therapy (preferentially 2 cycles of carboplatin at a dose of AUC = 7). The first endpoint was the proportion of pts in whom an adjuvant therapy could be omitted. The secondary endpoints were progression-free survival (PFS), overall survival (OS) and safety. **Results:** A total of 169 pts were recruited, and 166 patients underwent PET. The PET findings were negative in 160 of these pts (96%), 150 (94%, 95% confidence interval [CI], 90 -98) of whom were assigned to surveillance. PET was positive in 6 pts, 5 of whom were treated with immediate treatment. At a median follow-up of 2.5 years 22/150 (15%) pts with PET-negative experienced a relapse. No relapse occurred among the 15 pts treated with immediate treatment. There was one chemotherapy-related death. The 2-year PFS and OS rates were 88 % (95% CI, 81.7-92.1) and 99.4 % (95% CI, 96.6-99.9), respectively. **Conclusions:** Post-orchidectomy treatment can be avoided in a majority of pts with stage 1 seminoma. PET may help identifying about one fifth (6/28) pts with disseminated seminoma that are not detected by CT-scan. Surveillance remains necessary in men with negative PET. Clinical trial information: NCT01887340.

4549 Poster Session (Board #375), Sat, 8:00 AM-11:30 AM

Circulating miR-371a-3p for the detection of low volume viable germ cell tumor: Expanded pilot data, clinical implications and future study. *First Author: Lucia Nappi, Vancouver Prostate Centre and SWOG AYA, Prevention and Surveillance and SWOG YI Award, Vancouver, BC, Canada*

Background: Determining the histology of borderline enlarged nodes in clinical stage I (CSI) or post-chemotherapy residual disease (PCRD) patients (pts) with germ cell tumor (GCT) is challenging, especially when classic tumor markers are negative. Currently, accurate assessment requires clinical follow-up with imaging to establish patterns of growth or pathological confirmation. A blood-based approach to reliably identify patients with non teratoma viable GCT (NTVGCT) would be valuable. **Methods:** miR-371a-3p (miR371) extracted from plasma of pts with GCT was analyzed by RT-PCR and relative expression calculated by the 2-ΔΔCt method with appropriate negative and positive controls. The sensitivity and specificity of miR371 were calculated correlating miR371 expression to the presence of relapsed/residual NTVGCT. **Results:** 74 samples were analyzed in 56 patients: 24 CSI; 32 metastatic, of whom 21 had PCRD. Among CSI patients, 8 relapses occurred and miR371 was positive in 6/8 relapses. Among the CSI patients that did not relapse, 7 had borderline enlarged nodes but negative miR371. For the metastatic pts, miR371 was positive in 16/18 pts pre-chemotherapy and became negative in all post-chemotherapy. 3 miR371 negative pts (1 CSI and 2 metastatic) had pathologically confirmed primary teratoma. miR371 was negative in all the pts with PCRD (n = 21) and no residual NTVGCT was detected in those pts by either pathology (n = 13) or clinical follow-up (n = 8). Sensitivity and specificity were 93.3% and 100%, respectively across the entire cohort of samples in detecting the presence of relapse or residual NTVGCT. Both internal and external validation studies have been performed with excellent concordance. **Conclusions:** Detectable plasma levels of miR371 have excellent correlation with the presence of NTVGCT. More rational selection of adjuvant therapy in CSI, reduction in imaging and more precise post-chemotherapy evaluations are among the more obvious settings in which biomarker-based decision making can improve GCT management. These and other data informed the development of two large US/Canadian intergroup studies to define the role of miRNA clusters in management of GCT.

4550 Poster Session (Board #376), Sat, 8:00 AM-11:30 AM

Etoposide and cisplatin (EP) for metastatic good-risk germ cell tumors (GCTs): The Memorial Sloan-Kettering Cancer Center (MSKCC) experience in 944 patients (pts). *First Author: Samuel Funt, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Standard of care for pts with metastatic, good-risk GCTs consists of either 3 cycles of bleomycin, etoposide, and cisplatin (BEPx3) or 4 cycles of EP (EPx4). EPx4 avoids both pulmonary and vascular bleomycin toxicity. **Methods:** 944 pts with good-risk GCTs (LDH modified to $<$ 3 x upper limit of normal) were treated with EPx4 at MSKCC from1982 to 2015. EP consisted of cisplatin 20mg/m2 and etoposide 100mg/m2 on days 1 to 5 at 21-day intervals. Response, post-EP surgical findings, and survival were obtained for 655 pts treated from 2000 to 2015 and compared with the same outcomes plus updated follow-up for 289 pts treated from 1982 to 2002 previously reported by Kondagunta et al. (JCO, 2005). **Results:** Of the recent 655 pts, median age was 33 (range, 15-77), nonseminoma comprised 65%, seminomas 35%, AFP elevated in 27%, HCG 53%, and LDH 31% with 7.6% of nonseminoma with LDH 1.5 - 3 times upper limit of normal. 97% pts completed 4 cycles of EP. Of 655 pts, 313 underwent post-EP retroperitoneal lymph node dissection (RPLND): 59.1% necrosis or fibrotic debris, 38.0% pure teratoma, 2.6% viable, non-teratomatous GCT, 1 patient unclassified. Febrile neutropenia and thromboembolic events occurred in 15.9% and 8.9%, respectively. In the combined group of 944 pts, 927 (98.2%) achieved a favorable response (CR or PR-negative markers); there was 1 treatment-related death. With median follow up for the combined 944 pt group of 6.8 years, five-year PFS and OS rates were 93.4% and 97.9%, respectively. Outcomes summarized in the table. **Conclusions:** In the largest series of good-risk pts treated with EPx4 ever reported, our results confirm that this regimen is highly effective and well-tolerated. EPx4 remains a standard treatment option for good-risk GCT and remains the preferred regimen at MSKCC.

	JCO 2005	Current	Updated Total (%)
Number of Pts	289	655	944
Favorable Response (%)	282 (98)	645 (98)	927 (98)
Viable, non-teratomatous GCT at Post-EP Surgery (%)*	11/134 (8)	8/313 (3)	19/447 (4)
Relapse (%)	18 (6)^	26 (4)	44 (5)
Died of Disease (%)	10 (3)^	4 (1)	14 (2)

*JCO 2005 includes any post-EP surgery. Current limited to RPLND.
^1 pt relapsed and died of disease post-publication

4551 Poster Session (Board #377), Sat, 8:00 AM-11:30 AM

Retroperitoneal cancer viability after postchemotherapy retroperitoneal lymph node dissection (PC-RPLND) in good risk germ cell tumors (GCTs). *First Author: Fadi Taza, Division of Hematology and Oncology, Indiana University Simon Cancer Center, Indianapolis, IN*

Background: Four cycles of etoposide and cisplatin (EP $\times$ 4) or 3 cycles of bleomycin, etoposide, and cisplatin (BEP $\times$ 3) is the current standard of care for patients with good-risk testicular cancer. We sought to examine the differences in the tumor viability for patients treated with EP x 4 vs BEP x 3 in the (PC-RPLND) specimens. **Methods:** The Indiana University (IU) Testicular Cancer Database was queried to identify IGCCCG good-risk patients who received EP $\times$ 4 or BEP $\times$ 3 induction chemotherapy followed by PC-RPLND. The primary endpoint was PC-RPLND cancer viability vs teratoma presence. **Results:** A total of 291 patients treated between 1988 and 2017 met the inclusion criteria. Median age was 28 (14.6-70.8) years. Primary histology was non-seminoma in 92.8%. Induction chemotherapy consisted of EP $\times$ 4 in 45 (15.5%) patients and BEP $\times$ 3 in 246 (84.5%). One hundred and sixty-six patients (57.2%) received chemotherapy outside the IU and were subsequently referred for PC-RPLND. Using a logistic regression model after accounting for age and time to surgery, patients who received EP x 4 have approximately 2.5 times the odds of having residual cancer viability in the PC-RPLND (Odds ratio 2.548, 95% CI 1.130-5.744, p = 0.024) and no significant difference in the odds of having teratoma (Odds Ratio 0.669, 95% CI 0.343-1.303, p = 0.237). **Conclusions:** Our retrospective study has shown differences in pathological outcomes for good risk GCT patients treated with EP x 4 vs BEP x 3. Patients who received BEPx3 had less residual cancer in the RP specimen at the time of PC-RPLND compared to EPx4 after adjusting for age and time to surgery. We prefer to use BEPx3 as first line chemotherapy in good-risk patients unless there is a contraindication for bleomycin.

4552 Poster Session (Board #378), Sat, 8:00 AM-11:30 AM

Adjuvant etoposide plus cisplatin (EP) for pathologic stage (PS) II nonseminomatous germ cell tumor (NSGCT). *First Author: Deaglan Joseph McHugh, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The risk of relapse after primary retroperitoneal lymph node dissection (RPLND) for patients (pts) with PS IIA NSGCT is 10-20% and increases to over 50% for pts with PS IIB NSGCT. Cisplatin-based chemotherapy reduces the risk of relapse to approximately 1%. Standard adjuvant chemotherapy regimens consist of 2 cycles of EP or 2 cycles of bleomycin plus EP (BEP). **Methods:** From March 1989 to April 2016, 156 pts with PS II NSGCT seen at Memorial Sloan Kettering Cancer Center and assigned to two cycles of EP chemotherapy following RPLND were included. Pts from a prior analysis (Kondagunta, JCO, 2004) were included with updated survival outcomes and expanded histopathologic parameters. Each treatment cycle consisted of cisplatin 20mg/m^2 and etoposide 100mg/m^2 administered on days 1 to 5 at 21-day intervals. Demographics, histopathologic features, therapeutic and survival outcomes were recorded. **Results:** Median age was 28 years (range 15-52). 30 pts (19%) had pN1 disease, 122 (78%) pN2 disease and 4 (3%) pN3 disease. Median number of positive lymph nodes was 3 (range 1-37) and median size of the largest positive node was 2.0cm (range 0.4-7.0cm). 69 pts (45%) had extranodal tumor extension. Embryonal carcinoma, seminoma, mature teratoma and yolk sac were the predominant histological subtypes in the RPLND pathology in 115 (90%), 8 (6%), 4 (3%) and 1 (1%) pts respectively. 150 pts (96%) received 2 cycles of EP, 5 (3%) received 1 cycle of EP and one received 4 cycles of EP due to a transient marker increase following his first cycle. Dose delays occurred in 54 (38%) pts, mostly as a result of neutropenia (44/54 delays). With a median follow-up of 9 years, two pts (1 pN2 and 1 pN3) relapsed; both achieved a CR to TIP and are NED at 65 and 143 months respectively. 3 pts died, all unrelated to GCT or treatment, for 10-year relapse-free and overall survival rates of 98% and 99%, respectively. **Conclusions:** This is the largest series reported to date on adjuvant chemotherapy with EP for PS II NSGCT and confirms that 2 cycles of EP is highly effective in reducing recurrence with disease-specific survival of 100% and acceptable toxicity. These data suggest that inclusion of bleomycin (e.g., BEP) in this setting is not necessary.

4553 Poster Session (Board #379), Sat, 8:00 AM-11:30 AM

The prognostic value of teratoma in the primary tumor and postchemotherapy retroperitoneal lymph node dissection (PC-RPLND) specimens in patients with germ cell tumors (GCTs). *First Author: Fadi Taza, Division of Hematology and Oncology, Indiana University Simon Cancer Center, Indianapolis, IN*

Background: A retrospective study using an institutional database from MSKCC [ASCO 2017, abstract # 4555] on 231 patients, showed that the presence of teratoma (T) in the primary testicular cancer was proposed to be an important clinical predictor of long-term outcome in men with GCT. We hypothesized that neither the presence nor the absence of T predicts the long-term survival in GCT patients. **Methods:** Metastatic non-seminoma (NSGCT) patients who received chemotherapy and had a primary testicular cancer (PTC) specimens available were included in this retrospective study. The cohort was divided into two groups according to the presence or absence of T in the primary tumor. The Indiana University Testicular Cancer Database was reviewed and survival data were correlated with the histopathological findings. Differences in overall survival (OS) and progression free survival (PFS) between the two groups were evaluated using log-rank test **Results:** PTC specimens were available from 1224 pts diagnosed between 1990-2016. Median age was 27.3 years (range 13.1-70.8) and median follow-up 1.9 y (range 0.1-30.1) since the initiation of chemotherapy. The element of T was present in 689 pts vs 535 without T. At the start of chemotherapy, 61.5%, 14.1% and 24.4% of pts were stratified as good, intermediate, and poor IGCCCG risk. The 5-year PFS in pts with the T present vs. absent was 61.9% (95% CI, 57.1% to 66.2%) and 63.1% (95% CI, 58.0% to 67.8%); *P*= 0.66, respectively. The 5-year OS in pts with the T present vs. absent was 82.2% (95% CI, 77.9% to 85.8%) and 81.4% (95% CI, 76.5% to 85.3%); *P*= 0.91, respectively. We then evaluated 503/1224 who underwent PC-RPLND, 327 had pure T and 146 had only necrosis in the resected lymph nodes. Five-year OS for pts with T vs necrosis was 90.3% (95% CI, 83.6% to 94.4%) and 93.4% (95% CI, 85.8% to 97.0%) respectively, P = 0.21. **Conclusions:** The presence of teratoma in primary tumor and PC-RPLND was not a prognostic factor in this retrospective study of patients with NSGCT.

4554 Poster Session (Board #380), Sat, 8:00 AM-11:30 AM

Psychological stress in long-term survivors of testicular cancer: A Danish nationwide cohort study. *First Author: Michael Kreiberg, Rigshospitalet, Copenhagen, Denmark*

Background: Survival in cancer is generally increasing and in case of testicular cancer (TC) the majority of patients become long-term survivors (TCS). The aim of the present study was to investigate if long-term TCS experience a higher level of psychological stress than the Danish male general population (GP) and whether psychological stress is influenced by treatment modality. **Methods:** In 2014-2016, 2409 TCS with a mean time since diagnosis of 18 years (range 7-33 years) answered a questionnaire covering psychological stress (Perceived Stress Scale (PSS)), sociodemographic factors and physical health variables. In PSS, scores are summed up with 0 representing the least stressed and 40 the most stressed. PSS scores were compared with the GP (n = 67151) from The Danish National Health Survey 2013. Age adjusted linear regression with TCS who had been treated with orchiectomy alone serving as reference explored the effect of treatment modality on PSS score. **Results:** In TCS $<$ 65 years of age we found a higher mean PSS score than in the GP ($p < 0.01$) (table 1), while TCS $>$ 65 years of age had a lower PSS score than the GP ($p = 0.043$) There was no association between treatment modality and PSS score. **Conclusions:** Long-term TCS $<$ 65 years of age were more stressed than the general population, while treatment modality did not influence the levels of psychological stress. Research is needed to clarify if screening and treatment programs for psychological stress should be part of the follow-up for TCS.

Perceived stress scale (PSS) scores in long-term testicular cancer survivors (TCS) and a male danish general population (GP).

		GP (N = 67151)	TCS (N = 2409)	p-value
Age group mean PSS scores, (No.)	$<$ 45	11.02 (21680)	12.94 (508)	$<$ 0.001
	45-54	10.87 (12668)	11.53 (803)	0.008
	55-64	10.28 (13584)	11.81 (690)	$<$ 0.001
	$>$ 65	10.36 (19218)	9.68 (408)	0.043
Treatment mean PSS scores, (No.)	Surveillance		11.35 (1138)	
	3-4 courses of BEP		11.95 (876)	
	Abdominal RT		11.37 (312)	
	More than one line of treatment		12.07 (83)	

Age group mean PSS Scores were analysed with independent t-test between GP and TCS.
Abbreviations: BEP, bleomycin, etoposide, cisplatin; RT, radiotherapy.

4555 Poster Session (Board #381), Sat, 8:00 AM-11:30 AM

Comprehensive genomic characterization of chemotherapy-resistant testicular germ cell tumors (TGCT). *First Author: Andrea Necchi, Istituto Nazionale dei Tumori, Milan, Italy*

Background: Although both seminomatous (Sem) and nonseminomatous (NS) TGCT have a favorable response to platinum-based chemotherapy (CT), a small proportion of them are chemorefractory. Therapeutic options for these patients (pts) are limited, and relevant therapeutic targets are lacking. **Methods:** The database of Foundation Medicine Inc. was searched, integrated with relevant clinical data. Archival tissues from 108 CT-treated and relapsed TGCT pts (22 Sem and 86 NS) underwent hybrid-capture based comprehensive genomic profiling (CGP) to evaluate all classes of genomic alterations (GA). Tumor mutational burden (TMB) was determined on 1.1 Mbp of sequenced DNA and reported as mutations (mut) per megabase (Mb) and microsatellite instability (MSI) was determined on 114 loci. **Results:** Sem pts were older than NS ($p = 0.007$). All pts had failed at least 1 CT regimen for metastatic disease. The mean GA/tumor frequency was 4.1 mut/tumor for NS and 3.1 for Sem ($p = 0.08$). *KRAS* alterations (mainly amplifications) were the most frequent GA (47% and 36% in Sem and NS). *TP53*, *CCND2* and *FGF6/23* GA frequencies were similar in both Sem and NS. GA in *KIT* (21% vs 2%), *PIK3CA/MTOR* (10% vs 0%), *PTEN* (5% vs 0%) and *BRCA2* (5% vs 0%) were more frequent in Sem than NS whereas *BRAF* (2%) and *ERBB2* (1%) GA were found in NS only. Among pts with *MTOR* alterations, one Sem was treated based on genomic profiling and had an exceptional response to everolimus, after CT and immunotherapy (IT) failure. MSI-High status was not identified in Sem cases and was found only in 2% of NS. The median TMB for the Sem cases was 2.5 mut/Mb and for NS was 2.7 mut/Mb. TMB levels of $\geq$10 mut/Mb were not encountered in Sem. Higher levels of TMB were more frequent in NS with 5% of NS having $\geq$10 mut/B and 1% $\geq$20 mut/Mb. **Conclusions:** Clinical trials in molecularly-selected pts are warranted for refractory TGCT, particularly the high frequency of *KRAS* amplification may portend activity of MEK inhibitors. Overall, the GA found in refractory Sem and NS differ significantly. Sem features lower GA frequency with slightly higher potential for targeted therapies in KIT and PI3K/MTOR pathways. Based on rare high TMB and MSI-High status, IT may be of benefit in a small subset of NS.

4556 Poster Session (Board #382), Sat, 8:00 AM-11:30 AM

Quality-adjusted time without symptoms or toxicity (Q-TWiST): Analysis of cabozantinib (Cabo) vs sunitinib (Sun) in patients with advanced renal cell carcinoma (aRCC) of intermediate or poor risk (Alliance A031203). *First Author: Ronald C. Chen, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: CABOSUN (NCT01835158), a randomized, open-label phase II trial, demonstrated significant improvement in progression-free survival with Cabo (8.6 months) versus Sun (5.3) months) in the first-line treatment of patients with intermediate- or poor-risk clear cell aRCC. To evaluate the overall treatment difference, we conducted a post hoc analysis using a quality-adjusted time without symptoms of disease or toxicity of treatment (Q-TWiST) methodology. **Methods:** Each patient's overall survival was partitioned into 3 mutually exclusive health states: time with grade 3/4 toxicity (TOX) before progression; time without symptoms of disease progression or grade 3/4 toxicity (TWiST); and time after progression or relapse (REL). Time spent in each state was weighted by a health-state utility associated with that state and summed to calculate Q-TWiST. A threshold utility analysis was used, applying utilities across a range of 0 (death) to 1 (perfect health). **Results:** The analysis period was 650 days (d) (median survival follow-up period). Mean time spent with TWiST was 121 d (95% confidence interval, 43–199) longer for Cabo compared with Sun. Mean time spent with TOX was 8 d longer for Cabo; mean time spent with REL was 104 d shorter for Cabo. In the threshold utility analysis, the difference in Q-TWiST ranged from 129 d (TOX = 1, REL = 0) to 17 d (TOX = 0, REL = 1) in favor of Cabo across all utility combinations. When considering relative utility weights consistent with those observed in aRCC patients (TOX = 0.5, REL = 0.5), the difference in Q-TWiST was 73 d in favor of Cabo. **Conclusions:** Treatment with Cabo was associated with longer Q-TWiST compared with Sun, primarily due to longer time without symptoms of disease or grade 3/4 toxicities. This analysis, which accounts for disease control efficacy, treatment toxicity and health-related quality of life, provides clinicians with a measure of Cabo and Sun treatment differences on the quality of survival to help with clinical decision-making. Support for CaboSun: U10CA180821, U10CA180882; funding for present study: Ipsen. Clinical trial information: NCT01835158.

4557 Poster Session (Board #383), Sat, 8:00 AM-11:30 AM

Interim data analysis of the ADAPT trial using the modified intent to treat (mITT) population re-evaluates Rocapuldencel-T for clinical benefit over standard of care. *First Author: Robert A. Figlin, Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Medical Center, Los Angeles, CA*

Background: The Phase 3 ADAPT trial evaluates overall survival (OS) of Rocapuldencel-T (Roca) in combination (combo) with standard-of-care (SoC) for the treatment of newly diagnosed mRCC compared to SoC alone. At a February 2017 interim analysis, the study was judged unlikely to demonstrate statistically significant improvement in OS. However, the ITT patients included 39 patients (combo) that did not receive Roca and 14 SoC patients not treated. Therefore, additional analyses for the modified ITT (mITT) was evaluated for OS and immune response (IR) in patients receiving therapy. **Methods:** The mITT includes 268 combo patients who received $\geq$1 dose of Roca + sunitinib and 141 SoC patients that received $\geq$1 cycle of sunitinib. Median OS was calculated by log-rank analysis and correlated with IR measured over 1 year Roca dosing. Also, the potency of Roca product administered (measured by level of IL-12 secretion) was correlated with OS. IR and IL-12 levels were assayed by flow cytometry and correlations were analyzed by the Spearman's rank correlation coefficient method. **Results:** The mITT combo arm had a median OS of 30.4 months (mo) vs. 32.4 mo in the SoC arm (HR 0.97 95%CI 0.72, 1.33), however, $>$ 50% of patients were censored at the time of analysis. To test for delayed effects of Roca, we stratified patients based on follow-up time from randomization. For patients in the 1st quartile (longest follow-up time), OS was 35.5 mo for the combo arm (n = 66, 32% censored) and 22.5 mo for SoC (n = 35, 15% censored). As the percentage of censored subjects increased and follow-up time decreased, the OS advantage in the combo arm diminished (3.5 months, 1st 50% randomized and 3.1 months, 1st 75% randomized). Also, the magnitude of anti-tumor IR after 7 doses of Roca correlated with OS ($r = 0.4$, $p < 0.0001$) and IL-12 levels correlated with both IR ($r = 0.4$, $p < 0.0001$) and OS ($r = 0.27$, $p < 0.0002$). **Conclusions:** The mITT combo subjects, all of whom received Roca therapy, are anticipated to be the population that could benefit from this treatment. This analysis demonstrated correlations between Roca mechanism of action and OS and longer follow-up time is warranted to assess potential efficacy of Roca. Clinical trial information: NCT01582672.

4558 Poster Session (Board #384), Sat, 8:00 AM-11:30 AM

Phase ib and phase II studies of pembrolizumab (P) with bevacizumab (B) for the treatment of metastatic renal cell carcinoma (RCC): BTCRC-GU14-003. *First Author: Arkadiusz Z. Dudek, University of Illinois at Chicago, Chicago, IL*

Background: Hypoxic regions of RCC, impede homing of cytotoxic T cells into tumor. In addition, tumor angiogenesis enhances immunosuppressive activity of MDSC and TAM. Antiangiogenic therapy decreases the number of MDSC and changes polarization of TAM to an immunostimulatory phenotype. We hypothesized that therapy with B will potentiate the immune antitumor activity of P. We, therefore, performed phase 1b for safety of P and B, followed by phase 2. **Methods:** Study population included subjects (age $>$ 18 y) with metastatic clear cell RCC after failure of at least one systemic therapy (phase 1b) or treatment naïve (phase 2). In phase Ib, P (200 mg dose q 3 weeks) was given with B (either at 10 or 15 mg/kg q 3 weeks). Primary endpoint for phase 2 was response rate (RR) (PR or CR) using RECIST v1.1. With assumption of 80% power to detect a 55% improvement in RR of P and B, over historic data with single P activity in RCC (RR of 27%), and an a error of 0.1, 48 subjects were to be accrued to detect RR of 42%. **Results:** 13 subjects (ages 33-68, median 55) were enrolled to phase 1b study; 11 males. No dose-limiting toxicity have been reported. Best responses (BR) were 5 PR, 6 SD, 1 PD. Median time on treatment was 130 (21-659) days. 200 mg of P and 15 mg/kg of B, given q 3 weeks, was determined to be safe and used in phase 2. 48 subjects (ages 42-84, median 61); 33 males were accrued to phase 2 study. Primary endpoint of RR was reached at 60.9 % (95% CI = 45.4%, 74.9%) with median time on treatment 298 (range 21-741) days. BR: 28 PR, 18 SD, 2 UN. Progression occurred in 20 (41.7%) patients. Median PFS time was 17.0 months (95% CI = 11.3, 24.8). Median OS has not been reached. 12 (25%) died. Most common grade 3 toxicity were hypertension (21%), hyponatremia, proteinuria (9%), adrenal insufficiency, dehydration 6 %), pneumonitis, skin toxicity, weakness, nausea and vomiting (4%), diarrhea, and arthralgia (2 %). There were 2 grade 4 toxicities (hyponatremia and hyperglycemia). There was 1 grade 5 toxicity (heart failure). Presence of tumor infiltrating T cells, but not PD-L1 expression correlated with PR. **Conclusions:** The 200 mg of P and 15 mg/kg dose of B, given every 3 weeks, is safe and active in metastatic RCC. Clinical trial information: NCT02348008.

4559 Poster Session (Board #385), Sat, 8:00 AM-11:30 AM

Comprehensive molecular and immunohistochemical analysis of advanced renal cell carcinoma patients treated with mTOR inhibitors. *First Author: JesÃ̲os GarcÃa-Donas, Fundacion Hospital de Madrid, Madrid, Spain*

Background: The development of new combinations with mTOR inhibitors and the description of meaningful responses in cases with mutations in the mTOR pathway have raised the interest on these compounds. Predictive biomarkers of activity are crucial to ensure patients likely to benefit are properly treated. **Methods:** Through an observational prospective study by the Spanish Oncology Genitourinary Group (SOGUG), FFPE tumor samples were collected from 77 RCC patients treated with temsirolimus or everolimus. Patients with partial response (by RECIST), or stable disease for at least 6 months were classified as responders. Immunositochemistry (IHC) was performed in 64 patients for p-S6, p-S6K1, p-AKT, p21, BAP1 and PBRM1. Mutational analysis of key genes in mTOR pathway was performed through Next Generation Sequencing in tumor DNA. The association between expression of the proteins and response to mTOR inhibitors was analyzed through logistic regression. **Results:** The 77 patients studied had been treated with everolimus (79%) or temsirolimus (21%); 87% had ccRCC histology, 60% had intermediate, 39% good prognosis, and 1% poor prognosis (MSKCC); 29 patients were responders, 47 non-responders and 1 could not be classified. Among the five cases with mTOR pathway activating mutations (1 *TSC1* (p.P333HfsTer5), 1 *TSC2* (p.L826M); and 3 *MTOR* mutations (p.S2215_L2216delinsF, p.Y1974H, p.E773D)), three were responder patients and two non-responders. Regarding p-S6 staining, two responder patients and one non-responder had positive staining, while one responder had negative staining and one non-responder was not evaluable. In the full series, negative IHC expression for BAP1 and PBRM1 was associated with better mTOR inhibitor response (OR = 4.0, 95%CI = 1.4-11.9, P = 0.011 and OR = 3.9, 95%CI = 1.2-12.8, P = 0.025, respectively, multivariable analysis). However, no association between for p-S6, p-S6K1, p-AKT and p21 staining and mTOR inhibitor response was observed. **Conclusions:** *TSC1, TSC2* and *MTOR* mutations only partially correlated with response. Lack of BAP1 and PBRM1 expression was associated with improved response to mTOR inhibitors.

4560 Poster Session (Board #386), Sat, 8:00 AM-11:30 AM

Lenvatinib + pembrolizumab in patients with renal cell carcinoma: Updated results. *First Author: Chung-Han Lee, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Lenvatinib, a multikinase inhibitor of vascular endothelial growth factor (VEGF) receptors and other targets, has been approved in combination with everolimus to treat advanced renal cell carcinoma (RCC) after 1 prior VEGF-targeted therapy. We report results for the RCC cohort of a phase 1b/2 trial of lenvatinib + pembrolizumab in patients (pts) with selected solid tumors (NCT02501096). **Methods:** In this multicenter, open-label study, pts with metastatic clear cell RCC and measurable disease per immune-related RECIST (irRECIST) received oral lenvatinib 20 mg daily + pembrolizumab 200 mg IV every 3 weeks. Tumor assessments were performed by study investigators using irRECIST, and retrospectively by independent radiographic review (IRR) per irRECIST and RECIST 1.1. The phase 2 primary endpoint was objective response rate at 24 weeks (ORRWK24). **Results:** 30 Pts were enrolled: 12 (40%) pts had 0 and 18 (60%) pts had ≥1 prior anticancer therapy; 16 (53%) pts received ≥1 prior VEGF-targeted therapy. At data cutoff of August 1, 2017, median follow-up for progression-free survival (PFS) was 13.8 mos (95% CI, 11.9–15.7). ORRWK24 was 63.3% (95% CI, 43.9–80.1) by investigator review, per irRECIST. ORR by IRR using RECIST 1.1 was 66.7% (95% CI, 47.2–82.7), and median PFS was 17.7 mos (95% CI, 9.6–NE). Efficacy outcomes are summarized in the table. Grade 3 or 4 adverse events (AEs) occurred in 21 (70%) pts; however, 4 (13%) discontinued treatment due to AE. The most common AEs were diarrhea (83%), fatigue (70%), hypothyroidism (67%), stomatitis (63%), and nausea (60%). **Conclusions:** The combination regimen of lenvatinib + pembrolizumab showed promising antitumor activity with manageable AEs, and no new safety signals were identified. A phase 3 trial of lenvatinib + pembrolizumab and lenvatinib + everolimus versus sunitinib for the first-line treatment of advanced RCC is underway (NCT02811861). Clinical trial information: NCT02501096.

4561 Poster Session (Board #387), Sat, 8:00 AM-11:30 AM

Comparison of clinical outcomes with first-line pazopanib in clinical trial eligible and non-clinical trial eligible patients with renal cell carcinoma. *First Author: Eric Jonasch, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Although pazopanib (PAZ) has been evaluated in clinical trials of patients (pts) with renal cell carcinoma (RCC), limited real-world data on the effectiveness and safety of PAZ exist. The PRINCIPAL study (NCT01649778) assessed the effectiveness and safety of first-line PAZ in a real-world setting. **Methods:** In this nonrandomized, prospective study, pts with advanced and/or metastatic clear cell RCC were enrolled in PRINCIPAL within 30 days of initiating first-line PAZ. Data on progression, survival, and safety were collected approximately every 3 months (mos) until death, consent withdrawal, or loss to follow-up, for up to 30 mos. Pts in PRINCIPAL were separated into two groups based on key eligibility criteria from the Phase III COMPARZ trial (Motzer et al. *NEJM.* 2013;369:722). Key clinical trial eligible (CTE) criteria included no prior systemic therapy, presence of measurable disease per RECIST 1.1, Karnofsky performance status ≥70, adequate organ system function, no history or clinical evidence of central nervous system metastases, and no coronary or cerebral artery disease at baseline. CTE pts were compared to non-CTE (NCTE) pts. Clinical effectiveness (ie, median overall survival [mOS], median progression-free survival [mPFS], and overall response rate [ORR]), adverse event (AE) measures, and relative dose intensity (RDI) were assessed in both pt populations. **Results:** Of the 657 enrolled pts who received ≥1 dose of PAZ, 97 (14.8%) were CTE and 560 (85.2%) were NCTE. RDI ≥85% was achieved in 70.1% and 56.6% in the CTE and NCTE populations, respectively. Effectiveness was similar in the CTE and the NCTE populations (mPFS, 9.6 *vs* 10.7 mos; ORR, 33.0% *vs* 29.8%; mOS, 26.3 *vs* 32.9 mos). Serious AEs were reported by 23.7% of CTE and 28.2% of NCTE pts. AEs led to dose adjustment/interruption in 83.5% and 95.2%, respectively, and AEs led to treatment discontinuation in 8.2% of the CTE and 15.5% NCTE pts. **Conclusions:** The results of the PRINCIPAL study suggest that first-line PAZ for pts with advanced or metastatic RCC remains effective and safe in a real-world setting, showing similar outcomes to those reported in large randomized clinical trials. Clinical trial information: NCT01649778.

4562 Poster Session (Board #388), Sat, 8:00 AM-11:30 AM

Neutrophil-to-lymphocyte ratio as a potential prognostic factor of disease-free survival in high-risk renal cell carcinoma: Analysis of the S-TRAC trial. *First Author: Anup Patel, London, London, United Kingdom*

Background: Sunitinib significantly improved disease-free survival (DFS) vs placebo (PBO) in patients (pts) with loco-regional renal cell carcinoma (RCC) at high risk of recurrence post nephrectomy. Neutrophil-to-lymphocyte ratio (NLR) is a marker of systemic inflammatory response. A post hoc exploratory analysis of the S-TRAC trial evaluated NLR as a potential prognostic factor in the RCC adjuvant setting. **Methods:** Sunitinib- and PBO-treated pts from S-TRAC were categorized into baseline (BL) NLR < 3 and ≥ 3 subgroups to explore the association between BL NLR (post nephrectomy) and DFS. Subgroups were based on low NLR (< 3) being associated with long-term response in metastatic RCC. Associations between DFS and change in NLR from BL at Wk 4 were explored. Kaplan–Meier estimates were provided and Cox proportional analysis was performed. **Results:** In all, 605 pts from S-TRAC with BL NLR values were analyzed: 465 with NLR < 3 and 140 with NLR ≥ 3. At BL, significant differences between NLR < 3 vs ≥ 3 subgroups were seen for age (median 56.0 vs 60.0 y; $P = .0161$) and race (white [81.9% vs 90.0%], black [0.6% vs 0.7%], asian [14.6% vs 5.7%], other [2.8% vs 3.6%]; $P = .0226$). NLR < 3 vs ≥ 3 was statistically significant in the univariate analyses of DFS (hazard ratio [HR] 1.39; $P = .0418$); median 5.84 y (NLR < 3) vs not reached (NLR ≥ 3). A lower BL NLR was associated with shorter DFS. NLR < 3 vs ≥ 3 was also statistically significant in a multivariate analysis of DFS (HR 2.29; $P = .0348$). More pts treated with sunitinib (73%) had ≥25% decrease in NLR at Wk 4 vs PBO (20%). A ≥25% decrease in Wk 4 NLR showed a trend towards longer DFS vs no NLR change (HR 0.744; $P = .0729$), while a ≥25% increase in NLR at Wk 4 showed a trend towards shorter DFS vs no change (HR 1.112; $P = .6771$). NLR change from BL at Wk 4 was associated with treatment (sunitinib vs PBO; $P < .0001$). **Conclusions:** In S-TRAC, lower BL NLR might be a prognostic factor of shorter DFS. A ≥25% decrease in Wk 4 NLR showed a trend towards prolonged DFS. Additional data on CD8, neutrophils and lymphocytes will be presented. Clinical trial information: NCT00375674.

4563 Poster Session (Board #389), Sat, 8:00 AM-11:30 AM

A randomized phase II trial of pazopanib (PAZ) vs. temsirolimus (TEM) in patients (pts) with advanced clear-cell renal cell carcinoma (accRCC) with intermediate or poor-risk disease (the TemPa trial). *First Author: Amado J. Zurita, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: TEM has level 1 evidence in aRCC with poor-risk disease. No previous trial compared a VEGFR-TKI with TEM as first-line (1L) therapy. **Methods:** We randomly assigned (1:1) treatment-naïve pts with accRCC and > = 3 risk factors (Hudes et al., NEJM 2007) to receive PAZ 800 mg po qd or TEM 25 mg iv qw. The primary endpoint was progression-free survival (PFS), and the secondary endpoints were overall survival (OS), objective response rate (ORR) and safety. A blinded radiologist assessed the radiographic response using RECIST v1.1. A sample size of 90 pts was based on an assumption of improved median PFS from 3.8 mo (TEM) to 6.1 mo (PAZ). Pts were stratified by prior nephrectomy (Nx) and prior cytokine therapy. The Kaplan-Meier method was used for PFS/OS analysis, and the Fisher's exact test for comparison of ORR between PAZ and TEM. **Results:** TemPa was closed to new patient enrollment in Sept. 2017 after the results of CheckMate 214 and CABOSUN were released. A total of 69 pts were eligible and evaluable (median age 61, 52 males [75%], 44 [64%] with poor-risk by IMDC criteria). Thirty pts (43%) had prior Nx and 3 pts prior IL-2. Thirty-five pts received PAZ (intermediate-risk 15, poor-risk 20) and 34 pts TEM (intermediate-risk 10, poor-risk 24). Of the 69 pts, 67 had progressive disease or died. The median PFS was 5.2 mo (95% CI: 3.6 –7.4) for PAZ and 2.6 mo (95% CI: 1.9 –4.2) for TEM (p = 0.16). However, PFS was significantly longer with PAZ in IMDC intermediate-risk pts after adjustment for IMDC risk group (7.3 *v* 3.7 mo, HR 0.38, p = 0.03). Fifty-nine pts have died. The median OS was 12.0 mo (95% CI: 8.3–20.1) for PAZ and 7.3 mo (95% CI: 5.8–17.4) for TEM (p = 0.56). Sixty-eight pts were evaluable for response: 9/35 pts (26%) who received PAZ and 2/33 pts (6%) who received TEM had partial response (p = 0.046). Adverse events were consistent with the known safety profiles of PAZ and TEM, and resulted in treatment discontinuation in only 2 pts in each. Circulating biomarker analysis will be presented. **Conclusions:** PAZ extended PFS, particularly in intermediate-risk, and yielded a higher ORR than TEM as 1L therapy in pts with accRCC and poor prognosis features. Clinical trial information: NCT01392183.

4564 Poster Session (Board #390), Sat, 8:00 AM-11:30 AM

Patterns of relapse and implications for post-nephrectomy surveillance for patients with high-risk non-clear cell renal cell carcinoma: Subgroup analysis of the phase 3 ECOG-ACRIN E2805 trial. *First Author: Vivek Narayan, University of Pennsylvania, Philadelphia, PA*

Background: Non-clear cell renal cell carcinomas (non-ccRCC) comprise a diverse subgroup, with biology and clinical behavior that is distinct from clear cell RCC (ccRCC). However, the natural history of non-ccRCC remains poorly defined, and clinical practice relies on consensus guidelines largely intended for ccRCC. We evaluated the patterns of relapse and the implications for post-nephrectomy surveillance for patients with non-ccRCC enrolled on the first and largest randomized trial of adjuvant anti-angiogenic therapy for high-risk RCC. **Methods:** Retrospective subgroup analysis of patients with non-ccRCC enrolled on E2805. For recurrence rates (RR) by site, the cumulative incidence was estimated accounting for competing risks. Gray's test was used to compare the incidence between groups. The 2017 NCCN recommendations were used to evaluate the adequacy of strict adherence to post-nephrectomy surveillance guidelines. **Results:** 403 non-ccRCC patients were enrolled (37% papillary, 28% chromophobe, 21% mixed, 14% unclassified). 144 recurrences were detected over a median follow-up of 6.2 years. 5-year RRs (95% CI) were 22% (11, 28) and 49% (41, 56) for Int-High and Very-High UISS risk groups, respectively. Abdominal recurrences were most frequently identified, including lymph node (39%), nephrectomy bed (17%), and liver (13%). While overall 5-year RRs were comparable between non-ccRCC and ccRCC patients (34.6% vs 39.5%), non-ccRCC patients were significantly more likely to develop abdominal site relapse (5-yr RR 26.4% vs 18.2%, p = 0.0008) and less likely to relapse in the chest (5-yr RR 13.7% vs 20.9%, p = 0.0005). Surveillance imaging for 5.3 years would be required to capture 95% of abdominal non-ccRCC recurrences. **Conclusions:** This is the largest, standardized evaluation of the natural history of non-ccRCC following curative-intent nephrectomy. Our findings demonstrate that non-ccRCC exhibits a distinct pattern of relapse when compared to conventional ccRCC, and emphasize the importance of continued long-term imaging for patients with high-risk resected non-ccRCC.

4565 Poster Session (Board #391), Sat, 8:00 AM-11:30 AM

Disease-free survival in patients at highest risk of recurrent renal cell carcinoma in S-TRAC. *First Author: Alain Ravaud, Department of Medical Oncology, Hôpital Saint-André, University of Bordeaux-CHU, Bordeaux, France*

Background: Sunitinib (SU) is FDA-approved for adjuvant treatment of patients (pts) at high risk (≥T3, any Fuhrman grade and/or nodal involvement [N+]) of recurrent renal cell carcinoma (RCC) post nephrectomy, based on the phase 3 S-TRAC trial that showed significant improvement with SU vs placebo (PBO) in disease-free survival (DFS) based on blinded independent central review (hazard ratio [HR] 0.76; 95% confidence interval [CI] 0.59–0.98; *P*= 0.03). The definition of high risk in S-TRAC included both objective (T stage and Fuhrman grade) and more subjective (pre-nephrectomy Eastern Cooperative Oncology Group performance status [ECOG PS]) prognostic parameters. To delineate the highest risk pts from S-TRAC purely based on objective parameters, we performed an additional analysis classifying pts at highest risk of recurrence post nephrectomy, defined as T3 and Fuhrman grade > 2 or T4 or N+ and any T. **Methods:** DFS analyses were conducted using Cox proportional hazard model. **Results:** In S-TRAC, 398 (65%) patients were classified at highest risk. The results indicated a treatment benefit in DFS by independent review for SU vs PBO in this highest risk group (HR 0.73; 95% CI 0.54–0.97; *P*= 0.03), consistent with the HR for DFS previously reported in the S-TRAC trial for the T3 higher (HR 0.74; 95% CI 0.55–0.99; *P*= 0.04) group defined as T3 with Fuhrman grade ≥2 and ECOG PS ≥1 or T4 with any ECOG PS or N+ with any T, any ECOG PS, as well as with the overall population. Safety data did not identify major differences between the highest risk group vs overall S-TRAC pts. Incidence of key adverse events with SU was similar in highest risk group vs overall study pts (diarrhea: 58.2% vs 56.9%; palmar-plantar erythrodysesthesia syndrome: 51.5% vs 50.3%; hypertension: 35.7% vs 36.9%; fatigue: 37.2% vs 36.6%; hypothyroidism: 15.3% vs 18.3%). **Conclusions:** The clinically meaningful treatment benefit observed in pts at highest risk of recurrence and the overall S-TRAC population, together with a consistent safety profile between these groups, support the favorable benefit/risk assessment of SU as an adjuvant treatment option for pts with RCC at high risk of recurrence post nephrectomy. Clinical trial information: NCT00375674.

4566 Poster Session (Board #392), Sat, 8:00 AM-11:30 AM

Replication stress response deficiency (RSRD) and response to immune therapy in clear cell renal cell carcinoma (ccRCC). *First Author: Patrick Glen Pilie, University of Michigan, Ann Arbor, MI*

Background: Despite treatment advances with immune therapy (IO), advanced stage ccRCC still has poor prognosis, due in part to a lack of predictive biomarkers. Replication stress (RS) is a hallmark of ccRCC initiation, contributing to genomic instability. However, cancer evades death from instability via deficient DNA damage repair (DDR) and RS response (RSR). The ATM/ATR and CHK2/CHK1 axes are critical to DDR and RSR; and deficiencies in these axes may activate innate immune signaling and lead to improved IO response. In this study, we assessed protein signaling changes in early ccRCC patient tumors, performed *in silico* analysis of ccRCC cohorts for the presence of a novel RSR deficient (RSRD) score, and evaluated the prognostic and predictive value of this RSRD score in ccRCC. **Methods:** We performed reverse phase protein microarray (RPPA) on 12 stage I ccRCC tumors vs 12 normal kidney tissues. We analyzed the Cancer Genome Atlas (TCGA) for a novel gene expression score of RSRD, and its impact on OS. We assessed immune cell infiltrate in TCGA tumors using CIBERSORT. We assessed RNA data from previously published cohort of 28 ccRCC patients treated with IO (*Miao et al, Science 2018*) and clinical outcomes based on RSRD score. **Results:** Early ccRCC tumors already showed loss of p-ATM/p-CHK2 and p-ATR/p-CHK1 protein signaling with increased IRF1 and ADAR1 expression ($p < 0.05$). From TCGA, RSRD-high tumors were more likely to be advanced stage and had significantly worse OS in multivariate analysis. *In silico* analysis revealed RSRD-high tumors had significantly higher T cell infiltrate compared to RSRD-low tumors. In the *Miao et al* IO-treated ccRCC cohort, 11/33 tumors were RSRD-high, with 73% of RSRD-high showing clinical benefit compared to only 18% of the RSRD-low and 36% of the bulk study population even when controlling for PBRM1 mutation. **Conclusions:** RSR and DDR signaling are dysregulated in ccRCC and may activate innate immune pathways. A novel RSRD score has potential as both prognostic and predictive biomarker for IO response. Further studies are warranted to validate the predictive power of this biomarker and understand how DDR and RSR deficiencies in ccRCC may impact immune activation.

4567 Poster Session (Board #393), Sat, 8:00 AM-11:30 AM

A meta-analysis of randomized controlled trials for efficacy and safety of vascular endothelial growth factor tyrosine kinase inhibitors (VEGF-TKIs) adjuvant therapy in high-risk renal cell cancer (RCC). *First Author: Irbaz Bin Riaz, Mayo Clinic, Rochester, MN*

Background: Three large randomized placebo controlled trials (RCTs) (ASSURE, S-TARC, PROTECT) with adjuvant VEGF-TKIs in high risk RCCs have provided variable results for improving disease free survival (DFS) with concerns for increased toxicity. We performed a meta-analysis of these trial results to asses a risk-benefit for adjuvant post-op treatments in high risk RCC patients by assessing reported disease free survival (DFS) and toxicity endpoints. **Methods:** A generic variance weighted random effects model was used to derive estimates for DFS and common side effects in the three trials. A separate analysis was performed for Sunitinib alone because of its FDA approval. Heterogeneity was assessed with Cochrane Q -statistic and was quantified with I^2test. $I^2 > 75\%$ was consistent with a high degree of heterogeneity. **Results:** The three RCTs involved 4096 patients. Adjuvant therapy with TKIs yielded no significant improvement in DFS or OS as compared to placebo (DFS HR = 0.92, 95% CI 0.82-1.04 and OS HR = 1.00, 95% CI 0.86-1.17). Separate analysis of DFS in sunitinib vs placebo did not show any benefit (2 studies, N = 1909; HR = 0.90, 95% CI 0.67-1.19). Use of TKIs was associated with significantly increased risk of drug toxicity. Increased risk of grade 3 or 4 adverse events (RR = 2.73, 95% CI 2.51-2.97), diarrhea (RR = 14.57, 95% CI 7.93-26.79), fatigue (RR = 3.63, 95% CI 2.13-6.18), hypertension (RR = 3.95, 95% CI 3.18-4.91) and palmar/plantar dysesthesia (RR = 21.4, 95% CI 12.91-35.47) was observed. **Conclusions:** No OS or DFS benefit for VEGF TKIs including for Sunitinib was observed in this meta-analysis, while there was a significantly increased risk of toxicity in greater than half of the patient population. Subgroup analyses based on age, sex, pharamacokinetics, pharmacogenomics may help to identify potential candidates. Analysis from ongoing adjuvant TKI trial results (SORCE,ATLAS,2810) and immunotherapy (IMMotion,Keynote-564,checkmate 914) are awaited and may provide more refinement in selecting high risk RCC candidates with favorable benefit-risk ratios for post op drug therapies.

4568 Poster Session (Board #394), Sat, 8:00 AM-11:30 AM

Evaluation of the spectrum selective RTK inhibitor sitravatinib in clear cell renal cell carcinoma (ccRCC) refractory to anti-angiogenic therapy (AAT). *First Author: Shubham Pant, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Sitravatinib (MGCD516) is an oral, potent small molecule inhibitor of a closely related spectrum of receptor tyrosine kinases (RTKs) including the TAM family (AXL, MER), split RTKs (VEGFR2, PDGFR, KIT), RET and MET. Because of the importance of sitravatinib targets in the pathogenesis of ccRCC and putative roles for MET and AXL in intrinsic and acquired resistance to anti-angiogenic agents, sitravatinib was evaluated in patients (pts) with ccRCC after failure of AAT. **Methods:** Study 516-001 is a Phase 1/1b study of sitravatinib in pts with advanced solid tumors. After determination of the MTD in Phase 1, pts with ccRCC after failure of AAT and pts with qualifying genetic alterations in sitravatinib targets were enrolled into distinct Phase1b cohorts using respective multi-stage designs. Pts received 150mg sitravatinib once daily in continuous 21-day cycles and were evaluated for safety, PK and clinical activity. Here we report on the completion of Stage 2 enrollment of the Phase1b ccRCC cohort. **Results:** 89 pts (50 men/39 women; median age 67 years; range 36-84) with advanced solid tumors were enrolled in Phase1b cohorts, including 28 pts (20 men/8 women; median age 67.5 years; range 47-77) in the ccRCC cohort who received a median of 3 prior treatment regimens. Prior AAT included sunitinib (n=17), pazopanib (n=13) and axitinib (n=9); 12 pts received ≥2 prior angiogenesis inhibitors. One partial response (PR) among the first 10 evaluable ccRCC pts in Stage 1 met criteria for enrollment of a total of 20 evaluable pts for Stage 2, where 4 confirmed PRs were observed and an unconfirmed PR in a pt who had received 4 prior AATs. Prolonged stable disease for at least 24 weeks was observed in an additional 5 pts. Treatment-related AEs (>20% of pts; Grades 1-3) included diarrhea, hypertension, nausea, vomiting, fatigue and decreased appetite. **Conclusions:** Stage 2 enrollment of the Study 516-001 Phase1b cohort of ccRCC refractory to AAT was completed. Sitravatinib treatment resulted in 4 confirmed PRs in a heavily pre-treated patient population and demonstrated a manageable safety profile. Further evaluation of sitravatinib in ccRCC is warranted. Clinical trial information: NCT02219711.

4569 Poster Session (Board #395), Sat, 8:00 AM-11:30 AM

A FARETES study of the efficacy and safety of testosterone in metastatic renal cell carcinoma patients with fatigue. *First Author: Ilya Tsimafeyeu, Kidney Cancer Research Bureau, Moscow, Russia*

Background: Fatigue is a frequent symptom of metastatic renal cell carcinoma (mRCC), and most common adverse event of treatment with tyrosine kinase inhibitors. The aim of this multicenter randomized phase 2 study was to determine efficacy and safety of testosterone undecanoate (T) in mRCC patients with fatigue developed during targeted therapy. **Methods:** Sixty male patients with clear cell mRCC, normal PSA level, low testosterone level and no evidence of hypothyroidism receiving first-line sunitinib or pazopanib with fatigue were randomly assigned (1:1) to either T and targeted therapy or targeted therapy alone (control group). T (1,000 mg) was injected intramuscular deeply on Day 1 of a new treatment cycle. The primary endpoint of the study was the difference in mean change of fatigue according to Functional Assessment of Cancer Therapy-Fatigue (FACIT-F). Secondary endpoints were safety, FKSI-19 score, testosterone serum concentrations, red blood cells (RBC) count and hemoglobin level. The assessments were performed at baseline and Day 28 of a treatment cycle. **Results:** T was well tolerated. No unexpected toxicity was observed. The health-related quality-of-life scores in the T group were better than those in the control group (Table). The current study did achieve its primary endpoint based on the significant differences favored T over targeted therapy alone regarding fatigue (all P≤0.012). Clinical trial information: NCT03379012. **Conclusions:** Male patients with mRCC receiving targeted therapy had significantly less fatigue and better symptom control with T. There was non-significant positive trend in hemoglobin level between 2 groups. T therapy was safe. Long-term outcomes will be reported.

	Baseline		Day 28	
	T group, N=30	Control group, N=30	T group, N=30	Control group, N=30

4570 Poster Session (Board #396), Sat, 8:00 AM-11:30 AM

Patient-reported frustrations in renal cell carcinoma (RCC) care delivery: Results of a joint European Association of Urology (EAU)/KCCure survey. *First Author: Cristiane Decat Bergerot, City of Hope Comprehensive Cancer Center, Monrovia, CA*

Background: A joint survey was developed by the EAU RCC Guidelines Panel and KCCure, a non-profit patient advocacy group, to ascertain patient perceptions towards adjuvant therapy for RCC (Battle D *et al* ASCO GU 2018). This survey included open-ended questions pertaining to sources of frustration in cancer-related care, the results of which are summarized herein. **Methods:** An online survey was conducted from April to June, 2017, publicized through social media and patient networking platforms. The survey obtained basic clinicopathologic, treatment related information, and open-ended questions asking for common sources of frustration in cancer-related care. Patients were also asked how they might reconcile these sources of frustration. Each response was analyzed and categorized into descriptive categories. The Kruskal-Wallis test was used to define associations between baseline characteristics and sources of frustration. **Results:** Among 450 patients with RCC, median age was 56, and 56% were female. The majority was diagnosed with clear cell histology (85%) and most patients had non-metastatic disease (73%). The most common sources of frustration were related to poor communication (20%), lack of confidence in diagnosis (18%), fear of recurrence/progression (14%) and financial issues (9%). Practical sources of frustration (e.g., lack of information, financial issues) were more common among patients with non-clear cell histology (P = 0.05) and older age (P = 0.01). In contrast, emotional sources of frustration (e.g., fear of recurrence/progression) were more common in females (P = 0.001). Patients posited that care could be improved if physicians demonstrated greater compassion (21%), spent more time supplying information (20%) and if they could circumvent financial issues (11%). **Conclusions:** RCC patients have varied and multiple concerns around care delivery. Based on this findings, practitioners should aim to better inform patients and should be cognizant of psychosocial issues surrounding their care. Certain baseline characteristics (age, gender and histology) can be considered in individualizing care delivery to minimize patient frustration.

4571 Poster Session (Board #397), Sat, 8:00 AM-11:30 AM

Anxiety and patients: Perspectives on surveillance and adjuvant therapy in renal cell carcinoma. *First Author: Dena Battle, KCCure, Alexandria, VA*

Background: Until recently there has been no approved adjuvant therapy (AT) for renal cell carcinoma (RCC). Surveillance after nephrectomy is carried out with various modalities without clear recommendations from guidelines. In the S-TRAC trial, sunitinib improved disease-free survival (DFS) for high risk RCC patients (pts). Overall survival (OS) data is immature. Data on pts perception of AT vs surveillance are missing. The purpose of this study was to assess pts anxiety and perspectives regarding AT vs surveillance in RCC. **Methods:** We conducted a survey-monkey survey in n = 450 pts with RCC. The survey was promoted via kccure.org, Facebook and smartpatients.com. Questions focused on pts attitude towards AT. **Results:** Baseline pts characteristics include: median age 55.6 years (17-82 years); 56.4% female; 73.6% post-nephrectomy, 22.0% post-partial nephrectomy; 76.4% clear cell; 39.1% pts with RCC recurrence; 35.3% receiving systemic therapy for RCC. Median NCCN distress score was 6.39 in the majority of the pts. Main drivers of anxiety were cancer recurrence (74.4%), fear of the loss of renal function (38.7%), contrast media harming the kidney (27.1%) and exposure to radiation (20.7%). No differences in anxiety levels ranged between stage, age, gender, and type of surgery. Systemic therapy increased NCCN distress score (6.87, $p < 0.0001$). 63.1% of pts would use AT if it prolonged OS; 60.1% if AT prolonged DFS; 42.7% if AT demonstrated acceptable toxicity; 36.7% if guaranteed insurance coverage and efficacy. Use of systemic therapy correlated with a wish for a prolonged OS ($p < 0.0001$). Pts on systemic therapy had a significant higher acceptance of toxicity ($p < 0.0001$). **Conclusions:** Anxiety is a key driver for pts decisions and is unrelated to stage. Most pts are willing to use AT based on DFS benefits alone and place lower emphasis on toxicity. These data provide an important perspective on pts perceptions with RCC and the need for pts education on risks of AT.

4572 Poster Session (Board #398), Sat, 8:00 AM-11:30 AM

Real world experience and biomarkers of nivolumab in dutch advanced renal-cell carcinoma patients. *First Author: Saskia Lisa Verhaart, VU University Medical Center, Amsterdam, Netherlands*

Background: Although nivolumab, a programmed death 1 inhibitor, has been approved as a second line treatment for advanced renal-cell carcinoma (RCC) in Europe since 2016, its real-world experience is currently unknown. **Methods:** Efficacy, toxicity and potential biomarkers (histology, performance score, lactate dehydrogenase [LDH], eosinophils, neutrophils and lymphocytes) of nivolumab were retrospectively evaluated in Dutch RCC patients, who were consecutively registered in a national database between March 2016 and May 2017. **Results:** Data of 264 patients in 24 hospitals was analyzed. Twenty-one (9%), 122 (49%) and 104 (42%) patients were categorized in favorable, intermediate and poor MSKCC risk groups, respectively. Median overall survival (OS) was 18.7 months (95% CI, 13.7 – 23.7) and time to treatment failure (TTF) 6.0 months (95% CI, 5.1 – 6.8). Overall, 46 grade 3 or 4 adverse events (AEs) in 39 patients (15%) and two nivolumab related deaths were reported. After a median follow-up of 12.3 months, 78% (38 of 49) of responding patients had an ongoing response. Clear-cell histology patients had a median OS of 17.6 months (95% CI, 14.6 – 20.6) and TTF of 5.6 months (95% CI, 4.8 – 6.3) while non-clear-cell histology patients had a median TTF of 3.3 months (95% CI, 1.4 –5.1). Patients with a WHO performance score ≤ 1 had a better OS and TTF as compared to patients with a performance score of ≥ 2; median OS 18.7 months (95% CI, not estimable) *vs.* 5.4 months (95% CI, 1.2 – 9.6) and TTF 6.0 months (95% CI, 5.0 – 6.9) *vs.* 2.4 months (95% CI, 1.5 – 3.3). In patients with normal baseline LDH, median OS was not estimable and median TTF 6.7 months (95% CI, 5.2 – 8.2), while a decreased efficacy (median OS 9.7 months (95% CI, 7.5 – 11.9) and TTF 2.9 months (95% CI, 2.1 – 3.6) was observed in patients with elevated LDH at baseline. An increase in absolute eosinophil count between week 0 and 8 was related to improved OS (HR = 0.41; 95% CI, 0.23 – 0.73, P = 0.003) and TTF (HR = 0.65; 95% CI, 0.46 – 0.92, P = 0.015). **Conclusions:** In this real-world population, efficacy and safety of nivolumab are comparable to the results reported in the pivotal phase III trial. Remarkably, increase in eosinophil count during treatment with nivolumab predicts improved efficacy and survival.

4573 Poster Session (Board #399), Sat, 8:00 AM-11:30 AM

Safety and activity of hydroxychloroquine and aldesleukin in metastatic renal cell carcinoma: A cytokine working group phase II study. *First Author: Leonard Joseph Appleman, University of Pittsburgh, Pittsburgh, PA*

Background: Aldesleukin (recombinant human interleukin-2, IL-2) has been an FDA-approved treatment for mRCC since 1992 with a 5-10% rate of durable complete response. Hydroxychloroquine (HCQ) inhibits cellular autophagy, a protective mechanism that enables cells to survive metabolic stress. In murine models, the combination of IL-2 and HCQ was associated with diminished toxicity and increased efficacy. We hypothesized that this combination would be tolerable and active in patients with metastatic renal cell carcinoma (mRCC). **Methods:** The Cytokine Working Group studied high-dose IL-2 in combination with oral HCQ for patients with mRCC. Subjects received IL-2, 600,000 International Units/kg, every 8 hours up to 14 doses/cycle. HCQ was administered daily by mouth, starting 2 weeks prior to the first dose of IL-2 and continued up to one year. The initial HCQ dose was 600 mg daily, with a planned dose escalation to 1200 mg daily. Subjects were monitored for safety and tolerability as well as response per RECIST 1.1. **Results:** 30 patients (9F, 22M) received study treatment, and 29 were evaluable for response. MSKCC prognostic group: good- 38%; intermediate- 55%; poor- 11%. Five subjects were treated at 600 mg daily HCQ with no unexpected toxicity. Thirteen subjects were then treated at HCQ 1200 mg. Of these, 2 experienced hypotension and tachycardia, and 1 patient died from pulmonary emboli. The cardiac events, consistent with IL-2 toxicity, were observed earlier in the course of treatment than anticipated. HCQ dose was therefore de-escalated to 600 mg daily, and 12 additional subjects were enrolled with no unexpected toxicity. There were 3 confirmed complete responses and 3 partial responses (1 confirmed); the median overall survival has not been reached. Surprisingly, median progression-free survival was 5 months for the 1200 mg cohort and $>$ 17 months for the 600 mg group, 3-4x the historical duration. High baseline levels of serum hepatocyte growth factor $>$ median predicted for inferior overall survival. Soluble LAG-3 levels increased with IL-2 therapy. **Conclusions:** IL-2 plus HCQ was well tolerated and clinically active with encouraging PFS of 17 months at the 600 mg HCQ dose. Clinical trial information: NCT01550367.

4574 Poster Session (Board #400), Sat, 8:00 AM-11:30 AM

Prospective, multinational, observational study of real-world treatment outcomes with pazopanib in patients with advanced or metastatic renal cell carcinoma (PRINCIPAL study). *First Author: Manuela Schmidinger, Medical University of Vienna, Vienna, Austria*

Background: PRINCIPAL (NCT01649778) was the largest prospective real-world effectiveness and safety study of pazopanib (PAZ) in patients (pts) with renal cell carcinoma (RCC). **Methods:** Pts with advanced and/or metastatic clear cell RCC were enrolled within 30 days of initiating first-line PAZ. Follow-up data on progression, survival, and safety was collected approximately every 3 months until death, consent withdrawal, or loss to follow-up, for up to 30 months. Primary efficacy end points were median overall survival (mOS), median progression-free survival (mPFS), and overall response rate (ORR). Safety measures included frequency of adverse events (AEs), serious AEs, and AEs of special interest. **Results:** Among 657 pts who received $\geq$1 dose of PAZ, 76.3% completed the study (33.0% completed 30 months of follow-up and 43.2% died). Median enrollment age was 66 years, with 57.2% aged $\geq$65 years. 4.1%, 62.6%, and 33.3% of pts were grouped as favorable, intermediate, or poor risk by Heng criteria, respectively. Most pts (84%) initiated treatment at 800 mg, and the median treatment time with or without dose interruption was 6.9 and 7.6 months, respectively. mPFS and mOS are shown in the Table. Among the measurable disease population (n = 168), ORR was 30.3%, median duration of response was 11.0 months (95% confidence interval [CI] 8.6-14.6), and time to response, evaluated every 3 months, was 3.0 months (95% CI 2.9-3.1). Most pts had an AE (74.0%) that led to dose adjustment/interruption in 49.3% and treatment discontinuation in 14.6%. The most frequent ($>$ 10%) drug-related AEs were hypertension (20.9%), diarrhea (11.3%), and increased alanine aminotransferase (11.0%). **Conclusions:** Real-world effectiveness and safety outcomes in the PRINCIPAL study were consistent with clinical trials and support the first-line use of PAZ across all risk groups of pts with advanced or metastatic RCC. Clinical trial information: NCT01649778.

	mPFS, months (95% CI)	mOS, months (95% CI)
All pts	10.4 (9.3-12.0)	29.9 (24.7-NR)
Heng risk group		
· **Favorable**	16.1 (11.6-26.0)	NR (28.6-NR)
· **Intermediate**	12.5 (10.3-15.4)	32.9 (32.9-NR)
· **Poor**	6.7 (5.8-9.1)	14.8 (12.2-19.5)

4575 Poster Session (Board #401), Sat, 8:00 AM-11:30 AM

Comparative transcriptomic profiling of renal medullary carcinoma (RMC) to determine distinct signatures and pathways associated with response to chemotherapy. *First Author: Pavlos Msaouel, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: RMC is a highly aggressive renal cell carcinoma (RCC) with poor prognosis and variable response to chemotherapy. It is often treated with cytotoxic regimens used for collecting duct carcinoma (CDC) and upper tract urothelial carcinoma (UTUC). We analyzed the transcriptomic profile of RMC samples and compared it with that of CDC, UTUC, clear-cell renal cell carcinoma (ccRCC), papillary RCC (pRCC), and chromophobe RCC (chRCC). **Methods:** RNA sequencing (RNA-seq) was performed in primary tumor tissues from treatment-naïve patients with RMC (n = 11), CDC (n = 9), and UTUC (n = 22). We compared these profiles to ccRCC, pRCC, and chRCC samples (n = 20 each) randomly selected from The Cancer Genome Atlas (TCGA). Gene ontology (GO) analysis was performed using DAVID. *In vitro* cell proliferation was assessed using the MTT assay. **Results:** Unsupervised hierarchical clustering and principal component analyses showed that 9/11 RMC samples formed a distinct cluster while 2 samples overlapped with CDC (p = 0.0003). There was no overlap between RMC and UTUC, ccRCC, pRCC, or chRCC. Five patients with RMC showed at least partial response to subsequent chemotherapy (4/5 received a paclitaxel-based regimen) and their pre-treatment samples demonstrated upregulation of 62 genes (FDR $<$ 0.05) compared with the other patients. GO analysis revealed that these genes are associated with transmembrane transport pathways (enrichment score 3.87). The most upregulated gene ($>$ 3-fold) was guanine deaminase (GDA), a regulator of microtubule assembly normally expressed in human kidney collecting ducts. *In vitro* siRNA knockdown of GDA in the paclitaxel-sensitive RCC cell lines HCR-59 and UOK-146 conferred resistance to paclitaxel but not to drugs that do not target microtubules such as gemcitabine, doxorubicin, or platinum agents. **Conclusions:** RMC displays a unique transcriptomic signature that is closer to CDC than to UTUC or to other RCC subtypes. RMC tumors more likely to respond to chemotherapy show upregulation of genes such as GDA. Our results provide the first evidence that GDA may be a biomarker of response to microtubule-targeting agents in RMC.

4576 Poster Session (Board #402), Sat, 8:00 AM-11:30 AM

Functional biomarkers of homologous repair (HR) deficiency to guide novel DNA damage response targeted therapy in clear cell renal cell carcinoma (ccRCC). *First Author: Patrick Glen Pilie, University of Michigan, Ann Arbor, MI*

Background: Treatment for advanced ccRCC has rapidly evolved; however, responses are not uniform and synthetic lethal treatments with associated predictive biomarkers are still lacking. We previously reported that HR deficiency (HRD) is an early event in ccRCC, and that an HRD signature predicts for loss of RAD51 protein expression and improved OS. HRD has been shown to predict response to DNA damage response (DDR) inhibitors (DDRi) across many tumor types. In this current study, we posited that HRD positive RCC is sensitive to DDRi, that a stage dependent increase in phosphoinositide-3-kinase (PI3K) activation drives resistance to DDRi, and this resistance can be overcome with PI3K pathway inhibitors. **Methods:** We performed reverse phase protein microarray (RPPA) on 12 patient-derived stage I ccRCC tumors and 12 normal kidney tissues. We analyzed differential protein expression in HRD versus HR intact (HRI) ccRCC samples from the Cancer Genome Atlas (TCGA). We assessed apoptotic activity and colony formation in HRD (ACHN) and HRI (786-O) RCC lines with and without CHK1 inhibitor (CHK1i) and/or mammalian target of rapamycin (mTOR) inhibitor (mTORi). **Results:** Early ccRCC had loss of protein expression of FOXO3a, p-ATM, p-CHK2, p53 ($p < 0.05$) compared to normal, reflecting early defective ATM signaling. In TCGA, 75% of stage I ccRCC had an HRD signature, which decreased to less than 50% in stage IV tumors. HRI tumors had significantly higher protein expression of RAPTOR, CMYC, and PI3K than HRD tumors. In a preclinical model, HRD ACHN was sensitive to CHK1 inhibitor, whereas HRI 786-O was resistant. Adding mTORi overcame resistance to CHK1 inhibition in 786-0. **Conclusions:** Early stage ccRCC has defective DDR protein signaling with loss of ATM pathway activation. Increased oncogenic signaling, including in the mTOR/PI3K/AKT pathway, may alter HR gene activity and sensitivity to DDRi. The addition of mTORi to DDRi overcomes resistance to DDRi in HRI ccRCC. This study provides rationale for future biomarker-driven clinical trials of DDR inhibitors in advanced ccRCC patient populations.

4577 Poster Session (Board #403), Sat, 8:00 AM-11:30 AM

Single-center analysis of 109 patients (pts) with metastatic chromophobe renal cell carcinoma (ChRCC): Differences in outcomes by histologic variant. *First Author: Yasser Ged, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: ChRCC constitutes 5-10% of all RCC cases, and is generally associated with better prognosis including benefit from approved targeted agents (*Armstrong, Lancet Onc, 2016*). Presence of sarcomatoid features (SF) have previously been proposed as an adverse prognostic marker, but data for systemic therapy is limited. We assessed therapeutic outcomes for pts with metastatic ChRCC with and without SF. **Methods:** Retrospective chart reviews of pts with newly diagnosed metastatic ChRCC evaluated at Memorial Sloan Kettering Cancer Center (MSKCC) between 2002-17. MSKCC pathology reports determined presence/absence of SF to categorize pts. Evaluated endpoints included overall survival, time to treatment (TTF) for pts who initiated first line therapy at MSKCC and time to recurrence (TTR) post nephrectomy with metastatic disease. OS between the 2 groups was compared using log-rank analysis. A subset of pts had next generation sequencing (NGS) with MSK-IMPACT. **Results:** 109 pts with newly diagnosed metastatic ChRCC were identified (80 without SF, 29 with SF). Pts with SF were more likely to present with IMDC poor risk status (31% vs 10%) and de novo metastatic disease (48% vs 19%). 52 pts initiated first line therapy at MSKCC (35 without SF, 17 with SF). First line agents included VEGF tyrosine kinase inhibitors (60%), mTOR inhibitors (13%), cytokines (6%) and other investigational agents (21%). Outcomes are summarized in table below. NGS was performed in 22 pts, of which 64% and 45% harbored TP53 and PTEN alterations. **Conclusions:** Pts with metastatic ChRCC with SF had significantly worse outcomes compared to pts without SF. Median TTR < 3 months for this subgroup supports close surveillance following nephrectomy for localized tumors. The lack of benefit observed across various classes of systemic agents warrants study of underlying biology and investigating novel agents.

Outcome (Median)	All pts N = 109 Months (95% CI)	ChRCC without SF N = 80 Months (95% CI)	ChRCC with SF N = 29 Months (95% CI)	Log-rank
OS	25 (12, 33)	38 (26, 51)	7.5 (4.2, 10.7)	HR 4.7 (95% CI: 2.7, 8.2) $p < 0.001$
TTF	5.1 (2.7, 8.0)	8.0 (5.1, 13.0)	1.8 (0.9, 2.7)	-
TTR	25.5 (23.4, 58.3)	48.8 (30.8, 80.7)	2.7 (0.7, 6.9)	-

4578 Poster Session (Board #404), Sat, 8:00 AM-11:30 AM

Overall survival (OS) by clinical risk category for high dose interleukin-2 (HD IL-2) treated metastatic renal cell cancer (RCC): Data from PROCLAIM. *First Author: Mayer N. Fishman, Moffitt Cancer Center, Tampa, FL*

Background: Clinical risk factors continue to separate mRCC patient survival outcomes regardless of therapy. **Methods:** International Metastatic RCC Database Consortium (IMDC) risk criteria were utilized to assess survival among 939 mRCC patients in the PROCLAIM data base, with dates of treatment from 2006 to present. 810 patients (pts) had data for all 6 IMDC criteria and are described here. Median follow-up is 23.4 months (range 0.2 – 124 mo). Patients are grouped by prior or no prior therapy, IL-2 alone, or subsequent therapy. Some patients are in two groups. **Results:** The majority of patients were treatment-naïve and intermediate risk. Of the 249 patients with favorable risk, the median OS is 63.3 mo and the 2-year OS is 77.6%. Of 480 patients with intermediate risk, median OS is 42.4 mo, 2-year OS 68.2%, and of 81 patients with poor risk, median OS 14 mo, 2-year OS 40.4%. **Conclusions:** Among mRCC pts treated with HD IL-2, all risk groups have median and 2-year survival consistent with or better than recent reports of checkpoint or targeted therapies for RCC. Favorable and intermediate risk (by IMDC) patients treated with HD IL-2 have better OS compared with that of poor risk patients, with highest OS in favorable risk patients. Favorable risk patients treated with HD IL-2 alone have a 2-yr OS of 74%. These data continue to support a recommendation for HD IL-2 for patients with mRCC.

Patient Group (numbers)	Favorable	Intermediate	Poor
All patients (810)	249	480	81
Therapy prior to IL-2 (89)	17	57	15
No prior therapy (365)	113	220	32
Therapy post IL-2 (414)	122	254	38
IL-2 alone (356)	119	203	34
2-year Overall Survival			
All patients (810)	77.6%	68.2%	40.4%
No Prior Therapy (365)	83.6%	71.6%	53.3%
Post-IL-2 Therapy (414)	81%	72.0%	46.8%
IL-2 Alone (356)	73.8%	63.7%	39.8%

4579 Poster Session (Board #405), Sat, 8:00 AM-11:30 AM

Cabozantinib (Cabo) in advanced non-clear cell renal cell carcinoma (nccRCC): A retrospective multicenter analysis. *First Author: Nieves Martinez Chanza, Dana-Farber Cancer Institute, Boston, MA*

Background: Cabo shows robust clinical activity in advanced clear cell RCC. nccRCC, a heterogeneous mix of diseases, have been underrepresented in clinical trials and effective systemic therapy is lacking. We retrospectively characterized the clinical activity and toxicity of cabo in nccRCC. **Methods:** Medical records from advanced nccRCC patients (pts) treated with cabo across 18 institutions were reviewed. We captured baseline characteristics, clinical outcomes and genomic alterations by next-generation sequencing (NGS). Objective response rate (ORR) was assessed by RECIST. Clinical benefit (CB) included ORR or stable disease. Time to treatment failure (TTF) and overall survival (OS) were estimated by Kaplan-Meier. **Results:** We identified 80 pts with nccRCC: papillary (59%), chromophobe (10%), collecting duct (5%), Xp11.2 translocation (15%) or unclassified (11%). The majority were IMDC intermediate/poor risk (88%) and received cabo $\geq 3^{rd}$ line (53%). Median exposure was 4 months(mos) (range: $<$ 1-23). 48% remained on cabo while 42% had discontinued for progression and 5% for toxicity. Most common adverse events were fatigue (51%) and rash (33%). In 66 pts on cabo $\geq$8 weeks, ORR was 27.3%. 71% had CB; with 64% durable CB $\geq$6 mos. Median OS was 11 mos (95%CI 9-NR). TTF was 6.9 mos (95%CI 4.8-9.9). Subset analyses in Table. Most frequently altered genes in 43 pts with NGS were MET (21%) and CDKN2A (19%). Of the 7 evaluable papillary RCCs with MET alterations, 5 (71%) achieved CB. **Conclusions:** Cabo is safe and active in nccRCC. Support of ongoing (e.g.NCT02761057) and future prospective studies in nccRCC encompassing all histologies is warranted.

	ORR (%) N = 66	CB (%) N = 66	Median TTF (mos) N = 80	Median OS (mos) N = 80

4580 Poster Session (Board #406), Sat, 8:00 AM-11:30 AM

Pilot trial of ibrutinib plus nivolumab in patients with metastatic renal cell cancer (mRCC): results from a dose-finding cohort. *First Author: Primo Lara, University of California, Davis, Sacramento, CA*

Background: Immune checkpoint inhibitor therapy (CIT) has transformed the management of patients (pts) with mRCC, with a fraction experiencing durable tumor responses. However, most eventually develop disease progression after either an initial response to CIT or while on CIT. Newer agents that modulate immune response can possibly potentiate CIT therapy. The ITK/ETK/BTK inhibitor ibrutinib has been reported to inhibit myeloid derived suppressor cells in preclinical models and to potentiate CIT. We conducted an investigator-initiated pilot trial of ibrutinib plus the PD1 inhibitor nivolumab in mRCC pts, particularly in those previously exposed to CIT. Here we report initial safety and efficacy results from the dose-finding cohort. **Methods:** Pts with mRCC of any histologic subtype and who have completed at least one line of prior systemic therapy including prior CIT were eligible. Pts must have acceptable end-organ function and Zubrod PS of 0-2. Treatment consisted of nivolumab 240 mg IV q2 weeks plus ibrutinib 560 mg (dose level 0) or 420 mg (dose level -1) orally once daily. Cycle length was 28 days. Dose limiting toxicity (DLT) was defined as any Grade (Gr) 3+ adverse event (AE) attributable to therapy. **Results:** As of 9/18/17, 12 pts have been enrolled, six to each dose level. Patient characteristics: Mean age = 62 years (range 44-78); Male sex = 7 (58%); White race = 9 (75%); Prior CIT = 11 (92%). Three pts experienced one DLT each in dose level 0 (all Gr3): elevated lipase, hypoalbuminemia, & nausea. Only 1 DLT has been seen thus far in dose level -1 (Gr3 infection). The most common Gr3+ AEs include anemia (n = 5), ALT elevation (4), AST elevation (3), nausea (3), hypoalbuminemia (2), esophagitis, infection, lipase increase, and vomiting (1 each). Two pts with prior CIT had partial tumor response (both confirmed), 1 of which later became a CR. **Conclusions:** Ibrutinib at a dose of 420 mg orally once daily in combination with nivolumab 240mg IV q 2 weeks appears feasible and tolerable in mRCC patients. No unique immune-related AEs have been seen thus far. Anti-tumor activity was seen in 2 pts previously exposed to PD1-targeted therapy. Updated results will be presented. (Supported by Pharmacyclics and UCDCCC). Clinical trial information: NCT02899078.

4581 Poster Session (Board #407), Sat, 8:00 AM-11:30 AM

Active surveillance and deferred medical treatment (ASDT) in metastatic renal cell carcinoma (mRCC): Update of a single center experience and efficacy of medical treatment. *First Author: Philipp Ivanyi, Dept. Hematology, Hemostaseology, Oncology & Stem Cell Transplantation, Hanover Medical School, Hannover, Germany*

Background: ASDT is applicable to a fraction of mRCC patients (pts). We investigated clinical outcome of ASDT and report on efficacy of medical treatment (Rx). **Methods:** Between 4/2000-3/2016 patients (pts) with mRCC were identified from medical records, retrospectively. Pts alive ≥3 months after diagnosis of metastatic disease without Rx for ≥6 months were grouped as ASDT(+), all other pts were deemed ASDT(-). Overall survival (OS) and clinical progression free survival (cPFS) of administered Rx were analysed, as well as time from diagnosis mRCC to initiation of 2nd line treatment or death (= time to failure of treatment strategy [TTFS]). Descriptive statistics, Kaplan-Meier and Log-rank analyses were applied. **Results:** 142/370 (38.4%) mRCC received ASDT for a median duration of 24.1 (95%CI:20.2-28.1) months (mo). ASDT pts showed a superior OS: 67.3 (95%CI:50-84.6) mo vs. ASDT(-): 30.4 (95%CI:25-35.9) mo ($p < .001$). ASDT pts received a median of 1 (range(r): 0-8) lines of Rx compared to ASDT(-) with median 3 (r:1-10) lines of Rx ($p < 0.001$). cPFS in either 1st ($p = .052$), 2nd ($p = .062$) and 3rd ($p. = .067$) line Rx tends to be superior in in ASDT(+) pts compared to ASDT(-). TTFS compared favourably in ASDT(+) vs. ASDT(-) pts with 37.3 (95%CI: 28.2-46.4) mo vs. 10.0 (95%CI: 8.8-11.2) mo. ($p < .001$). **Conclusions:** Clinical selection by expert opinion was able to identify pts with indolent disease and favorable OS. Deferred treatment did not impact efficacy of subsequent Rx in ASDT(+) pts. ASDT is a feasible approach in selected pts in high-volume centers.

4582 Poster Session (Board #408), Sat, 8:00 AM-11:30 AM

Radiofrequency ablation of pathologically proven T1a renal tumors: 15 years follow up—A tertiary cancer center experience. *First Author: Mohamed E. Abdelsalam, Department of Interventional Radiology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: To evaluate the long term oncologic efficacy and overall survival of radiofrequency ablation (RFA) for pathologically proven T1a Renal cell carcinoma (RCC). **Methods:** we retrospectively reviewed our renal ablation data base between January 2001 and December 2014, we included only patients with histologically diagnosed T1a RCC (< 4 cm) who underwent RFA. Patient who underwent cryoablation, those with syndromes, and those with recurrent or bilateral RCC were excluded. For each patient, we recorded: Demographics, tumor size and histology, complications, recurrence at ablation site, development of metastases, history of another malignancy, survival/death and cause of death. Overall survival (OS) was estimated using Kaplan and Meier product-limit estimator. **Results:** Ninety four RFA procedures were performed for 92 lesions in 92 patients (54 males and 38 females, average age 68 years). Average tumor size was 2.7cm (range: 1-3.9 cm). The median follow-up for all subjects was 4.7 years (range: 0.16 – 14.4 years). Total of 7 patients developed complications (7.4%). Three, 1 and 3 patients developed Grades I, II and III (3.2%) complications respectively according to the Clavien-dindo classification. A total of 6 patients (6.4%) developed local recurrence at the ablation site, one patient underwent watchful observation, two underwent repeat ablation and 3 patients underwent partial nephrectomy. One patient had disease recurrence in the other kidney. Fifty four patients (56%) had another non-renal primary malignancy. None of the patients developed metastasis from RCC. The median overall survival was 8.31 years. The overall survival was 68 %, 34% and 21 % at 5, 10 and 14 years respectively. The cancer specific survival (CSS) was 100 %. **Conclusions:** Radiofrequency ablation is a safe and highly efficacious modality for treatment of small renal tumors. Fifteen-year follow up data reveals long standing oncologic control with low recurrence and complication rates.

4583 Poster Session (Board #409), Sat, 8:00 AM-11:30 AM

Outcomes of patients (pts) with metastatic renal cell carcinoma (mRCC) and sarcomatoid dedifferentiation (sRCC) after treatment with immune checkpoint inhibitors (ICI): A single-institution retrospective study. *First Author: Jeremy Aaron Ross, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Pts with mRCC and sarcomatoid dedifferentiation (sRCC) have a poor prognosis with approved targeted therapies (Keskin et al. JU 2017). The response to ICIs in mRCC pts with sRCC is unknown. **Methods:** This is a retrospective study of pts with metastatic sRCC who received ICIs (2013-2017). Data collected include tumor histology, demographics, type of ICI, response to ICI, and efficacy outcomes (response, progression-free survival [PFS], and overall survival [OS]). Descriptive statistics were used. **Results:** 33 pts (85%) had clear-cell RCC (ccRCC); 6 pts had variant histology RCC (vhRCC) including chromophobe (2), mucinous tubular and spindle cell carcinoma (1), and unclassified (3). All pts but 2 had intermediate- or poor- risk disease by International Metastatic Renal Cell Carcinoma Database Consortium (IMDC) criteria. 15 pts (38%) had greater than 50% sarcomatoid component (sarc) in primary tumor of nephrectomy specimen, 5 (13%) had > 80%, and 2 (5%) had 100%. 22 pts (56%) received nivolumab (nivo) as a single agent. 15 pts (38%) received nivo in combination with ipilimumab and 2 pts (5%) received pembrolizumab. 24 pts (62%) responded to treatment with ICIs. Of these, 14 (58%) received ICIs at first-line therapy, 9 pts in second, 1 in fourth. Median PFS was 8.3 months (95% CI 3.6 – 13.1). 5/33 pts with ccRCC (15%) achieved a complete response (CR) and 4 remain in CR at 52, 31, 31, and 22 months from start of ICI. 1 pt was not followed at our institution after 24 months of CR. These pts had 90%, 1%, 30%, 50%, and 90% sarc, respectively. 1 of these patients remains on treatment. 5/6 pts with vhRCC did not respond to therapy; 1 pt with unclassified histology had stable disease for 5 months 28 pts (77%) are alive at time of this analysis. The median OS was not reached. **Conclusions:** In pts with sRCC, ICIs appear to be effective in ccRCC with up to 15% achieving durable CR. The prognosis of vhRCC with sRCC remains poor despite treatment with ICI, underscoring the need to develop more effective therapies for these patients.

4584 Poster Session (Board #410), Sat, 8:00 AM-11:30 AM

Effectiveness and safety of pazopanib (PAZO) and everolimus (EVE) in a changing treatment (Tx) landscape: Interim results of the non-interventional study PAZOREAL. *First Author: Martin Boegemann, University of Muenster Medical Center, Münster, Germany*

Background: The therapeutic landscape for metastatic renal cell carcinoma (mRCC) has evolved rapidly with the approval of targeted therapies like tyrosine kinase-, mTOR-, multikinase-, and immune checkpoint inhibitors. Real-world data are urgently needed to monitor the translation of these approaches into daily practice. **Methods:** PAZOREAL is a prospective, non-interventional study to evaluate efficacy, tolerability, safety, and quality-of-life (QoL) in mRCC patients (pts) treated with first-line PAZO, second-line nivolumab (NIVO) or EVE, or third-line EVE (± lenvatinib) after NIVO. The primary variable was time on drug (TD) in the respective Tx lines. Other endpoints were overall survival (OS), dosing, safety, and QoL. **Results:** Between Dec 2015 and Nov 2017, 421 pts were enrolled. Interim results for 385 pts treated with PAZO in first line are presented here, majority of pts presented with ECOG 0-1 (81.0%) and clear cell carcinoma (80.3%). Median TD was 6.5 months (95%CI, 5.5-8.3). Using commonly applied trial eligibility criteria i.e. Karnofsky PS $\geq$ 70%, normal hemoglobin and clear-cell histology, the median TD in trial-eligible pts (39.5% of 385 pts) was 8.0 months (95%CI, 6.2-11.2). Progressive disease (n = 104/212 pts) was the most common reason for end of PAZO Tx, followed by toxicity (n = 34) and unrelated adverse events (AEs) (n = 20). 75 pts subsequently received NIVO as second-line treatment. Median OS was not reached. Death was reported for 20.8% of pts. Survival follow-up is ongoing. PAZO Tx was well tolerated. Treatment-emergent AEs (TEAEs) were reported for 308 of 378 pts included in the safety analysis, PAZO-related TEAEs for 246 pts (65.1%), and PAZO-related grade 3/4 TEAEs for 75 pts (19.8%). Most commonly reported AEs were diarrhea, nausea, and fatigue. QoL evaluated by EQ-5D-5L remained stable during PAZO Tx. **Conclusions:** The PAZOREAL study demonstrated acceptable efficacy, safety and tolerability of PAZO in the real-world setting. For patients considered trial-eligible, TD was comparable with results from clinical trials. The sequence of PAZO followed by NIVO as second line Tx is commonly applied in Germany.

4585 Poster Session (Board #411), Sat, 8:00 AM-11:30 AM

Nivolumab (nivo) for patients (pts) with metastatic non-clear cell renal cell carcinoma (nccRCC): A single-institution experience. *First Author: Jad Chahoud, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Nivo is approved for refractory metastatic renal cell carcinoma (RCC). However, the clinical activity of nivo in nccRCC is unknown as these patients were excluded from the trial population. **Methods:** We conducted a retrospective study of pts who received at least one dose of nivo for histologically-confirmed nccRCC. We tabulated treatment characteristics, objective response according to RECIST v1.1, adverse events (AEs), progression-free survival (PFS) and overall survival (OS). **Results:** Between 3/2010 and 12/2017, we identified 40 pts with nccRCC; 12 (30%) had papillary histology, 10 (25%) unclassified, 5 (12.5%) chromophobe, 3 (7.5%) translocation, 8 (20%) had ccRCC with rhabdoid component, 1 (2.5%) mucinous tubular and spindle cell carcinoma and 1 (2.5%) sarcomatoid RCC. Median age was 58 years (17-80) and 82.5% were male. The majority of pts had ECOG PS 1 (65%) or 2 (27.5%). At start of nivo therapy, 85% had metastatic disease in $\geq$ 2 sites; 7.5 % had International Metastatic RCC Database Consortium favorable-risk, 72.5% intermediate- and 20% poor-risk disease. Most pts (82.5%) had prior nephrectomy and median number of prior lines of therapy was 2 (0-8) with 60% of pts receiving $\geq$ 2 prior VEGFR-TKIs. The majority received nivo monotherapy (n = 32, 80%), and 20% (n = 8) received a combination of nivo with anti-VEGF or anti-CTLA4 therapy. At a median follow-up of 20 mo (16.2, 29.6), median PFS was 5.4 mo (3.4-10.2), with a 6-mo PFS rate of 45% (31.6%-64.2%). Median OS was 17.3 mo (7.8-NA), and 1-yr OS 60.1% (45.7%-79.1%). Disease control rate for 32 pts evaluable for best response was 78.1% (CR 6.25% + PR 9.37% + SD 62.5%), 12 pts (37.5%) had stable disease $\geq$ 6mo. Most common AEs were diarrhea (10%) and fatigue (17.5%). Nivo was stopped secondary to intolerance in 7 pts, 4 of whom achieved durable disease control. There were no treatment-related deaths. **Conclusions:** Nivo demonstrated clinical benefit and was well-tolerated in pts with nccRCC. Until there is evidence from prospective clinical trials, this retrospective data supports the use of nivo in pts with metastatic nccRCC.

TPS4586 Poster Session (Board #412a), Sat, 8:00 AM-11:30 AM

Pembrolizumab (pembro) plus epacadostat or placebo for locally advanced or metastatic urothelial carcinoma (UC) after failure of first-line platinum-containing chemotherapy: KEYNOTE-698/ECHO-303. *First Author: Thomas Powles, Barts Cancer Institute, Queen Mary University of London, London, United Kingdom*

Background: Pembro has shown clinical efficacy as monotherapy in locally advanced or metastatic UC in first-line (1L) cis-ineligible and second-line (2L) postplatinum settings. Combination of pembro and epacadostat, a potent and highly selective oral inhibitor of the indoleamine 2,3-dioxygenase 1 (IDO1) enzyme, in the ongoing ECHO-202/KEYNOTE-037 phase 1/2 study (NCT02178722) showed increased ORR compared with data from pembro monotherapy and durable responses in 1L and 2L advanced UC patients. Further evaluation of this combination in a phase 3 randomized trial in advanced/metastatic UC is warranted. **Methods:** KEYNOTE-698/ECHO-303 (NCT03374488) is a global, phase 3, randomized, double-blind, placebo-controlled trial to evaluate efficacy and safety of pembro plus epacadostat versus pembro plus placebo in patients with locally advanced or metastatic UC that progressed after prior platinum-containing chemotherapy. Eligibility criteria include age $\geq$18 years; confirmed transitional cell or predominantly transitional cell histology; progression or recurrence of UC after 1 prior platinum-containing chemotherapy regimen for advanced or metastatic UC or within 12 months of neoadjuvant or adjuvant treatment with platinum-containing chemotherapy; measurable disease per RECIST v1.1, ECOG 0-1, and good organ function at baseline; and provision of tumor sample for PD-L1 analysis. Eligible patients will be stratified by Bellmunt score (0, 1, $\geq$2) and PD-L1 expression (combined positive score [CPS] $\geq$10 or CPS $<$ 10), and randomly assigned 1:1 to receive pembro 200 mg IV Q3W plus epacadostat 100 mg orally twice daily (continuously) or pembro plus matching placebo. Study treatment will continue until disease progression, unacceptable toxicity, or completion of 35 pembro infusions. Imaging will be performed every 9 weeks for the first 12 months and every 12 weeks thereafter until disease progression. Primary end points include OS and PFS (RECIST v1.1) by investigator assessment. Secondary end points include ORR, patient-reported outcomes, and safety. Approximately 648 patients will be enrolled. Clinical trial information: NCT03374488.

TPS4587 Poster Session (Board #412b), Sat, 8:00 AM-11:30 AM

Phase 3, randomized, double-blind trial of pembrolizumab plus epacadostat or placebo for cisplatin-ineligible urothelial carcinoma (UC): KEYNOTE-672/ECHO-307. *First Author: Arjun Vasant Balar, Perlmutter Cancer Center, NYU Langone Medical Center, New York, NY*

Background: For patients ineligible to receive cisplatin, there is less benefit but still toxicity with alternative first-line cytotoxic chemotherapy. Upregulation of programmed death 1 (PD-1) and indoleamine 2,3- dioxygenase 1 (IDO1) enzyme may be therapeutically relevant in metastatic UC. Pembro is a PD-1 inhibitor effective in treatment of locally advanced/metastatic UC in cisplatin-ineligible and platinum-refractory patients. Epacadostat is a potent and highly selective oral inhibitor of IDO1. A recent phase 1/2 trial of pembro plus epacadostat (ECHO-202/KEYNOTE-037, NCT02178722) yielded encouraging efficacy and safety data in patients with advanced UC. **Methods:** KEYNOTE-672/ECHO-307 (NCT03361865) is a randomized, active-controlled, double-blind, global phase 3 trial conducted to evaluate efficacy and safety of first-line pembro in combination with epacadostat or placebo in cisplatin-ineligible patients with advanced/metastatic UC. Eligibility criteria include age $\geq$18 years; confirmed unresectable/metastatic UC of the urinary tract; ineligible for cisplatin-based therapy; no prior systemic chemotherapy for unresectable/metastatic UC (neoadjuvant/adjuvant treatment with platinum-containing chemotherapy with recurrence $>$ 12 months permitted); ECOG performance status 0-2; and available tumor sample for PD-L1 analysis. Patients will be randomly assigned 1:1 to receive pembro 200 mg IV Q3W plus epacadostat 100 mg orally twice daily (continuously) or pembro plus placebo. Randomization will be stratified by Bajorin risk score (0, 1, 2) and PD-L1 expression (combined positive score $\geq$10 or $<$ 10). Treatment will continue until disease progression, unacceptable toxicity, or completion of 35 pembro infusions. Imaging will be performed every 9 weeks for first 12 months and every 12 weeks thereafter. Adverse events will be assessed per NCI CTCAE, version 4.0. Dual primary end points are progression-free survival per blinded independent central review and overall survival. Secondary end points include objective response rate, patient-reported outcomes, and safety. Target enrollment is 650 patients. Clinical trial information: NCT03361865.

TPS4588 **Poster Session (Board #413a), Sat, 8:00 AM-11:30 AM**

A phase 3, open-label, randomized study of nivolumab plus ipilimumab or standard of care (SoC) vs SoC alone in patients (pts) with previously untreated unresectable or metastatic urothelial carcinoma (mUC; CheckMate 901). *First Author: Matt D. Galsky, Icahn School of Medicine at Mount Sinai/Tisch Cancer Institute, New York, NY*

Background: Cisplatin-containing regimens have been SoC for mUC for nearly 40 years, but durable responses are rare with such treatments. Furthermore, a large proportion of pts with unresectable/mUC are ineligible for cisplatin therapy. Treatment approaches conferring longer-term disease control and extending to broader mUC pt populations are urgently needed. Recently, the programmed death-1 (PD-1) inhibitor, nivolumab, induced durable responses in pts with unresectable/mUC progressing despite platinum-based chemotherapy, and nivolumab combined with ipilimumab (a CTLA-4 inhibitor) demonstrated acceptable safety and clinical activity. This phase 3 study will evaluate nivolumab + ipilimumab and nivolumab + SoC vs SoC in previously untreated pts with unresectable/mUC (NCT03036098). **Methods:** Key inclusion criteria: cisplatin-eligible and -ineligible pts with measurable disease, no prior systemic chemotherapy for unresectable/mUC, and evaluable tumor biopsy. Key exclusion criteria: active brain metastases, autoimmune disease, and prior treatment with drugs specifically targeting T-cell co-stimulation or checkpoint pathways. Cisplatin-eligible and -ineligible pts will be randomized 1:1 to arm A (nivolumab 1 mg/kg + ipilimumab 3 mg/kg every 3 weeks up to 4 doses, followed by nivolumab 480 mg every 4 weeks until disease progression or unacceptable toxicity) or arm B (gemcitabine-cisplatin or gemcitabine-carboplatin for up to 6 cycles). Additional cisplatin-eligible pts will be randomized to arm C (nivolumab 360 mg + gemcitabine-cisplatin every 3 weeks for up to 6 cycles, followed by nivolumab 480 mg) or arm D (gemcitabine-cisplatin for up to 6 cycles). Stratification factors: PD-1 ligand 1 status, cisplatin eligibility, and liver metastasis. Co-primary endpoints: overall and progression-free survival (OS and PFS) by blinded independent central review (BICR) in cisplatin-ineligible pts receiving nivolumab + ipilimumab vs SoC, and PFS by BICR in cisplatin-eligible pts receiving nivolumab + SoC vs SoC. Enrollment began March 2017 with a target of ~897 pts. Clinical trial information: NCT03036098.

TPS4589 **Poster Session (Board #413b), Sat, 8:00 AM-11:30 AM**

IMvigor130: A randomized, phase III study evaluating first-line (1L) atezolizumab (atezo) as monotherapy and in combination with platinum-based chemotherapy (chemo) in patients (pts) with locally advanced or metastatic urothelial carcinoma (mUC). *First Author: Matt D. Galsky, Icahn School of Medicine at Mount Sinai/Tisch Cancer Institute, New York, NY*

Background: Platinum-based chemo is the standard of care for most pts with untreated mUC, although clinical outcomes remain poor. Atezo (anti–PD-L1) was approved in the United States, European Union and elsewhere as monotherapy in both the 1L cisplatin (cis)–ineligible and post-platinum settings based on the single-arm, Phase II IMvigor210 trial. Data from other tumor types (e.g., NSCLC and TNBC) suggest that atezo may be tolerable when combined with chemo. Here we describe IMvigor130, a Phase III trial designed to evaluate the efficacy and safety of 1L atezo given alone or in combination with platinum-based chemo vs placebo and chemo, in pts with locally advanced or mUC. **Methods:** Across 35 countries, IMvigor130 (NCT02807636) is enrolling ≈ 1200 pts with histologically documented advanced or mUC (T4b, any N; or any T, N2-3; M1, stage IV) of the bladder, urethra, renal pelvis or ureters who have not received prior chemo for advanced disease. Eligible pts have measurable disease (per RECIST v1.1), ECOG PS 0-2 and a tissue sample for PD-L1 testing (VENTANA SP142 IHC assay). IMvigor130 was initially designed to enroll only cis-ineligible pts but was amended to include all platinum-eligible pts. Pts are randomized 1:1:1 to: (A) atezo + chemo (gemcitabine [gem] + cis or carboplatin [carbo]), (B) atezo alone or (C) placebo + chemo at the following doses (starting day 1 of a 21-day cycle): atezo (or placebo) 1200 mg IV q3w, gem 1000 mg/m^2 on days 1 and 8, carbo AUC 4.5 q3w, cis 70 mg/m^2 q3w. Atezo and chemo are administered, in the absence of unacceptable toxicity, until RECIST v1.1 progressive disease. Randomization is stratified by PD-L1 status on immune cells, number of Bajorin risk factors or liver metastases and investigator's chemo choice. The co-primary endpoints are PFS and OS in Arm A vs Arm C in the ITT population and OS in Arm B vs Arm C in the ITT population. Key secondary efficacy endpoints include investigator-assessed ORR, DOR and PFS per RECIST v1.1 (for atezo vs placebo + chemo arms). Safety, biomarkers and other exploratory endpoints will also be evaluated. Clinical trial information: NCT02807636.

TPS4590 **Poster Session (Board #414a), Sat, 8:00 AM-11:30 AM**

EV-201 Study: A single-arm, open-label, multicenter study of enfortumab vedotin for treatment of patients with locally advanced or metastatic urothelial cancer who previously received immune checkpoint inhibitor therapy. *First Author: Jonathan E. Rosenberg, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Most patients (pts) with locally advanced or metastatic urothelial cancer (la/mUC) treated with checkpoint inhibitor immunotherapy (CPI) will fail to achieve a durable response regardless of treatment setting (post-platinum or first-line cisplatin-ineligible). Enfortumab vedotin (EV), an antibody-drug conjugate, delivers the microtubule-disrupting agent monomethyl auristatin E to tumors expressing Nectin-4, which is overexpressed in mUC. Preliminary results from an ongoing phase 1 study of EV (Petrylak ASCO-GU 2018) showed that EV (1.25 mg/kg) was well-tolerated in pts with CPI-treated mUC (n = 67). Fatigue (55%), nausea (48%), and decreased appetite (45%) were the most commonly reported treatment-related AEs. Hyponatremia (n = 4, 6%) was the only AE grade ≥3 (regardless of attribution) in > 5% of the cohort; vomiting (n = 2, 3%) was the only treatment-related AE grade ≥3 occurring in ≥2 pts. Hyperglycemia, a new safety finding, emerged post-database cutoff; the protocol was revised. EV showed a confirmed objective response rate (ORR) of 31% in 55 of 67 evaluable pts (23.5% in pts with baseline liver metastases, n = 17) with most responses ongoing as of 02-Oct-2017. Nine pts with unconfirmed PR are pending response assessment. These encouraging results warrant further investigation in this population. **Methods:** This single-arm, open-label, multicenter phase 2 study (NCT03219333) evaluates the antitumor activity and safety of EV monotherapy in ~120 pts with la/mUC. Pts must have previously received a CPI and either have received prior platinum or be cisplatin-ineligible. Pts must have histologically or cytologically documented transitional cell carcinoma of the urothelium that progressed during or following receipt of most recent therapy. The primary objective is to determine antitumor activity as measured by ORR. Secondary objectives include assessment of duration of response, disease control rate, PFS, OS, and safety/tolerability. Pts must have tumor tissue available for exploratory analyses. Response is assessed per RECIST v1.1. Study enrollment began in Sep 2017. Clinical trial information: NCT03219333.

TPS4591 **Poster Session (Board #414b), Sat, 8:00 AM-11:30 AM**

Phase II randomized study of first line avelumab with carboplatin-gemcitabine versus carboplatin-gemcitabine alone in patients with metastatic urothelial carcinoma ineligible for cisplatin-based therapy. *First Author: Alejo Rodriguez Vida, Hospital del Mar, Barcelona, Spain*

Background: Cisplatin-based chemotherapy is standard first line treatment for metastatic urothelial carcinoma (mUC). However, around 50% of patients are ineligible for cisplatin due to poor performance status or comorbidities. For these cases, carboplatin-based combinations are valid alternative options, although they are associated with inferior survival. Additional new strategies for cisplatin-ineligible patients are therefore urgently needed. Recently, excellent clinical activity has been reported with immune checkpoint inhibitors as monotherapy for cisplatin-ineligible patients. The purpose of this study is to test the safety and efficacy of avelumab (anti PD-L1 therapy) given pre-emptively and combined with carboplatin-gemcitabine (carbo/gem) followed by maintenance avelumab. Priming the chemotherapy response giving immunotherapy first could enhance the overall response of the combination and prevent the detrimental effect of chemotherapy on immune cells. Up regulation of PD-L1 by chemotherapy could also enhance the immunotherapy efficacy. **Methods:** This is a multicenter, randomized, open label phase II study evaluating safety and efficacy of sequencing 2 cycles of induction avelumab prior to combining carboplatin-gemcitabine plus avelumab for 6 cycles, followed by avelumab maintenance, compared to carbo/gem alone. Eligibility criteria include patients with mUC, no prior systemic therapy, ineligibility for cisplatin and adequate organ function. Patients will be stratified by the presence/absence of visceral metastasis and ECOG 0-1 versus 2. Primary endpoint of the study is objective response rate (ORR). Secondary endpoints include progression free survival, overall survival and safety. Exploratory endpoints include potential immunologic and genomic predictive biomarkers. For sample size calculation, we hypothesized that the ORR with the combination will be ≥45%, compared to 30% with standard carbo/gem. A sample of 80 patients will provide a probability of 0.9 of confirming our hypothesis, based on a Simon randomised phase II design. The trial is open to accrual. Clinical trial information: NCT03390595.

TPS4592 **Poster Session (Board #415a), Sat, 8:00 AM-11:30 AM**

ATLAS: A phase 2, open-label study of rucaparib in patients (pts) with locally advanced or metastatic urothelial carcinoma (mUC). *First Author: Petros Grivas, University of Washington, Seattle, WA*

Background: There are limited treatment options for pts with mUC that has progressed during or after platinum-based chemotherapy and/or immune checkpoint inhibitors (ICIs), emphasizing the need for new therapies. Analysis of The Cancer Genome Atlas bladder cancer dataset suggests that approximately 60% of bladder cancer tumors have homologous recombination deficiency (HRD). Poly(ADP-ribose) polymerase inhibitors (PARPis) have demonstrated activity in tumors with HRD. In the United States, the PARPi rucaparib is approved for the treatment of pts with deleterious *BRCA* mutation (germline/somatic) associated advanced ovarian cancer treated with ≥2 chemotherapies. We hypothesize that PARP inhibition may have antitumor activity in mUC, particularly in tumors with HRD. The ATLAS (NCT03397394) trial will evaluate the efficacy and safety of rucaparib in pts with locally advanced or mUC previously treated with platinum-based chemotherapy and/or ICIs. **Methods:** Eligible pts must have measurable disease per RECIST v1.1, adequate organ function, and radiographic progression after 1–2 prior standard-of-care regimens. Confirmation of HRD status before enrollment is not required, but fresh tumor tissue or recently obtained archival tissue is mandatory for HRD profiling. Prior PARPi treatment is an exclusion. All pts will receive 600 mg rucaparib orally BID until disease progression or other reason for discontinuation. The primary endpoint is confirmed objective response rate (investigator-assessed per RECIST v1.1) in both HRD-positive (signature based on tumor genomic loss of heterozygosity) and intent-to-treat populations. Secondary endpoints include overall survival, progression-free survival, response duration, safety, and pharmacokinetics. Exploratory endpoints include evaluation of molecular biomarkers associated with response and resistance to rucaparib, including changes in plasma and tumor samples, and circulating tumor DNA. Patients are being enrolled in 6 countries, with a target enrollment of 200 pts. The study has > 90% power to reject the null hypothesis (P= 0.10) at a 5% significance level if the true response rate for rucaparib is 20%. Clinical trial information: NCT03397394.

TPS4593 **Poster Session (Board #415b), Sat, 8:00 AM-11:30 AM**

A phase I-II study to evaluate safety and efficacy of the combination of niraparib plus cabozantinib in patients with advanced kidney/urothelial carcinoma. *First Author: Daniel E. Castellano, Hospital 12 de Octubre, Madrid, Spain*

Background: Niraparib (N) is an orally available and selective poly(ADP-ribose) polymerase (PARP)-1/-2 inhibitor approved for maintenance treatment of patients (pt) with recurrent epithelial ovarian, fallopian tube, or primary peritoneal cancer after complete or partial response to platinum-based chemotherapy (CT). Cabozantinib (C) is a tyrosine kinase (TK) inhibitor with activity against TKs including VEGFR2, MET and AXL, approved on kidney cancer pt after TK failure, that has demonstrated clinical activity in heavily pretreated, advanced UC pt. c-Met receptor TK is activated in urothelial carcinoma (UC) cells. c-Met activity can decrease response to PARP inhibitors, whereas treatment with c-Met inhibitors renders cells more sensitive to PARP inhibition. UC pt with tumors overexpressing c-Met may benefit from the combination of c-Met and PARP inhibitors. This multicenter, open-label phase (ph) I-II study (NCT03425201) is to explore the maximum-tolerated dose (MTD) of N + C combination in pt with advanced genitourinary malignancies (UC and kidney cancer) follow by a preliminary efficacy of the combination in advanced UC. **Methods:** Eligible pt have confirmed histopathology of UC or clear cell renal cell carcinoma, advanced or metastatic disease, age ≥18 years, ECOG PS ≤1, progressive disease after platinum-based CT, measurable lesions, no prior therapy with PARP or c-Met inhibitors and adequate bone marrow, liver and renal functions. The ph I portion is enrolling ≈24 pt to identify the MTD proposed to use in a ph II (RP2D). Pt will receive N and C p.o. once daily in 28-day cycles: Dose level 1 (DL1) N/C 100/20 mg; DL2 200/20 mg; DL3 200/40 mg; DL4 200/60 mg. Pt will be accrued to each dose level in cohorts of 6 pt until the MTD is achieved (the highest dose at which ≤1 out of 6 pt experience a dose-limiting toxicity [DLT]). DLT will be evaluated during the first 2 cycles. The ph 2 portion will enroll 51 UC pt to receive the RP2D. Tumors will be assessed per RECIST v1.1. Endpoints of the ph 2 are 6-month PFS (primary), overall response rate, disease control rate, duration of response, PFS and OS. Tissue and plasma sample will be collected for translational study. Clinical trial information: NCT03425201.

TPS4594 **Poster Session (Board #416a), Sat, 8:00 AM-11:30 AM**

SPIRE: A phase Ib/randomised IIa open label clinical trial combining guadecitabine (SGI-110) with cisplatin and gemcitabine chemotherapy for solid malignancies including bladder cancer. *First Author: Simon J. Crabb, Southampton Experimental Cancer Medicine Centre, Southampton, United Kingdom*

Background: Cisplatin based chemotherapy is a standard of care therapy for urothelial bladder cancer for palliative first line treatment of advanced/metastatic disease or radical neoadjuvant treatment of localized muscle invasive disease. However, cisplatin resistance, associated with disease progression or relapse, is common and remains a critical barrier to therapeutic advance. Pre-clinical data suggest cisplatin resistance in bladder cancer, and other cancers, might be avoided by co-administration of a DNA hypomethylating agent. **Methods:** SPIRE is a phase Ib/IIa trial evaluating whether the DNA methyltransferase inhibitor SGI-110 (guadecitabine), in combination with gemcitabine and cisplatin chemotherapy (GC), is safe and biologically effective. It incorporates a dose escalation phase in advanced/metastatic solid tumors, including bladder cancer, followed by a randomized dose expansion phase as neoadjuvant treatment prior to cystectomy for bladder cancer (T2-4a N0 M0). The primary objective is to determine a recommended phase II dose (RP2D) of SGI-110 in combination with GC, using pre-defined dose limiting toxicity criteria assessed by CTCAE v4.03, and a biologically effective dose based on serum DNA LINE-1 methylation and hemoglobin F re-expression status. Dose Escalation Phase: Treatment comprises GC (G 1000 mg/m^2, IVI, days 8 and 15; C 70 mg/m^2, IVI, day 8), and SGI-110 (SC, days 1-5), for up to 6 cycles of 21 days. Up to 6 patients are enrolled in each of up to 4 SGI-110 dose level cohorts utilizing a 'rolling 6' design. Dose Expansion Phase: 20 patients will be randomized 1:1 to GC, or GC + SGI-110 at the established RP2D, to expand safety and pharmacodynamic endpoint data. SPIRE is coordinated by the CRUK Southampton Clinical Trials Unit and is currently recruiting to a 3rd dose escalation cohort through the UK Experimental Cancer Medicine Centre (ECMC) network. It was developed through the CRUK Combinations Alliance. Funding: Cancer Research UK (C9317/A19903) and Astex Pharmaceuticals. Sponsor: University Hospital Southampton NHS Foundation Trust. Clinical trial information: ISRCTN16332228.

TPS4595 **Poster Session (Board #416b), Sat, 8:00 AM-11:30 AM**

PECULIAR: An open label, multicenter, single-arm, phase 2 study of neoadjuvant pembrolizumab (PEM) and epacadostat (EPA), preceding radical cystectomy (Cy), for patients (pts) with muscle-invasive urothelial bladder cancer (MIUBC). *First Author: Andrea Necchi, Istituto Nazionale dei Tumori, Milan, Italy*

Background: MIUBC is a systemic disease and > 40% of pts develop recurrence after Cy. Despite neoadjuvant chemotherapy yields Level 1 evidence, it is underutilized worldwide and a small survival improvement is deemed over Cy alone. PEM is an EMA and FDA-approved therapy for metastatic UC after platinum failure or for cisplatin-ineligible pts. EPA, an anti-IDO1 agent, combined with PEM, safely improved the response-rate in UC in phase 1 trial. Our hypothesis is that PEM+EPA, given neoadjuvantly, could further improve downstaging MIUBC. **Methods:** Pts with T2-T3b N0 UC with residual disease after transurethral resection of the bladder (TURB, surgical opinion, cystoscopy or radiological presence) will receive 3 cycles of PEM 200mg intravenously, q3 weekly. EPA will be orally taken at the dose of 100 mg BID, from d1 until 10 days before Cy. Cy should be performed within 3 weeks of the last PEM dose. Computed tomography (CT) scan, ^{18}FDG-PET/CT scan, and multiparametric bladder MRI (mpMRI) will be done during screening and before Cy to stage and evaluate response. After Cy, pts will be managed according to EAU guidelines. Adjuvant anti PD-1 therapy is not allowed. PD-L1 status will be assessed using Dako anti-PD-L1 antibody (clone 22C3), relying on the combined positivity score (CPS). Pathologic complete response (pT0) is the primary endpoint. All pts enrolled who receive at least 1 cycle of study drug will be included in the ITT analysis. The H_1 is pT0≥25% and H_0 pT0≤15%. A MinMax 2-stage design will be used to estimate the number of pts required. Out of 71 total pts, with the first stage of 43 pts, ≥6 pT0 will be required in the first stage, and ≥14 pT0 in the whole study population. Correlative research on blood samples will include immune-cell profiling and cytokine assessment. In tumor samples, genomic analyses will be done with FoundationONE test (Foundation Medicine Inc.). Tumor mutational burden (TMB) will be determined on 1.1 Mbp of sequenced DNA and reported as mutations (mut) per megabase (Mb) and microsatellite instability (MSI) will determined on 114 loci (EudraCT number 2017-002379-24). Clinical trial information: 2017-002379-24.

TPS4596 Poster Session (Board #417a), Sat, 8:00 AM-11:30 AM

P3BEP (ANZUP 1302): An international randomised phase 3 trial of accelerated versus standard BEP chemotherapy for adult and paediatric male and female patients with intermediate and poor-risk metastatic germ cell tumours (GCTs). *First Author: Peter S. Grimison, Chris O'Brien Lifehouse, Sydney, Australia*

Background: Bleomycin, etoposide, cisplatin (BEP) given 3-weekly x 4 remains standard 1st line chemotherapy for metastatic GCTs. Acceleration of standard regimen with shorter cycle lengths has improved cure rates in other cancers. This is the first international randomised clinical trial for intermediate and poor-risk metastatic extracranial GCTs involving both adult and paediatric age group males and females. We aim to determine if accelerated BEP is superior to standard BEP. **Methods:** DESIGN: Open label, randomised, stratified multicentre, 2 stage, phase 3 trial. Primary endpoint for stage I (n = 150) is complete response rate (RR), and for entire trial (n = 500) is progression free survival (PFS). SAMPLE SIZE: 150 and 500 patients gives > 80% power to detect a 20% improvement in RR and 7% absolute improvement in 2yr PFS, respectively. POPULATION: Males and females aged 11-45 years with intermediate or poor-risk metastatic GCTs of the testis, ovary, retroperitoneum or mediastinum for 1st line chemotherapy. TREATMENT: Randomisation 1:1 to 4 cycles of "standard BEP" or "accelerated BEP": cisplatin 20mg/m^2 IV D1-5; etoposide 100mg/m^2 IV D1-5; bleomycin 30000 IU IV weekly; and pegylated G-CSF SC D6 or Filgrastim daily; given every 3 weeks or every 2 weeks respectively. Accelerated BEP arm receives 4 additional weekly doses of bleomycin. ASSESSMENTS: Response assessments at 30 day safety assessment, and 6 months from randomisation or after all post-chemotherapy intervention is completed. Regular follow-up up to 5 years, then annually. Archival tumour tissue and baseline blood collected for translational substudies. STATUS: 25 sites open in ANZ, 4/21 sites open in UK (led by Cambridge Clinical Trials Unit), 46 patients recruited by February 2018. International collaboration with USA (led by Children's Oncology Group) is confirmed with sites expected to open by mid2018 and more sites sought for stage 2. Clinical trial information: NCT02582697.

TPS4597 Poster Session (Board #417b), Sat, 8:00 AM-11:30 AM

PROSPER: A phase III randomized study comparing perioperative nivolumab (nivo) vs. observation in patients with localized renal cell carcinoma (RCC) undergoing nephrectomy (ECOG-ACRIN 8143). *First Author: Lauren Christine Harshman, Dana-Farber Cancer Institute, Boston, MA*

Background: As of 2018, there is no standard adjuvant systemic therapy that increases overall survival (OS) over surgery alone for patients with non-metastatic RCC. Nivolumab (nivo), an antibody against PD-1, improves overall survival in metastatic RCC and is well tolerated. Mouse solid tumor models have revealed an OS benefit to a short course of PD-1 blockade when given neoadjuvantly compared to adjuvantly. Two ongoing phase 2 studies of perioperative nivo in M0 RCC patients are showing preliminary feasibility and safety with no surgical delays (NCT02575222; NCT02595918). The PROSPER RCC trial will examine if administering perioperative nivo with radical or partial nephrectomy can increase cures, time to recurrence and survival in patients with high risk localized and locally advanced RCC. **Methods:** This global, unlinded, phase 3 National Clinical Trials Network study is accruing patients with clinical stage ≥T2 or node positive M0 RCC of any histology. Tumor biopsy prior to randomization is mandatory to ensure RCC and will also permit unparalleled correlative science. The investigational arm will receive two doses of nivo prior to surgery followed by adjuvant nivo for 9 months (q2 wks x 3 mo followed by q4 wks x 6 mo). The control arm will receive standard of care surgical resection followed by observation. Randomization will be stratified by clinical T stage, node positivity, and histology. With 766 patients, there is 84.2% power to detect a 14% absolute benefit in recurrence-free survival (RFS) at 5 years assuming the ASSURE historical control of ~56% to 70% (HR = 0.70). The study is also powered to evaluate a significant increase in overall survival (HR 0.67). Safety, feasibility, and quality of life endpoints critical to adjuvant therapy considerations will be evaluated. PROSPER RCC exemplifies team science with a wealth of embedded correlative work aimed at investigating the impact of the baseline immune milieu, the changes induced by neoadjuvant anti-PD-1 priming, and how both correlate with clinical outcomes. Clinical trial information: NCT03055013.

TPS4598 Poster Session (Board #418a), Sat, 8:00 AM-11:30 AM

A phase 3, randomized, open-label study of nivolumab combined with cabozantinib vs sunitinib in patients with previously untreated advanced or metastatic renal cell carcinoma (RCC; CheckMate 9ER). *First Author: Toni K. Choueiri, Dana-Farber Cancer Institute, Boston, MA*

Background: Over the past decade, treatment options for advanced RCC have evolved to include multiple agents targeting the vascular endothelial growth factor (VEGF) pathway. In addition, the recent innovation of treating cancer with immunotherapy has further expanded the therapeutic armamentarium. Biomarker studies suggest that promotion of an immune suppressive tumor microenvironment can contribute to anti-VEGF therapy resistance and point to a rationale for combining anti-VEGF therapy with immunotherapy. Cabozantinib, a tyrosine kinase inhibitor with targets including VEGF receptor, MET and the TAM receptor family has shown immunomodulatory properties suggestive of synergistic effects with immune checkpoint inhibitors. Indeed, in a recent phase 1 study, combination of the programmed death-1 (PD-1) inhibitor nivolumab with cabozantinib showed encouraging antitumor activity in pretreated patients with metastatic RCC and other advanced genitourinary tumors (Nadal et al. ASCO GU 2018). This phase 3 study will assess nivolumab plus cabozantinib vs sunitinib in previously untreated patients with advanced or metastatic RCC (NCT03141177). **Methods:** Key inclusion criteria: Measurable disease with a clear-cell component, no prior systemic therapy for RCC, evaluable tumor biopsy, and age ≥18 years. Key exclusion criteria: Active CNS metastases and autoimmune disease. Patients will be randomized 1:1 to either nivolumab plus cabozantinib or sunitinib. Treatment will continue until disease progression or unacceptable toxicity (maximum nivolumab treatment of 2 years). Stratification factors: International Metastatic RCC Database Consortium (IMDC) risk score, PD-1 ligand 1 (PD-L1) tumor expression, and geographic region. Primary endpoint: Progression-free survival by blinded independent central review (BICR) in all randomized patients; secondary endpoints: Overall survival and objective response rate by BICR in all randomized patients, and safety/tolerability in all treated patients. Enrollment began August 2017 with a target of 580 randomized patients. Clinical trial information: NCT03141177.

TPS4599 Poster Session (Board #418b), Sat, 8:00 AM-11:30 AM

KEYNOTE-564: A phase 3, randomized, double blind, trial of pembrolizumab in the adjuvant treatment of renal cell carcinoma. *First Author: Toni K. Choueiri, Dana-Farber Cancer Institute, Boston, MA*

Background: The typical management for renal cell carcinoma (RCC) is nephrectomy. Despite this, patients with intermediate- to high-risk advanced disease can experience relapse with metastatic, usually incurable, disease. Adjuvant therapies are needed for patients at risk for recurrence after nephrectomy. Upregulation of the programmed death 1 (PD-1) pathway is associated with poor prognosis in RCC, and drugs to target the PD-1 pathway have shown efficacy and reasonable safety in metastatic RCC. Therefore, the PD-1 pathway may represent a novel target to prevent disease recurrence. The randomized, double-blind, placebo-controlled phase 3 KEYNOTE-564 trial (NCT03142334) is designed to evaluate the efficacy and safety of pembrolizumab in the adjuvant treatment of RCC after nephrectomy. **Methods:** Key inclusion criteria include age ≥18 years, histologically confirmed clear cell RCC of intermediate-high risk (pT2, grade 4 or sarcomatoid, N0 M0; or pT3, any grade, N0 M0), high risk (pT4, any grade, N0 M0; or pT any stage, any grade, N+ M0), or M1 NED; no prior systemic therapy for advanced RCC; negative surgical margins; Eastern Cooperative Oncology Group (ECOG) performance status 0 or 1; and tumor sample available for biomarker analyses. Patients will be randomly assigned 1:1 to receive pembrolizumab 200 mg or placebo every 3 weeks by intravenous infusion. Treatment will continue until disease recurrence, treatment discontinuation, or the completion of 17 cycles. Imaging will be performed every 12 weeks. The primary end point is disease-free survival (DFS) per investigator assessment. The secondary end point is overall survival (OS). Additional secondary analyses include safety and tolerability, pharmacokinetic parameters, antidrug antibodies, and DFS and OS per PD-L1 expression status. Biomarkers that may be associated with response will be evaluated as an exploratory objective. Recruitment will continue until ~950 patients are enrolled. Clinical trial information: NCT03142334.

TPS4600 **Poster Session (Board #419a), Sat, 8:00 AM-11:30 AM**

Optimized management of nivolumab (NIVO) and ipilimumab (IPI) in advanced renal cell carcinoma (OMNIVORE): A response-based phase II study. *First Author: Xiao X. Wei, Dana-Farber Cancer Institute, Boston, MA*

Background: CheckMate 025 established NIVO as a standard of care (SOC) option for advanced clear cell RCC (ccRCC) after prior antiangiogenic therapy. The combination of IPI plus NIVO is anticipated to become a new SOC option for intermediate/poor risk patients (pts) with treatment-naïve advanced ccRCC based on CheckMate 214. Outstanding questions include optimal treatment duration in responders, ability of IPI to convert NIVO non-responders to responders, activity of these agents in non-clear cell RCC (nccRCC), and discovery of predictive biomarkers. **Methods:** This phase II, open-label, non-randomized trial enrolls treatment-naïve or previously treated pts with advanced ccRCC or nccRCC (NCT03203473). Pts previously treated with immune checkpoint inhibitor(s) are excluded. All pts start NIVO alone and subsequent management is based on RECIST response within the first 6 months of NIVO. Pts with confirmed partial response (PR) or complete response (CR) discontinue NIVO and are observed. At progression, NIVO is reinitiated, and if further progression, 2 doses of IPI are added to NIVO (Arm A). Pts with stable disease (SD) or progressive disease (PD) on initial NIVO will receive 2 doses of IPI with NIVO continuation until PD (Arm B). NIVO monotherapy dose is 240mg Q2W, and 3mg/kg Q3W when given with IPI. IPI dose is 1mg/kg Q3W. The co-primary endpoints are proportion of pts with durable CR/PR at 1-year (yr) after NIVO discontinuation (Arm A) and proportion of pts with SD or PD on NIVO alone who convert to PR/CR at 1-yr after adding IPI to NIVO (Arm B). Enrollment of 17 pts is planned for Arm A to achieve 90% power to assess a true 1-yr PR/CR rate of $\geq$35% vs a null PR/CR rate of 10%. Enrollment of 41 pts is planned for Arm B to achieve 90% power to assess a true 1-yr conversion rate of 20% vs a null conversion rate of 5%. Fresh tumor biopsy is required at baseline and optional at progression time points. Correlative studies are tightly integrated including circulating immune cells, cytokines/chemokines, circulating tumor cells, cfDNA, tumor immunohistochemistry, bulk genomic profiling, and bulk and single-cell transcriptomic analysis. As of February 2018, 18 of planned 58 patients have been accrued. Clinical trial information: NCT03203473.

TPS4601 **Poster Session (Board #419b), Sat, 8:00 AM-11:30 AM**

CANTATA: A randomized phase 2 study of CB-839 in combination with cabozantinib vs. placebo with cabozantinib in patients with advanced/metastatic renal cell carcinoma. *First Author: Nizar M. Tannir, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Glutamine utilization is a metabolic pathway upregulated in renal cell carcinoma (RCC) and important for RCC tumor cell proliferation and survival. CB-839 is a first-in-class, potent, oral inhibitor of the mitochondrial enzyme glutaminase (GLS) that controls a critical step in tumor cell utilization of glutamine. In preclinical RCC models, CB-839 demonstrated synergistic anti-tumor activity when combined with cabozantinib, a VEGFR/MET inhibitor. A phase 1 study cohort of CB-839 plus cabozantinib as 2L+ therapy showed encouraging safety and efficacy results, with 40% overall response rate (ORR; RECIST v1.1) and 100% disease control rate in patients with clear cell advanced/metastatic RCC (mRCC). These findings prompted the initiation of a randomized phase 2 study comparing CB-839 plus cabozantinib vs. placebo plus cabozantinib in patients with clear cell mRCC. **Methods:** This international, randomized, double-blind, placebo-controlled, multi-center study (NCT03428217) will enroll ~300 patients with clear cell mRCC. Eligible patients will have received 1-2 prior lines of systemic therapy for mRCC including $\geq$1 anti-angiogenic therapy or the combination of nivolumab + ipilimumab. Other eligibility criteria include KPS $\geq$70%, measurable disease (RECIST v1.1), and no prior cabozantinib (or other MET inhibitor). Patients will be randomized 1:1 to receive CB-839 (800 mg twice daily per oral [PO] route) or placebo in combination with cabozantinib (60 mg daily PO) in 28-day cycles until disease progression or unacceptable toxicity. Patients will be stratified by prior PD-1/PD-L1 inhibitor therapy (Y/N) and IMDC prognostic risk group (favorable vs intermediate vs poor). The primary endpoint is progression-free survival (PFS; RECIST v1.1) by blinded independent radiology review; secondary endpoints are investigator-assessed PFS and overall survival. Safety, disease responses per RECIST, and quality of life will also be assessed. This important study will contribute to understanding the efficacy and safety profile of CB-839, a first-in-class metabolic inhibitor, in combination with cabozantinib in patients with mRCC. Clinical trial information: NCT03428217.

TPS4602 **Poster Session (Board #420a), Sat, 8:00 AM-11:30 AM**

NIVES study: A phase II trial of nivolumab (NIVO) plus stereotactic body radiotherapy (SBRT) in II and III line of patients (pts) with metastatic renal cell carcinoma (mRCC). *First Author: Cristina Masini, Medical Oncology Unit, Clinical Cancer Center, AUSL-IRCCS Reggio Emilia, Reggio Emilia, Italy*

Background: Despite recent advances in drug therapy, pts with mRCC have about a 10% 5-year survival rate. Several preclinical studies have documented an increase in peripheral antitumour immunity following radiation, a phenomenon known as the abscopal effect. NIVO is an anti-programmed cell death-1 (PD-1) monoclonal antibody that blocks tumour growth in different ways by targeting certain cells. It might work even better when combined with SBRT. The irradiated tumour cell death can enhance antitumor immunity by inducing antigen expression on tumour cells and activating lymphocytes. The aim of the study is to evaluate whether the antitumour immunity of NIVO can be enhanced by SBRT. **Methods:** This is an ongoing phase II, single arm, multicentre study in pts with mRCC with progression disease after $\leq$ 2 prior anti-angiogenic therapies and with 2 or more measurable non-brain metastatic sites, at least one of which potentially suitable for treatment with SBRT. All pts will receive hypofractionated radiation at a lesion at a dose and schedule of 10 Gy/3 fractions respectively after 7 days from the first infusion of NIVO. NIVO will be given as flat dose of 240 mg in intravenous infusion beginning on day 1 every 14 days for 6 months, then switch to 480 mg q4-weekly in responding (CR, PR, SD) pts until PD or unacceptable toxicity. The primary objective is to evaluate the activity of this combination in terms of Objective Response Rate (ORR), the best response recorded on the ITT population according to RECIST v1.1. Our hypothesis is that treatment with NIVO plus SBRT compared to NIVO monotherapy can increase the ORR from 25% to 40%. Secondary endpoints are progression free survival (PFS), overall survival (OS), ORR of irradiated and non-irradiated metastases, duration of response and safety profile. An Exploratory Project also identifies molecular basis of synergistic effect of SBRT and immunotherapy, potential mechanisms of resistance to checkpoint inhibitors. Twenty of the planned 68 pts were enrolled from July 2017 to January 2018. Study duration will be 12 months for the accrual and 36 months for the follow-up. Clinical trial information: EudraCT Num 2016-003032-20.

TPS4603 **Poster Session (Board #420b), Sat, 8:00 AM-11:30 AM**

CABOPRE: Phase II study of cabozantinib prior to cytoreductive nephrectomy (CN) in locally advanced and/or metastatic renal cell carcinoma (mRCC). *First Author: Guillermo de Velasco, Department of Medical Oncology, University Hospital 12 de Octubre, i+12, Madrid, Spain., Madrid, Spain*

Background: Cabozantinib is a small molecule tyrosine kinase inhibitor (TKI) of VEGFR2, MET and AXL that has shown a statistically significant improvement for mRCC patients in all three endpoints of clinical efficacy (objective response rate [ORR], progression free survival [PFS], and overall survival [OS]) in a phase III randomized trial compared to everolimus, as well as a significant clinical benefit in PFS and ORR over sunitinib as first-line therapy in patients with IMDC intermediate- or poor-risk. Although no robust evidence is available, CN remains as the standard of care in patients who will be treated with VEGF TKI. CABOPRE is a multicenter, non-randomized, uncontrolled phase II trial that evaluates the efficacy and safety of cabozantinib as perioperative therapy in patients with advanced RCC who are candidates for CN. **Methods:** Eligible patients are aged $\geq$ 18 years, mRCC with a component of clear cell, suitable for CN with acceptable risk for surgery, PS 0-1, no prior systemic therapy. Cabozantinib 60mg PO QD is administered for 12 weeks before CN (cabozantinib is stopped at least 72 hours before CN). A 14-day treatment break is required after surgery and then cabozantinib is continued until progression disease or toxicity. The primary endpoint is ORR by RECIST 1.1 at 12 weeks after initiation of therapy. Secondary endpoints include PFS at 12 months and OS. Based on Simon two-stage minimax design (p0 = 0.25, p1 = 0.45, alpha = 0.05, power = 90%) up to 50 patients will be recruited consecutively. Tumor biopsies and peripheral blood will be collected to assess changes in tumor microenvironment at 3 different time points: 1) at baseline, prior to initiation of cabozantinib, 2) before cytoreductive nephrectomy 3) at disease progression. Biomarkers study will include, but not limited to the expression of c-MET and AXL in exosomes derived from tumor cells.

TPS4604 Poster Session (Board #421a), Sat, 8:00 AM-11:30 AM

A phase 2, single-arm trial of neoadjuvant axitinb plus avelumab in patients (pts) with localized renal cell carcinoma (RCC) who are at high risk of relapse after nephrectomy (NeoAvAx). *First Author: Axel Bex, The Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Surgery is the standard treatment for non-metastatic RCC. Despite curative intent, pts with a high risk of relapse have a 5-year metastasis-free survival rate of only 30 % and prevention of recurrence is an unmet need. In a phase 1b study (JAVELIN Renal 100), the axitinib + avelumab response rates (RR) and safety profile were promising with objective RR of 60 % and toxicity profiles as seen with VEGFR-treatment. The combination is currently being tested in a phase III trial against sunitinib in untreated metastatic RCC. We initiated a neoadjuvant study of axitinib + avelumab in pts with high-risk of relapse (NCT03341845). **Methods:** The study is designed as a open label, single arm, phase 2 trial with a Simon's two-stage design evaluating neoadjuvant axitinib + avelumab followed by complete surgical resection in 40 pts with high-risk non-metastatic clear-cell (cc) RCC. Key inclusion criteria are planned radical or partial nephrectomy with curative intent; biopsy proven ccRCC; clinical high risk defined as cT1b-cT2a grade (G) 4, cT2b G3, cT3a G 3-4, cT3b-cT4 any G cN0 cM0, or cT any cN1 cM0; World Health Organization (WHO) performance status of 0-1, and completely resectable primary tumours. Key exclusion criteria are metastatic disease, corticosteroid or immunosuppressive systemic treatment, active autoimmune disease, prior systemic treatment for RCC including immunotherapy, biologic therapy, investigational therapy or hormonal therapy. Pts receive axitinib 5 mg BID escalated to 10 mg BID if tolerated and avelumab 10 mg/kg iv Q2W for 6 cycles following H1 blockers and acetaminophen every 2 weeks . Pts with a tumour increase from baseline at CT after the first 6 weeks or no change after dose escalation will be taken off trial and undergo surgery. All others will complete 3 months followed by resection. Primary endpoint (ept): Partial RR (RECIST 1.1) following neoadjuvant therapy. Secondary epts: DFS, OS, rate of recurrence, safety, and tolerability. Exploratory epts include investigation of effects on neoangiogenesis, immune infiltrates and MDSC components to support a rationale for the combined use of axitinib and avelumab. Clinical trial information: NCT03341845.

TPS4605 Poster Session (Board #421b), Sat, 8:00 AM-11:30 AM

Vorolanib (CM082), everolimus, and the combination in patients with pretreated metastatic renal cell carcinoma (CONCEPT study): A randomized, phase 2/3, double-blind, multi-center trial. *First Author: Jun Guo, Peking University Cancer Hospital and Institute, Beijing, China*

Background: VEGF and mTOR pathways play key role in the development of renal cell carcinoma (RCC), the combination of agents targeting both VEGF- and mTOR-mediated pathways have been investigated with distinct results. Vorolanib (CM082) is a potent and selective inhibitor of VEGFR and PDGFR. Previous phase 1 study (NCT02577458) found that the combination of vorolanib 200 mg plus everolimus 5mg was associated with manageable toxicity consistent with individual agents and no new safety signals, antitumor activities was also seen in 35.7% patients with RCC patients who progressed on at least one VEGFR TKI therapy. Based on these findings, we conducted the CONCEPT study, a randomized, phase 2/3, double-bind, multicenter trial to assess vorolanib, everolimus, or their combination as second-line treatment in Chinese patients with metastatic RCC. **Methods:** Patients with cytologically or histologically confirmed RCC who had disease progression after one prior VEGFR TKI were eligible for participation in the study. They will be randomized by 1:1:1 ratio to receive matching placebo plus vorolanib or everolimus, or the combination. Randomization was stratified according to the MSKCC risk scores. The sample size was specified assuming a hazard ratio (HR) of 0.60, equating to an expected 6.5 months for everolimus and 10.5 months for vorolanib with or without everolimus. To provide 80% power at a two-sided 5% significance level, and an estimated 20% dropout rate, a total of 390 patients are required. This study is registered as NCT03095040. Progression: This study in conducted in 35 centers in China, so far 32 centers have been activated. Recruitment was started since March 10, 2017, and a total of 101 patients were randomized currently. Clinical trial information: NCT03095040.

5000 **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

A randomized phase III trial between adjuvant docetaxel and surveillance after radical radiotherapy for intermediate and high risk prostate cancer: Results of SPCG-13 trial. *First Author: Pirkko-Liisa Irmeli Kellokumpu-Lehtinen, Department of Oncology, Tampere University Hospital, Tampere, Finland*

Background: Docetaxel combined with androgen deprivation therapy (ADT) has improved survival in advanced prostate cancer (PCa). This randomized trial evaluates if six courses of docetaxel improves biochemical disease free survival (BDFS) after radical radiotherapy (RT) for intermediate or high risk PCa. **Methods:** : A total of 376 patients were randomised in this multinational phase III study, to receive either 6 cycles of adjuvant docetaxel 75mg/m^2 every 3 weeks without continuous prednisone (Arm A, n = 188) or surveillance (Arm B, n = 188) after RT (NTC006653848). Neoadjuvant/adjuvant ADT was mandatory for all patients. Primary end-point was a rising PSA $\geq$ 2 ng/ml above the nadir PSA value. Intermediate or high risk prostate cancer was defined as T2 with Gleason score (GS) 4+3, PSA $>$ 10; T2, GS 8-10 any PSA; or any T3. Patients were followed for 5 years with PSA every 3 months for two years and thereafter every 6 month. Study power was 89% to detect a difference between groups and the sample size calculation accounted for T2/T3 distribution (12%/15% difference in BDFS was assumed for T2/T3 patients). **Results:** All six cycles were completed in 147 (78.2%) of patients in arm A. Mean age was 66.2 years in Arm A and 66.4 years in ARM B; 75.0 % had T3 disease, 46.3% had GS 8-10. Median follow up was 59.4 months (range 1 to 111 months, one without follow-up). The primary endpoint was reached in 30.7% of patients; 31.0% in Arm A and 30.3% in Arm B. In a Kaplan-Meier analysis there showed no difference between the BDFS curves (p = 0.631) between treatment groups. Febrile neutropenia occurred in 16.1 % of docetaxel patients. No deaths were related to docetaxel treatment. There were 43 deaths during the trial (20 in Arm A and 23 in Arm B) of which 9 and 7 due to PrCa. In a Cox multivariate analysis, GS (p = 0.001) was significant predictor of PSA progression. Hazard Ratio for Arm A (docetaxel) vs Arm B (surveillance) was 1.14 (95% CI 0.79 to 1.64, p = 0.495). **Conclusions:** Adjuvant docetaxel without prednisone did not improve BDFS after radical radiotherapy with ADT for intermediate or high risk prostate cancer. Clinical trial information: NTC006653848.

5001 **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

Accuracy of ^{68}Ga-PSMA11 PET/CT on recurrent prostate cancer: Preliminary results from a phase 2/3 prospective trial. *First Author: Wolfgang Fendler, Department of Molecular and Medical Pharmacology, David Geffen School of Medicine at UCLA, Munich, CA*

Background: ^{68}Ga-PSMA11 PET/CT provides improved localization of biochemically recurrent prostate cancer. For approval and reimbursement, accuracy needs to be established in a prospective study employing independent lesion validation. **Methods:** In this phase 2/3 prospective trial (NCT02940262), patients with biochemically recurrent prostate cancer after primary prostatectomy (n = 205) or radiation therapy (n = 45) underwent ^{68}Ga-PSMA11 PET/CT. Presence of prostate cancer was recorded on a patient and region base. Regions were prostate bed, pelvis, extra-pelvic, and bone. Lesions were validated in 51% of PET/CT-positive patients by histopathology (n = 33), imaging (n = 62) and/or PSA after targeted radiation therapy (n = 9 patients). PSA response after ^{68}Ga-PSMA11 PET/CT guided focal salvage therapy (surgery/radiotherapy) was recorded in 23 of 25 patients (8% drop out). Endpoints were positive predictive value (PPV), detection rate and outcome. **Results:** PPV validated by histopathology was 85% on a patient base (primary endpoint). PPV as determined by any type of validation was 89% on a patient and 91% on a region base. ^{68}Ga-PSMA11 PET/CT localized recurrent prostate cancer in 197 of 250 (79%) patients; stratified by PSA: 41% for $<$ 0.5 ng/ml (n = 54), 66% for 0.5 to $<$ 1.0 ng/ml (n = 38), 86% for 1.0 to $<$ 2.0 ng/ml (n = 36), 96% for 2.0 to $<$ 5.0 ng/ml (n = 55), and 99% for $\geq$5.0 ng/ml (n = 67). Lesion location was in 35% prostate bed, 61% pelvis, 35% extra-pelvic, and 31% bone. Following focal salvage therapy alone, 18 (78%) patients had a PSA drop of 50% or more, 7 (30%) patients had biochemical complete response (PSA undetectable). **Conclusions:** Using an independent reference standard, we establish high ^{68}Ga-PSMA11 PET/CT PPV for localization of recurrent prostate cancer. PET/CT guided salvage therapy resulted in high biochemical response rates. Pooled multicenter findings will be submitted for a New Drug Application. Clinical trial information: NCT02940262.

5002 **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

A randomized study of finite abiraterone acetate (AA) plus leuprolide (LHRHa) versus LHRHa in biochemically recurrent non metastatic hormone naïve prostate cancer (M0HNPC). *First Author: Eleni Efstathiou, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Intermittent Androgen Deprivation (ADT) is an acceptable treatment option in M0HNPC with no significant survival difference and improved quality of life versus (vs) continuous. AA improves survival in metastatic HNPC. We hypothesize that AA added to intermittent ADT will improve outcome without delaying testosterone (T) recovery. **Methods:** Patients (Pts) with PSA recurrent, after definitive local treatment, M0HNPC were randomized 1:1 to 8 month AA(1g/qd)+ prednisone (5mg /qd)+LHRHa vs LHRHa. Pts were eligible to cross over upon progression We primarily studied difference in PSA free survival. Secondary endpoints included time to T recovery, safety and associations with clinical/tumor characteristics. Sample size had 93% power to detect 1 year post treatment PSA free survival difference of 20 %. Stratification factors were radical prostatectomy (RPS) vs radiation (EBRT), PSA $\geq$ vs $<$ 10, time to recurrence $\geq$ vs $<$ 3yrs. Rising PSA of 0.2 confirmed by subsequent $>$ 0.2 required after RPS and nadir PSA +2 for prior EBRT. **Results:** 197 of 200 randomized pts were treated (99 AA+LHRHa /98 LHRHa). Median age was 65 (range 42- 85), Performance Status 0, PSA 1 (0.3-33.3 ng/ml), T 346 (160-946 ng/dL). 186 (94%) had undergone RPS. 128 (65 %) had PSA relapse by Jan/18. Pts on 8 month AA+LHRHa had median PSA free survival 28.3 months (range 24.2—35.4) vs 21.1 (19.1-27.2) for LHRHa pts. (HR 0.62; 95 % Confidence Interval 0.44-0.88; p 0.007). Median time to T recovery for AA+LHRHa was 13.1 ms vs 12.9 for LHRHa. AA+LHRHa treatment outcome was favorable regardless of pre-treatment PSA, Gleason Score, pathology, time to relapse from treatment, definitive treatment type, including if RPS +EBRT (57%). No Grade 4 adverse events (AE) or new safety concerns reported. Grade 3 AEs: arterial hypertension 6 (5 AA+LHRHa arm), liver function test elevation 4 (AA+LHRHa arm). Most common AEs were Grade 1 hot flashes (71%) and fatigue (51%) with no difference between arms. **Conclusions:** Findings support that 8 month treatment with Abiraterone Acetate plus LHRHa in M0HNPC improves PSA free survival compared to LHRHa without delay in testosterone recovery or significant safety concerns. Clinical trial information: NCT01786265.

5003 **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

Olaparib combined with abiraterone in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC): A randomized phase II trial. *First Author: Noel Clarke, The Christie and Salford Royal NHS Foundation Trusts, Manchester, United Kingdom*

Background: mCRPC pts with a homologous recombination repair mutation (HRRm) previously showed improved response to the PARP inhibitor olaparib (Lynparza) as monotherapy vs pts without a HRRm (Mateo J *et al*, *NEJM* 2015). We report data from a Phase II, placebo-controlled trial of olaparib combined with the anti-hormonal therapy abiraterone in post-chemotherapy mCRPC pts whose tumors did not need to have a HRRm (NCT01972217). **Methods:** mCRPC pts were randomized (1:1) post-docetaxel to olaparib 300 mg bid (tablets; combination) or placebo (comparator) plus abiraterone (1000 mg od) and treated until disease progression. Primary endpoint was investigator-assessed radiologic progression-free survival (rPFS; RECIST 1.1, PCWG-2). HRRm status was assessed using optional tumor (n = 68), whole-blood and plasma samples. **Results:** 142 pts (median age: 69 yrs) were randomized and treated (both arms, n = 71). Overall, a statistically significant increase in rPFS was seen with the combination vs comparator (Table; *P*= 0.03). A rPFS benefit in the combination arm was suggested irrespective of HRRm status. Median overall survival was 23.3 vs 20.9 mths in the combination vs comparator arms, respectively (HR 0.89, 95% CI 0.581.35). 54% vs 28% of pts, respectively, had grade $\geq$3 AEs; 34% vs 18% reported serious AEs, including more cardiovascular AEs with the combination. 30% vs 10% of pts, respectively, discontinued treatment due to an AE. Median time to deterioration in quality of life (QoL; FACT-P) was 5.7 vs 6.0 mths, respectively (HR 0.97, 95% CI 0.681.40). **Conclusions:** This is the first trial to show clinical benefit for mCRPC pts treated with a PARP inhibitor combined with abiraterone, regardless of HRRm status. Safety data were less favorable for the combination, but no detriment to QoL was seen. Our study indicates synergy between olaparib and abiraterone. Clinical trial information: NCT01972217.

rPFS by HRRm status.

Pt group	Median rPFS,* mths (combination vs comparator)	HR (95% CI)
Overall, n = 142	13.8 vs 8.2	0.65 (0.44–0.97)
HRRm, n = 21	17.8 vs 6.5	0.74 (0.26–2.12)
HRRwt,† n = 35	15.0 vs 9.7	0.52 (0.24–1.15)
HRRm unknown, n = 86	13.1 vs 6.4	0.67 (0.40–1.13)

*Kaplan-Meier method; †tumor test result required. wt, wild-type.

5004 **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

The PROPHECY trial: Multicenter prospective trial of circulating tumor cell (CTC) AR-V7 detection in men with mCRPC receiving abiraterone (A) or enzalutamide (E). *First Author: Andrew J. Armstrong, Duke Cancer Institute, Duke University, Durham, NC*

Background: It is unclear if CTC AR-V7 detection is a valid predictive biomarker of clinical efficacy in men with mCRPC receiving A/E or just an indicator of aggressive disease and high tumor burden. **Methods:** We conducted a multicenter prospective study of circulating biomarkers in men with high-risk mCRPC (PROPHECY, NCT02269982) starting A/E. The primary endpoint was association of baseline AR-V7 with radiographic/clinical progression free survival (PFS), using the Johns Hopkins modified-AdnaTest CTC AR-V7 mRNA assay and the Epic Sciences CTC nuclear AR-V7 protein assay. Overall survival (OS) and PSA decline were key secondary endpoints. **Results:** We enrolled 118 men with mCRPC starting A/E; 52% had ≥5 Cellsearch CTCs, 36% had prior A/E. On study therapy was A (n = 56), E (n = 59) or both A/E (n = 3). AR-V7 detection by the JHU AR-V7 assay and the Epic AR-V7 assay were independently associated with worse PFS and OS after adjusting for CTC count and established clinical factors (see below table). Concordance between the two AR-V7 assays was 82%. Epic AR-V7 (+) men had more CTC phenotypic heterogeneity: 63% had Shannon Index > 1.5 vs 14% of AR-V7 (-) men; most CTCs in Epic AR-V7 (+) men were AR-V7 (-). We found genetic alterations of aggressive mCRPC in AR-V7 (+) and AR-V7 (-) men including gain of AR, MYCN, and MYC and loss of PTEN, TP53, and DNA repair enzymes in CTCs and ctDNA. **Conclusions:** We validate AR-V7 detection as an independent CTC-adjusted negative predictive biomarker of short PFS and OS with A/E treatment in men with mCRPC, identify CTC heterogeneity of AR-V7 expression, and highlight the importance of non-AR-V7 drivers of aggressive disease. Clinical trial information: NCT02269982.

Outcome	AR-V7 (JHU n = 116) (+) n = 28 (24%) / (-) n = 88 (66%)	AR-V7 (Epic n = 105) (+) n = 11 (10%) / (-) n = 94 (90%)
Median PFS (mo)	3.1 / 7.3	3.1 / 6.0
p-value	0.0003	0.007
HR* (95% CI)	2.4 (1.6-3.8)	2.4 (1.3-4.6)
HR^(95% CI)	2.4 (1.4-3.9)	2.2 (1.0-4.9)
Median OS (mo)	11.5 / 25.5	8.4 / 25.5
HR*(95% CI)	3.9 (2.1- 7.3)	4.5 (2.1-9.8)
HR^ (95% CI	4.6 (2.3-9.2)	3.6 (1.5-8.6)

LBA5005 **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

Overall survival between African-American (AA) and Caucasian (C) men with metastatic castration-resistant prostate cancer (mCRPC). *First Author: Susan Halabi, Duke University Medical Center, Durham, NC*

The full, final text of this abstract will be available at abstracts.asco.org at 2:00 p.m. ET on Friday, June 1, 2018, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2018, issue of the *Journal of Clinical Oncology*. On-site at the Meeting, this abstract will be printed in the Monday edition of *ASCO Daily News*.

5006 **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

Results of PROSPECT: A randomized phase 3 trial of PROSTVAC-V/F (PRO) in men with asymptomatic or minimally symptomatic metastatic, castration-resistant prostate cancer. *First Author: James L. Gulley, Genitourinary Malignancies Branch, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: PRO is a PSA-targeted, poxvirus-based cancer vaccine using a heterologous prime-boost regimen comprising a recombinant vaccinia vector prime followed by 6 booster doses with the recombinant fowlpox vector. PROSPECT was designed as a confirmatory trial of a prior randomized phase 2 trial (RandPh2) that showed 8.5 months prolongation of median OS (25.1 m PRO vs 16.6 m Placebo (Pbo)) (Kantoff, JCO 2010; 28:1099) **Methods:** Double-blind randomization to one of the following 3 arms: PRO+Pbo (V), PRO+GM-CSF (VG), or Pbo+Pbo (P). Stratified per PSA < or ≥ 50 ng/mL and LDH < or ≥ 200 U/L. Primary Endpoint: OS. Secondary endpoints: Alive without event at 6 months (AWE-6) and Safety. **Results:** Between Dec 2011 and Jan 2015, 1297 pts were randomized in 15 countries. Demographics: mean age: 71 (SD: 8.25), ECOG PS0/1-2: 74%/26%, mean PSA: 74.5 (SD:209). Site of metastasis: bone 74.7, lymph node 15.7, visceral 8.4%. The 3rd interim analysis was held in Sep 2017, after reaching 80% of the expected deaths, and the DMC recommended closure of the study on grounds of futility. The K-M OS curves showed a substantial overlap between the 3 arms and the planned statistical analysis showed statistically non-significant differences. Median OS was 34.8, 33.9 and 34.7 months for V, VG and P arms respectively. Two comparisons were prespecified: V vs P and VG vs P, and the HR were 1.02 (p = 0.40) and 1.03 (p = 0.66) respectively. No benefit was seen in the secondary endpoint AWE6. Although 91% of patients experienced AEs of any grade, and 65% experienced injection site reactions, only 5.8% lead to premature discontinuation of treatment. **Conclusions:** PROSPECT failed to confirm an OS benefit observed in a prior RandPh2. Of interest, OS observed in all arms was approximately one year longer than anticipated based upon historical controls, likely related to improved standard of care since study enrollment began in 2011. Clinical trial information: NCT01322490.

5007 **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

KEYNOTE-199: Pembrolizumab (pembro) for docetaxel-refractory metastatic castration-resistant prostate cancer (mCRPC). *First Author: Johann S. De Bono, Royal Marsden Hospital, London, United Kingdom*

Background: Efficacy of PD-1 inhibition has not been demonstrated in large-scale mCRPC trials. Pembro showed preliminary antitumor activity in PD-L1+ mCRPC in KEYNOTE-028 (n = 23). Here, we present results from cohorts 1-3 (n = 258) of the phase 2 KEYNOTE-199 study of pembro monotherapy in docetaxel-refractory mCRPC (NCT02787005). **Methods:** Cohorts 1 (C1) and 2 (C2) enrolled patients (pts) with RECIST-measurable PD-L1+ and PD-L1– disease, respectively. C3 enrolled pts with nonmeasurable, bone-predominant disease. All pts had ECOG PS 0-2 and received ≥1 novel endocrine therapy (eg, abiraterone, enzalutamide) and 1-2 prior chemotherapies including docetaxel. Pts received pembro 200 mg Q3W until PD or intolerable toxicity. Response was assessed Q9W in yr 1, then Q12W. Primary end point was ORR per RECIST v1.1 by central review in C1 and C2, separately and combined. Key secondary end points included DCR (CR + PR + SD) per PCWG3-modifed RECIST and safety in all 3 cohorts. **Results:** 131 pts enrolled in C1, 67 in C2, and 60 in C3. Median follow-up as of Oct 13, 2017, was 8.1 mo, 7.9 mo, and 11.8 mo, respectively. Antitumor activity was observed in all cohorts (Table). Across cohorts, DCR lasting ≥6 mo was 11%. In C1 and C2, 9% of pts had a ≥30% decrease in target lesions; 48% had target lesion changes between –30% and +20%. The response rate was numerically higher in pts with somatic *BRCA1/2* or *ATM* mutations (12%). Drug-related grade 3-5 AE rates were 13% in C1, 12% in C2, and 17% in C3. **Conclusions:** Pembro shows antitumor activity and disease control with acceptable safety in pts with docetaxel-refractory mCRPC, regardless of PD-L1 status, in both RECIST-measurable and nonmeasurable disease. These data support further evaluation of pembro in mCRPC, including in pts wth homologous recombination defects. Clinical trial information: NCT02787005.

5008 Oral Abstract Session, Mon, 3:00 PM-6:00 PM

A randomized phase 2 study investigating 3 dosing regimens of radium-223 dichloride (Ra-223) in bone metastatic castration-resistant prostate cancer (mCRPC). *First Author: Cora N. Sternberg, San Camillo-Forlanini Hospital, Rome, Italy*

Background: Ra-223, standard dose (SD) 55 kBq/kg q4w for 6 cycles improved overall survival (OS) and delayed time to symptomatic skeletal events (SSEs) in patients (pts) with mCRPC and bone metastases in the ALSYMPCA study (Parker C, N Engl J Med. 2013;369(3):213-23). The current study investigated different Ra-223 treatment regimens in a similar patient population. **Methods:** Pts with bone mCRPC were randomized 1:1:1 to Ra-223 SD or Ra-223 high dose (HD) 88 kBq/kg q4w for up to 6 cycles, or to Ra-223 SD extended (EXT) q4w for up to 12 cycles. The primary objective was to compare SSE-free survival (SSE-FS) between HD and SD, and EXT and SD. Hypothesis testing was performed at a 2-sided alpha level of 0.20 with no adjustment for multiplicity. **Results:** 391 pts were randomized; baseline characteristics were well balanced. No statistically significant differences in SSE-FS were observed between Ra-223 SD and HD [median 12.3 vs 12.9 months, hazard ratio (HR) 1.06, 80% CI 0.88–1.27, p = 0.70] or Ra-223 SD and EXT [median 13.2 vs 10.8 months, HR 1.26, 80% CI 0.94–1.69, p = 0.31]. Median OS was 15.8, 16.0 and 14.4 months in the SD, HD and EXT arms, respectively. A total of 370 pts received Ra-223 with a median number of doses of 6 in each arm. The most frequent treatment emergent adverse events (TEAEs) were fatigue, anemia and nausea. Grade ≥3 TEAEs were noted in 34%, 48% and 53% of pts in the SD, HD and EXT arms, respectively. The most frequent grade ≥3 TEAEs overall were anemia (13%), bone pain (5%), thrombocytopenia (4%) and hypertension (4%). TEAEs leading to permanent discontinuation occurred in 9%, 16% and 17% of pts in the SD, HD and EXT arms, respectively. **Conclusions:** No statistically significant differences in SSE-FS were noted between Ra-223 SD and HD or Ra-223 SD and EXT. However, HD and EXT arms had a higher incidence of grade ≥3 TEAEs than the SD arm. The study supports the currently approved dose and schedule of Ra-223. Clinical trial information: NCT02023697.

Health-related quality of life (HRQoL) deterioration and pain progression in men with non-metastatic castration-resistant prostate cancer (M0 CRPC): Results from the PROSPER study. *First Author: Gerhardt Attard, The Institute of Cancer Research and the Royal Marsden, Surrey, United Kingdom*

Background: The Phase 3 PROSPER trial (NCT02003924) showed a statistically significant improvement in metastasis-free survival (MFS) with enzalutamide (ENZA; n = 933) vs. placebo (PBO; n = 468) in asymptomatic men with M0 CRPC and prostate-specific antigen doubling time ≤10 months. We report the results of the HRQoL and pain evaluations. **Methods:** Functional Assessment of Cancer Therapy–Prostate (FACT-P) and Brief Pain Inventory, Short Form, were used to assess HRQoL and pain at baseline (BL) and every 16 weeks during treatment. Pain progression was defined as ≥2 points in pain severity items and mean scores increase from BL; HRQoL improvement/deterioration as an increase/decrease from BL using pre-established thresholds for clinically meaningful difference. Time to first confirmed (at two consecutive visits) and unconfirmed HRQoL deterioration/pain progression were assessed using Kaplan-Meier estimates and Cox proportional hazards models under censoring not at random assumption. **Results:** BL characteristics and scores were similar between arms with low pain (median 0) and high HRQoL (median FACT-P total score, 121). Decrease in attrition rate was greater in PBO vs. ENZA mainly due to disease progression (53% vs. 68% at week 49, respectively). Most patients reported no change or improvement in HRQoL. Proportion of patients with pain progression at week 49 was similar between ENZA (11–20%) and PBO (14–21%). Lower risk of pain progression was observed with ENZA vs. PBO in the confirmed analysis (hazard ratio [HR] 0.78–0.93; $p > 0.05$). Nominal statistically significant lower risk of deterioration was observed with ENZA for FACT-P total, FACT Advanced Prostate Symptom Index, prostate cancer subscale (PCS), and emotional well-being (EWB) in the confirmed (HR 0.75, 0.77, 0.77, 0.69, respectively; $p < 0.05$) and for PCS and EWB in the unconfirmed (HR 0.82, 0.80, respectively; $p < 0.05$) analyses. **Conclusions:** In PROSPER, ENZA significantly delayed MFS vs. PBO without worsening HRQoL and significantly reduced the risk of clinically meaningful HRQoL deterioration in several FACT-P domains. Pain progression was similarly low in both arms. Clinical trial information: NCT02003924.

Self-management in prostate cancer survivors: A randomized controlled trial. *First Author: Ted A. Skolarus, Department of Urology, Dow Division of Health Services Research, University of Michigan, Ann Arbor, MI*

Background: The purpose of this randomized trial was to compare a personally-tailored symptom management intervention consisting of 4 automated telephone assessments and tailored education for improving symptom self-management among prostate cancer survivors to usual care (1 non-tailored newsletter about symptom management). We hypothesized improved symptom self-management and prostate cancer quality of life following the intervention. **Methods:** A total of 556 prostate cancer survivors experiencing symptom burden were recruited from April 2015 to February 2017 across 4 sites. Participants were randomized to intervention (n = 278) and usual care (n = 278) groups as reported in our protocol. Our primary outcome was symptom burden assessed via patient report 5 months after enrollment using the EPIC-26 instrument. Secondary outcomes included psychosocial outcomes and domain-specific changes according to intervention participants' primary symptom area (urinary, bowel, sexual, general). We used multivariable regression analysis to evaluate intervention impact on outcomes. **Results:** The mean age of prostate cancer survivors was 66.7 years and the majority was treated with radiation therapy (56.7% vs. 46.2% surgery). The 5 month primary outcome assessment was completed by 89% of participants. There were no baseline differences across groups. At 5 months, we observed differences between groups in urinary domains (irritative - 61.8 control vs. 63.4 intervention, adjusted mean difference (aMD) 2.6, p = 0.07; obstructive - 74.5 control vs. 77.4 intervention, aMD 2.6, p = 0.07) with no significant differences in other outcomes. Intervention participants choosing urinary (crude mean difference (cMD) irritative 3.0; p = 0.09, obstructive 6.1; $p < 0.01$), bowel (cMD 9.1; p = 0.08), and sexual (cMD 5.6; $p < 0.01$) domains as their primary focus area reported improvements at 5 months. Participants reported high satisfaction with the intervention. **Conclusions:** A personally-tailored, automated telephone symptom management intervention for prostate cancer survivors was feasible and led to differences in urinary and sexual health symptoms in this randomized trial. Self-management of treatment-related side effects appears warranted. Clinical trial information: NCT01900561.

Phenotypic and genomic characterization of CTCs as a biomarker for prediction of Veliparib therapy benefit in mCRPC. *First Author: Ryan Dittamore, Epic Sciences, Inc., San Diego, CA*

Background: Response to PARPi in mCRPC patients (pts) particularly those with DNA damage response mutations (DDRm) was observed in the TOPARP trials (utilizing Olaparib) which enrolled heavily pre-treated, high CTC pts. However, the NCI 9012 study, randomizing 1st line mCRPC pts to Abiraterone (A) or A + Veliparib (V), did not demonstrate an advantage for V in any pre-specified subgroup, with DDRm pts having better outcomes on both arms. Here we explore the use of CTCs to ascertain phenotypic Genomic Instability (pGI) as a proposed selection biomarker for PARPi. **Methods:** 212 blood samples from 84 pts (n = 39 A & n = 42 A+V, 3 uneval) prior to and during therapy were processed utilizing the Epic Sciences CTC platform. 32 pts had a concomitant fresh biopsy sequenced by MI-ONCOSEQ. CTC pGI was determined using previously described algorithms (Scher et al. ASCO 2016) which predicts genomic instability with morphological features and protein expression. A subset of CTCs (n = 466) underwent single cell sequencing for genomic scarring/DDRm and results were compared to tissue DDRm. CTC biomarkers were correlated with pt outcomes. **Results:** 80.2% (65/81) of baseline (BL) blood samples had enumerable CTCs. 48% (39/81) of these had ≥ 1 CTCs with pGI detected (pGI+). pGI+ pts had improved PSA response in the A+V arm, 83% (20/24) compared to 33% (5/15) in A ($p = 0.002$). Higher BL CTC counts were detected in tissue DDRm vs. DDR wild type (wt) pts (med 3.8 CTC/mL vs. 2.7 CTC/mL). pGI+ CTCs were detected in 42% (5/12) DDRm pts and 35% (7/20) DDRwt pts. Discordant results between CTC genomic scarring and tissue DDRm were observed. 3 pts with tissue DDRm only had CTCs with low genomic scarring. Conversely, 3 DDRwt pts had CTCs with high genomic scarring. pGI+ CTCs decreased in pGI+ pts from baseline to on-therapy with A+ V, 82% (9/11) pts (mean of 40 pGI+ CTC/mL) had reductions to < 1 pGI CTC/mL , whereas on A, only 20% (1/5) pts. (mean of 6 pGI+ CTC/mL) had a reduction to < 1 pGI CTC/mL (p = 0.036). **Conclusions:** A CTC biomarker, pGI, is correlated to differential PSA responses associated with A + V. Single cell CTC sequencing highlights the heterogeneity of genomic scarring in patients with and without DDRm and may be more sensitive than tissue based markers. Clinical trial information: NCT01576172.

Genomic profiling of primary prostate tumors from patients who develop metastatic castration-resistant prostate cancer (mCRPC). *First Author: Joaquin Mateo, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain*

Background: mCRPC is enriched for genomic aberrations in *TP53*, *RB1*, *AR*, *PTEN* and DNA damage repair (DDR) compared to localized prostate cancer. Here we pursued NGS of 470 primary prostate tumors from patients who all later developed mCRPC to evaluate this enrichment in this poor prognosis population. We also compared 49 pairs of same patient primary tumor and mCRPC biopsies. **Methods:** Libraries for targeted DNA NGS were built using a customized amplicon-based panel (Generead v2 DNAseq, Qiagen) and read in a MiSeq (Illumina). Copy number aberrations (CNA) were assessed using a previously described bioinformatics pipeline (Seed, CCR 2017) for 98 genes. We compared gene aberration frequencies with previously reported cohorts. **Results:** A total of 470 treatment naïve primary prostate biopsies were sequenced and passed QC filters for mutation and CNA calling. Frequencies for TP53 (27%) and RB1 (5%) aberrations were higher than previously reported for localized prostate cancer (TCGA, $p<0.01$ each) but lower than for mCRPC (SU2C/PCF, *TP53* p = 0.001, *RB1* p = 0.07). Conversely DDR gene defects were more common: *BRCA2* 5% (p = 0.004); *CDK12* 5% (including 7 cases with two mutations; p = 0.06); *ATM* 4% (p = 0.2), and *PALB2*, *BRCA1*, RAD50, *FANCA* 1% each. Overall, 2% of primary tumors had detectable mutations in MMR genes. PTEN genomic loss was detected in 12% of primary tumors; 5% had activating mutations of *PIK3CA* or *AKT*. Other genes recurrently mutated were SPOP (7%) and CTNNB1 (3%). Surprisingly, in 5 cases (1%) AR mutations at low allele frequencies were detectable prior to ADT. Among the 49 patient matched sample pairs, mutations detectable only in mCRPC were identified in *AR* (n = 4), *TP53* (4), *RB1* (3) and *CTNNB1* (1). All 9 truncating mutations in *BRCA2*, *ATM*, *CDK12*, *PALB2* were shared between treatment naïve and mCRPC samples. **Conclusions:** *TP53* and *RB1* aberrations are more common in poor prognosis primary prostate cancer than in localized, more curable, disease (TCGA) but lower than in mCRPC (SU2C/PCF). Aberrations detected only at mCRPC in patient-matched samples support the evolution of these mutations under treatment selection pressures. Poorer prognosis prostate cancers are enriched for *BRCA2* aberrations.

The complete genomic landscape of metastatic prostate cancer pinpoints clinically targetable subgroups. *First Author: Lisanne Francisca van Dessel, Department of Medical Oncology, Erasmus MC Cancer Institute, Erasmus University, Rotterdam, Netherlands*

Background: Recent genome analysis efforts have shown that genomic alterations obtained from primary and metastatic prostate cancer (mPCa) vary widely, stressing the need to obtain comprehensive genomic data from metastatic tissue. Understanding the complete genomic atlas of mPCa will increase our understanding of cancer progression and improve management of these patients. **Methods:** Fresh-frozen tissue biopsies of 153 patients with mPCa were analyzed by whole-genome sequencing (WGS) to a minimum depth base coverage of 90x for tumor samples and 30x for peripheral blood (reference). Biopsy sites included bone, lymph node and viscera. Sequencing data were analyzed to call tumor specific single nucleotide variants (SNV), small insertions and deletions (InDels), copy number alterations (CNA) and chromosomal rearrangements and their incidence was compared to results reported for primary disease (Fraser et al. Nature 2017). **Results:** Median tumor cell content of the biopsied lesions was 60% (95% CI: 56-64%). Median SNV burden was 2.6 SNVs per million base pairs (Mbp; 95% CI: 2.44-2.88) compared to 0.53 SNVs per Mbp in primary disease. High SNV and InDel load correlated with microsatellite instability (MSI) mutational signatures (8/153 tumors). Furthermore, we identified a distinct subgroup harboring signature 3 mutations likely to be associated with *BRCA* deficiency (26/153 tumors; Alexandrov et al. Nature 2013). Median number of interchromosomal rearrangements was 58 (95% CI: 49-67) compared to 19 in primary disease. We found a total of 69 and 62 alterations, including SNVs and CNAs, in the genes *AR* and *TP53*, respectively, both important drivers in mPCa. We will present additional data on novel and recurrent genomic alterations and mutational signatures. **Conclusions:** WGS of metastatic tissue from patients with mPCa shows a clear evolution of aberrations compared to primary disease. Increased frequency of alterations in specific driver genes confirms their role in dissemination and/or therapy failure. Using whole-genome sequencing, we were able to stratify patients into clinically relevant groups (MSI, *BRCA*ness, *PI3K* and *RB*) advancing towards improved treatment management of patients with mPCa.

Phase 2 randomized cross-over trial of abiraterone + prednisone (ABI+P) vs enzalutamide (ENZ) for patients (pts) with metastatic castration resistant prostate cancer (mCPRC): Results for 2nd-line therapy. *First Author: Daniel Khalaf, British Columbia Cancer Agency - Vancouver Centre, Vancouver, BC, Canada*

Background: ABI+P and ENZ have similar efficacy for 1st-line treatment of mCRPC but cross-resistance confounds treatment with the alternate agent at progression. The optimal sequencing has not been prospectively investigated and predictive biomarkers are needed. **Methods:** A multi-centre trial of ABI+P followed by ENZ at PSA progression (arm A) vs ENZ followed by ABI+P (arm B). Primary endpoints were PSA decline > 50% (PSA50) on 2nd-line therapy and time to 2nd PSA progression (TT2P) (from start of 1st-line). Deep-targeted sequencing of serial samples of circulating tumour DNA (ctDNA) was performed. **Results:** 202 pts (101/ arm) were accrued with median follow-up 22.3 months (m). 65 pts from arm A and 71 from arm B crossed-over to 2nd-line treatment and 30 pts (15/arm) stopped treatment without cross-over. Baseline characteristics at time of 2nd-line therapy were balanced: median age 75 (range 50-93), PSA 14.5 (6.6-62.1), alkaline phosphatase > upper limit of normal (ULN) in 39% of pts and bone/liver metastasis (mets) in 89%/9%. ECOG PS was 0-1 in 89% vs 76% of pts for arm A vs arm B (p = 0.044) and LDH was > ULN in 25% vs 8% (p = 0.013). PSA50 for 2nd-line therapy for arm A vs arm B was 34% vs 4% ($p<0.001$) and median time to PSA progression on 2nd-line therapy (TTPP) was 2.7 m vs 1.3 m (HR 0.38, 95% CI 0.26-0.56). For the intention-to-treat population, TT2P was 13.6 vs 11.9 m (HR 0.75, 95% CI 0.53-1.06). Median overall survival (OS) was not reached vs 24.3 m (HR 0.82, 95% CI 0.53-1.27). On multivariable analysis, factors associated with 2nd-line TTPP were: bone mets (HR 2.22, 95% CI 1.08-4.54), liver mets (HR 3.18, 95% CI 1.21-8.41) and treatment arm A vs B (HR 0.27, 95% CI 0.17-0.40). At progression, AR gene copy number increased in 14% of evaluable pts (7/49) and AR L702H/T878A(S) mutations were present in 8% of pts. ctDNA fraction ≥2% at baseline was associated with worse TT2P (HR 2.04, 95% CI 1.43 - 2.90) and OS (HR 4.07, 95% CI 2.40-6.91). **Conclusions:** The sequence of ABI+P followed by ENZ was associated with superior PSA50 and TTPP on 2nd-line therapy. AR alterations associated with ABI+P and ENZ resistance were detectable in ctDNA. Clinical trial information: NCT02125357.

5016 Poster Discussion Session; Displayed in Poster Session (Board #243), Sat, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Sat, 4:45 PM-6:00 PM

Phase 2, randomized, 3-arm study of abiraterone acetate and prednisone (AAP), AAP plus degarelix (AAP+D), and degarelix (D) alone for patients (pts) with biochemically-recurrent prostate cancer (PC) following radical prostatectomy (RP). *First Author: Karen A. Autio, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Androgen deprivation therapy (ADT) with GnRH analogs does not entirely suppress androgen signaling. AAP + ADT decreases blood and intratumoral testosterone (T) levels by ≥1 log, and in pre-RP trials resulted in greater pathologic responses relative to ADT alone. Trial designs that can rapidly assess therapies (txs) are critical given the long natural history of PC and resources required for phase 3 trials. Using a novel endpoint (endpt) (undetectable PSA [PSA0] with T recovery [rec]), we hypothesized that AAP+D given in the rising PSA state post-RP, a low volume but potentially lethal setting, could eliminate all disease, a prerequisite to cure. **Methods:** Post RP ± salvage radiotherapy pts with a rising PSA ≥1.0 ng/ml, doubling time ≤9 months (mo), no metastases (met) on CT/bone scan, and T ≥150 ng/dl were eligible [NCT01751451]. Prior ADT ≤8 mo was allowed. Pts were randomized (1:1:1) to AA 1000 mg + P 5 mg QD (Grp 1), AAP + monthly D (Grp 2), or monthly D (Grp 3) for 8 mo, followed by cessation of txs. The primary (1^0) endpt was PSA0 with T > 150 at 18 mo and secondary, PSA0 at 8 mo. **Results:** 120 pts were treated; 113 were evaluable for the 1^0 endpt; 7 had PSA0 at 18mo without T rec. No difference was seen in PSA0 at 8 mo with AAP vs AAP+D (p > 0.99), or AAP vs D (p = 0.11) (Table). Overall, 11.5% of pts achieved the 1^0 endpt with no difference between groups (Grp 1 vs Grp 3; Grp 2 vs Grp 3 [p = 0.43; p = 0.75]). T rec was shortest in Grp 1 relative to Grp 3 (p < 0.001). Clinical trial information: NCT01751451. **Conclusions:** Although no difference between tx grps was identified by the 1^0 endpt (PSA0 + T rec), these results set a benchmark for future trials that 10-15% of pts can achieve this outcome. Given the survival benefit of AAP + ADT in non-castrate met PC, a longer duration of androgen suppression may yield greater benefit. In addition to novel systemic txs, use of PET directed imaging to identify and target micro-mets with focal txs may enhance the likelihood of eliminating disease in this setting.

Cohort	PSA0 at 8mo	Median time to T rec (wks)	PSA0 + T > 150 at 18mo
Grp 1: AAP	31/37 (84%)	36	2/37 (5%)
Grp 2: AAP+D	32/37 (86%)	57	6/37 (16%)
Grp 3: D	26/39 (67%)	54	5/39 (13%)

5017 Poster Discussion Session; Displayed in Poster Session (Board #244), Sat, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Sat, 4:45 PM-6:00 PM

Prostate radiotherapy in newly-diagnosed metastatic hormone-sensitive prostate cancer: A single-institution experience. *First Author: Scott Carlyle Morgan, Division of Radiation Oncology, University of Ottawa, Ottawa, ON, Canada*

Background: In patients presenting with metastatic prostate cancer (mPCa), the role of local therapy is undefined. Recent registry analyses have suggested, however, that external beam radiotherapy (RT) directed at the prostate may improve overall survival (OS). We reviewed the experience of primary tumor-directed RT in this setting at our center. **Methods:** The study population consisted of men with newly-diagnosed mPCa referred to a comprehensive cancer center between 2005 and 2015 and treated initially with androgen deprivation therapy. Patients were eligible for inclusion if they received 1) prostate RT with biologically effective dose at least that of a course of 40 Gy in 15 fractions or 2) no prostate RT. The association between receipt of prostate RT and OS was studied. OS was estimated using the Kaplan-Meier method while univariate and multivariate Cox regression were used to identify factors associated with OS. **Results:** A total of 304 cases were eligible. Prostate RT was received in 105 cases. Median age at diagnosis was 75 years (IQR, 67-82 years). Median follow-up was 72.2 months. On univariate analysis, prostate RT was associated with improved OS (HR 0.62, 95% CI 0.46-0.84, p = 0.002). 2-year and 5-year OS was 74.7% and 41.8% respectively in those receiving prostate RT and 56.9% and 27.6% respectively in those not receiving RT. Median OS in those receiving RT was 48.3 months versus 29.2 months in those not receiving RT. In a multivariate Cox model taking account of age at diagnosis, year of diagnosis, presenting PSA, T stage, N stage, and M1 subdivision, RT remained associated with improved survival (HR 0.64, 95% CI 0.43-0.96, p = 0.033). **Conclusions:** This cohort represents the largest single-center experience of primary tumor-directed RT in mPCa reported to date. In this population, receipt of prostate RT was associated with improved OS. The observed 19-month absolute difference in median OS is clinically significant. This analysis could not account for performance status, volume of metastatic disease, comorbidities, receipt of systemic therapies, and other potential confounders. Only large-scale RCTs will be able to definitively assess the value of prostate RT in this setting.

5018 Poster Discussion Session; Displayed in Poster Session (Board #245), Sat, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Sat, 4:45 PM-6:00 PM

Timing of androgen deprivation therapy for prostate cancer patients after radiation: Planned combined analysis of two randomized phase 3 trials. *First Author: Andrew Loblaw, Odette Cancer Centre, Sunnybrook Health Sciences Centre, Toronto, ON, Canada*

Background: The TOAD (TROG 03.06; NCT00110162) phase 3 randomized trial showed that immediate androgen deprivation therapy (IADT) improved overall survival (OS) and time to clinical progression compared with delayed ADT (DADT) in progressive or relapsed prostate cancer patients after radical radiotherapy (RT) or prostatectomy + RT. ELAAT (NCT00439751) was a similarly designed trial but failed to reach its accrual goal. The two investigative teams planned a combined analysis before ELAAT was activated. **Methods:** The PSA failures from TOAD and 78/79 patients accrued to ELAAT were combined (1 patient was excluded due to castrate resistant prostate cancer (CRPC)). Participants for both trials were randomized 1:1 to IADT or DADT. The primary endpoint was all-cause mortality by intention-to-treat. Secondary endpoints were cancer-specific mortality (CSM), local progression, distant progression, CRPC, and prostate cancer complications (PCC). **Results:** 261 patients from TOAD and 78 patients from ELAAT were followed a median of 5.0y. TOAD patients were younger (mean age 70.5 vs 73.8y) and more had a relapse-free interval < 2y from RT (30% vs 10%). In the DADT arms, 63% received ADT a median of 1.58y for TOAD; 38% received ADT a median 1.65y for ELAAT. For patients receiving ADT, the mean pre-ADT PSAs were 3.52 and 30.2 ng/ml in the IADT and DADT arms of TOAD and 3.98 and 18.1 ng/ml in ELAAT. There were 60 deaths, 40 and 20 respectively. Overall, for IADT and DADT arms the proportions of deaths in each trial were 15%, 11%, 19% and 26%, 27% and 24%. All-cause mortality (HR 0.75, 95% CI 0.40, 1.41; p = 0.37) and CSM (HR 0.57, 95% CI 0.22, 1.49) were not statistically different between IADT and DADT. Time to local progression (survival time ratio 1.97, 95% CI 1.28, 3.04; p = 0.002) and distant progression (survival time ratio 1.28, 95% CI 1.04, 1.58; p = 0.02) was higher while PCC (3.7 v 7.5%, p = 0.06) was lower with IADT. CRPC outcomes will be presented at conference. **Conclusions:** No difference in OS was detected between IADT and DADT in the combined analysis. A possible explanation is that ELAAT accrued older patients with lower risk of CSM and had a smaller difference in PSA between the IADT and DADT arms.

KEYNOTE-046: ADXS-PSA plus pembrolizumab (pembro) in metastatic castration-resistant prostate cancer (mCRPC). *First Author: Mark N. Stein, Columbia University Medical Center, New York, NY*

Background: ADXS–PSA, an attenuated *Listeria monocytogenes*-based immunotherapy that targets prostate-specific antigen (PSA), is designed to generate antigen-specific T cell effectors that kill tumor cells. Published data has shown synergy of ADXS Lm-LLO-TAA treatment with a PD-1 blocking antibody in an animal model. **Methods:** This phase 1/2 trial studied pts with progressive mCRPC, ≥18 yrs who received ≤2 prior chemo-/targeted-/immunotherapies or ≤1 prior chemotherapy in a metastatic setting. Part A (PA; n = 14) pts received ADXS-PSA doses $1x10^9$; $5 x10^9$ and $1x10^{10}$ colony forming units (CFU) IV every 3 wks and Part B (PB; n = 37) pts received $1x10^9$ CFU + 200 mg pembro IV every 3 wks with a 4^{th} pembro dose 3 wks later, for up to 2 yrs or until progression/toxicity. The 1° endpoint was safety/tolerability. Anti-tumor activity and effect on PSA level were evaluated. Preliminary results are presented. **Results:** At entry, PA and PB pts were similar in age (~70 yrs), Gleason score (~8.3) and prior abirateroneuse. PB pts had higher median BL PSA (40.6 v 20.8 ng/ml), and more prior enzalutamide (53 v 26%) and chemotherapy (49 v 36%) use v PA. 46 pts (94%) experienced treatment-related AEs (TRAE) with 16 pts having grade 3-4 events: fatigue, hypotension, hypertension, anemia. TRAEs ≥10% of any grade were cytokine release symptoms including chills, fever, nausea and hypotension. TRAE incidence was similar between groups and all resolved with supportive care. Accrual is complete but pts remain on trial. Overall, 2 PA (14%) v 16 PB pts (43%) had a decreased PSA post-BL. Of these, 8 PB (22%) v 0 PA pts achieved a PSA reduction ≥50% from BL; which was confirmed in 3 PB pts (38%). At the time of analysis, tumor measurements were available for 5 PA and 23 PB pts. One PA pt (20%) and 10 PB pts (43%) had SD (RECIST 1.1). Four PB pts (40%) with SD also had a decreased PSA post-BL; a confirmed response was seen in 2 of these pts. 9 PA and 14 PB pts had non-measurable disease at BL; 33% (3/9) and 79% (11/14) had disease stabilization (non-CR/non-PD). **Conclusions:** In this population of heavily pretreated mCRPC pts ADXS-PSA + pembro had a manageable safety profile and showed promising activity compared to monotherapy. These preliminary data warrant further study. Clinical trial information: NCT02325557.

Microsatellite instability in prostate cancer and response to immune checkpoint blockade. *First Author: Wassim Abida, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Immune checkpoint blockade has shown clinical benefit in mismatch repair deficient (dMMR) cancers, leading to accelerated FDA approval of pembrolizumab, a PD1-targeting agent, for the treatment of dMMR or microsatellite instability-high (MSI-H) advanced solid tumors. However, the frequency of MSI-H prostate cancer (PCa), as well as response to PD1/PDL1 agents in this disease subset, remain poorly defined. **Methods:** 839 PCa patients underwent targeted next-generation sequencing (NGS) of tumor and matched normal samples on an institutional protocol for the characterization of somatic mutations, copy number alterations and germline mutations (with specific consent). MSIsensor analysis, a computational method for detecting MSI, was performed. Tumor mutation burden (TMB) was calculated, with additional analysis for mutational signatures and immunohistochemical (IHC) staining of MMR proteins in selected cases. **Results:** 20/839 PCa patients (2.4%) were found to have MSI-H/dMMR tumors, defined as an MSIsensor score of ≥ 3 and TMB of ≥ 10, confirmed by IHC and mutational signature analysis. Of 13/20 MSI-H patients who consented to germline analysis, 3/13 (23%) had a germline MMR gene mutation. 3/5 MSI-H patients who underwent profiling of ≥ 2 matched tumors demonstrated MSI in the later tumor. In total, 10 patients with MSI-H tumors received a PD1/PDL1 targeting agent. 2/10 had radiographic PR with PSA decline of $> 80\%$. 3/10 are early in their treatment with PSA decline of $> 60\%$. 1/10 had stable disease for 6 months then progressed. 3/10 had no response. 1/10 was inevaluable. **Conclusions:** Tumor profiling for MSI status can be considered for patients with advanced PCa. MSI can develop as a later somatic event, arguing for profiling of a recent tumor when possible. Germline profiling should be recommended for patients with MSI-H PCa. While early in this dataset, responses to PD1/PDL1 therapy may occur in ~50% of patients with MSI-H/dMMR PCa. Longer follow up and additional prospective studies will be necessary to confirm responses in this patient population.

5021 Poster Session (Board #248), Sat, 1:15 PM-4:45 PM

Immunotherapy utilizing the combined use of NK and ADCC mediating agents with PARP inhibition. *First Author: Kathleen Fenerty, Laboratory of Tumor Immunology and Biology, Center for Cancer Research, National Cancer Institute, Bethesda, MD*

Background: Poly (ADP-ribose) polymerase inhibitors (PARPi) prevent single-stranded DNA repair. PARPi has antitumor activity in patients with known double-stranded DNA repair deficiencies (germline BRCA mutations). Olaparib is FDA approved for BRCA mutant ovarian and breast carcinoma. Emerging clinical data**NCT02484404. JCO, Karzai et al.* suggests a benefit of combining olaparib with checkpoint inhibition in prostate cancer patients. Here, we interrogated the immunomodulatory potential of olaparib *in-vitro,* focusing on prostate carcinoma. We hypothesized that olaparib increases immune cell killing of tumor cells independent of BRCA status or checkpoint modulation. **Methods:** BRCA mutant and BRCA wildtype prostate carcinoma cell lines were pretreated with olaparib and then exposed to human healthy donor natural killer (NK) cells with or without the antibody-dependent cellular cytotoxicity (ADCC)-mediating monoclonal antibodies (mAb) avelumab (anti-PD-L1) or cetuximab (anti-EGFR). Tumor cell lysis was monitored. Anti-CD16 antibody was used to confirm NK-induced ADCC. Flow cytometry was performed on tumor cells treated with olaparib to evaluate phenotypic changes of NK ligands and death receptors. **Results:** NK-mediated killing was significantly increased in both BRCA WT and mutant prostate cell lines. NK killing was further increased using ADCC-mediating mAbs in both WT and mutant cell lines. The enhanced ADCC was blocked using anti-CD16 mAb. Notably, the expression levels of PD-L1 and EGFR did not change with olaparib treatment. On tumor cells, olaparib exposure upregulated NK ligands and death ligands. Additional tumor cell lines (lung, breast) were also assessed. **Conclusions:** We show here for the first time that a) olaparib increased tumor cell sensitivity to NK-mediated killing and ADCC in both BRCA wild-type and BRCA deficient prostate carcinoma cells, independent of PD-L1 or EGFR modulation; b) olaparib treatment enhanced NK killing in 6/6 cell lines; and c) mechanistically, treatment with olaparib upregulated NK ligands MICA/B, CD112, and death receptors Fas and Trail-R. These studies support the combined use of NK and ADCC mediating agents with PARPi in BRCA mutant and WT prostate carcinoma.

5022 Poster Session (Board #249), Sat, 1:15 PM-4:45 PM

Radium-223 re-treatment in an international, open-label, phase 1/2 study in patients with castration-resistant prostate cancer and bone metastases: 2-year follow-up. *First Author: A. Oliver Sartor, Tulane Cancer Center, New Orleans, LA*

Background: Radium-223 (Ra-223) treatment (tx) is indicated for patients (pts) with castration-resistant prostate cancer (CRPC) and symptomatic bone metastases (mets) (6 $\times$ 55 kBq/kg IV injections [inj]; 1 inj q4wk). Early results of an international, open-label, phase 1/2 study (NCT01934790) showed that re-treating pts with Ra-223 was well tolerated with favorable effects on disease progression. Here we report safety and efficacy findings from a 2-year follow-up. **Methods:** Pts with CRPC and bone mets who completed 6 initial Ra-223 inj with no disease progression in bone and later progressed were eligible for Ra-223 re-tx (6 additional Ra-223 inj), provided that hematologic parameters were adequate. No concomitant cytotoxic chemotherapy was allowed; other concomitant agents for prostate cancer (including abiraterone and enzalutamide) were allowed at investigator discretion. The primary objective was safety. Exploratory objectives were time to radiographic bone progression, radiographic progression-free survival (rPFS), overall survival (OS), time to first symptomatic skeletal event (SSE), and SSE-free survival, all calculated from re-tx start. Pts will be followed for safety up to 7 years after last Ra-223 dose; an active 2-year follow-up evaluated exploratory objectives. Safety results from the active follow-up period and updated efficacy are reported. **Results:** 44 pts were re-treated with Ra-223; 29 (66%) completed all 6 inj (median number inj = 6). 34 (77%) of 44 pts entered active follow-up, during which no new safety concerns were noted. There were no serious drug-related adverse events. 26 (59%) of 44 pts had an rPFS event (radiographic progression or death); median rPFS was 12.0 months. Only 5 (11%) of 44 pts had radiographic bone progression; median time to radiographic bone progression was not reached. Median OS was 24.4 months. Median time to first SSE and SSE-free survival were 16.7 and 12.8 months, respectively. **Conclusions:** Re-treating with Ra-223 was well tolerated in this select pt population, led to minimal hematologic toxicity, and provided continued disease control in bone at 2-year follow-up. Clinical trial information: NCT01934790.

5023 Poster Session (Board #250), Sat, 1:15 PM-4:45 PM

Longer term preplanned efficacy and safety analysis of abiraterone acetate + prednisone (AA + P) in patients (pts) with newly diagnosed high-risk metastatic castration-naïve prostate cancer (NDx-HR mCNPC) from the phase 3 LATITUDE trial. *First Author: Karim Fizazi, Gustave Roussy, University of Paris Sud, Villejuif, France*

Background: The LATITUDE study in pts with NDx-HR mCNPC found significant improvements in OS, rPFS, and all secondary end points, including pt-reported outcomes when combining AA + P with androgen deprivation therapy (ADT) vs placebos (PBOs) + ADT, which led to unblinding of the study at first interim analysis. **Methods:** 1199 NDx-HR mCNPC pts were randomized 1:1 to AA (1 g QD) + P (5 mg QD) + ADT or PBOs + ADT. Co-primary end points were OS and rPFS. A stratified proportional hazards model assessed longer term follow-up on OS, secondary end points, and adverse events (AEs), including those associated with mineralocorticoid excess, from the preplanned second interim analysis, when approximately 65% (≈554) of expected deaths were observed. **Results:** With a median follow-up of 41 mo (range, 0.1-54.0), 205 (34%) pts in the AA + P arm and 70 (12%) in the PBOs arm (of whom 57 [81%] had crossed over to AA + P) remained on treatment. Updated OS continued to favor the AA + P arm (HR [95% CI] 0.638 [0.538-0.758]; $p < 0.0001$) as did secondary end points (Table). Serious AEs occurred in 27% of pts on AA + P and 20% of pts on PBOs. Grade 3/4 AEs included (AA + P vs PBOs; %): hypertension (21 vs 10), hepatotoxicity (8 vs 3), hypokalemia (12 vs 2), fluid retention (1 vs 1), and cardiac disorders (4 vs 1). 328 pts (54%) from the PBOs arm received a life-prolonging therapy. **Conclusions:** This long-term analysis continues to demonstrate the OS benefit of adding AA + P to ADT in NDx-HR mCNPC pts, with a 36% reduction in the risk of death, although most pts remaining on PBOs treatment had crossed over to AA + P. The secondary end points also continued to favor the AA + P arm, underscoring AA + P as a standard of care for pts with NDx-HR mCNPC. Clinical trial information: NCT01715285.

	AA + P + ADT (n = 597)	PBOs + ADT (n = 602)	HR (95% CI)	p Value

5024 Poster Session (Board #251), Sat, 1:15 PM-4:45 PM

Radium-223: Disease response and fracture assessment by whole body diffusion-weighted MRI (WB-DWMRI) in metastatic castration resistant prostate cancer (mCRPC). *First Author: Chris C. Parker, The Royal Marsden NHS Foundation Trust and The Institute of Cancer Research, London, United Kingdom*

Background: Ra-223 improves overall survival in patients with mCRPC. Imaging criteria to assess response in bone are lacking but could inform treatment strategies. **Methods:** We did a prospective phase II study to evaluate potential response biomarkers to Ra-223. Patients with chemotherapy-naïve, bone mCRPC were randomised (1:1) to receive Ra-223 at 55 or 88 kBq/kg for 6 cycles, at 4-week intervals. WB-DWMRI was done at baseline, at cycles 2 and 4, and 1 month post-treatment. MRI response was defined as a 30% increase in the mean of the mean Apparent Diffusion Coefficient (ADC) using up to 5 target lesions. PSA response was defined per PCWG2 criteria. Circulating tumour cells (CTC) response was defined as decrease from ≥5 cells/7.5ml to < 5/7.5ml. **Results:** 27 evaluable patients received a median of 6 cycles of Ra-223. Overall MRI response was seen in 56% (15/27), PSA response in 11% (3/27) and CTC response in 55% (5/9) evaluable patients. There was an association between the greatest percentage increase in ADC and greatest percentage decline in PSA during treatment, rho = -0.59; p = 0.001. Responders on MRI received higher administered activity per cycle of Ra-223 than non-responders (median 5840kBq versus 4820kBq; rank sum test p = 0.04). Discordant ADC response, with both response (ADC ≥30% increase) and non-response (ADC < 30% increase) in different bone metastases, was seen in 44% (12/27) of patients. New bone metastases were seen during the treatment period in 67% (18/27), including 60% (9/15) who had an overall response by MRI. Four patients developed 11 new fractures in uninvolved bone during the treatment period. **Conclusions:** WB-DWMRI demonstrates marked inter- and intra-patient heterogeneity of response to Ra-223, and a dose-response relationship. Both new bone metastases, and fractures in uninvolved bone, are common during treatment. Future research should aim to test the role of Ra-223 dose-escalation, of intermittent treatment and of combination therapy with bone health agents. Clinical trial information: ISRCTN17805587.

5025 Poster Session (Board #252), Sat, 1:15 PM-4:45 PM

Cabazitaxel in metastatic castration-resistant prostate cancer (mCRPC): Real-life use, effectiveness, safety, and quality of life (QoL) in the FUJI cohort. *First Author: Stephane Oudard, Hopital Europeen Georges Pompidou, Paris, France*

Background: Cabazitaxel (CAB) was marketed in March 2012 in France, based on overall survival (OS) benefit in mCRPC in 2nd-line (2L) post-docetaxel (DOC). FUJI is a post-authorisation study of the real-life performance of CAB. **Methods:** FUJI is a multicenter (n = 42) cohort study describing OS, safety, QoL (using FACT-P) and pain (using BPI-SF) in mCRPC CAB initiators in real-life, included from Sept 2013 to Aug 2015 in a retrospective cohort (follow-up (FU) 18 mths), and from March 2016 to March 2017 in a prospective cohort (FU 6 mths). **Results:** The retrospective cohort included 401 pts (median age 70) with CAB in 2L (18%), 3L (39%), 4L (23%), or > 4L (20%). Treatments before CAB included DOC (100%), abiraterone acetate (ABI 77%), enzalutamide (ENZ 33%). Median CAB use was 3.4 mths. Median OS was 11.9 mths [95%CI, 10.1-12.9]. In multivariate analyses, factors associated with a shorter OS were: grade ≥ 3 adverse event (AE) (HR = 2.05 [1.53-2.73]), visceral metastases (HR = 1.98 [1.40-2.80]), polymedication > 5 drugs (HR = 1.74 [1.23-2.45]), > 5 bone metastases (HR = 1.74 [1.20-2.53]), disease progression during DOC (HR = 1.69 [1.13-2.53]) or within 3 mths of last DOC cycle (HR = 1.51 [1.07-2.14]), ≥3 drugs such as DOC, ABI, ENZ before CAB (HR = 1.39 [1.00-1.92]), and PSA ≥ 135 ng/ml (HR = 1.36 [1.01-1.82]). Factors associated with better OS were ≥ 10-yr cancer history before CAB (HR = 0.66 [0.46-0.96]), ≥ 6 mths from last DOC dose to CAB initiation (HR = 0.71, [0.52-0.97]). Grade ≥ 3 AEs occurred in 55%, mainly anaemia (27%), neutropenia (15%), febrile neutropenia (8%), renal failure (7%), septicaemia/septic shock (5%). The prospective cohort included 61 pts (median age 72) previously treated with DOC (98%), ABI (61%) and ENZ (61%). 49 pts were evaluable for QoL and 44 for pain. QoL improved in 41%, was maintained in 29%, and deteriorated in 38%. 25% had pain decrease ≥ 1 level, 50% were stable and 25% increase ≥ 1 level. **Conclusions:** Real-life median OS in FUJI was lower than in TROPIC (11.9 *vs.* 15.1 mths), but very few FUJI pts would have satisfied TROPIC inclusion criteria. There were no new safety issues. Improved/stable QoL and pain were reported by 70% and 75% of pts treated by CAB, respectively.

5026 Poster Session (Board #253), Sat, 1:15 PM-4:45 PM

Survival outcomes from a cumulative analysis from worldwide observational studies on sequential use of new agents (NAs) in metastatic castration-resistant prostate cancer (mCRPC) (CASTOR study). *First Author: Orazio Caffo, Santa Chiara Hospital, Trento, Italy*

Background: After the introduction in the daily clinical practice of cabazitaxel (CABA) and new hormone agents (NHAs), abiraterone acetate (AA) and enzalutamide (ENZ), several small retrospective reports described their activity when sequentially used as second- and third-line after docetaxel (DOC) failure. Data from survival plots suggested that after DOC, CABA-based sequences led to a better overall survival (OS) than sequences based on NHAs only. The present work is based on individual-data analysis from some of the published reports on sequential use of at least two NAs after DOC. **Methods:** All authors of the published papers meeting the study criteria were prompted to provide individual data of the pts evaluated in their work. We calculated the overall survival (OS) from the second-line start by sequence strategy. For the OS analysis we considered three different types of NAs sequences after DOC: one new hormone agent (AA or ENZ) followed by CABA (NHA→CABA); CABA followed by AA or ENZ (CABA→NHA); one NHA followed by the other NHA (NHA→NHA). **Results:** We collected data from 1,099 pts. Cumulative OS did not differ significantly among the three different strategies (median cumulative OS ranging 21.0-22.1 mos, p = 0.957). Pts treated with NHA second-line had a statistically significant longer PFS although marginal in clinical terms (6.1 vs 5.6 mos, p < 0.0001), while in third-line CABA led to a statistically significant prolongation of OS (from the third-line start) compared to NHAs: 12.2 vs 9.1 mos (p = 0.039). These results were confirmed after adjustment by age and visceral mets presence. Interestingly, in the case of a NHA-based second-line pts with a longer PFS (> 6 mos) were more frequently treated with a NHA in third-line: in this setting of pts the sequence NHA→ NHA led to a cumulative OS worse than NHA → CABA: 24.8 vs 30.0 (p = 0.022). **Conclusions:** Recognizing the limits of a retrospective analysis, this report is the largest on sequencing use of NAs after DOC and provides some useful suggestions for the therapeutic strategy in DOC pre-treated mCRPC pts.

5027 Poster Session (Board #254), Sat, 1:15 PM-4:45 PM

Relationship between sipuleucel-T (sip-T) cytolytic T lymphocyte (CTL) activity and overall survival (OS) in patients (pts) with metastatic castration resistant prostate cancer (mCRPC). *First Author: Charles G. Drake, Columbia University Herbert Irving Comprehensive Cancer Center, New York, NY*

Background: Sip-T, an autologous cellular immunotherapy approved in the US for pts with asymptomatic/minimally symptomatic mCRPC, is produced by culturing peripheral blood mononuclear cells with the immunogen PA2024 (prostatic acid phosphatase [PAP] conjugated to granulocyte macrophage colony-stimulating factor). A biomarker that can identify mCRPC pts who are likely to respond well to sip-T may inform therapeutic decisions. PA2024 and PAP cellular and humoral immune responses induced by sip-T correlate with prolonged OS (Sheikh, CCI 2013;62:137). Robust CTL activity post sip-T treatment has been reported (Drake, ASCO 2017). We investigated the relationship between sip-T lytic activity (using CD107a expression, a cell surface surrogate marker) and OS in mCRPC pts. **Methods:** PA2024- and PAP-specific CD8+ T (CTL) cells expressing CD107a were identified via flow cytometry at baseline (BL, prior to sip-T infusion), and at 6 and 26 weeks (wks) post-sip-T in pts who were treated in 2 clinical trials (STRIDE: NCT01981122, n = 12 and STAMP: NCT01487863, n = 10), and 3 healthy volunteers (control). **Results:** CTL activity was significantly (p < 0.0001) increased in response to PA2024 and PAP at wks 6 and 26 post-sip-T vs BL. A strong correlation between PAP and PA2024-specific CTL activity was seen at wk 26 (Pearson's R = 0.8973, p < 0.0001), but not at BL or wk 6. At wk 26, there were positive correlations between both PAP-specific CTL activity (R = 0.5187, p = 0.0134) and PA2024-specific CTL activity (R = 0.6735, p = 0.0006) and OS. Median OS for pts with PAP- or PA2024-specific CD107a expression above or below the median CTL activity at 26 wks was 37.1 and 25.2 months, respectively. **Conclusions:** These analyses demonstrate that sip-T induces a robust PAP-specific CTL activity, indicative of tumor lytic activity, which is positively correlated with prolonged OS in mCRPC pts. This finding is a significant addition to the elucidation of the mechanism of sip-T induced immune responses and OS benefit. Clinical trial information: STRIDE: NCT01981122, STAMP: NCT01487863.

5028 Poster Session (Board #255), Sat, 1:15 PM-4:45 PM

Subsequent treatment after abiraterone acetate + prednisone (AA + P) in patients (pts) with newly diagnosed high-risk metastatic castration-naïve prostate cancer (NDx-HR mCNPC): Detailed analyses from the phase 3 LATITUDE trial. *First Author: Kim N. Chi, BC Cancer Agency - Vancouver Centre, Vancouver, BC, Canada*

Background: Pts with NDx-HR mCNPC quickly progress to castration-resistant disease when using androgen deprivation therapy (ADT) alone. The LATITUDE study found significant improvement in OS and rPFS when AA + P was added to ADT. Pts receiving placebo (PBO) could cross over after unblinding at the first interim analysis. We present details on subsequent therapies pts received after unblinding at this second preplanned analysis. **Methods:** NDx-HR mCNPC pts were randomized 1: 1 to AA (1 g QD) + P (5 mg QD) + ADT or PBOs + ADT. Secondary end points, median time to subsequent prostate cancer (PC) therapy and chemotherapy (chemo), and a post hoc exploratory end point, time to life-prolonging therapy, were analyzed by stratified proportional hazards model. **Results:** 1199 pts were enrolled (ITT). At median follow-up of 41.4 mo, median treatment exposure was 25.8 vs 14.4 mo (AA + P vs PBOs, respectively), and treatment was ongoing for 34% and 12% of pts receiving AA + P and PBOs, respectively. 60 PBOs pts crossed over to AA + P, with a median AA + P exposure of 2 mo (57/60 still on AA + P). The most common reason for discontinuation was progressive disease (AA + P, 40%; PBOs, 64%). Pts receiving subsequent and life-prolonging therapies (Table) were 37% and 26% on AA + P, and 58% and 45% on PBOs, respectively. Compared with PBOs, AA + P delayed time to subsequent PC therapy (HR [95% CI] 0.428 [0.361-0.507]), life-extending PC therapy (HR [95% CI] 0.398 [0.326-0.486]), and chemo (HR [95% CI] 0.471 [0.378-0.586]). Median duration of first life-prolonging therapy was 3.7 mo for AA + P (n = 155) and 5.7 mo for PBOs (n = 268). **Conclusions:** Adding AA + P to ADT delays the need for subsequent PC therapy vs ADT for pts with NDx-HR mCNPC. Time to subsequent therapy, life-prolonging therapy, and chemo strongly favored AA + P, even though most pts receiving PBOs remaining on treatment had crossed over to AA + P or other life-prolonging subsequent therapy. Clinical trial information: NCT01715285.

Life-prolonging therapy	AA + P (n = 597)	PBOs (n = 602)
Any, n (%)	155 (26)	268 (45)
Docetaxel	127 (21)	207 (34)
Enzalutamide	47 (8)	89 (15)
Radium-223	23 (4)	39 (6)
Cabazitaxel	17 (3)	42 (7)
AA + P	12 (2)	76 (13)

5029 Poster Session (Board #256), Sat, 1:15 PM-4:45 PM

Genomic and phenotypic evidence for prostate cancer osteomimicry in circulating tumor cells from men with metastatic castration resistant prostate cancer (mCRPC) treated with radium-223. *First Author: Andrew J. Armstrong, Duke Cancer Institute, Duke University, Durham, NC*

Background: Radium-223 is a targeted alpha-therapy that improves survival in men with mCRPC. The biologic basis for radium-223 efficacy is not completely understood. We hypothesized that PC osteomimicry, a form of epithelial plasticity leading to an osteoblastic phenotype, may contribute to the intralesional deposition of radium-223 and subsequent irradiation of the tumor microenvironment. **Methods:** We conducted a pharmacodynamic study (NCT02204943) of radium-223 in men with bone metastatic CRPC to investigate genomic and phenotypic alterations in circulating tumor cells (CTCs), ctDNA, and metastases. Prior to and 3 & 6 months after radium, we collected liquid and metastatic biopsies including CTCs for phenotypic characterization and CTC/ctDNA genomic analysis. The primary objective was to describe the prevalence of CTC bone alkaline phosphatase (BAP) over time. We measured radium-223 decay products in tumor and surrounding normal bone during treatment. **Results:** We enrolled 20 men with heavily pre-treated symptomatic bone predominant mCRPC and treated with radium-223 over a median of 6 doses; 55% had elevated serum BAP. PFS was 5.5 mo; OS was 13.3 mo; 13% had unfavorable ($\geq$5) to favorable ($<$ 5) Cellsearch CTC conversion; 5% had $\geq$30% PSA decline. We found evidence of persistent BAP+CTCs in the majority of men over time during radium-223 therapy despite serum BAP normalization in 53% of men. We identified genomic gain of key osteomimicry regions in CTC DNA, including gains of BAP, osteopontin, and OB-cadherin. We observed greater gamma emission from radium-223 from tumor biopsies than adjacent normal bone. CTC DNA and matched ctDNA studies suggested persistence of aggressive genomic alterations such as AR, FOXA1, and MYC/N-MYC gain and PTEN, GRHL2, FGFR2, and BRCA1 loss. We established several prostate CTC cultures exhibiting evidence of epithelial plasticity and BAP expression. **Conclusions:** Osteomimicry may contribute to the uptake of Radium-223 within bone metastases and may thereby enhance the therapeutic benefit of radium-223. We found genomic and phenotypic evidence of osteomimicry in CTCs from men with mCRPC. Clinical trial information: NCT02204943.

5030 Poster Session (Board #257), Sat, 1:15 PM-4:45 PM

Genomic characterization of ductal adenocarcinoma of the prostate. *First Author: Michael Thomas Schweizer, University of Washington/Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: Ductal prostate cancer (dPC) is a rare prostate cancer variant associated with poor outcomes. Prior small case series have documented that dPCs may be enriched for alterations in DNA damage repair (DDR) pathway genes and activation of WNT- and PI3K-pathways. To expand these findings, we formed a multicenter collaboration with the goal to provide a comprehensive overview of the spectrum of mutations associated with dPC. **Methods:** We assembled three case series across multiple institutions in the United States and Canada. All patients carried a diagnosis of dPC, and histopathologic classification was confirmed by an expert genitourinary pathologist at each respective institution. All tumor tissue was sequenced on a targeted next-generation sequencing (NGS) assay, UW-OncoPlex, according to previously published methods. Tumor samples were acquired from men with dPC treated at the University of Washington/Seattle Cancer Care Alliance (N = 21), Johns Hopkins Hospital (N = 21) and University of Calgary (N = 8). Only pathogenic/likely pathogenic mutations are reported. **Results:** Tumors from 50 patients with known dPC were sequenced. Overall, 26 (52%) individuals had at least one alteration in a DDR gene, including 7 (14%) with a mismatch repair (MMR) gene mutation. Twenty (40%) cases had mutations predicted to result in PI3k-pathway activation, 15 (30%) patients had mutations that were predicted to result in activation of the WNT-signaling pathway (N = 11 inactivating *APC* mutations; N = 4 activating *CTNNB1* mutations), and 12 (24%) had mutations in genes involved in MAPK-signaling. Other frequently altered genes included: *FOXA1* (N = 17, 34%), *TP53* (N = 9, 18%) and *SPOP* (N = 6, 12%). Alterations in *AR* were relatively infrequent (N = 4, 8%). **Conclusions:** This study confirmed that dPCs are enriched for actionable mutations. Over 50% of cases demonstrated at least one alteration in a DDR pathway gene, including a high percentage of cases with MMR deficiency. Patients with dPC should be offered NGS to guide standard of care treatment (e.g. anti-PD1 therapy, platinum-based chemotherapy) or to triage toward an appropriate clinical trial (e.g. PARP inhibitor trials).

5031 Poster Session (Board #258), Sat, 1:15 PM-4:45 PM

Combination of niclosamide to target androgen receptor variant 7 (AR-V7) and abiraterone to target androgen synthesis for the treatment of castration-resistant prostate cancer (CRPC): Initial results from a phase Ib/II trial. *First Author: Chong-xian Pan, University of California Davis Comprehensive Cancer Center, Sacramento, CA*

Background: The androgen receptor (AR) variant AR-V7 lacks the ligand binding domain, constitutively activates the AR pathway, and confers resistance to Abiraterone (Abi) and enzalutamide (Enza). We discovered that the anti-helminthic drug niclosamide targets AR-V7 and sensitizes resistant CRPC to Enza and Abi. We hypothesize that niclosamide/PDMX1001 potentiates the efficacy of Abi against CRPC. **Methods:** Eligible patients (pts) have progressive CRPC with serum testosterone $<$ 50 ng/dl. No prior Abi was allowed. In the Phase Ib cohort, pts received Abi 1000 mg PO qd, prednisone 5 mg PO bid, with intrapatient dose-escalation of niclosamide/PDMX1001 from 400 mg PO bid to 1600 mg PO tid. Trough niclosamide/PDMX1001 levels were measured. The Phase II cohort will enroll 27 patients with detectable AR-V7 in the peripheral blood. Co-primary endpoints include toxicity and response as determined by the Prostate Cancer Working Group 2 criteria. **Results:** Of 6 pts (age 74-83) in the Phase Ib cohort, five pts tolerated a niclosamide/PDMX1001 dose of 1,600 mg po tid without dose limiting toxicity; per protocol, this is the recommended Phase II dose. Niclosamide/PDMX1001 trough level was 0.305-0.648 μM in the three pts analyzed thus far, higher than the target level of 0.1μM required for anti-cancer activity. Of 6 pts, two pts achieved undetectable PSA ($<$ 0.01 ng/ml) for over 16 cycles and are still going on, compared to historical control 0/30 pts treated with Abi alone; two with partial PSA response ($\geq$50% decrease). Of the remaining two pts, one was prematurely taken off from the study after one cycle because of rising PSA, and the other had PSA decrease of 17.1%, but biopsy of the only enlarged lymph node showed all necrotic tissue. No dose-limiting toxicity was observed. The Phase II cohort will now enroll. Molecular correlative studies will be presented. **Conclusions:** The combination of niclosamide/PDMX1001, Abi and prednisone is well tolerated with promising safety and efficacy data. Targeted serum trough levels of niclosamide are clinically achievable. Clinical trial information: NCT02807805.

5032 Poster Session (Board #259), Sat, 1:15 PM-4:45 PM

Association of metastasis-free survival (MFS) and overall survival (OS) in nonmetastatic castration-resistant prostate cancer (nmCRPC). *First Author: Matthew Raymond Smith, Massachusetts General Hospital Cancer Center and Harvard Medical School, Boston, MA*

Background: Intermediate clinical end points are needed for prostate cancer to inform clinical decisions and facilitate drug development. The international Intermediate Clinical Endpoints in Cancer of the Prostate (ICECaP) working group reported that MFS is a strong surrogate of OS in hormone-sensitive localized prostate cancer. We sought to determine the relationship between MFS and OS in patients with nmCRPC. **Methods:** Data from the phase 3 SPARTAN trial in men with high-risk nmCRPC were used to undertake a landmark analysis for MFS. A Cox proportional hazard regression model, adjusted for covariates, evaluated the relationship of OS and development of metastases. The correlation of MFS and OS was assessed by Spearman's and Fleischer's correlation statistics. **Results:** As of May 2017, 1207 patients with nmCRPC had a median time to metastasis of 40.5 months. A landmark analysis showed that patients who developed metastases at 6, 9, and 12 months had significantly shorter median OS compared with those patients without metastasis (Table); after adjusting for baseline covariates, the development of metastases remained associated with OS. A significant positive correlation was observed between MFS and OS (Spearman's correlation coefficient: 0.62; $p < 0.0001$). The more robust, parametric Fleischer's statistical model confirmed the positive correlation (correlation coefficient: 0.69), with ≈50% of variability in OS explained by MFS. **Conclusions:** MFS has a significant association with OS and is predictive of OS in high-risk nmCRPC. This analysis demonstrates that MFS is a meaningful and valid intermediate clinical end point for OS. Clinical trial information: NCT01946204.

5033 Poster Session (Board #260), Sat, 1:15 PM-4:45 PM

Relationship of time to metastasis (TTM) and site of metastases in patients (pts) with nonmetastatic castration-resistant prostate cancer (nmCRPC): Results from the phase 3 SPARTAN trial. *First Author: Matthew Raymond Smith, Massachusetts General Hospital Cancer Center and Harvard Medical School, Boston, MA*

Background: SPARTAN, a randomized placebo (PBO)-controlled phase 3 study, evaluated the effect of apalutamide (APA), an orally administered next-generation androgen receptor inhibitor, in men with nmCRPC and a rapidly rising PSA. In SPARTAN, APA was associated with a 73% relative risk reduction of distant metastasis. We assessed the relationship between TTM and site of metastases after androgen deprivation therapy (ADT) plus APA or PBO. **Methods:** 1207 pts with nmCRPC and PSA doubling time (PSADT) ≤ 10 months were randomized 2:1 to APA (240 mg QD) or PBO, with concurrent ADT (both arms). TTM, defined as time from randomization to first evidence of blinded central review–confirmed radiographically detectable distant metastasis, was assessed by site of metastases, nodal (M1 nodes + soft tissue) vs bone (bone ± M1 nodes) vs visceral (visceral, regardless of other sites). Kaplan-Meier methods were used to analyze TTM. A stratified proportional hazards model with treatment group as a factor, stratified by PSADT, bone-sparing agent use, and loco-regional disease, was used to estimate HR and 95% CI. **Results:** Of those pts with metastases (APA vs PBO, respectively), 30% (52/175) and 40% (76/191) developed nodal metastases, while 57% (100/175) and 52% (100/191) developed bone metastases, and 13% (23/175) and 8% (15/191) developed visceral metastases. The HRs (APA vs PBO; 95% CI) for TTM for the intent-to-treat population were 0.19 (0.13-0.27) and 0.31 (0.23-0.41) for nodal and bone metastases, respectively ($p < 0.0001$). **Conclusions:** Treatment with APA markedly decreased the risk of metastases, regardless of the site of metastasis. The consistency of these results provides further evidence for the clinical benefit of APA in nmCRPC. Clinical trial information: NCT01946204.

5034 Poster Session (Board #261), Sat, 1:15 PM-4:45 PM

Predicting disease progression in patients (pts) with nonmetastatic castration-resistant prostate cancer (nmCRPC): An analysis from the phase 3 SPARTAN trial. *First Author: Eric Jay Small, Helen Diller Family Comprehensive Cancer Center, University of California, San Francisco, San Francisco, CA*

Background: Men with nmCRPC and prostate-specific antigen doubling time (PSADT) of ≤ 10 mo are at high risk for metastatic disease and associated death. Apalutamide (APA), a next-generation androgen receptor inhibitor, extended metastasis-free survival (MFS) by median > 2 years in men with nmCRPC (HR [95% CI] 0.28 [0.23-0.35]; $p < 0.0001$) in SPARTAN. A multivariate analysis (MVA) was undertaken to identify independent predictors of MFS in this pt population. **Methods:** A nonstratified proportional hazards model assessed predictors of clinical end points and examined the following covariates: treatment, PSADT, use of bone-sparing agents, N0 vs N1 at study entry, Eastern Cooperative Oncology Group performance status (ECOG PS), prior therapies, Gleason score, age, and baseline PSA. **Results:** 1207 pts were randomized (806, APA; 401, PBO), and the overall population was evaluated. The following covariates emerged as independent predictors of longer MFS for the combined arms: APA treatment, PSADT > 6 mo, N0 disease, Gleason score at diagnosis ≤ 7, and baseline PSA ≤ 7.8 ng/mL (Table). A relationship between shorter PSADT and faster time to metastasis or death was observed. **Conclusions:** APA treatment, PSADT, nodal disease, Gleason score, and baseline PSA were independent predictors of MFS in pts with nmCRPC from SPARTAN. The treatment effect of APA remained highly significant after adjusting for covariates, with a similar magnitude of risk reduction for MFS in the MVA to that of the original primary analysis. Furthermore, there is a continuous relationship between PSADT and time to metastasis or death. Clinical trial information: NCT01946204.

Covariate	HR (95% CI)	p Value
Treatment, APA vs PBO	0.26 (0.21-0.32)	< 0.0001
Baseline PSA, ≤ 7.8 ng/mL vs > 7.8 ng/mL	0.59 (0.47-0.73)	< 0.0001
PSADT, > 6 mo vs ≤ 6 mo	0.65 (0.51-0.84)	0.0007
Loco-regional disease, N0 vs N1	0.68 (0.52-0.89)	0.0055
Gleason score at diagnosis, ≤ 7 vs ≥ 8	0.75 (0.61-0.92)	0.0063
Age per 10 years	0.88 (0.77-1.01)	0.0784
ECOG PS at baseline, 0 vs 1	0.84 (0.66-1.07)	0.154
Use of bone-sparing agent, yes vs no	0.78 (0.55-1.12)	0.174
Prior hormonal therapies; n, ≥ 2 vs 1	0.90 (0.69-1.16)	0.406

5035 Poster Session (Board #262), Sat, 1:15 PM-4:45 PM

Testing the impact of adjuvant radiotherapy (aRT) after radical prostatectomy (RP) on overall mortality (OM) in prostate cancer patients with pathologically node positive disease: A nationwide analysis. *First Author: Firas Abdollah, Vattikuti Urology Institute, Detroit, MI*

Background: Using institutional data, we have previously identified subgroups of patients with pN1 prostate cancer, who can benefit from aRT plus adjuvant hormonal therapy (aHT) after RP. Our objective is to assess the generalizability of our previous findings using nationwide database. **Methods:** We identified 4276 patients with pN1 disease, who were treated with RP followed by aHT ± aRT, between 2004 and 2013, within the National Cancer DataBase. We stratified patients into five risk groups using pathological data, and based on previously established criteria - Group 1: men with 1-2 positive nodes and Gleason score (GS) < = 6; Group 2: men with 1-2 positive nodes, GS = 7, and stage < = pT3a with negative surgical margins; Group 3: men with 1-2 positive nodes, GS = 7, and stage > = pT3b or positive surgical margins; Group 4: men with 3-4 positive nodes; and Group 5: men with > 4 positive nodes. Univariable and multivariable analyses tested the relationship between aRT status and OM in each group. **Results:** Median (interquartile range) age, # of nodes removed, and # of positive nodes were 62 yrs (56-67), 9 nodes (5-15), and 1 node (1-2), respectively. Mean and median follow-up were 53.6, and 49.4 months, respectively. The percentage of men included in Groups 1 to 5 was respectively 0.6%, 14.6%, 60.1%, 14.2%, and 10.4%. On univariable analysis, aRT improved outcomes in Group 3 and Group 4 only. Specifically, in patients treated without aRT vs with aRT, the 5-year OM was 15.2% vs 11.4% ($p = .01$) in Group3, and 24.7% vs 14.1% ($p < .001$) in Group 4. In multivariable analysis adjusting to age and comorbidity, aRT decrease OM risk in Group 3 (hazard ratio [HR]: 0.78, $p = .01$), and Group 4 (HR: 0.37, $p < .001$), but not in the other groups. **Conclusions:** We validated our previously published results, and demonstrate that certain sub-groups of patients with pathologically proven node positive prostate cancer can benefit from maximizing local control by adding aRT to RP. Our new findings generalize our results to a nationwide setting, and shows that the beneficial impact of aRT is evident also for OM, which is the most significant endpoint in cancer treatment.

5036 Poster Session (Board #263), Sat, 1:15 PM-4:45 PM

Correlates of response to anti-PD-1 immune checkpoint blockade (ICB) in mismatch repair proficient (MMRp) and deficient (MMRd) patients (pts) with metastatic castration resistant prostate cancer (mCRPC). *First Author: Minke Smits, Department of Medical Oncology, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands*

Background: Predictive biomarkers are needed to improve the proportion of pts with mCRPC that may benefit from anti-PD-1/PD-L1 ICB. A comprehensive characterization of both genomic alterations as the immunological landscape during ICB may prove fundamental. **Methods:** We investigated correlates of response and progression in pts with mCRPC treated with anti-PD-1 ICB. Pts were selected by PD-L1 $>$ 1% and/or MMRd. Optional pre-treatment and post-progression biopsies were collected for whole-genome sequencing and multiplex IHC. 8-color flow cytometry was performed on frozen mononuclear cells at baseline and on treatment (Tx) using 6 immune-panels. MMR status was evaluated in exosome subsets using nested amplification PCR. Response was evaluated per PCWG3 criteria and Tx was continued until radiological progression with lack of clinical benefit or due to ICB-toxicity. **Results:** At present 13 CRPC pts started Tx with median follow-up of 5.3 months. 10/13 pts had PD-L1 expression $>$ 1%, 6/13 pts were MMRd. Tx is ongoing in 4/13 pts. In evaluable pts with MMRp and MMRd, range of mutational burden (TMB) was 2-8 and 25-74 mutations per megabase, respectively (resp); objective responses were only seen in MMRd pts; PSA $>$ 50% declines were seen in 75% and 13%, resp; median progression-free survival was 3.7 vs 7.8 months, resp ($p = 0.007$). No relationship was seen between PD-L1, TMB and CD3+tumour infiltrating lymphocytes (TILs); TILs were increased in MMRd vs MMRp pts ($p = 0.06$). During Tx, significant changes were seen in circulating T cell populations, including CD4+PD-1+, CD4+CD28+PD-1+, CD8+PD-1+, CD4+ICOS+and CD8+ICOS+ subsets, with on Tx CD4+PD-1+ cells differing between responders and non-responders ($p = 0.03$). Additional results on genomic and immune correlates will be presented in more detail. **Conclusions:** Deep and durable responses to anti-PD-1 ICB were seen in pts with mCRPC, particular those with MMRd. Circulating T cell subsets are associated with response to ICB. An integrative biomarker suite to predict for responsive mCRPC pts to anti-PD-1 ICB is key and these and other correlates should be further investigated.

5038 Poster Session (Board #265), Sat, 1:15 PM-4:45 PM

A transcriptome analysis of castration resistant prostate cancer metastases in a prospective cohort study reveals high expression of AKT pathway genes predictive of long term response to abiraterone acetate/prednisone. *First Author: Manish Kohli, Mayo Clinic, Rochester, MN*

Background: To determine transcriptome based markers associated with long-term response to abiraterone acetate/prednisone (AA/P) in metastatic castration-resistant prostate cancer (mCRPC). **Methods:** RNAsequencing (RNA-seq) of metastatic biopsies were performed in a prospective cohort study of treatment naïve mCRPC patients initiating AA/P (visit1) and repeated after 12 weeks on treatment (visit2). Patients (pts) were followed for time to treatment change (TTTC), defined as time from enrollment until change of AA/P treatment due to progressive disease. The lower and upper quartiles of TTTC for the whole cohort defined short term and long term responders. Previously we published the primary analysis revealing Wnt pathway activation as markers of primary resistance to AA/P (*Annals of Oncology;*2017; PMID29069303). As a secondary study goal gene-set variation analysis (GSVA) of 113 prostate cancer related gene sets was performed with post treatment visit2 RNA-seq data to identify associations with long from short-term responders. RNA-seq based candidates identified as associated with long term response were also evaluated in visit1 biopsies. **Results:** 83/90 enrolled pts had a visit2 biopsy of which 58 biopsy specimens had good quality RNA for analysis. 18/58 had short (median 3.6 months; range 1.4-4.5) and 11/58 patients and long- (median 29 months; range 23.5-41.7) term responses. In the metastases of Visit2 biopsies, long-term responders had lowered expression of steroid-biosynthesis genes (e.g., *CYP7B1, CYP39A1, AKR1D1*) (p-value $<$ 0.005) and higher expression of genes upregulated by AKT activation (e.g. *GOT1, PPP4C, KRT8*) (p-value $<$ 0.02). Similar elevated expression of AKT activation was observed at Visit1 (p-value $<$ 0.04) in long-term responders. The AKT activation signature was also negatively correlated with the steroid biosynthesis signature (Spearman correlation of -0.61, p-value $<$ 2e-7). **Conclusions:** AA/P was more effective in pts with high pre-treatment AKT pathway gene expression signatures suggesting that AKT activation can be used as a predictive biomarker for AA/P. Clinical trial information: NCT# 01953640.

5039 Poster Session (Board #266), Sat, 1:15 PM-4:45 PM

DNA repair mutations and treatment-emergent small cell neuroendocrine prostate cancer (t-SCNC) as hallmarks of distinct subgroups of metastatic castration resistant prostate cancer (mCRPC): Data from the West Coast Prostate Cancer Dream Team. *First Author: Rahul Raj Aggarwal, UC San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

Background: Genomic alterations in DNA repair genes are present in approximately 20-30% of patients with mCRPC. t-SCNC may be increasing in prevalence and is associated with adverse clinical outcomes. Potential overlap between these two subsets of mCRPC was assessed. **Methods:** Eligible patients (pts) underwent a metastatic tumor core needle biopsy at one of 5 centers. Tumor tissue was sent for consensus pathology call (JH, GT, LT) and targeted next-generation DNA sequencing. Chi-square test was used to compare the frequency of genomic alterations in select DNA repair genes (*BRCA1*, *BRCA2*, *ATM*, *CDK12, RAD51*, *PALB2*, *FANCA*, *CHEK2, MLH1*, *MSH2*, *MLH3*, and *MSH6*) between tumors with versus those without small cell histology. Frozen tissue from the same metastatic tumor underwent RNA sequencing (RNA-seq). Pts were prospectively followed for overall survival (OS). **Results:** 119 consecutive biopsies with sufficient tumor to permit histologic assessment and targeted NGS were included, including 14 biopsies (13%) with t-SCNC. In the overall cohort, DNA repair mutations were present in 41 biopsies (34%). By histologic subtype, mutations were present in 40/105 (38%) of adenocarcinoma tumors vs. only 1 of 14 (7%) biopsies with t-SCNC histology ($p = 0.047$). In contrast, *TP53* and/or *RB1* loss were enriched in the t-SCNC cohort (83% vs. 34%, $p = 0.0015$). Unsupervised hierarchical analysis of the transcriptome identified small cell-enriched cluster of biopsies ($N = 12$) that were mutually exclusive of DNA repair mutations and enriched for E2F transcriptional targets on RNA-seq. The presence of t-SCNC histologic differentiation was associated with worse OS from date of mCRPC (median OS 44.5 vs. 36.6 months; log-rank $p = 0.027$); the presence of DNA repair mutations was not ($p = 0.734$). **Conclusions:** Tumors harboring DNA repair pathway mutations or t-SCNC differentiation may represent distinct disease subsets of mCRPC with differing clinical outcomes. Added together, the two subsets account for approximately 40% of mCRPC pts. Independent prospective validation of these findings is warranted. Clinical trial information: NCT02432001.

5040 Poster Session (Board #267), Sat, 1:15 PM-4:45 PM

Lutetium-177 PSMA617 theranostics in metastatic castrate-resistant prostate cancer (mCRPC): Interim results of a phase II trial. *First Author: Shahneen Kaur Sandhu, Department of Medical Oncology, Peter MacCallum Cancer Centre, Australia, Melbourne, Australia*

Background: Lutetium-177 (^{177}Lu)-PSMA617 (LuPSMA) is a radiolabelled small molecule that binds with high affinity to prostate specific membrane antigen (PSMA) enabling tumor-targeted delivery of beta-radiation. We previously reported favourable activity and toxicity in 30 patients with mCRPC and now report updated safety and efficacy results including an additional 20 patient expansion cohort. **Methods:** In this phase II trial, 50 patients with PSMA-avid mCRPC who had progressed after conventional therapies received up to 4 cycles of LuPSMA every 6 weeks. The primary endpoints were 50% PSA response rate (PCWG2) and toxicity (CTCAE v4.3). Other endpoints were objective response rate (ORR), quality of life (EORTC QLQ-C30, BPI), PSA progression free survival (PFS) and overall survival (OS). **Results:** 50 patients (median age 71, range: 50-87) were eligible for treatment. 90% had progressed after abiraterone and/or enzalutamide, and 88% progressed after chemotherapy (84% post docetaxel and 48% following docetaxel and cabazitaxel). A median of 4 (range: 1-4) cycles and mean radioactivity of 7.5 GBq/cycle was administered. At this interim analysis (cut-off: 19 Jan 2018), the primary endpoint of PSA decline $\geq$ 50% was achieved in 31 of 50 patients (62%, 95% CI 47-75%), including 22 patients (44%, 95% CI 30-59%) with a PSA decline $\geq$ 80%. Common toxicities included dry mouth (68%), fatigue (38%), nausea (48%) and pain flare (10%). These were all Grade 1-2, self-limiting or manageable. G3-4 hematological toxicities attributed as possibly related to LuPSMA included thrombocytopenia (10%), anemia (10%), and neutropenia (6%). Median PSA PFS was 7.0 months (95% CI 5.7-8.8) and median OS was 12.0 months (95% CI 10.0-18.7). **Conclusions:** This LuPSMA Phase II trial suggests high response rates and low toxicity in men with mCRPC who progressed after multiple conventional therapies. These compelling results have justified a randomized trial comparing LuPSMA to carbazitaxel (NCT03392428). Updated QOL, ORR, PSA-PFS and OS data will be presented. Clinical trial information: 12615000912583.

5041 Poster Session (Board #268), Sat, 1:15 PM-4:45 PM

Sipuleucel-T (sip-T) overall survival (OS) and clinical outcomes by baseline (BL) prostate-specific antigen (PSA) quartiles in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC): PROCEED registry. *First Author: A. Oliver Sartor, Tulane Medical School, New Orleans, LA*

Background: Sip-T is an autologous cellular immunotherapy for asymptomatic/minimally symptomatic mCRPC. IMPACT analyses suggested that OS was longer in treated and control pts with low baseline PSA, and OS benefit was greatest for sip-T vs control in the pts with the lowest PSA (Schellhammer Urol 2013). We analyzed the prognostic value of BL PSA in PROCEED (NCT01306890), a phase 4 registry study in mCRPC pts. **Methods:** Eligible mCRPC pts were scheduled to receive 3 sip-T infusions at ~2-weekly intervals. Objectives included cerebrovascular event risk (primary) and OS (secondary). Follow-up was every 3 months after sip-T for 3 years minimum or until death or withdrawal. This is a *post-hoc* analysis (see Table for tests) of outcomes by PSA quartile. **Results:** 1976 pts were enrolled between 2011–2017: median age 72 yrs; 87% Caucasians, 12% African Americans; 51% had a Gleason score ≥8; prior therapies 78% (local) & 99% (hormonal). 1255 pts died. Median (range) BL PSA was 15 (0–7497) ng/mL. All outcomes in Table were significantly worse in the 2nd, 3rd & 4th PSA quartiles vs the 1st (lowest PSA) quartile. Clinical trial information: NCT01306890. **Conclusions:** OS & time to first ACI are longer in sip-T treated pts in the lowest BL PSA quartile vs sip-T treated pts with higher PSA. Survival of nearly 5 years was seen in the lowest PSA quartile. Although PROCEED did not have a comparator arm, the trend for longer OS is concordant with that seen in IMPACT.

Cancer-related morbidity at the end of life in men with prostate cancer. *First Author: Divya Yerramilli, Harvard Radiation Oncology, Boston, MA*

Background: Limited data exist regarding disease-related complications (DRCs), such as bone fractures and urinary obstruction (UO), near end of life of men who die with prostate cancer. We aimed to describe the burden of DRCs in these patients. **Methods:** As part of the Cancer Research-UK funded Clustered randomised trial of PSA testing for prostate cancer, we examined a cohort of 2603 men who died within 10 years of diagnosis. We collected clinical factors and DRCs. We used univariate analysis to examine association between diagnostic risk-group (low/intermediate, high, and metastatic, as defined by NCCN) and Kaplan-Meier analyses to compare median times to each DRC. We also explored a subgroup of men with metastatic disease who became castrate-resistant. **Results:** Men with higher risk disease at time of enrolment had higher frequency of DRCs and shorter time to each DRC (Table 1). 19% of high risk men developed cord compression, 16% had pathologic fracture, and 10% had renal failure. High risk men had bone metastases (BM) 2.9 months from diagnosis (IQR 1.7-4.9) versus men with low/int. risk disease (4.2 mos, 2.8-6.3), $p < 0.001$. Men with castrate resistance had higher odds of developing BM (OR 1.97, 95% CI (1.53-2.55), $p < 0.001$) and UO (OR 2.10, 95% CI (1.47-3.02), $p < 0.001$). **Conclusions:** In the largest contemporary cohort prostate cancer patients, we found that a significant proportion of men experience cancer-related morbidity prior to death. Men with localized disease at diagnosis can have long intervals until development of DRCs. Furthermore, men who become castrate resistance are particularly vulnerable to DRCs.

5043 Poster Session (Board #270), Sat, 1:15 PM-4:45 PM

Association between health-related quality of life (HRQoL) and clinical outcomes in non-metastatic castration-resistant prostate cancer (M0 CRPC): Results from the PROSPER study. *First Author: Gerhardt Attard, The Institute of Cancer Research and the Royal Marsden, Surrey, United Kingdom*

Background: We used the PROSPER trial (NCT02003924) to assess (a) the relationship between time to HRQoL deterioration and prostate-specific antigen (PSA) response and (b) the association between HRQoL and metastasis-free survival (MFS). **Methods:** In PROSPER, 1401 men with M0 CRPC at high risk of metastasis were randomized 2:1 to enzalutamide (ENZA) or placebo. HRQoL was assessed with the Functional Assessment of Cancer Therapy–Prostate (FACT-P) at baseline (BL) and every 16 weeks during treatment. Association between time to first HRQoL clinically meaningful deterioration and PSA response (defined as a ≥50% decline from BL) was explored with stratified Cox regression analyses, and between longitudinal HRQoL changes and MFS with joint models including HRQoL as longitudinal covariate, after adjusting for treatment and relevant clinical/demographic variables. **Results:** Overall, 723 of 1401 (52%) patients were confirmed PSA responders, significantly less likely to deteriorate on all FACT-P scores than non-responders (hazard ratio [HR] 0.56–0.82), except on physical well-being (PWB) [HR 0.90; p = 0.244]. When treatment is included in the model, stronger effects were observed, explained by 98% of PSA responders receiving ENZA. Most FACT-P scores were prognostic for MFS (7 of 10 scores). Every 10-point increase in FACT-P total score (i.e. improvement) was associated with a 6% decreased risk of metastasis (HR [95% confidence interval] 0.94 [0.88, 1.00]). Every 3-point increase in PWB, emotional well-being, or prostate cancer subscale was associated with a 14% (0.86 [0.81, 0.92]), 12% (0.88 [0.78, 0.99]), and 9% (0.91 [0.86, 0.96]) decreased risk of metastasis, respectively. **Conclusions:** The research indicates a ≥50% reduction in PSA from BL would result in reduced risk of HRQoL deterioration, also showing a relationship between changes from BL in HRQoL and metastases. Thus, patient-reported outcomes are not only useful in describing patient experience in clinical trials, but may complement traditional clinical practice methods to monitor disease progression. Clinical trial information: NCT02003924.

5044 Poster Session (Board #271), Sat, 1:15 PM-4:45 PM

Transcriptional and post-transcriptional regulation of ribonucleotide reductase (RRM2) control its oncogenic role in prostate cancer progression. *First Author: Ying Zhang Mazzu, Memorial Sloan Kettering Cancer Center, New York*

Background: The role of DNA repair pathways has been recognized in prostate cancer (PC) progression. Ribonucleotide reductase (RNR) is essential for DNA synthesis and repair. The subunit of RNR complex, RRM2, can regulate tumor initiation, progression and drug resistance in multiple cancer types. There is limited knowledge of RRM2 function in PC. **Methods:** The clinical cohort was analyzed for the correlation of RRM2 and clinical outcomes. RNA-seq and protein array were applied for the mechanism studies. ChIP and reporter assays were used for transcriptional study. **Results:** High level of RRM2 was associated with lethal disease, independent from Gleason grade (odds ratio:3.54; 95% CI, 1.76-7.4) in a cohort of men in the Physicians' Health Study and the Health Professionals' Follow-up Study (n = 404). Transcriptomic analysis revealed that multiple oncogenic transcription factor networks were inhibited by inhibition of RRM2, while p53 signaling was strongly activated. Phosphoproteomic analysis showed inhibition of RRM2 could repress multiple oncogenic signals including SFK, STAT, and Akt/mTOR signaling. Intriguingly, inhibition of RRM2 by siRRM2 and the inhibitor (COH29) could specially target gene profiling of poor-prognosis subtypes (PCS1 and PAM50) in PC. In an *in vivo* PC xenograft model, COH29 strongly inhibited tumor growth. Amplification of RRM2 is rarely observed in PC, thus, transcription and post transcription may largely contribute to overexpression of RRM2. A bioinformatics strategy was developed to search the putative RRM2-targeting transcription factors (TFs). Among 13 TFs candidates, FoxM1 and E2F1 were validated to target the RRM2 promoter. Additionally, we found that methylation-induced silencing of miR-193b could release the inhibition control of FoxM1 and RRM2 in PC cells. DNMTs inhibitor (5-Aza) restored miR-193b expression, leading to the upregulation of RRM2 and FoxM1 in PC cells. **Conclusions:** We reveal the function of RRM2 in PC and unravel the mechanism of dysregulation of RRM2 in PC. Our findings suggest that RRM2 may serve as a key regulator of PC growth and a possible therapeutic target for PC therapy.

5045 Poster Session (Board #272), Sat, 1:15 PM-4:45 PM

c15-160: Enzalutamide (ENZA) plus CC-115 in men with metastatic castration-resistant prostate cancer (mCRPC): A phase 1b Prostate Cancer Clinical Trials Consortium study. *First Author: Dana E. Rathkopf, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Studies in PTEN-deficient prostate cancer (PC) models have shown additive anti-tumor activity when ENZA is combined with PI3K pathway inhibition due to modulation of reciprocal feedback loops. In addition, interplay between AR and DNA-PK regulates hormone-dependent DNA repair and PC progression. This phase Ib trial aims to optimize therapy for mCRPC with the combination of ENZA and the dual mTOR/DNA-PK inhibitor CC-115. **Methods:** This was a phase Ib multicenter trial (NCT02833883) for first-line mCRPC patients. Treatment was fixed dose ENZA (160 mg PO QD) with escalating doses of CC-115 (5 mg and 10 mg PO BID) using a 3 x 3 design. The primary endpoints were safety, PK and the recommended phase 2 dose (RP2D) of the combination. Secondary endpoints were PSA response, time on study and exploratory correlates using tumor biopsies, CTCs and ctDNA. **Results:** 16 patients were treated: 9 in dose escalation and 7 in dose expansion, for a total of 13 patients treated at the RP2D of CC-115 10 mg PO BID. There were no drug-drug interactions. Median time on study was 26 (18-74+) weeks (wks), and 9 patients remain on active treatment. All evaluable patients had a $>$ 50% PSA response, and 60% of patients achieved a $\geq$90% decline. The most common AEs were low grade fatigue (31%) and diarrhea (25%). At the RP2D, 8/13 (62%) patients developed rash: grade 3 (n = 6), grade 2 (n = 1) and grade 1 (n = 1) prompting dose reduction. 12 patients had baseline tissue analysis by IHC and/or NGS: 6 men had PTEN inactivation and 3 had DNA damage response and repair (DDR) alterations. Median time on study for those with PTEN deletions was 25 wks (7-57+), and was 29 wks (28-41+) for those with DDR alterations. Data on ctDNA and CTC biomarkers is pending. **Conclusions:** The combination of ENZA and CC-115 is safe and active in mCRPC, as demonstrated by all evaluable patients achieving a $>$ 50% PSA decline and 60% achieving a $\geq$90% PSA decline. Due to a higher than expected incidence of rash, the protocol was amended to continue with CC-115 at 7.5 mg PO BID for the phase 2 expansion. Funding: Celgene and Gateway for Cancer Research. Clinical trial information: NCT02833883.

5046 Poster Session (Board #273), Sat, 1:15 PM-4:45 PM

Patterns of PSA versus clinically progressive disease in the E3805 CHAARTED trial. *First Author: Alan Haruo Bryce, Mayo Clinic, Phoenix, AZ*

Background: Recent data has highlighted the high frequency with which metastatic prostate cancer can progress either radiographically or symptomatically without a rise in PSA, so called PSA-Clinical discordance. Recognizing this clinical phenomenon is important to implementing appropriate criteria for disease monitoring during treatment. **Methods:** 790 men were accrued from 7/28/06 to 11/21/2012 and randomized to ADT or ADT + Docetaxel at 75mg/m2 every 3 weeks for 6 cycles. Patients were prospectively stratified into high volume (HV) vs. low volume (LV) disease. Clinical PD was defined as increasing symptomatic bone metastases, progression per RECIST criteria, or clinical deterioration due to cancer per investigator's opinion. PSA PD was defined as an increase in PSA of more than 50% above the on-treatment nadir, with two consecutive increases at least 2 weeks apart. Concurrent PSA PD and Clinical PD is defined as both events occurring within 1 month. **Results:** As of the data cutoff of 4/30/2016 403 men with HV disease and 157 with LV disease had progressed. In HV disease, the most common progression pattern was PSA PD followed by clinical PD in both the ADT + D and ADT arms (39.5 vs 43.2%). Clinical PD without PSA progression occurred in 29.5% and 31.0% of patients. In LV disease, the dominant pattern of progression was Clinical PD without PSA PD, occurring in 44.8% and 34.4% of patients. PSA PD followed by clinical PD occurred in 28.4% and 37.8% of patients. Table 1: Disease progression pattern by treatment arm and disease volume Clinical trial information: NCT00309985. **Conclusions:** Clinical progression of disease in the absence of a PSA rise is frequent in patients treated for metastatic castration sensitive prostate cancer. The results highlight the need to incorporate imaging into treatment monitoring rather than relying on PSA alone to trigger imaging.

	High volume		Low volume	
Disease progression pattern	**ADT+D**	**ADT alone**	**ADT+D**	**ADT alone**
Concurrent PSA PD and clinical PD	11 (5.8%)	18 (8.5%)	3 (4.5%)	1 (1.1%)
PSA PD first and then clinical PD	75 (39.5%)	92 (43.2%)	19 (28.4%)	34 (37.8%)
PSA PD only	48 (25.3%)	37 (17.4%)	15 (22.4%)	24 (26.7%)
Clinical PD only	56 (29.5%)	66 (31.0%)	30 (44.8%)	31 (34.4%)
Total	190	213	67	90

5047 Poster Session (Board #274), Sat, 1:15 PM-4:45 PM

Pembrolizumab (Pembro) plus enzalutamide (Enz) in metastatic castration resistant prostate cancer (mCRPC): Extended follow up. *First Author: Julie Nicole Graff, VA Portland Health Care System, Knight Cancer Institute, Oregon Health & Science University, Portland, OR*

Background: Anti-PD1 treatment with Pembro is a promising treatment strategy in many solid tumors. Here, we report clinical outcomes of adding Pembro to men with mCRPC progressing on Enz. **Methods:** We enrolled 28 patients with mCRPC who had not previously had chemotherapy for mCRPC or checkpoint inhibitors. Pembro was given 200 mg IV every 3 weeks for 4 doses, which could be repeated for the patients who had stable or responsive disease. The primary endpoint was prostate specific antigen (PSA) response (PSA decline of $\geq$ 50%). Secondary endpoints were radiographic objective response (RECIST 1.1), PSA progression free survival, time to subsequent treatment, and time to death from any cause. Baseline tumor biopsies were done if there was a metastatic deposit amenable to biopsy. We are presenting updated clinical outcomes and evaluation of samples for presence of Program Death-Ligand 1 (PD-L1), microsatellite instability (MSI) and DNA repair defects. **Results:** Five of 28 patients (18%) had a PSA decline of $\geq$ 50%. Three of 12 patients (25%) with measurable disease at baseline achieved an objective response on radiographs. Of the responders (R), one passed away from an unrelated cause without PSA recurrence after 14.2 mos, and one relapsed after 10 mos and did not respond to a second course of Pembro. The other 3 continue to be in response (range 21.9-33.8 mos). For the entire cohort, the median follow up was 22.7 mos, and the median PSA-PFS time was 3.8 mos (95% CI: 2.8 – 9.9 mos). Time to subsequent treatment was 8.2 mos (95% CI: 5.1 – 12.8 mos). Median overall survival was 22.2 mos (95% CI: 14.7 – 28 .4 mos). Median radiographic PFS was 10.8 mos (5-22 mos). There were 8 immune related adverse events in 7 unique patients (hypothyroid 3, hyperthyroid 1, myositis 2, colitis 2). Seventeen patients had baseline biopsies of a metastatic deposit: 3 R, 14 non-responders (NR). Of the 3 R who had baseline biopsies, one had MSI and DNA repair defects. The other 2 had neither. Of the NR who had sequencing, 4 had a DNA repair defects, and none had MSI. None of the biopsies showed tumoral PD-L1 expression (Qualtek, 22C3). **Conclusions:** Pembro has activity in mCRPC when added to Enz. Responses were deep and durable in a subset of patients. Clinical trial information: NCT02312557.

5048 Poster Session (Board #275), Sat, 1:15 PM-4:45 PM

Association of genomic alterations (GAs) in circulating tumor DNA (ctDNA) with progression on abiraterone acetate (AA) or enzalutamide (enza) in advanced prostate cancer. *First Author: Andrew W Hahn, University of Utah Hunstman Cancer Institute, Salt Lake City, UT*

Background: Two androgen axis inhibitors, enza and AA plus prednisone, are approved for the treatment of advanced prostate cancer (aPC). Although initial responses are common with these agents, almost all men experience disease progression. Due to advances in next-generation sequencing (NGS) of ctDNA, it is feasible to assess the tumor genomic landscape in these men at different time points in their treatment. Here, we aim to identify GAs in ctDNA that contribute to resistance to AA and/or enza, which may guide development of novel therapies targeting these GAs. **Methods:** Men with aPC who underwent NGS of ctDNA using G360 (Guardant Health, Inc., Redwood City, CA) from the Huntsman Cancer Institute, University of Utah, and Tulane University were included. Non-matched men were classified as pre-AA/enza, post-AA/enza, and others were excluded. Post-AA/enza was defined as disease progression on AA or enza as one's most recent treatment at the time of testing. G360 is a 73 gene panel that provides complete sequencing of selected exons in order to maximize detection of known somatic mutations, as well as, copy number amplifications across 18 genes and selected fusions in 6 genes. Two-sided Fisher exact tests and t-tests were used to assess the frequency and number of alterations pre- or post-AA/enza, respectively. *P* values of less than .05 were considered statistically significant. **Results:** Of 354 men with advanced prostate cancer and ctDNA NGS available, 128 were pre AA/enza and 84 were post AA/enza. Compared with pre-AA/enza profiles, post-AA/enza studies showed higher mean number of GAs (5.01 vs. 3.03, p=0.02). GAs were significantly higher in *AR* (54.8% vs. 25.8%, p$<$0.0001), *TP53* (51.2% vs. 32.0%, p=0.006), *PIK3CA* (20.2% vs. 9.4%, p=0.04), and *CCNE1* (10.7% vs. 3.1%, p=0.04). Patients with liver metastases had significantly more GAs than those without (11.7 vs. 3.5, p$<$0.0001). **Conclusions:** In these hypothesis-generating data, men who progress on AA or enza have more alterations in *AR*, *TP53*, *PIK3CA*, and CCNE1 and increased number of GAs. These alterations may contribute to treatment resistance and be targets of interest for further drug development.

5049 Poster Session (Board #276), Sat, 1:15 PM-4:45 PM

Bone targeted therapy and skeletal related events in the era of modern therapies for castration resistant prostate cancer with bone metastases. *First Author: Li Zhang, DFCI at St. Elizabeth Medical Center, Boston, MA*

Background: Bone metastases in castration resistant prostate cancer (CRPC) is associated with serious morbidity and costs. The optimal timing of initiation and duration of bone targeted therapy (BTT) Zoledronic acid and Denosumab is unknown in the current era with four classes of therapy for CRPC prolonging overall survival (OS). We sought to define the practice patterns of BTT use and outcomes (skeletal related events - SRE and OS) in a high-volume center in the modern era of metastatic CRPC management. **Methods:** A retrospective cohort of patients (pts) who have received Abiraterone and/or Enzalutamide for CRPC from 2007 to 2017 was identified based on a single-institution's clinical database. The database and electronic medical record review was used for data collection, including pts' characteristics and pattern of BTT uses. Kaplan Meier method and Cox proportional hazards model assessed association of BTT use with time to first SRE and OS, respectively. **Results:** 197 pts were identified, and 79(40%) had $\geq$ 4 bone metastases (BM) and median follow-up was 4.7 (95%CI: 4.2-5.9) years. More pts with $\geq$ 4 BM received BTT with first line therapy (49% vs 32% - p-int $<$ 0.01). Pts with $\geq$ 4 BM, receiving BTT with first line therapy for CRPC had a 19% reduced risk of developing SRE - HR 0.81 (95%CI: 0.45-1.45). Pts with $<$ 4 BM did not have a lower HR when starting BTT with first line CRPC therapy. No OS difference was noted in pts who received BTT with first line therapy or not, regardless of the volume of bone metastases. **Conclusions:** Our cohort suggested that in the modern era, with more effective and greater number of CRPC therapies, pts with $\geq$ 4 BM still benefit from starting BTT with first line CRPC therapy.

5050 Poster Session (Board #277), Sat, 1:15 PM-4:45 PM

Phase II safety and tolerability study of Radium-223 (R223) in combination with enzalutamide (ENZA) in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC): CTRIAL-IE (ICORG) 13-21. *First Author: Raymond S. McDermott, Adelaide and Meath Hospital, Dublin, Ireland*

Background: R223 and ENZA are standard of care agents in the treatment of patients (pts) with mCRPC. The combination of R223 and ENZA is of interest due to differing modes of action and non-overlapping toxicity profiles, leading to the potential for synergy. **Methods:** This phase II, open-label, multicentre single arm study (NCT02225704) enrolled pts with mCRPC to bone with or without visceral/lymph node involvement who had progressed on androgen deprivation therapy. Prior docetaxel chemotherapy for hormone sensitive prostate cancer was allowed. Pts received 6 cycles of R223 (55 kBq/kg IV Q4W) in combination with ENZA (160mg/day), followed by ENZA alone until disease progression (PD), unacceptable toxicity or consent withdrawal. The primary endpoint was safety for the 6 months of combination therapy which is reported here. **Results:** From July 2015 to July 2017, 45 pts were enrolled in Ireland. 42 pts (93.3%) received all 6 cycles of combination therapy. A total of 13 pts (28.9 %) had grade (gr) 3/4 adverse events (AEs). The most frequent gr 3/4 AEs (Table) were neutropenia (n = 3, 6.6%) and fatigue (n = 3, 6.6%) followed by nausea, lower respiratory tract infection (LRTI), lymphocytopaenia, leukopaenia, hyperkalaemia, hypokalaemia, back pain, headache, urticaria, syncope and hypertension (all n = 1, 2.2%). 2 pts (4.4%) discontinued treatment due to AEs, gr 3 LRTI (n = 1) and gr 2 nausea and pain (n = 1). One pt discontinued due to symptomatic PD. There were no therapy-related deaths. **Conclusions:** R223 in combination with ENZA is well tolerated with acceptable early safety and toxicity profiles consistent with those seen when they are used as single agents and allowing for concomitant administration. Evaluation of secondary endpoints including skeletal related events with longer follow up is ongoing. Clinical trial information: NCT02225704.

	R223 + ENZA (n = 45)				
AE	**Gr 1**	**Gr 2**	**Gr 3**	**Gr 4**	**n (%)**
Fatigue	14	8	3		25 (55.5)
Nausea	14	6	1		21 (46.6)
Back pain	6	3	1		10 (22.2)
Neutropenia	1	5	2	1	9 (20)
Headache	4	1	1		6 (13.3)

5051 Poster Session (Board #278), Sat, 1:15 PM-4:45 PM

Efficacy and tolerability of first-line abiraterone + prednisone (ABI) versus enzalutamide (ENZ) for metastatic castration-resistant prostate cancer (mCRPC) in men $\geq$ 80 years: A retrospective cohort study. *First Author: Daniel Khalaf, British Columbia Cancer Agency - Vancouver Centre, Vancouver, BC, Canada*

Background: ABI and ENZ are first-line treatment options for mCRPC with comparable efficacy. In men $\geq$ 75 years, ABI and ENZ are associated with higher rates of adverse events. For very elderly patients (pts), the efficacy and tolerability of ABI and ENZ have not been directly compared. **Methods:** Retrospective analysis in pts $\geq$ 80 years of age who received ABI or ENZ for first-line treatment of mCRPC between July 2009 and September 2016 at the BC Cancer Agency. Medical records were reviewed for clinical characteristics and outcomes including PSA response rate (PSA50) (decrease of $\geq$50% from baseline), time to first progression (TTP) (PSA, radiographic or clinical progression) and overall survival (OS). **Results:** There were 106 pts in the ABI cohort and 104 in the ENZ cohort. Baseline characteristics were well balanced including median age 85 years (IQR 83-88); median Charlson Comorbidity Index (CCI) 7 (IQR 7-8); hemoglobin (HB) $<$ 130 in 75%; ECOG PS 0-1 in 60%; serum alkaline phosphatase (ALP)/LDH $>$ upper limit of normal (ULN) in 32%/35% and bone/lung/liver metastasis in 86%/10%/6%. Time from start of androgen deprivation therapy to castration-resistance (TTCR) was $<$ 12 months (m) in 16% vs 29% for ABI vs ENZ (p = 0.031). PSA50 was 43.4 % for ABI vs 77.9 % for ENZ ($p < 0.001$, X^2) and median TTP was 4.7 m vs 8.0 m (HR 1.52, 95% CI 1.12-2.08). On multivariable analysis, factors associated with TTP were: treatment arm ABI vs ENZ (HR 1.76, 95% CI 1.27-2.45), ALP $>$ ULN (HR 1.89, 95% CI 1.34-2.68), HB $<$ 130 (HR 1.61, 95% CI 1.13-2.30), CCI $>$ 7 (HR 1.57, 95% CI 1.13-2.19) and TTCR $>$ 12 months (HR 1.73, 95% CI 1.18-2.55). At least one dose reduction due to toxicity was required for 7.5% of pts for ABI vs 29.8% for ENZ ($P<0.001$, X^2). For pts in the ENZ cohort who had a dose reduction, the median TTP was 11.8 m vs 6.2 m for those without (HR 0.65, 95% CI 0.40-1.08). Median OS was 13.2 m for ABI vs 18.7 m for ENZ (HR 1.20, 95% CI 0.89-1.63). **Conclusions:** In this very elderly cohort, the PSA50 and TTP were superior for the ENZ cohort compared to the ABI cohort despite more dose reductions in the ENZ cohort. The retrospective nature of the analysis is a limitation of this study.

5052 Poster Session (Board #279), Sat, 1:15 PM-4:45 PM

Evolution of the genomic landscape of circulating tumor DNA (ctDNA) in advanced prostate cancer (aPC) over treatment and time. *First Author: David D. Stenehjem, University of Minnesota College of Pharmacy, Duluth, MN*

Background: While men with aPC respond to initial treatment, most will progress and require sequential therapies. Due to advances in next-generation sequencing (NGS), it is feasible to assess the tumor genomic landscape via blood or tumor tissue at different time points in treatment. Much debate exists over the concordance of tissue (tDNA) and ctDNA NGS. Some hypothesize that the genomic landscape of aPC evolves with treatment and time; however, there is a paucity of experimental data to support these statements. In this exploratory analysis, we compare the genomic landscape of aPC as detected by commercially available tDNA and ctDNA NGS platforms at different points during the course of disease. **Methods:** Men with aPC from the Huntsman Cancer Institute, University of Utah with matched tDNA NGS using FoundationOne (Foundation Medicine, Cambridge, MA) and ctDNA NGS using G360 (Guardant Health, Inc., Redwood City, CA) were included. Clinical data was collected retrospectively. Exonic regions from 69 genes covered by both platforms were included for analysis. Paired *t*-tests were used to assess number of genomic alterations (GAs) between testing platforms and were confirmed with nonparametric testing. Number of alterations was assessed by time and number of treatments between tDNA and ctDNA testing by multivariate nonparametric trend tests. **Results:** 101 men with aPC who had matched tissue and ctDNA NGS were included. In men with no new treatments and $\leq$ 1 year between tests, a similar number of GAs were detected in both tests (2.0 vs. 2.2, p=0.78). In contrast, men with $\geq$ 1 new treatment between tests had significantly more GAs after treatment (5.0 vs. 2.4, p=0.005). Total number of GAs was correlated with number of new treatments between testing (p=0.003) and not time between testing (p=0.76). **Conclusions:** In these hypothesis-generating data, the genomic landscape of aPC evolves with subsequent therapies. These data suggest that, in addition to baseline tumor genomic profiling, a contemporary tumor genomic profile at the time of disease progression may optimize guidance towards subsequent therapy selection.

5053 Poster Session (Board #280), Sat, 1:15 PM-4:45 PM

Unique patterns of the selection and change in circulating tumor cell (CTC) phenotypes and genotypes by drug class in metastatic castration-resistant prostate cancer (mCRPC). *First Author: Howard I. Scher, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Biomarkers to predict outcomes for individual patients (pts) on standard of care Rx is an unmet medical need in the treatment of mCRPC. Using baseline (BL) blood draws, we previously reported a phenotypic CTC heterogeneity algorithm that predicted for differential survival times on ARSi vs. taxanes. We have also observed that certain gene alterations as well as genomic instability are linked to different CTC phenotypic subtypes. We sought to associate CTC phenotypes to response, and to characterize phenotypic and genotypic changes to populations of CTCs associated from selection pressures by specific drug classes. **Methods:** 456 blood samples (228 matched BL and on-therapy) from 184 unique mCRPC pts were collected and processed utilizing the Epic Sciences CTC platform. CTCs were enumerated and characterized for phenotype (n = 11,722) including CTC subtypes, from pts who received ARSi therapy (n = 131), taxanes (n = 57) or a platinum containing regimen (n = 40). 985 CTCs of various phenotypic subtypes were single cell sequenced for DNA copy number variation. **Results:** CTCs were detected in 88.6% (202/228) BL and in 76.3% (174/228) on therapy samples, med = 3.5mL (0 to 490) and median = 2.7mL (0 to 992) respectively. Changes in CTC phenotypic features were observed unique to specific therapy classes, including changes to nuclear size, shape and texture. Persistent CTC phenotypes in pts treated with ARSi and taxane, but not platinum, were enriched with cells having AR over-expression and genomic instability ($p < 0.001$) while those in pts treated with ARSi but not taxane, were enriched with PTEN, RB1 and TP53 loss (all $p < 0.001$). Models to predict resistance to the therapies based on specific CTC prevalence in early on-therapy draws will be presented. **Conclusions:** We observed broad CTC phenotypic and genotypic heterogeneity prior to Rx, and patterns of clonal selection specific to different standard of care drug classes. Models utilizing these insights have potential to predict resistance if observed pre-therapy or during therapy to enable a change in therapy prior to clinical manifestation. Further development of these models is ongoing.

5054 Poster Session (Board #281), Sat, 1:15 PM-4:45 PM

Clonal concordance and genomic heterogeneity in single CTC copy number alterations vs. paired IMPACT metastatic tissue sequencing from mCRPC patient samples. *First Author: Howard I. Scher, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: High CTC phenotypic heterogeneity is associated with non-response to ARSi but not taxane chemotherapy assessed using a non-invasive rapid blood test. The MSK-IMPACT™ NGS assay is FDA approved for tumor tissue profiling to guide treatment selection. The frequency of directly actionable alterations in prostate cancer (PC) is ~35%. Recognizing many cancers harbor intra, inter and intracellular heterogeneity, we sought to evaluate concordance of sequencing single CTCs vs. paired biopsy analyzed by MSK-IMPACT, to assess CTC clonality in circulation vs. tumor, the relationship to CTC phenotypic heterogeneity and response. **Methods:** Metastatic tumor biopsies collected from 50 mCRPC patients (lymph nodes n = 26, bone n = 9, visceral n = 10 and other soft tissue n = 5) prior to new treatment were sequenced by MSK-IMPACT. Time matched blood samples (n = 50) were collected for CTC analysis (Epic Sciences). CTCs (n = 644, range 2-27, med = 13) underwent single cell low pass whole genome sequencing for copy number variation (CNV). Intra-patient CTC clonality was estimated based on similarity of DNA copy number segments. Phenotypic CTC heterogeneity was estimated by previously developed algorithms and compared to genomic clonal heterogeneity. **Results:** Large chromosomal CNV were detected in CTCs from 47/50 (94%) patients, 34/50 (67%) had multiple subclones with distinguishable CNV. Overall, a median of 3 distinct clones/pt (range 1-6) were observed across the cohort, with the number of clones not associated with the number of CTCs detected. Genomic clones observed in tissue were confirmed in CTCs from 32/50 (64%) pts, while 16/50 (32%) pts were discordant in CTCs, 2 pts were unevaluable. > 4 genomic clones were found in 13/50 pts, 12 of which had high phenotypic heterogeneity scores (top 50%). **Conclusions:** Single CTC sequencing is often concordant to metastatic tissue, but unique CTC clones highlight the prevalence of sub-clonal disease in mCRPC patients under-sampled by tissue biopsy. High genomic heterogeneity can be predicted by phenotypic CTC heterogeneity and may be useful to find patients unlikely to respond to targeted therapy.

5055 Poster Session (Board #282), Sat, 1:15 PM-4:45 PM

Clinical outcomes with cumulative tumor suppressor gene (TSG) alterations in castration sensitive (CSPC) and resistant (CRPC) prostate cancer. *First Author: Anis Hamid, Lank Center for Genitourinary Oncology, Dana-Farber Cancer Institute, Boston, MA*

Background: Alterations (alt) in *TP53*, *PTEN* and *RB1* TSGs have been identified in some prostate cancers. Preclinical data suggest that co-operative loss of 2 or more TSGs drives development of more aggressive disease. **Methods:** We identified men who underwent targeted exome sequencing (DFCI PROFILE) of CSPC (localized [L] and M1 presentation) and CRPC tissue samples. Biomarker(BM)-positive(+) was defined as copy number loss or deleterious mutation of ≥1 TSG (*TP53*, *PTEN* or *RB1*). For pts presenting with L-CSPC, Kaplan-Meier method estimated time from biopsy to PSA relapse/metastasis/death (EFS), CRPC, and death (OS). Cox model assessed association of BM status and outcomes, adjusted for age, stage and Gleason score in multivariate analyses (MVA). Time from ADT start for M1-CSPC to CRPC and death was also estimated. For M1-CRPC, duration on 1st line CRPC therapy and time from CRPC to death was estimated, adjusting for age, volume and location of metastasis in MVA. Association of cumulative BM+ hits (0 vs 1 vs 2 vs 3) and outcomes was assessed. **Results:** For BM+ frequencies see table. L-CSPC with BM+ had a shorter EFS (median 2.6 years, HR 1.95, 95% CI 1.22-3.13) and time to CRPC (HR 3.36, 95% CI 1.01-11.16). MVA confirmed association with EFS (HR 1.84, p = 0.029). More gene hits lead to greater risk of relapse (MVA; 1 vs 0 hit: HR 1.75, p = 0.05; 2/3 vs 0: HR 2.74, p = 0.04). None of the 43 M1-CSPC pts who were BM-neg had died with median follow-up of 3.3 yrs; BM+ 4-year OS was 64%. Only 4 (8%) of the CRPC cohort (n = 48) were BM-neg and with a median follow-up 4.1 years, only 1 had died (5.2 yrs). Cumulative TSG loss was associated with shorter duration on 1st line therapy in MVA (3 vs 0/1 hit: HR 2.86, p = 0.013). **Conclusions:** Deleterious *TP53*, *PTEN* and *RB1* variants are associated with increased risk of relapse (M0) and death (M1) in CSPC and shorter duration on 1st line therapy in CRPC. BM-neg in CRPC is rare but may represent a subset of pts with very good prognosis. Poorer outcomes are seen with cumulative gene hits across cohorts.

Cohort	N	Median follow-up (yrs)	1 or more TSG-alt	2 or more TSG-alt
L-CSPC	205	3.1	39%	8%
M1-CSPC	43	3.3	63%	18%
M1-CRPC	48	4.1	92%	63%

5056 Poster Session (Board #283), Sat, 1:15 PM-4:45 PM

Clinical outcomes following androgen receptor axis therapies (ARAT) among men with prostate cancer (PCa) having major cardiovascular diseases (CVDs) or extreme polypharmacy (EPP): A population based study. *First Author: Grace L. Lu-Yao, Sidney Kimmel Cancer Center at Jefferson, Philadelphia, PA*

Background: The safety of ARAT (Abiraterone acetate (AA) and Enzalutamide (ENZ)) among men with existing CVDs or EPP (≥10 concurrent medications) is unknown since patients with these conditions are often excluded from the clinical trials. This study was undertaken to fill these knowledge gaps. **Methods:** This population-based study identified PCa patients from the linked Surveillance, Epidemiology and End Result-Medicare files diagnosed during 1/1/1991-12/31/2013. The primary endpoint was 6-month overall mortality after drug initiation. CVDs include acute myocardial infarction (AMI), atrial fibrillation (AFIB), congestive heart failure (CHF), stroke, and ischemic heart disease (IHD). Cox proportional hazard models were used to assess the risk of 6-month mortality. **Results:** Our study included 3,116 patients treated with AA only or AA as first ARAT and 1,162 patients treated with ENZ only or ENZ as first ARAT. The characteristics of the patients treated with AA and ENZ were similar. The majority of patients (67%) treated with ARAT had existing CVDs and the prevalence of EPP before drug initiation was high (46% for AA and 44% for ENZ). Six-month mortality was elevated among men with existing CVDs treated with ARAT (Table 1). EPP with ARAT was associated with an increase in 6-month mortality (AA: HR 3.22, 95% CI 2.16-4.81; ENZ: HR 1.63, 95% 1.03-2.58). To our knowledge, this is the largest population-based study to provide outcomes data among patients with existing CVDs or EPP, who were under-represented in the pivotal trials. The elevated 6-month mortality of men with CVDs or EPP treated with ARAT suggested that these patients represent a vulnerable patient population. Further studies are needed to determine the clinical benefits and risks of ARAT in men with advanced PCa and existing CVDs or EPP.

Hazard ratios for 6-month mortality among men with cvds conclusions.

	AMI/no CVD	CHF/no CVD	AFIB/no CVD	Stroke/no CVD	IHD/no CVD
AA	1.89 (1.27-2.80)	1.54 (1.20-1.97)	1.61 (1.22-2.12)	1.61 (1.18-2.20)	1.14 (1.13-1.77)
ENZ	1.46 (0.73-2.92)	1.20 (0.79-1.81)	1.80 (1.14-2.82)	1.50 (0.90-2.50)	1.40 (0.99-1.99)

5057 Poster Session (Board #284), Sat, 1:15 PM-4:45 PM

Safety data from a phase II randomized trial of radium-223 dichloride (Ra-223) plus enzalutamide (Enza) vs. Enza alone in men with metastatic castration refractory prostate cancer (mCRPC). *First Author: Benjamin Louis Maughan, Huntsman Cancer Institute at the University of Utah, Salt Lake City, UT*

Background: Ra-233, a bone targeting alpha radiopharmaceutical, and Enza, are approved for mCRPC. Per SWOG0421, the subset of men with mCRPC with the highest bone metabolism marker levels had improved survival with concomitant decrease in these markers on treatment (Rx) with atrasentan, a bone targeting agent (Lara P et al, JNCI, 2014). Our hypothesis was that Rx with Ra-223+ Enza will be safe and feasible, and decrease bone metabolism markers compared to Enza alone. **Methods:** In this phase 2 trial (NCT02199197), men with progressive CRPC on continuous androgen deprivation therapy were included. Ra-223 was administered at standard dose of 55 kBq/kg IV Q4 weeks x 6, and Enza at 160 mg orally daily until disease progression or unacceptable toxicities. Primary objectives: 1) Safety and feasibility of combining Ra-223+Enza, 2) changes in the bone metabolism markers with Rx. Secondary objectives included time to progression, skeletal events, percent change in opioid use. The pre-specified primary safety endpoint was the proportion of patients treated with the combination who experienced grade 3+ cytopenias relative to historic controls (21%) from the phase 3 ALSYMPCA trial using an exact binomial test with a one-sided 0.05 significance level. All adverse events between arms were compared using Fisher's Exact Test. **Results:** Safety data are presented. 49 patients were accrued between 2014-2017. 35 men received Rx with Ra-223+Enza and 14 men with Enza alone. The primary safety endpoint occurred in 3 patients in the combination arm (incidence 8.6%, n = 35 patients), and in 0 patients in the Enza only arm (n=14). These were similar to historic data (ALSYMPCA trial) of monotherapy with Ra-223 (P = 1.00), and not different between arms (P=0.55). Serious adverse events (SAEs), "regardless" of attribution were similar in both arms (P=0.66). **Conclusions:** Combining Ra-223+Enza is safe and feasible in men with progressive mCRPC with no difference observed in SAEs regardless of attribution between two arms. Specifically, there was no incidence of skeletal related events in either arm. Safety data will be elaborated during the meeting. Clinical trial information: NCT02199197.

5058 Poster Session (Board #285), Sat, 1:15 PM-4:45 PM

Six-month patient-reported outcome (PRO) results from AQUARiUS, a prospective, observational, multicenter phase 4 study in patients (Pts) with metastatic castration-resistant prostate cancer (mCRPC) receiving abiraterone acetate + prednisone (AAP) or enzalutamide (ENZ). *First Author: Antoine Thiery Vuillemin, Medical Oncology Unit, CHU Minjoz, Besançon, France*

Background: AQUARiUS is an ongoing study of PROs and medical resource use in chemotherapy-naïve pts with mCRPC newly initiated on AAP or ENZ in a real-world setting. Initial 3-month (mo) subset analyses suggested favorable outcomes for AAP vs ENZ in cognition and fatigue. We report 6-mo results. **Methods:** AQUARiUS prospectively collects PROs on quality of life, cognition, fatigue, and pain using EORTC QLQ-C30, FACT-Cog, BFI-SF, and BPI-SF questionnaires, over 12 mos. PROs were collected at baseline (BL) and during visits based on real-world practice schedules. Incidence of clinically meaningful worsening (CMW) and change from BL scores were determined, adjusting for BL characteristics. **Results:** All 211 pts were analyzed (AAP, n = 105; ENZ, n = 106). BL characteristics were well balanced (no significant differences). A significantly lower proportion of pts on AAP vs ENZ experienced CMW for cognition and fatigue during the first 6 mos of treatment (TABLE). Clinical trial information: NCT02813408. PRO scales with consistent significant differences ($p < 0.05$ for ≥ 3 consecutive time points) in change from BL scores were "perceived cognitive impairments" and "comments from others" (FACT-Cog); "fatigue right now," "usual level of fatigue," and "worst level of fatigue" (BFI-SF); and "cognitive functioning" and "fatigue" (EORTC QLQ-C30); all favored AAP over ENZ. Where significant differences for these scales were not maintained through the full 6-mo period, nonsignificant trends in favor of AAP were observed. **Conclusions:** These 6-mo results continue to suggest that AAP provides favorable outcomes vs ENZ for certain measures of cognition and fatigue in pts with mCRPC.

	Pts with ≥ 1 episode of CMW during first 6 mos of treatment			
	AAP, %	ENZ, %	Odds ratio[a] (95% CI)	*p*
FACT-Cog				
Perceived cognitive impairments	27	56	0.27 (0.13-0.56)	0.0004

Expression of immune checkpoints (ICs) on circulating tumor cells (CTCs) in men with metastatic prostate cancer (mPC). *First Author: Tian Zhang, Duke University Medical Center, Durham, NC*

Background: Most immune checkpoint inhibitors have shown limited efficacy in unselected men with mPC, and there is limited understanding about which ICs are relevant in mPC. We evaluated ICs on the cell surface of CTCs in patients (pts) with mPC. **Methods:** Pts were enrolled prospectively at the Duke Cancer Center in three cohorts: A) metastatic castration resistant prostate cancer (mCRPC) starting abiraterone acetate (AA) or enzalutamide (enza), B) mCRPC after AA or enza, and C) metastatic hormone sensitive PC (mHSPC). The Cellsearch platform was used to capture EpCAM- and CK-expressing CTCs and analyzed for PD-L1, PD-L2, B7-H3, and CTLA-4 expression at baseline, 12 weeks, and disease progression. **Results:** Through December 2017, we enrolled 18 pts (6 in cohort A, 8 in cohort B, and 4 in cohort C). CTCs were detectable in every cohort. At baseline, B7-H3 was the most prevalent IC while the other ICs were detected less frequently (**Table 1**). PD-L1 expression on CTCs was heterogeneous between and within pts; PD-L1 expression also changed during treatment and upon disease progression (Table 1). Rare CTCs expressed CTLA-4 and PD-L2, mostly in cohort B. **Conclusions:** Patients with mPC have detectable and heterogeneous ICs on CTCs, particularly PD-L1 and B7-H3, which can be monitored over time. B7-H3 was the most prevalent IC on CTCs, regardless of disease state. Our preliminary data suggest that pts with mCRPC post-enza/AA have higher levels of IC expression on CTCs compared with pts with mHSPC and mCRPC prior to enza/AA. We found evidence for heterogeneous CTC expression of CTLA-4 and PD-L2, particularly in men with mCRPC post-AA/enza.

Percentage of CTCs with immune checkpoint over total CTCs at baseline, week 12, and disease progression.

	Median (range) of CTCs at baseline/ week 12/PD	PD-L1 (%) baseline/week 12/PD	PD-L2 (%) baseline/week 12/PD	CTLA-4 (%) baseline/week 12/PD	B7-H3 (%) baseline/week 12/PD

5060 Poster Session (Board #287), Sat, 1:15 PM-4:45 PM

The association of *BRCA1* and *BRCA2* mutations on prostate cancer risk, frequency, and mortality: Systematic review and meta-analysis. *First Author: Mok Oh, University of Arizona College of Pharmacy, Tucson, AZ*

Background: A prior meta-analysis (Fachal, Prostate, 2011) suggested no association between *BRCA1* mutation and prostate cancer (PCa). Several additional *BRCA2* studies have shown an association with PCa risk and mortality. We conducted a systematic review and meta-analysis of *BRCA1* and *BRCA2* studies to estimate PCa risk in *BRCA* mutation carriers, evaluate the frequency of *BRCA* mutation carriers in PCa patients (pts) and compare survival rate among *BRCA* mutation carriers and non-carriers. **Methods:** PubMed/ MEDLINE, Embase and Cochrane databases were searched for relevant studies for the above objectives. Meta-analyses were conducted using unadjusted odds ratio (OR) with 95% confidence interval (95%CI) for PCa incidence; frequency (%) of BRCA mutation in PCa pts; and hazard ratio (HR) with 95%CI for cancer-specific survival (CSS) and overall survival (OS). Random effects analyses were performed for overall *BRCA* (*BRCA1* or *BRCA2*), with subgroup analyses for *BRCA1* and *BRCA2* separately. **Results:** 10 cohort, 10 case-control, 38 frequency and 11 survival studies were included. Being a *BRCA* carrier was associated with a significant increase in PCa risk (OR 1.97, 95%CI 1.60-2.42), with *BRCA2* mutation being associated with a greater risk of PCa (OR 2.72, 95%CI 2.10-3.54) than *BRCA1* (OR 1.39, 95%CI 1.07-1.81). The frequency of *BRCA1* and *BRCA2* carriers in PCa patients was 1.8% and 2.7% respectively. OS (HR 2.21, 95%CI 1.64-2.30) and CSS (HR 2.63, 95%CI 2.00-3.45) were significantly worse among *BRCA2* carriers compared to non-carriers, whereas OS (HR 0.47, 95%CI 0.11-1.99) and CSS (HR 1.07, 95%CI 0.38-2.96) were not statistically significant when comparing *BRCA1* carriers and non-carriers. **Conclusions:** Meta-analyses revealed a 1.97-fold greater risk of prostate cancer in overall *BRCA* mutation carriers. This elevated PCa risk was attributable largely to a 2.72-fold greater risk of PCa in *BRCA2* carriers and a moderate 1.39-fold greater risk in *BRCA1* carrier. *BRCA2, but not BRCA1,* mutations were associated with higher PCa mortality. *BRCA* mutation may be a clinical factor to stratify high-risk patients and provide clinical strategies for more effective targeted treatments for patients with PCa.

5061 Poster Session (Board #288), Sat, 1:15 PM-4:45 PM

Differences in genomic signatures and opportunities for targeted and immunotherapy treatment between castrate-resistant *TMPRSS2:ERG* fusion-positive and -negative refractory acinar (CRPC) and neuroendocrine prostate cancer (CRNEPC). *First Author: Leszek Kotula, Upstate Medical University, Syracuse, NY*

Background: We hypothesized that sub-categorization of *TMPRSS2* fusion status would impact therapy opportunities in patients with clinically advanced CRPC and CRNEPC. **Methods:** CGP was performed on FFPE samples of 2,424 CRPC and 143 CRNEPC. Tumor mutational burden (TMB) was determined on 1.1 Mbp of sequenced DNA and microsatellite instability (MSI) was determined by principal components analysis of optimal homopolymer loci. **Results:** All (100%) CRPC and CRNEPC were advanced and therapy resistant. *TMPRSS2*+ CRPC features significantly more *TP53* and *PTEN* GA, whereas *TMPRSS2*- CRPC featured more *MYC* and *ATM* GA; differences in *BRCA2* and *RB1* GA were not significant. *RB1* GA were significantly more frequent in CRNEPC than CRPC, whereas GA in *AR* and *ATM* were more frequent in CRPC. *TP53* GA frequencies were higher in *TMPRSS2*+ CRNEPC than in *TMPRSS*+ CRPC, whereas GA in *PTEN* and *MYC* were similar in comparative groups. Median TMB was higher in CRNEPC than CRPC, and higher in *TMPRSS2*- compared with *TMPRSS*+ tumors; TMB was more often ≥10 or ≥20 mut/Mb in *TMPRSS2*- tumors. MSI-High status was more frequently identified in the *TMPRSS2*- CRPC and CRNEPC groups. **Conclusions:** The 31% frequency of *TMPRSS2*+ CRPC in this study, lower than the 46% reported in early stage disease (TCGA data) suggests that this biomarker may be linked to a favorable prognosis. For CRNEPC, the higher frequency of *TMPRSS2*- tumors is not as striking. CGP reveals significant differences in both targetable GA and markers of immunotherapy response between *TMPRSS*+ and *TMPRSS2*- prostate tumors.

5062 Poster Session (Board #289), Sat, 1:15 PM-4:45 PM

Prevalence of homologous recombination deficiency (HRD) mutations in localized prostate cancer according to Gleason grade: Implications for neoadjuvant clinical trial design. *First Author: Catherine Handy, Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD*

Background: Approximately 5-10% of men with localized prostate cancer have homologous recombination deficiency (HRD) mutations, yet it is unknown if these vary by Gleason score. In order to help design neoadjuvant trials for the HRD+ population and to minimize the number-needed-to-screen, we sought to determine if the prevalence of HRD mutations is influenced by Gleason grade. **Methods:** 484 localized prostate adenocarcinoma cases with somatic DNA sequencing data and Gleason grade information were interrogated using The Cancer Genome Atlas (TCGA) repository. HRD mutations were defined as pathogenic lesions in the following genes: *ATM, BRCA1/2, CDK12, CHEK1/2, FANCA, FANCD2, FANCL*, *GEN1, NBN, PALB2, RAD51* and *RAD51C*. A separate analysis was also conducted restricting the gene list to *BRCA1/2* and *ATM*, since deficiencies in these genes have the strongest association with PARP-inhibitor response. R software was used for analyses. **Results:** The prevalence of (any) HRD mutation was 11.6%, 10.8%, 14%, 16.8% and 25.0% for Gleason sums 6, 7, 8, 9 and 10, respectively. When analyzed using Grade Groups, the prevalence of (any) HRD mutation was 11.6%, 6%, 17.8%, 14% and 17% for Grade Groups 1, 2, 3, 4 and 5, respectively (Table). Those in Grade Group 3 and greater had 2.5 times higher odds of harboring at least one HRD mutation compared to those in Grade Groups 1 and 2 (16.8% vs 7.3%, P= 0.002). When specifically considering only *BRCA1/2* or *ATM* lesions, the mutation prevalence was 6.1 times higher in Grade Group 3 and above compared to Grade Groups 1 and 2 (8.9% vs 1.6%, P= 0.0006) (Table). **Conclusions:** HRD mutations in general, and *BRCA1/2/ATM* mutations specifically, are enriched in localized prostate cancers with Gleason Grade Group 3 and higher (*i.e.* primary pattern 4 and higher). We propose that these patients could be targeted for neoadjuvant (or adjuvant) clinical trials using PARP inhibitors in HRD+ populations.

HRD mutation prevalence by gleason grade group.

	At least 1 HRD mutation			At least 1 *BRCA1/2/ATM* mutation

5063 Poster Session (Board #290), Sat, 1:15 PM-4:45 PM

Early changes in PSA and association with outcomes in mCRPC patients. *First Author: Pasquale Rescigno, The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Sutton, United Kingdom*

Background: Declines in prostate specific antigen (PSA) levels at 12-weeks are currently used to evaluate treatments response in metastatic castration resistant prostate cancer (mCRPC). Early PSA fall by 30% at 4-weeks (PSA4w30) has been previously shown to be associated with better outcome in mCRPC in a small single-centre cohort. **Methods:** We identified mCRPC patients who had received Abiraterone Acetate (AA) between 06.01.06 and 08.09.17 in 13 cancer centres worldwide. Eligible patients had PSA levels assessed at baseline, after 4-weeks and/or 12-weeks of treatment. PSA response was defined as a ≥30% decline from baseline and PSA progression as a ≥25% increase from baseline. Association with overall survival (OS) was analysed using landmark multivariable Cox regression adjusting for previous chemotherapy, including cancer centre as a shared frailty term. **Results:** We identified 1057 patients who had received AA (447 pre-chemotherapy, 610 post-chemotherapy), with 835 patients having PSA values available at 4 and 12 weeks. Overall, 372/835 (44.5%) had PSA4w30; this associated with longer OS (mOS 22vs15 months; HR = 0.62; 95%CI 0.53–0.72; p < 0.001). A ≥30% PSA decline at 12-weeks (PSA12w30) associated with a lower mortality (mOS 22vs14; HR = 0.57; 95%CI = 0.48–0.67; p < 0.001). Sensitivity analyses confirmed the association between PSA4w30 and OS when pre- and post-chemotherapy cohorts were analysed separately. PSA4w30 strongly correlated with PSA12w30 (ρ = 0.92; p < 0.001). In total, 320/372 (86%) patients with a PSA decline at 4-weeks had a PSA decline at 12-weeks. Conversely, 11/835 (1.3%) patients progressed at 4-weeks and then met the criteria for PSA12w30. PSA4w30 remained correlated with OS (HR = 0.56; 95%CI = 0.48–0.65; p < 0.001) in multivariate analyses including other established prognostic factors in mCRPC (baseline ALP, LDH, Hb, M status and Gleason at diagnosis). **Conclusions:** PSA changes in the first 4-weeks of AA therapy are strongly associated with clinical outcome in mCRPC patients and should be prospectively evaluated in early treatment switch decision trials.

5064 Poster Session (Board #291), Sat, 1:15 PM-4:45 PM

Molecular and clinical implications of *CHD1* loss and *SPOP* mutations in advanced prostate cancer. *First Author: Pasquale Rescigno, The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Sutton, United Kingdom*

Background: *CHD1* deletions (*CHD1*del) and *SPOP* mutations (*SPOP*mut) frequently co-occur in prostate cancer (PCa) with lower frequencies observed in castration-resistant PCa (CRPC). Responses to standard treatments in this subset of patients have not been previously reported. We studied the molecular and clinical characteristics of *CHD1*del/*SPOP*mut metastatic CRPC (mCRPC) analyzing CHD1 presence/loss during disease progression and correlation to response to Abiraterone acetate (AA). **Methods:** We identified mCRPC patients who had hormone naïve (HNPC) and CRPC tumor samples available: these were analyzed for CHD1, PTEN and ERG expression by immunohistochemistry (IHC). *SPOP* status was determined by targeted next generation sequencing (NGS). Correlations with *CHD1/SPOP* status and clinical outcomes and responses to AA were analysed using Cox-regression and Log-Rank analyses. **Results:** Tumor samples from 89 patients who had progressed from HNPC to CRPC were analyzed in a cohort enriched for *SPOP*mut. CHD1 protein loss was detected in 11 (15%) and 13 (17%) of HNPC and mCRPC biopsies, respectively. Comparison of CHD1 protein levels were feasible in 56 matched, same patient HNPC and mCRPC biopsies. CHD1 protein status correlated in 55 of 56 cases of the matched samples (98%). We identified 22 patients with somatic *SPOP*mut, with 6 of these mutations not reported previously in PCa, including one (p.A187T) located in the BTB domain in an area reported to be necessary for homodimerisation and other two located in residues (E50, R121) previously associated with endometrial cancer. *SPOP*mut and/or CHD1 loss was associated with a higher response rate to AA (SPOP: OR = 14.50 p = 0.001; CHD1: OR = 7.30, p = 0.08) and a longer time on abiraterone (SPOP: HR = 0.37, p = 0.002, CHD1: HR = 0.50, p = 0.06). **Conclusions:** *SPOP* mutated mCRPCs are strongly enriched for CHD1 loss and seem to be likely sensitive to AA. We envision that determination of *SPOP/CHD1* status might serve treatment selection in mCRPC.

5065 Poster Session (Board #292), Sat, 1:15 PM-4:45 PM

Analysis of genomic alterations in matched circulating tumor cell DNA (CTC DNA) and plasma tumor DNA (ctDNA) in men with metastatic castration resistant prostate cancer (mCRPC). *First Author: Santosh Gupta, Medical Oncology, Duke University, Durham, NC*

Background: CTC and ctDNA-based, actionable genomic alterations are being increasingly utilized for precision oncology therapies. However, the concordance of genomic alterations in CTC DNA vs. ctDNA is not established. **Methods:** After CTC/ctDNA isolation, we performed whole genome copy number alteration (CNA) analysis in 88 men with mCRPC treated with enzalutamide (E) or abiraterone acetate (A) (n = 72), and radium-223 (n = 16). We performed comparative genomic hybridization (aCGH) and low-pass whole genome sequencing (~0.1x, lpWGS) for CNA assessment and evaluated the concordance between gains/losses in matched CTCs, ctDNA and germline DNA in 63 samples; 32 from 16 men receiving radium-223, and 31 from 16 men receiving E/A. **Results:** Of the 88 enrolled men with mCRPC, 51% had ≥5 Cellsearch CTCs. We identified common genomic gains in 63 CTCs and matched ctDNA in FOXA1 (56 vs. 75%), KDM6A (51 vs. 21%), AR (48 vs. 64%), MYCN (30 vs. 5%), and MYC (18 vs. 24%). Common copy losses included ZFHX3 (60 vs. 44%), FGFR2 (43 vs. 32%), PHLPP1 (33 vs. 33%), BRCA1 (29 vs. 30%), and RB1 (13 vs. 21%). We analyzed AR copy gain status in 21 ctDNA specimens by aCGH and lpWGS, finding a concordance of 89%; detection correlated with high ctDNA content and CTC number. However, we found only 33% AR gain concordance in 38 CTC aCGH samples vs ctDNA lpWGS samples, and 63% AR gain concordance for CTC aCGH vs. ctDNA aCGH samples collected at the same time points. In 63 matched CTCs and ctDNA samples, we observed high concordance in gain of FOXA1 (91%) and AR (63%), moderate concordance for gain of MYC (55%), NCOR2 (41%), loss of ZFHX3 (53%) and PHLPP1 (48%), but low concordance for gain of KDM6A (25%) and loss of BRCA1 (39%), RB1 (38%), and FGFR2 (37%). **Conclusions:** Detection of genomic alterations at the whole genome level is feasible in ctDNA and CTC DNA and concordance across ctDNA platforms was high. However, we found variable concordance in CTC DNA vs. ctDNA copy number alterations depending on the specific gene, type of alteration, ctDNA concentration, and CTC enumeration likely reflecting biologic variability or differences in assay sensitivity. Clinical trial information: NCT02269982, NCT02204943.

5066 Poster Session (Board #293), Sat, 1:15 PM-4:45 PM

Prostate cancer (PCa) incidence and severity in hypogonadal men treated with testosterone compared to untreated controls: Experience from 6,500 patient-years from a controlled registry study. *First Author: Ahmad Haider, Private Urology Practice, Bremerhaven, Germany*

Background: EAU Guidelines state that there is no evidence that testosterone (T) treatment in hypogonadal men increases PCa risk. **Methods:** 412 symptomatic men with T≤350 ng/dL received T undecanoate 1000 mg every 3 months following an initial 6-month interval for up to 12 years (T-group). 393 hypogonadal men (age range 51-74) decided against testosterone (CTRL). Total observation time covered approximately 6,500 patient-years. PCa was excluded by transrectal ultrasound, digital rectal examination and PSA measurement before treatment/observation initiation. Examinations were repeated between one and four times per year. Biopsies were performed when indicated according to EAU Guidelines. **Results:** In the T-group, 11 men (2.7%) were diagnosed with PCa. In CTRL, 35 (8.9%) were diagnosed with PCa. The mean baseline age of PCa patients was 65.3 years in the T-group and 63.7 in CTRL. In the T-group, the average time span between the day of first injection and positive biopsy was 386 days (range: 260-546). In CTRL, PCa was diagnosed at any time during the observation time. In the T-group, radical prostatectomy was performed in all men. All but 2 patients had a Gleason score (GS) ≤6, and all had a primary GS of 3. Tumor grade was G2 in all 11 (100%), tumor stage T2a in 7 (64%), T2b in 3 (27%), and T2c in 1 (9%) patient(s). In CTRL, radical prostatectomy (RP) was performed in all but 6 patients who received radiation therapy (RT). 7 patients received RP+RT. GS was ≤6 in 2 patients, 7 men had a GS of 7, 16 a GS of 8, and 10 a GS of 9. 4 men had a primary Gleason score of 3, 22 had 4, and 9 had 5. Tumor grade was G2 in 8 (22.9%) and G3 in 27 (77.1%) patients, tumor stage T2a in 2 (5.7%), T2c in 1 (2.0%), T3b in 13 (37.1%) and T3c in 19 (54.3%) patients. In CTRL, biochemical recurrence occurred in 10 (28.6%) patients. These patients received androgen deprivation therapy (ADT). 12 (34.3%) patients died of whom 7 were on ADT. In the T-group, no biochemical recurrences or deaths occurred during the observation time. **Conclusions:** PCa incidence and severity in testosterone-treated hypogonadal patients were less compared to untreated hypogonadal controls.

5067 Poster Session (Board #294), Sat, 1:15 PM-4:45 PM

Clinical qualification of plasma androgen receptor (p*AR*) status and outcome on abiraterone acetate (AA) plus prednisone or dexamethasone (+P/D) in a phase II multi-institutional study in metastatic castration resistant prostate cancer (mCRPC). *First Author: Anuradha Jayaram, Institute of Cancer Research and The Royal Marsden NHS Trust Foundation, Sutton, United Kingdom*

Background: p*AR* gene aberrations in mCRPC patients (pts) may be associated with worse outcome on AA+P/D. **Methods:** This was an international, multi-institutional, open-label phase 2 study of AA (1000mg QD) and 1 of 4 steroid regimens in asymptomatic, chemo-naïve mCRPC pts (NCT01867710). A pre-defined exploratory objective was to evaluate the association of p*AR* status and radiographic progression free survival (rPFS), PFS and time of long-term ADT to randomisation. We used a validated droplet digital PCR assay to classify pts as p*AR* copy number (CN) gain. **Results:** Baseline plasma DNA was collected from 151 pts of the 164 intention-to-treat pts; 135 pts were available for p*AR* CN analysis, excluding samples with long-fragment DNA. 21(15%) pts had *AR* CN gain. There was a significant association for *AR* gain and shorter rPFS (median 5.7 months [m]:p*AR* gain vs 23.7 m:p*AR* normal; HR: 2.78; 95% CI 1.34 - 4.6; p = 0.004) and PFS (median, 4.90m: p*AR* gain vs 16.2m: p*AR* normal; HR: 2.28; 95% CI 1.3 - 4; p = 0.004). Multivariate analysis is in Table 1. PSA ≥50% decline was 65% for p*AR* normal vs 53.3% for p*AR* gain. (OR: 0.6; 95% CI, 0.2 – 1.7; = 0.33). The time from start of long-term ADT to randomisation, was significantly shorter in pts with *AR* CN gain at castration resistance (8m: p*AR* gain vs 29.5m: p*AR* normal; p = 0.004). **Conclusions:** In this prospectively defined cohort, p*AR* normal in chemo-naïve mCRPC pts had a significantly longer rPFS with AA+P/D. Previous data suggests shorter response to ADT associates with primary resistance to AA +P/D. The novel observation that these pts are enriched for p*AR* gain provides a biological rationale for this. Clinical trial information: NCT01867710.

5068 Poster Session (Board #295), Sat, 1:15 PM-4:45 PM

Association of high CD8+ tumor infiltrating lymphocytes at prostatectomy with improved survival of prostate cancer patients. *First Author: Yuanquan Yang, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: High $CD8^+$ tumor infiltrating lymphocytes (TILs) are associated with improved survival in many solid tumors. However, its prognostic value in prostate cancer (PCa) is unclear. **Methods:** Tumor microarrays of 290 patients with localized PCa who underwent radical prostatectomy (RP) at Roswell Park Comprehensive Cancer Center were retrospectively analyzed using immunohistochemistry. High risk patients were preferentially included to ensure adequate post-RP events for correlation. Six malignant and three benign cores from each patient were stained with anti-CD8 antibody (Dako, M7103). $CD8^+$ cells were scored using Aperio (Leica Biosystems). Patients with < 5-year follow-up were excluded. The $CD8^+$ cell density was dichotomized at 25th percentile. Clinical outcomes collected from a prospective quality assurance database were compared in high vs low TIL group. PSA persistence and recurrence were defined using NCCN prostate cancer guidelines. **Results:** 230 patients with median age 61 years met follow-up requirement. There were no significant differences in age, Gleason sum (GS), diagnostic PSA, margin status and pTNM stage between high vs low TIL group. High TILs were associated with improved 5-year overall survival (OS) (98% vs 91%, p = 0.008) and PCa-specific survival (99% vs 95%, p = 0.041) when compared to low TILs. High intratumoral/benign CD8 ratio (> 1) was associated with improved metastasis-free survival (p = 0.031). The median biochemical recurrence (BCR)-free survival was longer in high TIL group (62 vs 42 m). However, statistical significance was not reached (p = 0.18). The prognostic import of high TILs was independent of surgical pathology. In subgroup analysis, it was also associated with improved 5-year OS (97% vs 88%, p = 0.042) in GS > 7 or pT3/4 patients (n = 149, 65%) and prolonged BCR-free survival (NR vs 58 months, p = 0.036) in GS < = 7 and < = pT2 patients. In contrast, the CD8 density of benign cores was not associated with clinical outcomes. **Conclusions:** High $CD8^+$ TILs are independently associated with improved survival after RP in this majority of high-risk PCa population. This observation suggests that immunomodulation aimed at promoting $CD8^+$ TILs may be beneficial.

5069 Poster Session (Board #296), Sat, 1:15 PM-4:45 PM

Treatment outcomes for patients (Pts) with metastatic castration resistant prostate cancer (mCRPC) pts and DNA damage repair gene mutations. *First Author: Steven Yip, BC Cancer Agency Vancouver Cancer Centre, Vancouver, BC, Canada*

Background: DDRm occur in 15-30% of pts with mCRPC. While BRCA2 germline mutations are linked to aggressive local disease, outcomes in pts with mCRPC and DDRm continue to be characterized. **Methods:** Leukocyte DNA from 631 consecutive mCRPC pts were screened for germline ATM, BRCA1/2, CDK12, and PALB2 truncating mutations using targeted sequencing. 312/631 were assessed for somatic DDRm (sDDRm) and homozygous deletions in the same genes, using matched plasma cell-free DNA. Additional pts with gDDRm were identified through our hereditary cancer program (HCP). We examined time from androgen deprivation therapy (ADT) initiation (± docetaxel) to CRPC; time to PSA progression (TTPP), PSA response (50% decline from baseline), and objective response rate (ORR) on 1st-line AR-targeted therapy, docetaxel, PARP inhibitor, platinum-based chemotherapy, and radium-223 for mCRPC; and overall survival (OS). Outcomes in pts with DDRm and pts with DDR wild-type (WT) status (with available clinical data, n = 113) were compared using the log-rank test. **Results:** gDDRm and sDDRm were identified in 33/631 (5.2%, BRCA2 = 25) and 35/312 (11.2%, BRCA2 = 13) pts, respectively. The HCP identified an extra 3 BRCA2 and 1 BRCA1 pts. Across 59/72 pts with available clinical data, 23/59 (39.0%) presented with de novo metastatic disease. Median time to CRPC from ADT (± docetaxel) initiation was 12.1 mo (gDDRm = 12.5 mo, sDDRm = 11.5 mo). The Table displays outcomes in pts with DDRm. All pts with DDRm had a TTPP on 1st-line AR-targeted therapy of 3.6 mo vs 7.4 mo in WT pts (p = 0.002). Median OS from the time of ADT initiation and time of CRPC was 41.5 mo (gDDRm = 41.5 mo, sDDRm = 43.5 mo) and 28.4 mo (gDDRm = 28.4 mo, sDDRm = 20.9 mo), respectively. **Conclusions:** In our cohort, pts with DDRm have poor AR-targeted therapy outcomes. Encouraging responses were observed with docetaxel, PARP inhibitors and platinum-based therapy.

	AR-Targeted Therapy	Docetaxel Chemo	PARP Inhibitor	Radium-223	Platinum Chemo
N	46	13	7	11	4
Median TTPP in mo (95% CI)	3.6 (2.7-5.8)	5.0 (2.7-6.9)	11.3 (5.5-NR)	3.0 (0.3-4.6)	NR (NR-NR)
PSA Response (N)	54% (25/46)	54% (7/13)	14% (1/7)	9% (1/11)	75% (3/4)
ORR (N)	3% (1/32)	45% (5/11)	50% (3/6)	0% (0/6)	50% (2/4)

5070 Poster Session (Board #297), Sat, 1:15 PM-4:45 PM

Tumor-infiltrating lymphocytes in biallelic-CDK12 mutated prostate cancer. *First Author: Maialen Barrero, The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Sutton, United Kingdom*

Background: Cyclin-dependent kinase 12 (CDK12) mutations have been described in lethal prostate cancer (PCa) and are reported to impact DNA repair including homologous recombination repair, and associate with an inflamed phenotype. Biomarker studies evaluating tumor infiltrating lymphocytes (TILs) enumeration have reported their prognostic and predictive utility. Here we evaluate the clinical outcomes and the immune-infiltrate characteristics of a cohort of PCa patients with biallelic CDK12 mutations. **Methods:** 418 PCa patients were sequenced in our Institution with targeted next-generation sequencing between February 2015 and December 2017. Biallelic-CDK12 cohort (n = 11) was compared to a control group (n = 47), including other mutations and monoallelic-CDK12 alterations. Immunofluorescence (IF) was performed on primary or metastatic tumor samples to identify TILs. Lymphocyte infiltration per cell type was examined using a negative binomial regression model with the sum of tumor area included as an exposure term. Kaplan-Meier method and Cox model were used for the survival analyses. **Results:** Among 418 patients sequenced, 20 were CDK12 mutant (4.8%), of which 11 (2.6%) had biallelic mutations. The median overall survival (OS) from diagnosis was 7.6 years for the control group and 10.0 years for the biallelic-CDK12 cohort (HR 0.63; 95%CI 0.27-1.51; P = 0.30). One biallelic-CDK12 mutated patient was excluded from IF analysis due to poor quality tumor tissue. TIL counts/mm^2 were significantly higher in CDK12 mutated tumors, with higher CD4$^+$ (95%CI 0.11-1.94; P = 0.03), CD8$^+$ (95%CI 0.24-2.18; P = 0.02) and overall T cell counts (95%CI 0.09-1.73; P = 0.03). No significant difference was noted for CD4$^+$/FOXP3$^+$ (95%CI -1.49-0.69; P = 0.47). **Conclusions:** This is the first study reporting survival outcomes and TILs characteristics in biallelic-CDK12 mutated PCa. Despite being limited by the retrospective design and limited sample size, these pilot data provide a rationale to further explore the role of biallelic-CDK12 mutations in PCa as a predictive biomarker for immunotherapy.

5071 Poster Session (Board #298), Sat, 1:15 PM-4:45 PM

Impact of treatment sequence on the outcomes of metastatic castration resistant prostate cancer patients (mCRPC) with germline BRCA2 mutations: A subanalysis of the PROREPAIR-B study. *First Author: Nuria Romero-Laorden, Hospital Universitario La Princesa, Madrid, Spain*

Background: Germline mutations in BRCA2 have been identified in 3-5% of mCRPC patients. PROREPAIR-B (Castro et al ESMO 2017) is the first prospective study to report a worse survival from mCRPC associated to these mutations. Significant interactions between treatment-type (androgen signaling inhibitors:ASI/Taxane) and *BRCA2* status for cause-specific survival (CSS) from 1st line (1L; p = 0.015) and 2nd line (2L; p = 0.006) were identified. In this exploratory subanalysis, we report mCRPC outcomes according to *BRCA2* status and treatment sequence. **Methods:** PROREPAIR-B (NCT03075735) is a prospective multicentre observational cohort study. Patients who were taxane- and ASI-naïve at time of mCRPC, and who were treated or intended to treat with any of these two sequences: a) 1L ASI, 2L taxane; or b) 1L taxane; 2L ASI were elegible. Enpoints: assessment of the impact of *BRCA2* on CSS, PFS from 1L initiation to clinical/radiological progression on 2L or death (PFS2). Analyses were stratified according to treatment sequence. **Results:** 348 out of 419 patients were eligible: 190 (7 *BRCA2*) for the ASI-taxane and 158 (7 *BRCA2*) for the taxane-ASI sequence. Patients in the taxane-ASI cohort were significantly younger (p < 0.001) and have worse ECOG (p = 0.002), higher PSA (p = 0.007), elevated LDH (p < 0.001) and elevated ALP (p = 0.01) compared to the ASI-taxane group, but there were not significant differences between *BRCA2* patients in both groups. No significant differences in outcomes between *BRCA2* carriers and non-carriers were observed with the ASI-Taxane sequence: CSS (median 24.0 vs 31.1 months, p = 0.9) and PFS2 (18.9 vs 21.1 months, p = 0.6). Conversely, in the taxane-ASI sequence BRCA2 status was associated to significantly worse CSS (10.7 vs 28.4 m, p < 0.001) and PFS2 (8.6 vs 17.1 m; p < 0.001). In the multivariable analyses *BRCA2* remained an independent prognostic factor for CSS (HR 2.95; CI95% 1.21-7.15) and PFS2 (HR 5.50; CI95% 2.35-12.89). **Conclusions:** These results suggest that the outcomes of *BRCA2* mutation carriers may differ according to treatment sequences. This contributes to explain the differences in outcomes reported by previous series. Clinical trial information: NCT03075735.

5072 Poster Session (Board #299), Sat, 1:15 PM-4:45 PM

Association of changes in the B-cell receptor (BCR) repertoire with overall survival after sipuleucel-T (sip-T) treatment for prostate cancer. *First Author: Li Zhang, University of California San Francisco, San Francisco, CA*

Background: Sip-T, an autologous cellular immunotherapy for asymptomatic or minimally symptomatic metastatic castration-resistant prostate cancer (mCRPC), induces antibody responses to prostatic acid phosphatase and secondary antigens (antigen spread) that correlate with improved survival (Sheikh 2013, GuhaThakurta 2015); however, little is known about cancer immunotherapy-induced changes to the BCR repertoire. We evaluated the correlation between BCR diversity/dynamics and overall survival (OS) after sip-T. **Methods:** mCRPC pts (N = 52) received sip-T (wk 0, 2, 4) with enzalutamide (NCT01981122; Petrylak 2018). Blood samples were collected at wk 0, 2, 4, 6, 26, and 52. BCR diversity was assessed by clonality in samples from 19 pts. Dynamics of BCR repertoire changes were evaluated by the proportion of overlapping clones at two time points (Zhang 2017). Correlations between OS and BCR diversity/dynamics were analyzed by logrank test and Cox proportional hazards models. **Results:** There was minimal overlap of BCR clones from wk 0 to later time points suggesting clonal shuffling in BCR repertoire. BCR clonality peaked at wk 6 (wk 6 vs wk 0, p = 0.039; wk 6 vs wk 2, p = 0.030), indicating focusing of the BCR repertoire during and soon after sip-T. Clonality decreased from wk 6 to wk 26 and wk 52 (p = 0.049 and 0.037, respectively), reflecting long-term increase in diversity after sip-T. The proportion of overlapping clones from wk 0 to wk 2 and wk 0 to wk 4 were inversely correlated with OS during sip-T (p = 0.048 and p = 0.043, respectively) showing that a lower proportion of overlapping clones predicted better OS. Thus, greater changes in BCR repertoire during treatment, including creation of new clones and disappearance or reduction in frequency of preexisting clones, were associated with an OS benefit. **Conclusions:** Sip-T led to focusing of BCR repertoire during and soon after treatment, which may signify the magnification of relevant clones and transition of clones out of the periphery. Greater dynamic change in the BCR repertoire induced by sip-T correlated with longer survival. These findings corroborate the prior association between the breadth of antigen spread and OS after sip-T. Clinical trial information: NCT01981122.

5073 Poster Session (Board #300), Sat, 1:15 PM-4:45 PM

A pre-specified statistical model based on four kallikrein markers in blood to predict advanced pathology on radical prostatectomy. *First Author: Thomas Steuber, Martini-Clinic Prostate Cancer Center Hamburg-Eppendorf, Hamburg, Germany*

Background: Four kallikrein markers in blood – commercially available as the 4Kscore – has been shown to be highly predictive of Gleason Grade Group (GGG) 2 or higher prostate cancer at biopsy. However, tissue sampling and grading at biopsy is an imperfect gold standard and may miss aggressive disease. We measured the kallikrein in cryopreserved blood in patients undergoing radical prostatectomy at a tertiary referral center during 2000 - 2010, during which it was common to treat GGG1 prostate cancer. **Methods:** Aggressive disease was defined as primary Gleason grade 4, any grade 5, seminal vesicle invasion, extra-capsular extension (ECE) or lymph node invasion. ECE was excluded in a sensitivity analysis. A second sensitivity analysis excluded patients with low scores from the kallikrein panel, who may never have been biopsied had they received a 4Kscore. We assessed improvement in discrimination when the kallikrein panel was added to a base model using established clinical predictors: age, prostate specific antigen, clinical stage and grade. We also examined a model that included number of positive cores and mm of cancer. We pre-specified that we would separately assess men with GGG1 – where the decision concerns confirmatory biopsy – and GGG2 – where the decision would concern treatment vs. active surveillance. **Results:** The cohort included 2284 men with data on cores for 1294. The kallikrein panel was significantly associated with advanced pathology after adjusting for clinical variables ($P < 0.001$). Overall, the panel added 0.014 to the AUC of clinical model, with larger effects within GGG1 (0.047) and GGG2 (0.017). Results were similar when cores data were included and not sensitive to alternative definitions of advanced disease, or exclusion of patients with low panel risks. Decision curve analysis confirmed the additional value of the panel in appropriate ranges for decision thresholds: 5 – 20% for confirmatory biopsy and 20 – 60% for treatment. **Conclusions:** The kallikrein panel is strongly associated with pathologic outcome, and can be used to make subsequent management decisions for patients found with GGG1 or GGG2-cancer at biopsy and the need for confirmatory biopsy and treatment.

5074 Poster Session (Board #301), Sat, 1:15 PM-4:45 PM

Plasma androgen receptor (p*AR*) status and activity of taxanes in metastatic castration resistant prostate cancer (mCRPC). *First Author: Vincenza Conteduca, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori IRCCS, Meldola, Italy*

Background: Plasma *AR* (p*AR*) gain identifies CRPC with worse outcome on abiraterone (abi) or enzalutamide (enza). We aimed to evaluate whether taxanes in CRPC are active regardless of *AR* status **Methods:** Between May 2011 and June 2017, pretherapy plasma samples were collected from 115 evaluable patients (pts) prior to abi/enza-naïve docetaxel (doce) and 130 prior to cabazitaxel (caba) in biomarker protocols at 19 different Institutions. We used droplet digital PCR to assess p*AR* copy number (CN). Primary objective was to evaluate associations of p*AR* gain with treatment outcome. In addition, after incorporating updated data from our prior study of 73 chemotherapy-naïve abi/enza pts, we also investigated if p*AR* could have a differential impact on taxanes compared with abi/enza pts. Both taxanes were administered at standard or reduced-dose at the discretion of treating physician **Results:** We observed *AR* gain in 32 (27.8%) doce pts. No differences were observed in OS/PFS (HR 1.2 95%CI 0.74-1.96 p = 0.45; HR 0.77 95%CI 0.51-1.17 p = 0.21 respectively) or PSA decline ≥50% (OR 1.0 95%CI 0.99-1.0 p = 0.75). A significant interaction was observed between p*AR* and doce vs abi/enza for OS (p = 0.003) and PFS (p = 0.013). In addition, we showed *AR* gain in 24 (37.5%) caba pts and confirmed no association of *AR* status with OS/PFS/PSA response. As an exploratory analysis, we reported in *AR* gained pts treated with initial reduced dose of taxanes a meaningful shorter OS (HR 2.15 95%CI 1.13-4.06 p = 0.019) in doce pts and a trend toward a worse OS in caba pts (HR 1.67 95%CI 0.94-2.95 p = 0.079). Multivariable analysis, adjusting for *AR* CN, LDH, alkaline phosphatase, hemoglobin, PSA, sites of metastasis, age, showed only liver metastasis as an independent predictor of OS in doce and caba pts (HR 2.78 95%CI 1.13-6.85 p = 0.026; HR 6.6195%CI 1.65-26.56 p = 0.008 respectively). **Conclusions:** p*AR* gained pts do not have a worse outcome when treated with taxanes when compared to p*AR* normal pts. This contrasts with a significantly worse outcome for p*AR* gained compared to p*AR* normal when treated with abi or enza and introduce the opportunity to use p*AR* status to select for doce vs abi/enza in mCRPC. Prospective evaluation in a randomized trial is warranted

5075 Poster Session (Board #302), Sat, 1:15 PM-4:45 PM

Exploration of the cGAS-STING pathway in prostate cancer. *First Author: Emma Reilly, Almac Diagnostics, Craigavon, United Kingdom*

Background: Recent studies have demonstrated limited success of immune checkpoint therapies in unselected prostate cancer. We therefore assessed an immune based DNA Damage Repair Deficiency (DDRD) assay, that we previously reported represents activation of the cGAS STING pathway, in the TCGA prostate cancer dataset to investigate the presence of targetable immune biology. In order to assess if immune therapy could have a role in treating high risk disease, we applied a second assay (the prostate cancer metastatic signature-PCM) that predicts the risk of metastatic recurrence for early prostate cancer. **Methods:** 498 samples with RNA sequencing data were scored with the PCM and DDRD assays. Integrative analysis was performed on 488 samples with RNA sequencing, promoter site methylation, somatic mutation and somatic copy number variation. The subgroups were assessed for leukocyte infiltration and the expression of n = 6 immune checkpoint targets. The viability of reproducing those subgroups with RNA sequencing alone was tested in the TCGA dataset and an independent validation dataset of 321 resected primary prostate cancers. Cox proportional hazards regression analysis was performed for biochemical recurrence and metastatic events in both datasets. **Results:** Integrative analysis identified four patient subgroups characterised primarily by variances in copy number and genomic mutation. One of these subgroups 'Metastatic-like DDRD' had significantly higher PCM scores and DDRD immune scores compared to the other subgroups ($p < 2E-12$). This subgroup of patients showed elevated immune signalling ($p < 2e-6$) and greater genomic instability with amplification of 8q and a higher incidence of TP53 mutations. The 'Metastatic-like DDRD' subgroup was found to have a significant association with poor survival outcome in TCGA (multivariable: $p < 0.008$) and the independent dataset (multivariable: $p < 0.01$). **Conclusions:** We have identified and validated a poor prognostic subgroup, representing 10-20% of early prostate cancer patients that are at increased risk of developing metastatic disease and present with targetable immune biology. These patients may represent a viable target population for immune checkpoint and DNA damaging therapies in prostate cancer.

5076 Poster Session (Board #303), Sat, 1:15 PM-4:45 PM

Germline variant alleles in rs12422149 of *SLCO2B1* and response to abiraterone acetate (AA) in men with metastatic castration-resistant prostate cancer (mCRPC). *First Author: Andrew W Hahn, University of Utah Hunstman Cancer Institute, Salt Lake City, UT*

Background: Predictive biomarkers of response to AA in advanced prostate cancer are needed. *SLCO2B1* encodes a protein that mediates transport of AA into tissue. A pre-clinical study showed that variant alleles in select single nucleotide polymorphisms (SNPs) for *SLCO2B1*, rs12422149 and rs1789693, result in higher tumor tissue AA levels (Mostaghel EA, *Clin. Can. Res.*, 28389510). In an exploratory analysis, we found a non-significant trend towards improved progression-free survival (PFS) in men with variant alleles for rs12422149 but not for rs1789693 on AA in mCRPC patients. Here, we interrogate the correlation of variant alleles in rs12422149 with PFS on first-line therapy with AA in men with new mCRPC. **Methods:** Clinical data and samples were analyzed from a prospective prostate cancer registry at the University of Utah. Genotyping was performed using the Illumina OmniExpress genotyping platform. Primary endpoint was PFS on first-line AA in men with mCRPC. We performed a pre-specified multivariate Cox regression analysis to assess the independent predictive value of rs12422149 on PFS on AA. **Results:** Of 401 men with advanced prostate cancer genotyped. 323 were homozygous wild type for rs12422149 (80.5%), 74 were heterozygous (18.5%), and 4 were homozygous variant (1.0%). In a multivariate analysis of 79 men treated with first-line AA for mCRPC, men heterozygous for rs12422149 had significantly improved median PFS compared to the homozygous group (8.9 months vs. 6.3 months, HR 0.46, 95% CI 0.23-0.94, p=0.03) (Table). **Conclusions:** In this first clinical validation of pre-clinical data reported by Mostaghel, et al., variant alleles in rs12422149 of *SLCO2B1* are common and predict improved response to first-line AA In men with mCRPC. These findings need external validation.

Long-term patterns in race-specific, distant metastasis-free survival following radiation treatment for prostate cancer. *First Author: Jennifer Cullen, Center for Prostate Disease Research, Rockville, MD*

Background: Racial differences in prostate cancer (PCa) outcomes are widely observed, irrespective of risk stratum at diagnosis. The primary study aim was to compare distant metastasis-free survival (DMFS) for African American (AA) and Caucasian American (CA) military health care beneficiaries undergoing radiation therapy (RT) for PCa over 20+ years. **Methods:** A retrospective cohort study of Center for Prostate Disease Research Multi-Center National Database enrollees was conducted. Eligibility requirements included a diagnosis with biopsy-confirmed PCa between January 1, 1989 and December 31, 2013, primary treatment ($<$ 6 months post-diagnosis) with external beam radiation therapy (EBRT) or brachytherapy (BRY), and $\geq$2 years follow-up. EBRT combined CT-based, 3D conformal, and intensity modulated RT (IMRT). DMFS was compared across race using Kaplan Meier (KM) estimation curve analysis, stratified by treatment type (EBRT vs. BRY). Multivariable (MV) Cox Proportional Hazards (PH) analysis was used to model DMFS as a function of race, stratified by treatment type (EBRT vs. BRY), controlling for clinical covariates. **Results:** Of the 4,299 eligible men who had primary RT, 2,022 (77.6%) had EBRT and 583 (22.4%) had BRY (N = 2605). Among EBRT patients, 28% were AA and 66% were CA. For BRY patients, 18% were AA and 77% were CA. Median follow up times and ages were 6.7 and 69.8 years for EBRT patients and 6.9 and 65.4 years for BRY, respectively. In KM analysis race did not predict DMFS for EBRT group (p = 0.56) but there were significant racial differences among BRY group (p = 0.013). Table 1 shows DMFS estimates by race and treatment group. In MV Cox PH models, race did not predict DMFS among EBRT patients (p = 0.695); however, among BRY group, AA men had a 4.7-fold increased probability of developing distant metastasis compared to CA men (p = 0.045), controlling for age at RT, year of treatment, and NCCN risk stratum. **Conclusions:** In this racially diverse, equal access health care system, comparable DMFS was observed across patient race over this 20+ years for EBRT but not BRY patients who had significantly poorer DMFS. Subsequent work will examine cancer-specific survival, comorbidity, and prostate volume.

5078 Poster Session (Board #305), Sat, 1:15 PM-4:45 PM

Evaluation of an immunotherapeutic DNA-vaccine in biochemically relapsed prostate cancer. *First Author: Neal D. Shore, Carolina Urologic Research Center, Myrtle Beach, SC*

Background: The DNA immunotherapy, INO-5150 (PSA and PSMA) +/- INO-9012 (IL-12) was assessed for safety, immunogenicity and the effect on PSA kinetics in biochemically recurrent prostate cancer patients (pts). **Methods:** Phase I, open-label, multi-center study included pts with rising PSA after surgery and/or RT, PSA doubling time (PSADT) $>$ 3 months (mos), testosterone $>$ 150 ng/dL, no concurrent ADT and no evidence of metastases by conventional imaging. Safety, immunogenicity and efficacy were evaluated in 4 treatment arms in 60 planned pts (A: 16, 2mg INO-5150; B: 15, 8.5 mg INO-5150; C: 15, 2mg INO-5150+1mg INO-9012; D: 16, 8.5mg INO-5150+ 1mg INO-9012). Pts received 4 IM doses of vaccine followed by electroporation on day 0, wks 3, 12 and 24 and followed for 72 wks. **Results:** The study has concluded and 50/62 (80%) pts completed all visits. 90% of pts had Grade (Gr) 1-3 AEs, primarily injection site reactions which were Gr 1. Across 4 cohorts, 47/61 (77%) of all evaluable pts demonstrated immunogenicity, [35/58 (60%) had IFN-γ reactivity by ELISPOT, 6/61 (10%) and 5/61 (8%) had antibody titers against PSA and PSMA, respectively, and 19/50 (38%) had CD38, Perforin+CD8 T cell responses]. Pts (38%) with CD38 and Perforin + CD8 T cell immune reactivity had attenuated % PSA rise compared to non-reactive pts (p = 0.05, n = 50). Pts with no known progression during the study showed significant differences in $\log_2$PSA change and PSADT pre-treatment baseline (D0) vs wk 27 (post-immunotherapy time point, n = 34, p $<$ 0.0001) or wk 72 (end of follow-up, n = 27, p $<$ 0.0001). Furthermore, pts with D0 PSADT$\leq$ 6 mos and no known progression during the study showed significant differences in $\log_2$PSA change and PSADT in D0 vs wk 27 (n = 15, p $<$ 0.0001) or wk 72 (n = 10, p = 0.002). **Conclusions:** INO-5150 +/- INO-9012 was safe, well tolerated and immunogenic. A clinical effect was demonstrated by evidence of dampening % rise in PSA and increased PSADT in the majority of patients. In patients with no known disease progression during the study, a significant PSA stabilizing effect of the immunotherapy was observed. Additional analyses are ongoing to further elucidate the correlation of immunologic efficacy and clinical benefit. Clinical trial information: NCT02514213.

5079 Poster Session (Board #306), Sat, 1:15 PM-4:45 PM

Ten year treatment outcomes of radical prostatectomy vs external beam radiation therapy vs brachytherapy for 1,503 patients with intermediate risk prostate cancer. *First Author: Barry W. Goy, Kaiser Permanente Los Angeles Medical Center, Los Angeles, CA*

Background: To compare 10-year treatment outcomes of radical prostatectomy (RP) vs external beam radiation therapy (EBRT) vs brachytherapy (BT) for patients with intermediate risk prostate cancer (IRPC). **Methods:** A retrospective analysis using propensity score matching was performed on 1,503 IRPC patients who underwent treatment from 2004 to 2007. 819 underwent RP, 574 underwent EBRT to a median dose of 75.3 Gray, and 110 underwent BT using iodine-125. Biochemical failure was defined by the American Urological Association (AUA) definition of prostate specific antigen (PSA) failure for RP patients, and the American Society of Therapeutic Radiology and Oncology (ASTRO) - Phoenix definition for the EBRT and BT patients. **Results:** Median follow up was 10.0 years for RP, 9.6 for EBRT, and 9.8 for BT (range 1.0-13.4 years). With RP 76.3% had Gleason score 7 vs 72.8% for EBRT vs 57.3% for BT, p = 0.0001. Median initial PSA was 7.4 for RP, 9.4 for EBRT, and 8.3 for BT, p $<$ 0.0001. Neoadjuvant androgen deprivation therapy was given in 58.9% of EBRT patients vs 12.7% of BT vs 0.6% for RP, p $<$ 0.0001. Only 14% of BT received supplemental external radiation. The 10-year freedom from biochemical failure (FFBF) was 82.0% for BT vs 58.0% for RP vs 58.8% for EBRT, p $<$ 0.0001. Subset analysis of unfavorable IRPC patients showed a 10 year FFBF of 81.6% for BT vs 55.8% for RP vs 51.0% for EBRT, p $<$ 0.0001. The 10-year freedom from salvage therapy was 89.5% for BT vs 64.0% for RP vs 73.4% for EBRT, p $<$ 0.0001. There were no significant differences in distant metastases-free survival, prostate cancer-specific survival, or overall survival after adjusting for age. Multivariable analysis between pairwise groups with BT balanced by stabilized inverse probability of treatment weights showed that BT remained an independent predictor for improved FFBF, p = 0.049 for BT vs EBRT, and p $<$ 0.0001 for BT vs RP. **Conclusions:** Brachytherapy using iodine-125 is a reasonable treatment option for IRPC patients. Although BT showed improved FFBF after propensity score matching, this did not impact overall survival.

5080 Poster Session (Board #307), Sat, 1:15 PM-4:45 PM

Long-term androgen deprivation, with or without radiotherapy, in locally-advanced prostate cancer: Updated results from a phase III randomized trial. *First Author: Paul Sargos, Institut Bergonié, Bordeaux, France*

Background: We previsously reported results of a randomized phase III trial comparing androgen-deprivation therapy (ADT) combined with external beam radiation therapy (EBRT) and ADT alone in patients treated with localized cancer. We report here long-term oncological outcomes of this trial. **Methods:** In this multicenter phase III trial, patients with biopsy-proven locally advanced prostate cancer (T3-4) randomly assigned to ADT alone or ADT+EBRT. In both arms, leuprorelin 11.25 mg, subcutaneous, was started within seven days of randomization and continued every three months for three years and oral flutamide (750 mg/day) was administered during the first month. For the ADT-EBRT arm, the whole pelvis was treated at a dose of 46+/-2 Gy and the prostate with a boost from 20 Gy to 28 Gy. Primary endpoint was progression-free Survival (PFS) which included biochemical and clinical events and deaths. Secondary endpoints included overall survival (OS), disease-specific survival (DSS), locoregional progression free survival (LPFS), metastasis-free survival (MFS), biochemical progression free survival (BPFS) and tolerance. Competing-risk analysis was used whenever appropriate. **Results:** With a median follow-up of 7.3 years, 263 patients were included in the Intent-to-treat analyses. The 8-year PFS rate was significantly higher in the ADT+EBRT arm than in the ADT arm (47.9% versus 7.0%; hazard ratio: 0.27, p $<$ 0.0001). The risk of death from prostate cancer was significantly reduced for ADT+EBRT arm as compared to ADT alone (sub-hazard ratio (SHR): 0.48; p = 0.02). The 8-year OS rate was respectively 56.8% in the ADT arm and 65.1% in the ADT+EBRT arm (p = 0.43). LPFS was significantly in favor of ADT+EBRT arm (SHR = 0.61; p = 0.01). MFS was comparable between both arms (p = 0.88). Analysis of toxicities revealed acute lower tolerance (mainly gastro-intestinal and genito-urinary) in the ADT+EBRT arm with a gradual decrease in intensity during follow up from 6 months after the end of EBRT. **Conclusions:** These long-term results confirm the oncological benefit of combining EBRT with ADT in the treatment of locally advanced prostate cancer. Clinical trial information: NCT01122121.

5081 Poster Session (Board #308), Sat, 1:15 PM-4:45 PM

A pharmacodynamic biomarker study of vistusertib (AZD2014), an mTORC1/2 inhibitor, given prior to radical prostatectomy (CANCAP02). *First Author: Simon Pacey, University of Cambridge, Cambridge, United Kingdom*

Background: The effect of novel drugs can be studied in primary prostate cancer (PC), if given prior to radical prostatectomy (RP). Altered PI3K/AKT/mTOR signalling is associated with aggressive primary PC and progression. CanCap02 investigated the effects of vistusertib (AZD2014), an oral, dual mTORC1/mTORC2 inhibitor in men with PC. **Methods:** Men, due for RP, with high volume or aggressive PC consented and received vistusertib, 50mg bd, for 15 days prior to RP. Diagnostic biopsy, attempted intra-operative biopsy and RP tissue were collected for IHC analysis. Adverse events (AE) were graded using CTCAE v4. Blood was collected to determine plasma vistusertib concentrations. The primary endpoint was to measure mTOR1/2 inhibition by immunohistochemistry (IHC). Secondary endpoints were feasibility, safety, tolerability and vistusertib plasma pharmacokinetics. Exploratory objectives included interrogating biological pathways related to mTOR and anti-cancer effects. **Results:** Median age 62 (50 – 69) yrs, 48% intermediate and 52% high risk recurrence. 20/23 pt were evaluable for primary endpoint analysis. The majority of AEs (67%) were Gr1 includin: mucositis, diarrhoea, thrombocytopenia, rash, transaminitis, lymphopenia and hyperglycaemia. Two pts discontinued vistusertib due to AEs (mucositis, thrombocytopenia, raised liver enzymes/ bilirubin) which resolved prior to RP. RP was only delayed in one pt to allow resolution of AE (Gr 1 thrombocytopenia). Vistusetib inhibited mTOR1/2 (pS6, 4EBP1 and NDRG1 were reduced). PSA declined in 3 pt (15%, range -48 to +332%) over two week dosing period. Analysis of tumour PTEN status, tumour infiltrating lymphocytes and Ki67 are ongoing. Mean plasma vistusertib concentration during RP was 738 ± 287 ng/mL. Mean fasting plasma glucose was 4.88 ± 0.56 mmol/L at baseline and rose after vistusertib to 6.16 ± 0.78 mmol/L, correlated with plasma vistusertib levels. **Conclusions:** Vistusertib (50mg bd) is feasible for a two week course prior to RP, mTORC1/ 2 were inhibited in tumour tissue as well as surrogate tests (ie plasma glucose) and in some pt (15% pt) a fall in PSA occurred. The AE profile might be improved by an intermittent dosing schedule. Clinical trial information: NCT02064608.

5082 Poster Session (Board #309), Sat, 1:15 PM-4:45 PM

Neoadjuvant androgen deprivation therapy and enzalutamide: Imaging and pathological responses. *First Author: David James VanderWeele, University of Chicago Medical Center, Chicago, IL*

Background: Neoadjuvant androgen deprivation therapy (nADT) with abiraterone and prednisone for localized disease leads to pathological complete response (pCR) rates of up to 10%. In this study we tested the efficacy of nADT with enzalutamide for patients with high risk, localized disease. We also tested the ability of post-treatment multiparametric MRI (mpMRI) to evaluate response. **Methods:** A single institution trial (NCT02430480) evaluated nADT (goserelin) and enzalutamide 160 mg daily in patients with high risk non-metastatic prostate cancer. Patients underwent MRI-TRUS-guided fusion biopsy at screening and repeat mpMRI followed by radical prostatectomy (RP) after completing six months of therapy. **Results:** Twenty-two patients have completed therapy and undergone radical prostatectomy. Baseline clinical characteristics were typical of those with high risk disease: median PSA 10.3 ng/ml (range 2.1-985.9) and clinical stage by mpMRI cT2-cT4. Following 6 months of therapy, median pre-RP PSA was 0.02 ng/ml (range $<$ 0.02 – 0.35). On final pathology, 0 patients were upstaged, 5 (23%) were unchanged, and 15 (77%) were downstaged, including 4 (18%) with pCR or near pCR (Residual Cancer Burden $<$ 0.001 cc). Five of 9 patients with bulky nodes at baseline were downstaged to pN0. Of 9 patients with pT3 disease at prostatectomy, 6 were cT3 on post-treatment mpMRI. Of 4 patients with pCR or near pCR, 1 was cT0, 1 was cT2, and 2 were cT3 on post-treatment mpMRI. One additional patient had radiographic complete response but was pT3a on pathological review. **Conclusions:** Six months of nADT with enzalutamide has activity in high risk, localized prostate cancer, with a small number of patients having exceptional responses. Standard analysis of mpMRI identifies most patients with persistent T3 disease but does not reliably identify exceptional responses. Evaluation of molecular characteristics that predict exceptional response or intrinsic resistance is on-going. Clinical trial information: NCT02430480.

5083 Poster Session (Board #310), Sat, 1:15 PM-4:45 PM

Effect of rilimogene galvacirepvec/rilimogene glafolivec on intra/peritumoral immune infiltrate in patients with localized prostate cancer undergoing radical prostatectomy. *First Author: James L. Gulley, Genitourinary Malignancies Branch, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: PSA-TRICOM (Prostvac) is a vector-based vaccine designed to generate a robust immune response (IR) against PSA–expressing tumor cells. To date, studies of Prostvac in patients with mCRPC have shown IR in peripheral blood but effects on prostate tumors are unknown. **Methods:** An open label phase 2 study of neoadjuvant Prostvac (NCT02153918) enrolled patients (pts) with localized prostate cancer undergoing radical prostatectomy (RP). Priming vaccination was given followed by boosts on days 15, 29 and 57 prior to RP (~day 64). The 1° objective evaluated increases in CD4 and CD8 cell infiltrate (RP tissue vs. baseline biopsies) by IHC. IR to tumor associated antigens (TAA) was measured using intracellular cytokine staining (ICS) in PBMC from baseline and ~day 63. **Results:** 27 pts (median age 64.8 years) enrolled. All pts received 4 pre-RP vaccine injections. Matched tissue IHC analysis and peripheral IR is available on 24 pts. TAA specific T cell peripheral IR to PSA, Muc-1 or Brachyury were observed in 12/24 (50%) pts post vaccine, with 25% of pts responding to each antigen. Table comparing peripheral IR vs. tumoral IR. Clinical trial information: NCT02153918. 19 pts were evaluable for tissue RNA expression profiles pre/post vaccine and observed upregulation of genes such as RANKL (DC maturation), CCL25 (chemotaxis), and FLT3 (T-cell development) suggests vaccine-induced IRs. Conversely, increased expression of immunosuppressive genes (e.g., FOXP3, IL-10) suggests adaptive resistance post vaccination. **Conclusions:** Prostvac treatment is associated with a ≥2X increase in CD8 and CD4 intra/ peritumoral infiltrate in 17/24 and 21/24 pts, respectively. However only 12/24 had a TAA response in the peripheral blood. Anti-tumor IRs may become broader and more immunologically relevant over time (Ag spreading) and may be underestimated by peripheral IRs to TAA. These data better inform the immunodynamic effects of Prostvac which are incompletely represented by peripheral IR data. Work is ongoing to more fully characterize the IR with multispectral imaging, targeted RNASeq and TCRSeq analysis.

5084 Poster Session (Board #311), Sat, 1:15 PM-4:45 PM

Combination of a therapeutic cancer vaccine and immune checkpoint inhibitors in prostate cancer. *First Author: Ravi Amrit Madan, National Cancer Institute at the National Institutes of Health, Bethesda, MD*

Background: Immune checkpoint inhibitors (ICIs) have yet to demonstrated efficacy as monotherapy in non-MSI-HI prostate cancer. Vaccines may increase immune cells in the tumor microenvironment, potentiating ICIs. **Methods:** This study combines PROSTVAC(P), a pox-viral based vaccine targeting PSA, ipilimumab (Ipi; 1 mg/kg) and nivolumab (Nivo; 240 mg) in patients (pts) with castration resistant prostate cancer (CRPC). The initial regimen was P on Day 1, all 3 agents (PIN) 2 weeks(wks) later, and PIN every 3 wks thereafter. After Ipi was removed the regimen = P on Day 1, P+Nivo on wks 2,4 and then Nivo every 2 wks with P monthly. **Results:** 11 pts enrolled with median age = 75 and PSA = 16.1. 10 were metastatic CRPC, 6 pts had an ECOG PS = 0 (5 PS = 1). 3 pts had grade 3 immune-related adverse events (irAE; all responded to steroids and continued P once complete). Only the first 2 pts were treated with PIN but had cystitis and hepatitis, respectively, after which Ipi was removed from the regimen. Of 9 P+Nivo pts, 1 had transient myocarditis. 1 of 2 pts treated with PIN had an 88% PSA decline and a partial response (PR) for 10+ months. Of the P+Nivo pts, 6 are evaluable for response (on trial $>$ 3 months). The 2 pts with the greatest PSA decline have been evaluated for MSI-HI status, 1 was positive. Some patients have had late PSA declines from intra-study peak PSA. Clinical trial information: NCT01875250. **Conclusions:** Ipi was removed from regimen after first 2 pts had≥Gr 3 irAEs, only 1 irAE from the 9 pts on P+Nivo. P+Nivo may have activity in CRPC, additional follow-up and further MSI-HI testing is warranted.

Pt #	PSA decline > 30% from baseline	Time on study (+ still on study)	Additional information
1 (PIN)	88% (PR)	10+ months	irAE cystitis, treated with steroids MSI-HI negative CDK12 mutation (bi-allelic)
2 (PIN)	n/a	7.2 months	irAE hepatitis, treated with steroids delayed PSA decline of 23% lasting 4.25 months
3 (P+N)	n/a	4.5 months	Off study for 2nd cancer diagnosis, not treatment related
4 (P+N)	97%	7.5+ months	Substantial reduction in bladder mass MSI-HI positive
5 (P+N)	36%	4.8+ months	n/a
6 (P+N)	n/a	4.6+ months	irAE myocarditis, treated with steroids delayed PSA decline of 34% continuing at 2 months
7 (P+N)	n/a	3.5 months	Progressive disease
8 (P+N)	n/a	3.8+ months	delayed PSA decline of 20% lasting 2.5 months

5085 Poster Session (Board #312), Sat, 1:15 PM-4:45 PM

The influence of decision aids on prostate cancer screening preferences: A randomized survey study. *First Author: Kyle Tsai, Northwestern University, Chicago, IL*

Background: Shared decision making between a patient and caregiver is important when discussing prostate cancer (PCa) screening. Decision aids (DAs) are tools intended to facilitate this process and improve patient participation through education, yet little is known about how DAs affect screening preferences. We administered an online survey study to determine how different DAs impact the decision to undergo or recommend a loved one undergo PCa screening. **Methods:** Using ResearchMatch, an online, study recruitment registry, participants matched for age, race, and gender were randomized to one of six different major professional society's free, online DA on PCa screening. We compared pre- and post-DA responses. The primary outcome was change in participant likelihood to undergo or recommend a loved one undergo PCa screening on a scale of 1 (unlikely) to 100 (extremely likely). Secondary outcomes included change in participant comfort with PCa screening based on the average of six, five-point Likert-scale questions. **Results:** Median age was 53 years for the 1,336 participants, and 50% were men. Randomized groups did not differ significantly by race, age, gender, income, marital status, or education level. Likelihood to undergo or recommend PCa screening decreased from 83 to 78 following DA exposure ($p < 0.001$). Reviewing the DAs from the Center for Disease Control or American Academy of Family Physicians did not alter likelihood (both $p > 0.2$), while reviewing the DA from the United States Preventive Services Task Force was associated with the largest decrease (-16.0, $p < 0.001$). Participants reported increased comfort with the decision-making process for PCa screening from 3.5 to 4.1 (out of 5, $p < 0.001$) following exposure to a DA. **Conclusions:** In this online survey, after exposure to most DAs from major professional societies, participants were less likely to undergo or recommend their loved one undergo PCa screening. DAs improved participant comfort with the PCa screening shared decision-making process. These results illustrate how different DAs may disparately influence men and their loved ones about the tradeoffs of PCa screening.

TPS5086 Poster Session (Board #313a), Sat, 1:15 PM-4:45 PM

Investigation of metformin (MET) in patients with castration resistant prostate cancer (CRPC) in combination with enzalutamide (ENZ) vs. ENZ alone: A randomized, open label, phase 2 trial. SAKK 08/14—IMPROVE. *First Author: Christian Alexander Rothermundt, Kantonsspital St Gallen, St Gallen, Switzerland*

Background: The current first-line treatment for patients with CRPC and disease progression is either treatment with abiraterone acetate/prednisone, ENZ, or treatment with docetaxel in more symptomatic patients. There is preclinical data on synergism of ENZ and the biguanide MET: studies on mice orthotopically implanted with ENZ-resistant cells demonstrated that the combination of ENZ and clomipramine or MET significantly reduced tumor growth compared to control groups. Rothermundt et al. previously reported favorable effects of single agent MET in a phase 2 trial: objective PSA responses, disease stabilization and improvement of metabolic endpoints in patients with CRPC. Therefore addition of MET to ENZ might have positive impact on tumor progression, on body composition and insulin sensitivity. **Methods:** This is a prospective 1:1 randomized multicenter phase 2 trial. Primary endpoint is disease control (DC) at 15 months. Progression is defined as having 2 of the following events: radiographic progression, symptomatic/clinical progression, or PSA progression. Secondary endpoints include overall response according to modified RECIST v1.1 and PCWG2 recommendations, event-free survival, adverse events, quality of life, pain and overall survival. Translation research comprises liquid biopsy, metabolomics, hyperglycemia, and pyruvate dehydrogenase substudies. Assuming a 20% difference in the DC rate at 15 months (50% vs. 70% in the combination arm) with alpha 0.10 and power 80%, 168 patients are required in total. Eligibility criteria are as follows: asymptomatic or minimally symptomatic mCPRC (adenocarcinoma) documented by imaging, ongoing androgen deprivation therapy (ADT) with GnRH agonists or antagonists or bilateral orchiectomy, total testosterone levels $\leq$ 1.7 nmol/L, tumor progression at the time of registration, no prior treatment for mCRPC other than ADT, no history of diabetes and metformin use, and adequate organ function. Patients receive either ENZ 160mg qd in combination with MET 850mg bd or ENZ 160mg qd alone. 62 patients have been enrolled since accrual began in March, 2016. Clinical trial information: NCT02640534.

TPS5087 Poster Session (Board #313b), Sat, 1:15 PM-4:45 PM

A phase 2 trial of darolutamide maintenance therapy in patients with metastatic castration resistant prostate cancer (mCRPC) previously treated with AR targeting agents and non-progressive on a subsequent taxane (SAKK 08/16). *First Author: Richard Cathomas, Kantonsspital, Chur, Switzerland*

Background: Treatment with the AR targeting agents abiraterone or enzalutamide followed by a taxane is currently the most used treatment for men with mCRPC. Further treatment after response to chemotherapy is only indicated in case of disease progression, with limited treatment options available. Darolutamide is a second-generation oral androgen receptor antagonist which has demonstrated a good safety profile and antitumor activity in mCRPC. This trial evaluates whether the immediate use of darolutamide after successful chemotherapy can prolong radiographic progression-free survival (rPFS) compared to watchful waiting in patients with mCRPC. **Methods:** This is a multicenter, randomized, double-blind, placebo-controlled phase 2 trial (NCT02933801) conducted in approximately 19 sites in Switzerland and Italy. Patients with mCRPC are required to have been previously treated with abiraterone and/or enzalutamide and have no evidence of disease progression on subsequent docetaxel or cabazitaxel. Patients (N = 88) will be randomized 1:1 to receive 600 mg darolutamide BID or placebo BIDuntil disease progression. Patients will be stratified by country, WHO performance status (0, 1 vs 2), presence/absence of visceral metastases, enzalutamide vs abiraterone vs both prior to chemotherapy, and planned start of trial treatment after last taxane dose ($<$ 35 days vs $\geq$35 days). The primary endpoint is rPFS at 12 weeks after treatment initiation. The secondary endpoints are rPFS, time to PSA progression, time to symptomatic/clinical progression, event-free survival, overall survival, PSA response (30%, 50%, 90%, and best), duration of PSA response (50%), adverse events, and fatigue. The rPFS rate at 12 weeks after treatment initiation will be compared between the two treatment arms using a one-sided test statistic using the Kaplan–Meier method. Recruitment is ongoing, with the first patient randomized on 20.04.2017. Clinical trial information: NCT02933801.

TPS5088 Poster Session (Board #314a), Sat, 1:15 PM-4:45 PM

A phase I study of ^{177}Lu-DKFZ PSMA 617 combined with the radiosensitizer idronoxil in men with metastatic castrate-resistant prostate cancer (mCRPC) (LuPin trial). *First Author: Megan Crumbaker, The Kinghorn Cancer Centre, St. Vincent's Hospital, Darlinghurst, Australia*

Background: Despite recent treatment advances, mCRPC remains a challenging disease associated with significant mortality and morbidity. Prostate specific membrane antigen (PSMA) is a transmembrane glycoprotein that is overexpressed in most prostate adenocarcinomas. Radiolabelled peptides which bind PSMA receptors induce internalization of the ligand-receptor complex, allowing concentration of PSMA-bound isotopes within targeted prostate cancer cells. ^{177}Lutetium (^{177}Lu) bound to PSMA ligands has a favorable therapeutic-toxic ratio and yields PSA responses in 30-70% of selected patients. However, responses are often partial and acquired resistance common, suggesting a need to augment the clinical benefit of beta-radiation. Idronoxil is an inhibitor of external NADH oxidase type 2, and has a variety of downstream actions including radiosensitization. Given the reassuring safety data of idronoxil as a single agent, we initiated a phase 1 clinical trial of ^{177}Lu-PSMA plus idronoxil. **Methods:** Sixteen patients will be recruited. Participants will receive up to 6 doses of ^{177}Lu-PSMA at 6-weekly intervals; the first 8 patients will also receive 400mg idronoxil daily for 10 days from day 1 of each cycle, while subsequent patients will receive 800mg daily for 10 days if no major adverse events are noted. Entry criteria include (i) failure of, or (ii) ineligibility to receive both docetaxel and a second-generation androgen pathway inhibitor. Imaging criteria include a PSMA PET that shows significant uptake at all sites of disease with no discordant disease on FDG PET. The primary endpoint is the toxicity (safety, tolerability) of the combination as assessed by CTCAE criteria. Secondary endpoints include PSA response, radiological response, changes in quality of life, radiation dosimetry, overall survival and progression-free survival. Plasma for ctDNA testing will be collected to explore whether DNA repair defects are predictive biomarkers for response and/or mechanisms of resistance. Four of 16 patients have been enrolled, with no significant toxicities or safety concerns as yet.

TPS5089 **Poster Session (Board #314b), Sat, 1:15 PM-4:45 PM**

Phase Ib study of avelumab plus carboplatin in patients with metastatic castration resistant prostate cancer progressing after one line of chemotherapy and one novel androgen receptor axis inhibitor. *First Author: Alejo Rodriguez Vida, Hospital del Mar, Barcelona, Spain*

Background: The management of metastatic castration resistant prostate cancer (mCRPC) has been revolutionized with the approval of several agents improving overall survival. However, despite an initial response, most patients will experience disease progression. New studies assessing new agents are still needed. Recently, several immune check-point inhibitors targeting the PD-1 pathway have been approved for the treatment of several solid tumors. However, their use in mCRPC is still at a very early phase of development. The purpose of this study is to test the safety and efficacy of combining carboplatin with avelumab in pretreated mCRPC patients. Genomic aberrations are frequent in CRPC, especially in advanced cases. By selecting pre-treated patients, we will enrich the amount of genetic aberrations (like high mutational burden or DDR mutations) potentially increasing the likelihood of response to avelumab. Cytotoxic chemotherapy like carboplatin has been shown to induce immunogenic tumor cell death, tumor-antigens release and stimulation of the immune system. It has been hypothesized that this "autovaccination" could be enhanced with the addition of immunotherapy such as avelumab. **Methods:** This is a phase Ib, open-label, single-arm study in patients with mCRPC progressing on at least 1 line of chemotherapy and 1 line of novel androgen receptor axis inhibitors. Inclusion criteria include performance status 0-1 and adequate organ function. Patients will receive 2 cycles of carboplatin AUC5 monotherapy followed by 2 cycles of carboplatin AUC5 plus avelumab 10mg/kg. Maintenance avelumab will continue for up to 2 years. This trial will have 2 stages. In the Safety phase (6 patients) the safety of combining both agents will be analyzed (primary endpoint). If safety is confirmed, an Expansion phase (20 patients) will assess the efficacy of the combination in terms of PSA and radiographic assessment as per PCWG3 (secondary endpoints). As exploratory endpoint, potential immunologic and genomic predictive biomarkers will be analyzed. The trial is open, and enrollment is ongoing. Clinical trial information: 2017-004552-39.

TPS5090 **Poster Session (Board #315a), Sat, 1:15 PM-4:45 PM**

A phase 3 study of androgen annihilation in high-risk biochemically relapsed prostate cancer: An Alliance Foundation trial (AFT-19). *First Author: Rahul Raj Aggarwal, UC San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

Background: Men with biochemically relapsed prostate cancer (BRPC) following prior radical prostatectomy (RP) and a short PSA doubling time (PSADT) are at high risk for the development of metastatic disease and prostate cancer-related mortality. Intermittent androgen deprivation therapy (ADT) is a commonly applied treatment in this disease setting, but fails to achieve prolonged progression-free and treatment-free intervals for the majority of patients (pts). Apalutamide is a next generation androgen receptor (AR) antagonist that has efficacy in non-metastatic castration-resistant prostate cancer (CRPC). Abiraterone acetate, a prodrug of the CYP17 androgen synthesis inhibitor abiraterone, has been shown to prolong survival in both CRPC and metastatic hormone-sensitive prostate cancer. We hypothesize that the addition of apalutamide with or without abiraterone acetate/prednisone, as compared to ADT alone, will prolong disease suppression and potentially eradicate micrometastatic disease with a finite duration of treatment in pts with BRPC. **Methods:** AFT-19 is a randomized, open-label, three arm phase 3 study (first patient enrolled March 2017) of a) degarelix monotherapy compared to each of two experimental arms: b) degarelix plus apalutamide, and c) degarelix plus apalutamide plus abiraterone acetate/prednisone, in pts with BRPC following prior RP without metastases on conventional imaging, and a PSADT of $\leq$ 9 months. Pts are treated for up to 52 weeks in the absence of progression or unacceptable toxicity, and subsequently followed off treatment until PSA progression, defined as serum PSA $>$ 0.2 ng/mL. The primary endpoint is PSA progression-free survival (PFS). Secondary endpoints are 36-month PSA PFS rate, metastasis-free survival, time to CRPC, overall survival, and quality of life. Planned accrual is 504 pts, estimated to provide 85% power to detect a hazard ratio of 0.63 in the comparison of PSA PFS between each experimental arm versus the control arm, with an overall two-sided type I error rate of 0.025 for each comparison. The DSMB last reviewed the trial in November 2017 and recommended that the trial continue as planned. Clinical trial information: NCT03009981.

TPS5091 **Poster Session (Board #315b), Sat, 1:15 PM-4:45 PM**

Talapro-2: A 2-part, placebo-controlled phase 3 study of talazoparib (TALA) with background enzalutamide (ENZA) in metastatic castration-resistant prostate cancer (mCRPC) with DNA damage repair deficiencies. *First Author: Neeraj Agarwal, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT*

Background: ENZA is approved to treat men with mCRPC. TALA is a dual-mechanism PARP inhibitor that inhibits PARP1 and PARP2 catalytic activity and traps PARP on DNA, preventing DNA damage repair and causing cell death in *BRCA1/2*-mutated cells. A combination of TALA with ENZA in DNA damage repair (DDR)+ mCRPC may improve clinical outcomes. **Methods:** Part 1 (P1) is open label to confirm the starting dose of TALA to be given in combination with ENZA. Part 2 (P2) is a double-blind assessment of efficacy and safety. Approximately 352 patients (pts) will be enrolled (P1, n=12; P2, n=340). Eligible pts for both parts are $\geq$18 yrs of age ($\geq$20 in Japan) with asymptomatic or mildly symptomatic mCRPC; ECOG PS $\leq$1; no brain metastases; and who have not been treated with taxanes or novel hormonal therapy (NHT) initiated after the onset of mCRPC. Pts who received cytotoxic chemotherapy (CT), other HT, biologic, or radionuclide therapy within 28 days of screening or who received a prior PARP inhibitor, platinum-based CT, cyclophosphamide, or mitoxantrone are excluded. For P2, pts must have DDR+ mCRPC. In P1, pts will receive open-label TALA 1 mg/d orally with ENZA 160 mg/d. In P2, pts will receive open-label ENZA and will be randomized 1:1 to also receive TALA 0.5-1 mg/d or placebo. The starting dose of TALA for P2 will be determined in P1. Randomization will be stratified by prior treatment with NHT for castration-sensitive prostate cancer or non-mCRPC and prior treatment with taxane-based CT for castration-sensitive prostate cancer (yes/no). For P1, the primary endpoint is safety; the secondary endpoint is pharmacokinetics of TALA and ENZA. For P2, the primary endpoint is radiographic progression-free survival (rPFS); key secondary endpoints include overall survival, objective response in measurable soft tissue disease, PSA progression, and time to initiation of cytotoxic CT. Efficacy will be assessed by radiographic assessments every 8 wks through week 25 and every 8-12 wks thereafter. P2 analysis for rPFS is powered at 90% using a 2-sided log-rank test with alpha of 0.05. Clinical trial information: NCT03395197.

TPS5092 **Poster Session (Board #316a), Sat, 1:15 PM-4:45 PM**

A prospective phase 2/3 multicenter study of ^{18}F-DCFPyL PET/CT imaging in patients with prostate cancer: Examination of diagnostic accuracy (OSPREY). *First Author: Michael J. Morris, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Accurate localization of sites of disease is essential for delivering optimal care to patients with prostate cancer. This is especially true for patients who may have distant disease either at initial staging or at relapse and may benefit from curative local primary or salvage treatments. ^{18}F-DCFPyL (PyL) is a novel, high specific activity, highly selective, low-molecular weight prostate-specific membrane antigen (PSMA)-targeted PET radiopharmaceutical. This trial seeks to analytically validate the performance characteristics of PyL PET/CT for the detection of metastatic and/or recurrent prostate cancer. **Methods:** This is a multi-center, open-label, phase 2/3 study evaluating the diagnostic performance of PyL PET/CT in patients with at least high-risk (as defined by NCCN guideline v3.2016) prostate cancer prior to radical prostatectomy [cohort A] or radiologically confirmed metastatic/recurrent prostate cancer [cohort B]. A total of approximately 400 subjects will be enrolled in the study. All patients must be at least 18 years of age with histologically confirmed adenocarcinoma of the prostate. A single administration of PyL (9 $\pm$ 1 mCi [333 $\pm$ 37 MBq]) is administered 1-2 hours prior to PET/CT imaging on Day 1. The primary objective is to assess the diagnostic performance (sensitivity and specificity) of PyL PET/CT in the detection of metastatic prostate cancer within the pelvic lymph nodes relative to histopathology in pre-prostatectomy patients [cohort A], as determined by independent central review. Key secondary objectives include safety and tolerability of PyL, diagnostic performance of PyL PET/CT in the detection of prostate cancer within sites of distant metastasis or local recurrence [cohort B], and pharmacokinetic parameters of PyL in a subset of subjects. The clinical impact of PyL PET/CT imaging on the intended management of prostate cancer patients will also be assessed as an exploratory endpoint. Clinical trial information: NCT02981368.

TPS5093 Poster Session (Board #316b), Sat, 1:15 PM-4:45 PM

ODENZA: A study of patient preference between ODM-201 (darolutamide) and enzalutamide in men with metastatic castrate-resistant prostate cancer (mCRPC). *First Author: Geraldine Martineau, Clinical Research Department, Institut Gustave Roussy, Villejuif, France*

Background: In recent years, the treatment of mCRPC has evolved and next-generation androgen receptor (AR)-axis targeting drugs (enzalutamide (ENZ), and abiraterone) have been approved and are routinely used. Darolutamide (DARO) is a new next-generation AR inhibitor which has shown strong activity and minimal toxicity in two phase I-II trials ARADES (Fizazi, Lancet Oncol 2014) and ARAFOR (Massard, Eur Urol 2016) and is currently evaluated in a study in men with non-metastatic CRPC (ARAMIS trial). In contrast to ENZ, DARO does not significantly penetrate the blood-brain barrier in vivo, and this may reduce the risk of fatigue, cognitive impairment, and seizure. Assessing patient preference between DARO and ENZ may contribute further differentiating between these two agents. **Methods:** ODENZA is a prospective, randomized, open-label, multicenter, cross-over phase II trial assessing patient preference between DARO and ENZ (NCT03314324). It was initiated in November 2017. Eligibility criteria include: men with asymptomatic or mildly symptomatic mCRPC, performance status 0-1, no prior next generation AR axis-targeted agent. The randomization is stratified on performance status and prior treatment with a taxane for CSPC. 250 patients will be randomized 1:1 to: 12-week ENZ followed by 12-week DARO or 12-week DARO followed by 12-week ENZ. The primary endpoint is patient preference between DARO and ENZ, assessed after the second treatment period. A two-sided binomial test with a power of 80% and a bilateral α of 0.05 will be used. Secondary endpoints include: reasons for patient preference, dose modifications and time to dose modification, safety, fatigue (BFI), cognitive function as assessed by Cogstate computerized cognitive tests, depression screening (CES-D) test, frequency of falls, PSA declines using Waterfall plots after each treatment period, Progression-Free Survival (PFS), association between 4-weeks PSA value and PFS, incidence of cancer progression or death, and tumor response. The study is recruiting. By February 13, 2018, 10 patients have been enrolled. Clinical trial information: NCT03314324.

TPS5094 Poster Session (Board #317a), Sat, 1:15 PM-4:45 PM

A phase II trial of enzalutamide, docetaxel and androgen deprivation therapy (ENZADA) in patients with metastatic castrate sensitive prostate cancer (mCSPC). *First Author: Earle Frederick Burgess, Levine Cancer Institute, Carolinas HealthCare System, Charlotte, NC*

Background: The addition of docetaxel (Doc) or abiraterone to androgen deprivation therapy (ADT) in men with mCSPC improves survival. Whether the triple combination of ADT, Doc and next generation endocrine therapy further improves patient outcome is unknown. Enzalutamide (Enz) is a potent anti-androgen that has activity in the advanced, castration-resistant setting. Preclinical data support the use of Enz in combination with Doc. Enz inhibits the ABCB1 drug efflux pump implicated in Doc resistance, and Doc may eradicate Enz-resistant clones harboring the androgen receptor splice variant 7 (ARv7). The combination of Enz with Doc at standard doses was safe in the phase I setting. This study tests the hypothesis that men with newly diagnosed mCSPC may benefit from adding Enz to standard Doc and ADT. **Methods:** This is a phase II, single arm trial of Enz plus Doc and ADT in men with newly diagnosed mCSPC. The study is designed to enroll 39 eligible participants who must have metastatic prostate adenocarcinoma with confirmed soft tissue and/or skeletal metastasis, ECOG 0-2, and PSA $\geq$ 5. Subjects who previously received up to 3 years of ADT with radiation for localized disease are eligible if ADT was discontinued $>$ 6 months before diagnosis of mCSPC and testosterone recovery is confirmed. Prior treatment with cytotoxic chemotherapy or next generation endocrine therapy is not allowed. Patients will be stratified by volume of metastatic disease. Treatment consists of Doc 75 mg/m2 IV every 3 weeks for 6 cycles and Enz 160 mg daily commencing at enrollment and continued until radiographic progression or study withdrawal. Continuous ADT is required during the study period. The primary endpoint is 12-month PSA complete response rate. Secondary endpoints include adverse events, best PSA response, radiographic objective response, time to castration resistance, progression free and overall survival. Exploratory biomarker analysis includes sequential measurement of circulating tumor cell (CTC) levels and CTC ARv7 status during study treatment. Clinical trial information: NCT03246347.

TPS5095 Poster Session (Board #317b), Sat, 1:15 PM-4:45 PM

Phase II trial of rucaparib (Without ADT) in patients with metastatic hormone-sensitive prostate cancer harboring germline DNA repair gene mutations (TRIUMPH). *First Author: Mark Christopher Markowski, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD*

Background: The clinical activity of PARPi in patients with homologous recombination DNA-repair mutations and metastatic prostate cancer has now been established. Focusing specifically on patients with a germline mutation in a pre-specified group of DNA-repair genes, we hypothesize that targeted therapy with PARPi should be sufficient to induce a clinical response irrespective of hormonal (castration-sensitive/resistant) status. For men with metastatic hormone sensitive prostate cancer (mHSPC), this trial would also provide an alternative to ADT. **Methods:** This study is a multicenter, open-label, single arm Phase II trial. Eligible patients are those with mHSPC without prior ADT. All patients must have a documented germline mutation in a homologous recombination DNA-repair gene (*BRCA1, BRCA2, ATM, CHEK2, NBN, RAD50, RAD51C, RAD51D, PALB2, MRE11, FANCA, FANCB, FANCC, FANCD2, FANCE, FANCF, FANCG, FANCI, FANCL, FANCM*). Patients on trial must be ineligible for or decline standard-of-care hormonal treatment. A mandatory tumor biopsy will be performed prior to therapy. A second, optional tumor biopsy is planned after three months of therapy. Patients will be treated with Rucaparib 600mg po twice daily. Patients will be followed monthly with clinic visits and safety labs with PSA. The primary endpoint is the proportion of patients with a $\geq$ 50% decrease in PSA from baseline (PSA_{50} response). A total enrollment of 30 patients is planned to detect an improved PSA_{50} response rate from 50% to 75% with 90% power (one sided type I error of 0.1). The total number of patients allowed with a non-*BRCA1*, -*BRCA2*, or –*ATM* mutations will be capped at 10. For patients who do not respond to PARPi, we have incorporated safety rules into the study design to take patients off study at first signs of progression. Secondary endpoints include safety, progression-free survival, and objective response. Exploratory analysis will involve biomarker discovery including somatic DNA mutation analysis, RNA expression analysis, and immunohistochemistry for DNA damage markers. Clinical trial information: NCT03413995.

TPS5096 Poster Session (Board #318a), Sat, 1:15 PM-4:45 PM

CRLX101 plus olaparib in patients with metastatic castration-resistant prostate cancer. *First Author: Gang Chen, NCI/NIH, Bethesda, MD*

Background: Prostate cancer is the most commonly diagnosed cancer among men in the United States. While prostate cancer is initially responsive to androgen deprivation therapy (ADT), most patients will develop castration-resistant disease. In the past several years, despite multiple new therapeutics (docetaxel, abiraterone and enzalutamide) have been approved by FDA, the majority patients will become resistant to treatments in 2-3 years. Therefore, it is necessary to find new treatments in metastatic castration-resistant prostate cancer (mCRPC). **Methods:** This phase II expansion cohort will evaluate the efficacy and safety of CRLX101 plus Olaparib in patients with mCRPC. CRLX101 is a nanoparticle drug conjugate with a camptothecin (CPT) payload that provides durable inhibition of topoisomerase I (Top1) specifically in the tumor. CPT stabilizes the Top1-DNA cleavage complex during DNA replication and prevents Top1-mediated DNA relegation, ultimately leads to apoptosis. Poly ADP ribose polymerase (PARP) plays a role in the repair of topoisomerase I-induced DNA damage. By inhibiting PARP, Olaparib may increase the potency of CPT and thus olaparib plus CRLX101 offers a potential treatment option in patients with mCRPC. Synergistic activity between camptothecin and olaparib has been shown in preclinical data. The primary endpoint of this study is overall response rate (ORR), the secondary endpoints include safety and progression-free survival (PFS), duration of response and PSA responses. Clinical trial registry number of this study is NCT02769962. **Results:** N/A. **Conclusions:** N/A. Clinical trial information: NCT02769962.

TPS5097 **Poster Session (Board #318b), Sat, 1:15 PM-4:45 PM**

c15-148: Phase I/II trial of concurrent chemohormonal therapy using enzalutamide and cabazitaxel in patients with metastatic castration resistant prostate cancer (mCRPC). *First Author: Julie Nicole Graff, VA Portland Health Care System, Knight Cancer Institute, Oregon Health & Science University, Portland, OR*

Background: The management of mCRPC has been both enhanced and complicated by the rapid emergence of at least five new agents that can lengthen survival. While great strides have been made in developing new agents for mCRPC, response rates and duration have remained modest, and men ultimately succumb to their disease. Historically, combined chemohormonal therapy has not improved outcomes for patients with prostate cancer, but earlier trials were hindered by lack of efficacious chemotherapy and weaker hormonal agents. In this study, we aim to determine if potential synergistic effects between two newer and more effective agents can be identified and exploited for therapeutic effect, and to obtain correlative biological information that may offer predictive and response value. **Methods:** An initial 3-12 study subjects will be treated with cabazitaxel at 25 mg/m^2 on day 1 and enzalutamide 160 mg daily every 21 days. These subjects will be permitted to continue on cabazitaxel and enzalutamide until progression and will be included in the final analysis of efficacy. The trial will proceed to phase II stage at the dose of 25 mg/m^2 if 0/3 or 1/6 patients receiving 25 mg/m^2 had DLT. The dose de-escalation will happen if $\geq$2/3 or $\geq$2/6 patients receiving 25 mg/m^2 had DLT. The trial will proceed to Phase II stage at the dose of 20 mg/m^2 if 0/3 or 1/6 patients receiving 20 mg/m^2 had DLT. In the absence of treatment delays due to adverse events, treatment with cabazitaxel and enzalutamide will continue for 6-10 cycles. Patients may then continue enzalutamide monotherapy on a 28-day cycle until progression or limiting toxicity. For the phase I portion of this trial an initial 3 study subjects were treated with cabazitaxel at 25 mg/m^2 on day 1 and enzalutamide 160 mg daily every 21 days; no DLTs occurred. These subjects will be permitted to continue on cabazitaxel and enzalutamide until progression and will be included in the final analysis of efficacy. The phase II patients are treated with 25 mg/m2 cabazitaxel and 160 mg enzalutamide. The trial is open at 2 sites and managed by the Prostate Cancer Clinical Trials Consortium (PCCTC). Clinical trial information: NCT02522715.

TPS5098 **Poster Session (Board #319a), Sat, 1:15 PM-4:45 PM**

The GENTleMEN study: Genetic testing for men with metastatic prostate cancer in Washington state and beyond. *First Author: Heather H. Cheng, University of Washington, Seattle, WA*

Background: Germline DNA repair gene mutations are present in ~10% of patients with metastatic prostate cancer (mPC) irrespective of age at diagnosis or family history, and have potential profound implications for treatment, clinical trial selection and family counseling. However, patient/provider lack of awareness, limited access to genetic counseling services, variable insurance coverage and high out-of-pocket costs are known barriers. To remove these barriers and to assess feasibility and acceptability, we are conducting a research study, Genetic Testing for Men with Metastatic Prostate Cancer (GENTleMEN) that offers germline genetic testing to all men in Washington State with mPC. **Methods:** GENTleMEN is a prospective, observational study. Informed consent is provided via internet access (www.gentlemenstudy.org). Participants complete a HIPAA-compliant, RedCap (web-based) questionnaire including demographics, self-reported family cancer history and validated instruments including GAD7, PHQ9, Cancer Distress, Risk Perception, Decision Conflict, Knowledge of and Concern with Genetic Testing (~40 min). Supporting medical data are uploaded by the participant or, with permission, by the study team. Germline genetic testing is performed on a saliva sample via the CLIA-certified Color Genomics 30-gene targeted panel of cancer predisposition genes (www.color.com) through mail, and results are returned by email and/or phone. Men who test positive for pathogenic or likely pathogenic germline variants are required to receive results by phone from a genetic counselor and are strongly encouraged to share results with their medical providers and families. The study offers follow-up support and access to clinical trials, research and registry participation. **Conclusions:** Germline genetic testing is expected to become increasingly pertinent to the care of men with mPC and their families. The GENTleMEN study is investigating a novel mechanism to supplement existing genetics services and remove barriers to germline genetic testing. (*NCT number pending)*

TPS5099 **Poster Session (Board #319b), Sat, 1:15 PM-4:45 PM**

Phase II neoadjuvant and immunologic study of B7-H3 targeting with enoblituzumab in localized intermediate- and high-risk prostate cancer. *First Author: Eugene Shenderov, Johns Hopkins University School of Medicine, Baltimore, MD*

Background: B7-H3 is part of the B7 superfamily and is an immune checkpoint expressed on multiple tumor types. B7-H3 inhibition limits tumor growth by enhancing cytotoxic T lymphocyte function through engagement with an unknown receptor. B7-H3 is highly expressed in prostate cancer (PCa) and is negatively correlated with both biochemical recurrence and metastasis. Enoblituzumab is a humanized Fc-optimized B7-H3–targeting antibody that induces antibody-dependent cellular cytotoxicity (ADCC). To date, approximately 180 patients have received Enoblituzumab monotherapy in a phase I study, with good tolerability. To determine the antitumor, immunological and biological effects of B7-H3 inhibition in high-risk localized PCa, we are currently conducting a neoadjuvant and pharmacodynamic phase II study (NCT02923180). *We hypothesize that neoadjuvant enoblituzumab treatment will be feasible, safe, and will produce a robust antitumor immune responses that will correlate with clinical outcomes in high-risk prostate patients undergoing prostatectomy.* **Methods:** In this investigator-initiated single-center, single-arm, open-label phase II neoadjuvant trial we plan to enroll 32 patients with localized PCa (16/32 accrued). Patients must have clinical stage T1c–T3b, N0, M0 disease and Gleason sum 7-10. Eligible patients undergo a pre-treatment prostate biopsy and receive enoblituzumab at a dose of 15mg/kg IV weekly for 6 doses beginning 50 days prior to radical prostatectomy. Fourteen days after the last dose of enoblituzumab, prostate glands are harvested at the time of radical prostatectomy, and prostate tissue is examined for the secondary pharmacodynamic endpoints. The primary co-endpoints are (1) to characterize safety and tolerability of enoblituzumab treatment in the neoadjuvant setting, and (2) to estimate clinical benefit based on PSA0 response (PSA $<$ 0.1 ng/mL) 12 months after radical prostatectomy. Secondary endpoints include evaluation of anti-tumor effects consistent with enoblituzumab's proposed mechanism of action (apoptosis, proliferation), ADCC markers, and assessment of immunologic correlates (CD8, FOXP3, PD-L1 expression). Clinical trial information: NCT02923180.

TPS5100 **Poster Session (Board #320a), Sat, 1:15 PM-4:45 PM**

Apalutamide + abiraterone + leuprolide with stereotactic, ultra-hypofractionated radiation (AASUR) in very high risk prostate cancer (PCa). *First Author: Sean Matthew McBride, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Radiotherapy and long course (18-28 months) androgen deprivation therapy (ADT) is a current standard of care in very high risk PCa; however, biochemical failure remains frequent. We hypothesize that stereotactic, hypofractionated radiotherapy (SBRT) delivered with a total of 6 months of apalutamide, abiraterone (Abi), and leuprolide will result in a superior 3-year rate of biochemical control compared to the historical control of conventionally fractionated radiation therapy (42-48 treatments) and long term ADT in pts with very high risk PCa (Gleason 9-10 or 2 high risk features or $>$ 4 Gleason 8 cores). The regimen, if proven in a phase 3 setting, would enable very high risk PCa pts to receive curative therapy with potentially decreased morbidity compared with extended androgen ablation. **Methods:** We present a single arm, phase 2 trial to determine the efficacy of anti-androgen therapy combined with SBRT in very high risk PCa, with the proportion of pts who have had biochemical failure (nadir+2) by 36-months post completion of anti-androgen therapy as the primary endpoint. Eligible pts will receive 6 months of leuprolide, abi, and apalutamide to begin 3 months prior to SBRT with continuation 3 months post-SBRT. Pts will be assessed every 4 weeks ($\pm$1 week) (cycle = 28 days) throughout study treatment, and at least once during SBRT. A prostate biopsy will be required prior to the start of SBRT; 2 additional biopsies (at 24 months and, if applicable, metastatic progression) will be performed; partial exome analyses using the MSKCC genomic platform (IMPACT) will be performed on all biopsies; additional correlatives include circulating tumor cell evaluation and cell-free DNA measurement pre and post treatment. Interim analysis will ensure early trial termination should toxicities exceed historical controls. 32 of planned 58 pts have been enrolled. The trial is open at 5 sites and managed by the Prostate Cancer Clinical Trials Consortium and funded by Janssen. Clinical trial information: NCT02772588.

TPS5101 Poster Session (Board #320b), Sat, 1:15 PM-4:45 PM

A multicenter, randomized, controlled trial comparing the occurrence of major adverse cardiovascular events (MACEs) in patients (pts) with prostate cancer (pc) and cardiovascular disease (CVD) receiving degarelix (GnRH receptor antagonist) or leuprolide (GnRH receptor agonist). *First Author: Susan F. Slovin, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Background: Epidemiological studies showed an association between GnRH agonists and a long-term increased risk of CVD, early after treatment initiation and with a higher risk seen in pts with pre-existing CVD. Retrospective pooled safety analyses of 6 randomized trials showed that significantly fewer pts treated with the GnRH receptor antagonists, degarelix, had a CV event or death compared with pts receiving a GnRH receptor agonist. In those studies showing an increased CV risk, Androgen-Deprivation Therapy (ADT) was primarily with GnRH receptor agonists. The mechanistic differences between GnRH antagonists and agonists, including testosterone surge and time to suppression at initiation, effect on follicle-stimulating hormone and on GnRH receptors e.g. T-lymphocytes in atherosclerotic plaque, raises the possibility of different CV risk profiles. The PRONOUNCE trial is the first to prospectively assess whether a GnRH agonist/antagonist can worsen pre-existing CVD; assess the impact of GnRH agonist/antagonist on CV risk biomarkers; and effects on the immune system. **Methods:** PRONOUNCE is a multi-center, randomized, controlled trial of 900 men with pc and concomitant CVD, assessing adjudicated MACEs, i.e. myocardial infarction (fatal, non-fatal), stroke (fatal, non-fatal), or death in pts randomized 1:1 to either degarelix or leuprolide according to label recommendations for up to one year. Eligibility include pre-defined CVD, metastatic or locally advanced pc; high-risk disease with plan for definitive radiation therapy (RT); recurrence after local therapy with PSA doubling time $<$ 12 months; or salvage RT with neoadjuvant/adjuvant ADT for at least 12 months. Serum samples are collected for the analysis of various CV, inflammatory, and immune biomarkers. The primary endpoint will be based on Kaplan-Meier estimator of survival function and stratified for age group and region. Interim analysis is scheduled when 50% of MACE events have occurred allowing the DSMB to recommend for sample size correction. Clinical trial information: NCT02663908.

5500 Oral Abstract Session, Tue, 9:45 AM-12:45 PM

Comparison of survival between upfront primary debulking surgery versus neoadjuvant chemotherapy for stage III/IV ovarian, tubal and peritoneal cancers in phase III randomized trial: JCOG0602. *First Author: Takashi ONDA, Department of Gynecology, Kitasato University School of Medicine, Sagamihara, Japan*

Background: We conducted a phase III non-inferiority trial comparing upfront primary debulking surgery (PDS) and neoadjuvant chemotherapy (NAC) for stage III/IV ovarian, tubal and peritoneal cancers (JCOG0602). Two preceding studies, EORTC55971 and CHORUS demonstrated non-inferior overall survival (OS) of patients treated with NAC. We have already reported reduced invasiveness of NAC setting treatment (NACT) compared to PDS setting treatment (PDST) in analysis of short-term outcomes of JCOG0602. This is a final analysis including primary endpoint of OS. **Methods:** Target cancer was diagnosed by 1) imaging studies (CT and/or MRI), 2) cytology of ascites, pleural effusions or fluids obtained by tumor centesis, and 3) CA125 $>$ 200 U/ml and CEA $<$ 20 ng/ml. Patients were randomized to PDS arm (PDS followed by 8 cycles of paclitaxel and carboplatin, i.e. TC regimen) and NAC arm (4 cycles of TC, interval debulking surgery [IDS], 4 cycles of TC). Planned sample size was 300 with 3-year OS of 25% in PDS arm, 30.3% in NAC arm and non-inferiority margin of hazard ratio (HR) of 1.161 (these corresponds to median OS of 18 months in PDS arm, 20.9 months in NAC arm and non-inferiority margin of 2.5 months), one-sided alpha of 5% and 80% power. **Results:** From Nov 2006 to Oct 2011, 301 patients (149 PDS arm and 152 NAC arm) were randomized. Median OS was 49.0 months in PDS arm and 44.3 months in NAC arm. HR was 1.052 [90.8%CI 0.835-1.326] and one-sided non-inferior p value was 0.24. Median progression-free survival was 15.1 months for PDS arm and 16.4 months for NAC arm (HR: 0.987 [95%CI 0.774-1.259]). In PDS arm 147/149 underwent PDS. 49 of them and 130/152 in NAC arm underwent IDS. Complete resection was achieved in 12% (17/147) of PDS and 31% (45/147) of PDS $\pm$ IDS in PDS arm and in 64% (83/130) of IDS in NAC arm. Optimal surgery (maximum residual tumor $<$ 1cm) was achieved in 37% (55/147) of PDS and 63% (92/147) of PDS $\pm$ IDS in PDS arm and in 82% (107/130) of IDS in NAC arm. **Conclusions:** The non-inferiority of NAC arm was not confirmed and NACT cannot be always a substitute for PDST. Further studies may be necessary to demonstrate a role of NACT for more limited target. Clinical trial information: UMIN000000523.

5501 Oral Abstract Session, Tue, 9:45 AM-12:45 PM

A phase III randomized controlled trial of secondary surgical cytoreduction (SSC) followed by platinum-based combination chemotherapy (PBC), with or without bevacizumab (B) in platinum-sensitive, recurrent ovarian cancer (PSOC): A NRG Oncology/Gynecologic Oncology Group (GOG) study. *First Author: Robert L. Coleman, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: GOG-0213 is an international, open-label, randomized phase 3 trial in women with PSOC with two objectives: 1) to study the addition of B to paclitaxel/carboplatin concurrently and as maintenance; and 2) to evaluate the impact of SSC. The primary endpoint is overall survival (OS). We previously reported the results of Objective 1 [HR 0.829; 95% CI: 0.683-1.005; p = 0.056) Coleman RL, et al Lancet Oncol 2017], and now report the outcomes of Objective 2. **Methods:** From Dec-2007 until Jun-2017, 485 women with investigator-determined resectable PSOC were randomized 1:1 to SSC followed by PBC (n = 240) or PBC alone (n = 245). Stratification factors included the platinum-free interval (PFI). Surgical candidacy was predicated on the likelihood to achieve complete resection (R_0). For Objective 2, the use of B was investigator's choice. The primary endpoint reached maturity for a pre-specified interim analysis in Nov-2017. Results are based on 2-sided alpha = 0.05. **Results:** 215/240 (90%) evaluable patients who were randomized to SSC underwent the procedure. R_0 was achieved in 63%. Adjuvant B was common (84%). Median follow-up duration is 34.6 mos. The HR for death (SSC vs. none) is 1.28 (95%CI: 0.92-1.79) corresponding to a median OS of 53.6 mos vs. 65.7 mos, respectively. There is a significantly different effect of SCC on OS in those receiving PBC+B vs. those who did not (p = 0.022). The HR for death (SCC vs. none) among 77 patients receiving PBC is 2.18 (95% CI: 0.86 – 5.51), while the HR for death among 408 patients receiving PBC+B is 1.03 (95% CI: 0.57 – 1.88). The median progression-free survival was 18.2 mos in the SSC cohort vs.16.5 mos without SCC, HR: 0.88 (95% CI: 0.70 – 1.11). One patient died due to complications from SSC. No new safety signals were observed. **Conclusions:** SSC can be safely performed in patients with PSOC, but did not improve OS in this population. Additional analyses (e.g. impact of PFI, SSC outcome, disease burden and chemotherapy regimen on OS by SSC allocation) are underway and will be presented. Clinical trial information: NCT00565851.

5502 Oral Abstract Session, Tue, 9:45 AM-12:45 PM

Outcomes and costs of open, robotic, and laparoscopic radical hysterectomy for stage IB1 cervical cancer. *First Author: Daniel Jacob Margul, Northwestern University, Chicago, IL*

Background: Surgery is the primary treatment modality for early cervical cancer. Compared to open (ORH), a robotic (RRH) or laparoscopic (LRH) approach to radical hysterectomy may have decreased morbidity, but the influence of surgical approach on survival, specific perioperative complications, and costs is unknown. **Methods:** The 2010-2013 National Cancer Database (NCDB) was used to evaluate the 5-year survival (5YS) of women with stage IB1 cervical squamous cell carcinoma or adenocarcinoma after radical hysterectomy performed open or by minimally invasive surgery (MIS). Survival times were estimated with the Kaplan-Meier method. Multivariable Cox proportional-hazards model (CPH) was used to adjust for measured confounders. The 2010-2015 Premier Healthcare Database was used to compare complications, length of stay (LOS), readmission rates, and hospitalization costs between ORH, RRH, and LRH. All p-values are two-sided. **Results:** From the NCDB, 982 and 910 women underwent ORH versus MIS radical hysterectomy, respectively. Women with a tumor size $\geq$ 2 cm who underwent MIS radical hysterectomy had decreased survival compared to women who underwent ORH (5YS (95% CI): 81.3% (75.6%-87.3%) versus 90.8% (87.7%-93.9%); hazard ratio (95% CI) 2.14 (1.36-3.38), P $<$ 0.001). From Premier, 2830 women had radical hysterectomy: 45.1% (1277) ORH, 48.9% (1384) RRH, and 6% (169) LRH. ORH was associated with longer LOS compared to RRH or LRH (days, median (IQR): ORH 3 (3-5); RRH 1 (0-2); LRH 0 (0-2), P $<$ 0.001). ORH also had a higher composite complication rate than RRH or LRH (ORH 44.9%; RRH 13.9%; LRH; 12.4%, P $<$ 0.001), with increased bowel injuries, infections, electrolyte or fluid disorders, transfusions, and ileus (all P $\leq$ 0.001) associated with ORH. Thirty-day readmission rates were similar (ORH 2.3%; RRH 1.4%; LRH 1.8%, P = 0.17). Total surgical hospitalization costs favored MIS (P $<$ 0.001 between groups) with median (IQR) values: ORH $12080 (8957-16052); RRH $11562 (8636-14600); LRH $9649 (7478- 13010). **Conclusions:** MIS is associated with decreased morbidity and costs. However, among women with $\geq$ 2 cm stage IB1 cervical cancer, MIS was associated with significantly decreased survival.

5503 Oral Abstract Session, Tue, 9:45 AM-12:45 PM

ZoptEC: Phase III randomized controlled study comparing zoptarelin with doxorubicin as second line therapy for locally advanced, recurrent, or metastatic endometrial cancer (NCT01767155). *First Author: David S. Miller, The University of Texas Southwestern Medical Center, Dallas, TX*

Background: Zoptarelin (AEZS-108, AN-152, ZEN-008) is a luteinizing hormone-releasing hormone (LHRH)-cytotoxic hybrid molecule composed of doxorubicin chemically linked to the carrier molecule D-Lys6-LHRH. The primary objective of this study was to compare the overall survival (OS) of patients treated with zoptarelin vs doxorubicin. The secondary objectives included comparing efficacy based on progression-free survival (PFS), objective response rate (ORR), clinical benefit rate (CBR), and safety. **Methods:** In an international multi-center trial, patients with advanced, recurrent, or metastatic endometrial cancers who had failed prior platinum and taxane therapy were centrally randomized 1:1 to zoptarelin (267mg/m2) or doxorubicin (60 mg/m2), I.V. every 21 days for up to nine cycles. **Results:** Zoptarelin was given to 256 patients and doxorubicin to 255 for a median of 5 vs 4 cycles respectively. The median OS for patients treated with zoptarelin was 10.9 months compared to 10.8 months for patients treated with doxorubicin (HR = 1.06; C.I. 0.87, 1.30). PFS was 4.7 months for both (HR = 0.89, C.I. 0.71, 1.11). ORR was 12% vs 14% and CBR was 54% vs 52% (p = NS). The most common grade $>$ 2 adverse events were Neutropenia 47% vs 45%, Leukopenia 21% vs 18%, and Anemia 20% vs 15%. Febrile neutropenia was seen in 9% vs 4%. Absolute decline of LVEF from baseline of $>$ 15% or absolute value $<$ 45% was found in 7% vs 13%. **Conclusions:** Zoptarelin did not improve OS, PFS, ORR, CBR, or adverse events compared to doxorubicin as second line therapy for advanced endometrial cancers. Clinical trial information: NCT01767155.

5504 Oral Abstract Session, Tue, 9:45 AM-12:45 PM

Phase I trial of olaparib (PARP inhibitor) and vistusertib (mTORC1/2 inhibitor) in recurrent endometrial, ovarian and triple negative breast cancer. *First Author: Shannon Neville Westin, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: We sought to determine the recommended phase II dose (RP2D) of olaparib (O) and vistusertib (V) and evaluate molecular markers of response. **Methods:**Two oral schedules for V were explored with O tablet BID. Arm 1: BID continuous (5 dose levels (DL)) and Arm 2: BID 2 days on/5 days off (4 DL). Clinical benefit rate (CBR) was defined as objective response or stable disease ≥ 6 cycles by RECIST 1.1. Patients (pts) were evaluable for response if they received at least 1 cycle (28 days). An expansion phase (n = 30) was performed at RP2D of Arm 2 with biopsies at baseline and 28 days. **Results:** 74 pts were enrolled, 8 with BRCA mutation (11%). Median prior therapies was 4 (1-8). There were 2 DLTs on Arm 1 at DL 5 (O 300mg/V 50mg; G4 thrombocytopenia, G3 allergic reaction). There were 3 DLTs on Arm 2. 2 DLTs at DL 1 (O 100mg/V 125mg; G3 neutropenia > 7 days (n = 1); G3 hyperglycemia (n = 1)) and 1 DLT at DL1b (O 200mg/V 100mg; G3 fatigue). RP2D of Arm 1 was O 200mg/V 50mg. RP2D of Arm 2 was O 300mg/V 100mg. Most common adverse events (≥20%) were nausea (84%, G3/4 4%), anemia (83%, G3/4 15%), hyperglycemia (76%, G3/4 3%), fatigue (73%, G3/4 11%), leukopenia (55%, G3/4 9%), increased creatinine (50%, G3/4 0%), headache (42%, G3/4 0%), vomiting (41%, G3/4 5%), hypercholesterolemia (41%, G3/4 0%), diarrhea (39%, G3/4 0%), hypertriglyceridemia (38%, G3/4 1%), thrombocytopenia (38%, G3/4 14%), mucositis (28%, G3/4 4%), transaminitis (28%, G3/4 1%), constipation (28%, G3/4 1%), and pain (28%, G3/4 1%). Of 64 evaluable pts, response rate (RR) across all DL was 19% with median duration 14 mo (4-34). CBR was 34%. RR was 27%, 20%, and 6% for endometrial, ovarian, and breast cancer, respectively. Among 49 evaluable pts treated on Arm 2, RR was 19% and CBR 37%. In Arm 2, RR was 31%, 15%, and 8% for endometrial, ovarian and breast cancer, respectively. Among 6 endometrial cancer responders (3 endometrioid, 3 serous), PI3K pathway, ARID1A, or FBXW7 mutations were common (67%). **Conclusions:** The combination of olaparib and vistusertib is well tolerated with durable anti-tumor activity. Promising response was seen in both histologies of endometrial cancer. Assessment of molecular correlatives of response will be presented. Clinical trial information: NCT02208375.

5505 Oral Abstract Session, Tue, 9:45 AM-12:45 PM

Adjuvant gemcitabine plus docetaxel followed by doxorubicin versus observation for uterus-limited, high-grade leiomyosarcoma: A phase III GOG study. *First Author: Martee Leigh Hensley, Memorial Sloan Kettering Cancer Center and Weil Cornell Medical College, New York, NY*

Background: We conducted a phase III trial to determine whether adjuvant chemotherapy with gemcitabine-docetaxel followed by doxorubicin improves survival compared to observation in women with resected, uterus-confined, high grade LMS. **Methods:** Women with uterus-confined high grade LMS, confirmed disease-free by post-resection imaging, were randomly assigned to treatment with gemcitabine-docetaxel x 4 cycles, followed by doxorubicin x 4 cycles (CHEMO) or to observation (OBS). All were followed by CT or MR imaging every 4 mos for 3 yrs, then every 6 mos for 2 yrs for recurrence. The primary endpoint was overall survival. **Results:** The study was opened with international collaboration. 38 of the target accrual of 216 patients (pts) were enrolled, after which the study was closed for National Cancer Institute-defined accrual futility. 20 pts were assigned to CHEMO and 18 to OBS. 3 pts assigned to CHEMO never received treatment. Among the 17 pts treated with at least one cycle of CHEMO grade 3 or 4 toxicities were observed in 47%; among 18 pts assigned to OBS, 1 had grade 3 hypertension. There were 6 deaths, (5 - CHEMO, 1-OBS), all due to disease. Over 48 mos, the restricted mean survival time (RMST) for OS in the CHEMO arm was estimated to be 34.3 mos (95% CI: 25.3 mos – 43.3 mos); RMST for OS in the OBS arm was estimated to be 46.4 mos (95% CI: 43.6 mos – 49.1 mos). There were 8 recurrences in each arm. Over 24 mos, the RMST for RFS in the CHEMO arm was estimated to be 18.1 mos (95% CI: 14.2 mos – 22.0 mos) and the RMST for RFS in the OBS arm was estimated to be 14.6 mos (95% CI: 10.3 mos – 19.0 mos). The difference in RMST comparing the CHEMO arm to the OBS arm was estimated as 3.4 mos (95% CI: -2.4 mos – 9.3 mos). Neither survival outcome comparison is considered statistically robust due to the small sample size and low number of events. **Conclusions:** Despite international collaboration to answer the critical question of the role of adjuvant chemotherapy in early-stage uterine LMS, this study was closed for accrual futility. While sample size and number of events preclude robust statistical comparison, observed OS and RFS data do not suggest superior outcomes for patients treated with adjuvant chemotherapy. Clinical trial information: NCT01533207.

5506 Oral Abstract Session, Tue, 9:45 AM-12:45 PM

Chemotherapy plus or minus bevacizumab for platinum-sensitive ovarian cancer patients recurring after a bevacizumab containing first line treatment: The randomized phase 3 trial MITO16B-MaNGO OV2B-ENGOT OV17. *First Author: Sandro Pignata, Istituto Nazionale Tumori "Fondazione G.Pascale"-IRCCS, Naples, Italy*

Background: Bevacizumab (BEV) is approved in recurrent ovarian cancer (rOC) for patients not previously treated with the drug. Our study aimed at evaluating whether the addition of BEV to a platinum-based chemotherapy prolongs progression-free survival (PFS) for rOC patients who had already received it during first line. **Methods:** FIGO stage IIIB-IV rOC patients relapsing at least 6 months after last dose of platinum, who had received BEV during first-line treatment, ECOG PS≤2, were randomized to 6 cycles of platinum-based doublets (carboplatin/paclitaxel or carboplatin/gemcitabine or carboplatin/PLD) with or without BEV administered concomitant with chemotherapy and as maintenance until disease progression. The primary endpoint is PFS. With 90% power in detecting a 0.67 HR, with 2-sided α error 0.05, 265 events were needed. All efficacy analyses are done on an intention-to-treat basis. PFS and OS curves are estimated by Kaplan-Meier method, and compared with a two-sided log-rank test. Toxicity is graded according to NCI-CTCAE v 4.0. **Results:** 405 pts were enrolled. Median age was 61; 64% of patients had progressed ≥12 months after last dose of platinum and 72% of patients after completion of first-line BEV maintenance. With a median follow-up of 20.3 months, 304 PFS events and 147 deaths were recorded. Median PFS was 8.8 months and 11.8 months without and with BEV, respectively (HR 0.51, 95%CI: 0.41-0.64, p < 0.001). Median OS was 27.1 months and 26.7 months without and with BEV, respectively (HR 1.00, 95%CI: 0.73-1.39, p = 0.98). Severe (≥G3) hypertension (27.5% vs 9.7%, p < 0.001) and proteinuria (4% vs 0, p = 0.007) were more frequent with BEV. **Conclusion:** This study shows that for rOC patients previously treated with BEV in first line relapsing ≥6 months after last platinum, rechallenge with BEV in combination with platinum-based doublets is associated with a significantly prolonged PFS, with no unexpected toxicity.Supported by Roche. Clinical trial information: NCT01802749.

5507 Oral Abstract Session, Tue, 9:45 AM-12:45 PM

Correlation of imaging and plasma-based biomarkers to predict response to bevacizumab in epithelial ovarian cancer (EOC): A GOG 218 ancillary data analysis. *First Author: Megan Buechel, University of Oklahoma Health Science Center, Oklahoma City, OK*

Background: Increasing measures of adiposity can correlate with poor oncologic outcomes and lack of response to antiangiogenic therapies. Limited data exists on the impact of subcutaneous fat and visceral fat density(SFD/VFD) on oncologic outcomes. IL-6 has been suggested as a predictive serum biomarker for overall survival (OS) with use of bevacizumab (bev) in EOC. **Methods:** 1249 patients(pts) (67%) from GOG 218 with imaging measurements were included in the OS analysis. Predictive analyses for bev responsiveness used pts who received chemotherapy (CT) + placebo and placebo maintenance and CT + bev and bev maintenance (851 pts). Of these, 522 pts (61%) had IL-6 measurements. SFD and VFD were calculated utilizing Hounsfield units (HU). Proportional hazards models were used to assess the association between BMI, SFD, and VFD with OS. Spearman correlation was used to assess the relationship between IL-6 and VFD. **Results:** Demographic characteristics for pts included in this analysis did not differ from the entire cohort. Increased SFD and VFD showed an increased HR for death (HR per 1-SD increase 1.12, 95% CI:1.05-1.19 p = 0.0009 and 1.13, 95% CI: 1.05-1.20 p = 0.0006 respectively). OS curves for high SFD and VFD show the most separation within quartiles (difference of ~10 months between the 2nd and 4th quartiles). In the predictive analysis, VFD showed a significantly different effect in the two treatment groups (p = 0.025). High VFD showed an increased hazard for death in the placebo group (HR per 1-SD increase 1.22, 95% CI: 1.09-1.37). However, in the bev group there was no effect seen (HR per 1-SD increase: 1.01, 95% CI: 0.90-1.14). OS curves show median OS of 45 vs 47 months in the VFD low groups and 36 vs 42 months in the VFD High groups on placebo versus bev respectively. There was no correlation between IL-6 and high VFD (r = 0.02, p = 0.57). **Conclusions:** High SFD and VFD may be prognostic biomarkers for EOC. High VFD may be a predictive biomarker for use of bev. Pts with high VFD improved their OS curve to the low VFD group with the addition of bev. A similar association was seen with IL-6; however, high IL-6 and high VFD occur in different populations. Further biomarker study is warranted.

5508 Oral Abstract Session, Tue, 9:45 AM-12:45 PM

Cost-effectiveness of maintenance therapy in advanced ovarian cancer: Paclitaxel, bevacizumab, niraparib, rucaparib, olaparib, and pembrolizumab. *First Author: Juliet Elizabeth Wolford, University of California, Irvine, Orange, CA*

Background: Acquired drug resistance remains the greatest clinical hurdle in advanced ovarian cancer suggesting that effective maintenance therapies are lacking. We evaluated cost-effectiveness of available strategies, adjusting for pre-treatment medication costs, infusion center charges, and costs of managing adverse events. **Methods:** Registration trial data was used to obtain toxicity and median PFS for a) paclitaxel (GOG 212); b) bevacizumab (GOG 218, ICON 7, OCEANS, GOG 213); c) niraparib (NOVA), olaparib (SOLO-2), rucaparib (ARIEL-3); and d) pembrolizumab. Because anti-angiogenesis therapy was studied in different populations, each trial was modeled separately. As phase III randomized trials involving checkpoint inhibition in ovarian cancer are not mature, data for pembrolizumab (available via agnostic indication) were obtained from the phase IB ovarian cohort of KEYNOTE-028. Costs of germline/somatic BRCA testing and those associated with management of neuropathy and immune-mediated adverse events, including endocrinopathies, also factored into the model. Utilizing a Markov chain, patients transitioned through response, hematological and non-hematological complications, progression, and death. Using Medicare data, the costs of infusions and managing toxicities were estimated. Incremental cost-effectiveness ratios (ICER) and quality of adjusted life-months gained were determined for each therapy. **Results:** Maintenance paclitaxel was most cost-effective at $870/PFS month. Expected costs of PARP inhibitors (PARPi(s)) prior to progression were approx. $471,989 (18.8x paclitaxel, 6.9x pembrolizumab, and 2.2-2.7x bevacizumab). Comparing pembrolizumab to PARPi(s) in BRCA-deficient patients, anti-PD-1 maintenance yielded ICERs per month of life gained of $20,032 (niraparib), $18,444 (rucaparib), and $17,520 (olaparib). **Conclusions:** Using PFS as the benchmark, high costs of maintenance PARPi(s)/immunotherapy are not mitigated by adjusting for the sequelae that may manifest with maintenance chemotherapy/VEGF inhibition. In terms of economic toxicity, the current trend to study novel combinations is problematic.

5509 Clinical Science Symposium, Sun, 9:45 AM-11:15 AM

Dendritic cell vaccine (DCVAC) with chemotherapy (ct) in patients (pts) with epithelial ovarian carcinoma (EOC) after primary debulking surgery (PDS): Interim analysis of a phase 2, open-label, randomized, multicenter trial. *First Author: Lukas Rob, Department of Obstetrics and Gynaecology, University Hospital Kralovske Vinohrady, Prague, Czech Republic*

Background: Most pts with EOC relapse after PDS and ct. Autologous DCVAC can present tumor antigens to elicit a durable immune response. We hypothesized that adding DCVAC to ct could improve outcomes, including progression-free survival (PFS). **Methods:** Key eligibility criteria were FIGO stage III EOC (serous, endometrioid, or mucinous), PS 0 - 2, post-PDS with $<$ 1cm maximal residuum and no prior systemic therapy. We randomized pts up to 6 weeks after PDS, 1:1:1, into arm A (A; DCVAC concomitantly with ct), arm B (B; DCVAC sequentially after ct) and arm C (C; ct alone). Pts were stratified by tumor residuum (0 or $<$ 1cm). Ct consisted of 6 cycles of carboplatin (AUC 5 - 7) and paclitaxel (175mg/m^2). Pts in A and B were to receive 10 doses of DCVAC (1×10^7 DCs/dose). The primary endpoint was investigator-assessed PFS. Key secondary endpoint was overall survival (OS). **Results:** Between November 2013 and March 2016, 99 pts were randomized in 3 countries (A/B/C, 34/34/31). Median age was comparable in all arms (range, 61.5 - 62.0 years). The % of pts with complete cytoreduction was 85% in A and B, and 84% in C. At the planned interim analysis, the ITT population included 31 pts in A, 30 pts in B, and 31 pts in C; pts who failed leukapheresis (LP) or manufacturing were excluded. A mean of 9.6 and 9.5 doses of DCVAC were administered in A and B, respectively. Median follow-up time was 26.8 months (range, 3.24 - 43.0; 1 pt withdrew informed consent early in the trial). Median PFS was 18.3 months in A, 24.3 months in B, and 18.6 months in C. Compared to C, PFS hazard ratios (95% CI) were 1.08 (0.53 - 2.21) in A and 0.43 (0.18 - 1.03) in B. The gain in PFS in the sequential arm was statistically significant ($p = 0.05$), and this was supported by the same trend in OS. Median OS was not reached in any arm (14% events). There were no grade $\geq$ 3 adverse events (AEs) related solely to DCVAC and it did not worsen the side effects of ct. Most common LP-related AEs were mild pyrexia and moderate hypocalcemia. **Conclusions:** DCVAC improved PFS when administered sequentially after ct. This provides a promising maintenance treatment option delaying progression of the disease. Clinical trial information: NCT02107937.

5510 Clinical Science Symposium, Sun, 9:45 AM-11:15 AM

Clinical data from the DeCidE^1 trial: Assessing the first combination of DPX-Survivac, low dose cyclophosphamide (CPA), and epacadostat (INCB024360) in subjects with stage IIc-IV recurrent epithelial ovarian cancer. *First Author: Oliver Dorigo, Stanford Cancer Institute, Stanford, CA*

Background: DPX-Survivac is a novel T cell activating therapy containing a mix of HLA class I peptides designed to evoke a T cell response against survivin and previously optimized for immunogenicity when delivered with intermittent metronomic cyclophosphamide (CPA). It can induce robust, sustained and specific T-cell responses in subjects with ovarian cancer. Epacadostat (E) is a potent and selective inhibitor of indoleamine 2,3-dioxygenase 1 that may reverse tumor-associated immune suppression. This Phase 1b is evaluating if a *de novo* tumor-specific T cell response, combined with the alteration of the immune suppression will result in clinical benefits. **Methods:** Subjects with advanced ovarian cancer (stage IIc-IV with evidence of disease progression) were treated with DPX-Survivac (2x 0.25 mL priming doses q3w and up to 6x 0.1 mL boosting doses q8w), metronomic CPA (50 mg BID on alternating weeks), and epacadostat (up to 300 mg BID). Primary endpoints include safety and immunogenicity. Secondary endpoints include objective response by modified RECIST v1.1. **Results:** Fourteen subjects were enrolled in the initial dose cohort (E 100 mg BID), 10 of which were considered evaluable. The incidence of adverse events has been collected and the presence of survivin-specific activated T-cells detected in the blood. Three subjects reached an objective response of PR with 1 subject attaining a response of PR within 8 weeks of beginning treatment. Two subjects reached SD followed by PR, one of which is still ongoing, maintained for more than 6 months post-response; both have had disease control for more than 12 months. A best response of SD was shown in 3 of 10 subjects, with an additional subject showing SD (+6%) after an initial PD (+26%). **Conclusions:** The first triple combination of DPX-Survivac, low dose CPA, and epacadostat resulted in clinical responses in subjects with recurrent ovarian cancer. The combination was well-tolerated and immunogenicity to DPX-Survivac was demonstrated. The rate of response observed so far in this study is promising and warrants additional development. Clinical trial information: NCT02785250.

5511 Clinical Science Symposium, Sun, 9:45 AM-11:15 AM

Antitumor activity and safety of pembrolizumab in patients with advanced recurrent ovarian cancer: Interim results from the phase 2 KEYNOTE-100 study. *First Author: Ursula A. Matulonis, Dana-Farber Cancer Institute, Boston, MA*

Background: Data from the KEYNOTE-028 study (NCT02054806) suggested that pembrolizumab (pembro) has clinical activity in patients (pts) with PD-L1+ advanced ovarian cancer (AOC). We assessed the antitumor activity and safety of pembro in pts with recurrent AOC in the ongoing, 2-cohort, phase 2 KEYNOTE-100 study (NCT02674061). **Methods:** Key eligibility criteria included epithelial ovarian, fallopian tube, or primary peritoneal cancer, confirmed recurrence following front-line platinum-based therapy, ECOG PS 0/1, and provision of a tumor sample for biomarker analysis. Cohort A pts received $\leq$2 prior chemotherapy lines for recurrent AOC and had a platinum-free or treatment-free interval (PFI/TFI) of $\geq$3 to 12 mo. Cohort B pts received 3-5 prior chemotherapy lines and had a PFI/TFI of $\geq$3 mo. Pts received pembro 200 mg Q3W IV for 2 yrs or until progression, death, unacceptable toxicity, or consent withdrawal. Tumor imaging was performed every 9 wks for 1 yr and every 12 wks thereafter. Primary study endpoint was ORR per RECIST v1.1 by independent central review for both cohorts and by tumor PD-L1 expression. The effect of PD-L1 expression on ORR was tested with the combined positive score (CPS) assay. Cutpoints were established using the first 100 pts enrolled into Cohort A (training set). Validation was performed among all subsequent pts enrolled. Training set results are presented here. Complete results (n = 378) will be available for presentation. **Results:** 378 pts were enrolled in KEYNOTE-100. 97/100 training set pts had analyzable results. Mean ($\pm$SD) age for this group was 61 ($\pm$12) yr, 68% had ECOG PS 0, and 77% had high grade serous disease. ORR was 9% (95% CI, 4, 17). ORR was higher in pts with PD-L1 expression: 14% (8/59) with CPS $\geq$1 and 25% (5/20) with CPS $\geq$10. 73% of pts had treatment-related (TR) AEs and 17% had grade 3-5 TR AEs. There was 1 TR death in a pt with Stevens-Johnson syndrome. **Conclusions:** Pembro monotherapy was associated with antitumor activity in pts with recurrent AOC. ORR increased with PD-L1 expression, better defining a population benefiting from single agent pembro. No new safety signals were identified in this population. Clinical trial information: NCT02674061.

5512 Clinical Science Symposium, Sun, 9:45 AM-11:15 AM

Association of high tumor mutation (TMB) with DNA damage repair (DDR) alterations and better prognosis in ovarian cancer. *First Author: Wenjuan Tian, Department of Gynecologic Oncology, Fudan University Shanghai Cancer Center; Department of Oncology, Shanghai Medical College, Fudan University, Shanghai, China*

Background: Defects in DNA damage repair (DDR) system may lead to genomic instability and manifest as increased tumor mutation burden (TMB) in multiple types of cancers. But the prognostic value of TMB and association between DDR and TMB in ovarian cancer is still unclear. **Methods:** Whole-exome sequencing data of 434 ovarian tumors from The Cancer Genome Altas (TCGA) and next generation sequencing (NGS) data of 93 ovarian tumors from 3D Medicines were analyzed to explore the association between 21 cancer-related DDR genes and TMB, defined as number of somatic non-synonymous mutations. We also performed analysis of clinical data from TCGA to identify the impact of TMB on ovarian cancer prognosis. **Results:** 27.4% of ovarian tumors in TCGA and 40.9% in 3D Med harbored at least one DDR alteration. The most frequently mutated genes were POLE (21%), BRCA1 (5.1%), BRCA2 (4.1%), ATM (3.0%), FANCA (2.5%), PALB2 (2.3%), FANCD2 (2.1%), and ATR (2.1%) in TCGA, and BRCA1 (12.9%), BRCA2 (10.8%), ATM (5.4%), RAD51 (3.2%), BRIP1 (3.2%), FANCD2 (3.2%), and PALB2 (3.2%) in 3D Med. Any DDR alteration was significantly associated with higher TMB in both TCGA ($P < 0.00$) and 3D Med ($P = 0.021$). Any two DDR gene alterations were associated with even much higher degree of TMB in both TCGA ($P < 0.00$) and 3D Med ($P = 0.03$) compared with DDR wild type. Co-mutated TP53 and any DDR significantly associated with higher TMB in both TCGA ($P < 0.00$) and 3D Med ($P = 0.02$). Prognosis analysis was performed on patients from TCGA. High TMB (cut off as median) was associated with significantly longer DFS (16.4m vs. 14.1m, HR 0.83, $P = 0.04$) and OS (41.0m vs. 32.1m, HR 0.77, $P < 0.00$). Moreover, median PFS for patients with and without DDR alterations was 19.2m and 16.7m ($P = 0.07$). Median OS was 54.6m and 41.5m respectively ($P = 0.02$). **Conclusions:** DDR deficiency is prevalent in ovarian cancer and associated with higher TMB. High TMB was associated with more favorable DFS and OS in ovarian cancer patients. Our results suggest that DDR gene alterations may correlated with anti-tumor immunity in forms of increased TMB, which is known to increase the neoantigen load of tumors. This may assist with the selection of ovarian cancer patients likely to benefit from immunotherapy.

5514 Poster Discussion Session; Displayed in Poster Session (Board #241), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

QUADRA: A phase 2, open-label, single-arm study to evaluate niraparib in patients (pts) with relapsed ovarian cancer (ROC) who have received ≥3 prior chemotherapy regimens. *First Author: Kathleen N. Moore, University of Oklahoma Health Sciences Center, Oklahoma City, OK*

Background: PARP inhibitors (PARPi) are approved as active treatment only for pts with *BRCA* mutations. The PARPi niraparib demonstrated increased PFS vs placebo in the maintenance setting of platinum (plat) responsive ROC. Niraparib was effective regardless of *BRCA*mut or homologous recombination deficiency (HRD) status, but an increased treatment effect was observed in the HRDpos population. QUADRA (NCT02354586) evaluated niraparib active treatment in ROC pts. Based on the results of NOVA, the primary objective in QUADRA was to determine ORR in plat sensitive, HRDpos patients. **Methods:** Eligible pts had grade 2 or 3 serous ROC, ≥3 prior lines of chemo and measurable disease. Pts were evaluated for *BRCA*mut and HRD status (MyChoice HRD Test). HRDpos included germline or tumor *BRCA* mutation or an HRD score ≥42. Pts received niraparib 300 mg once daily until progression; treatment emergent adverse events (TEAEs) were managed with dose reduction to 200 or 100 mg. The primary endpoint was ORR per RECIST v1.1. **Results:** 463 pts were treated. Median age was 65 (range: 29-91). 162 pts were plat refractory; 152 plat resistant; 118 plat sensitive; 31 unknown. In HRDpos, plat sensitive pts who had received ≥3 regimens (median: 3 [range: 3-9]), without prior PARPi ($N = 51$) ORR was 27.5% (95% CI: 15.9%, 41.7%); DCR was 68.6%; DOR was 9.2 mos. Of the 51 pts, ORR was 38.9% (7/18) in *BRCA*mut and 21.2% in *BRCA*wt pts (7/33). 260 (56.2%) pts had grade ≥3 treatment-related TEAEs. The most common grade ≥3 TEAEs were thrombocytopenia (27.9%), anemia (24.9%), and neutropenia (12.4%). Grade ≥3 thrombocytopenia was 27.5% at 300 mg, 4.7% at 200 mg, and 2.7% at 100 mg. Hematologic TEAEs were most frequent in the first month and decreased in frequency and severity after dose reduction during months 2-3. **Conclusions:** Niraparib demonstrated durable anti-cancer activity in this heavily treated, HRDpos ROC population (4th line or greater), including *BRCA*wt pts. Toxicities, consistent with previous niraparib studies, were manageable with dose reduction and generally resolved within 3 mos. Final data including ORR in the total population ($N = 463$) and results in other subgroups will be presented. **Disclosure** Funded by TESARO, Inc. Clinical trial information: NCT02354586.

5515 Poster Discussion Session; Displayed in Poster Session (Board #242), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Apatinib, a novel VEGFR inhibitor, combined with oral etoposide in patients with platinum-resistant or platinum-refractory ovarian cancer: A single-arm, open-label, phase 2 study. *First Author: Chunyan Lan, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Anti-angiogenic therapy combined with chemotherapy could improve the outcome of platinum-resistant ovarian cancer. Apatinib is an oral tyrosine kinase inhibitor which selectively inhibits VEGFR2. We assessed the efficacy and safety of combination of apatinib and oral etoposide, which has the advantage of home administration without an infusion pump and hospitalization, in patients with platinum-resistant or platinum-refractory ovarian cancer. **Methods:** In this phase 2, single-arm, open-label study, we included patients aged 18-70 years with platinum-resistant or platinum-refractory ovarian cancer. Patients received oral etoposide 50 mg on days 1 to 14 in a 21-day cycle for a maximum of six cycles. In addition to the chemotherapy, apatinib 500 mg was administered orally once daily. The primary endpoint was objective response rate by RECIST version 1.1. A Simon two-stage design was employed. This study was registered with ClinicalTrials.gov, number NCT02867956. **Results:** Between Aug 10, 2016 and Nov 9, 2017, 35 patients were enrolled. At data cutoff (Dec 31, 2017), 20 (57.1%) of 35 patients had discontinued study, and 15 (42.9%) patients remained on treatment. The reasons for treatment discontinuation included disease progression (n = 10), adverse events (n = 4), consent withdrawal (n = 2), lost of follow-up (n = 2), and others (n = 2). Objective responses were achieved in 19 (54.3%; 95% CI: 36.6–71.2) of 35 patients and disease control was obtained in 30 (85.7%; 95% CI: 69.7–95.2) patients. The median progression-free survival was 8.1 months (95% CI: 2.8–13.4). The most common grade 3 or 4 adverse events were neutropenia (41.2%), fatigue (32.4%), anaemia (29.4%), and mucositis (23.5%). No treatment-related death was recorded. All of the adverse events were manageable. Dose reductions occurred in 82.4% of the patients for apatinib and 76.5% of the patients for oral etoposide. **Conclusions:** The combination of apatinib with oral etoposide shows promising activities and manageable toxicities in patients with platinum resistant or refractory recurrent ovarian cancer, and warrants further study in phase 3 trials. Clinical trial information: NCT02867956.

Survival analyses from a randomized trial of primary debulking surgery versus neoadjuvant chemotherapy for advanced epithelial ovarian cancer with high tumor load (SCORPION trial). *First Author: Anna Fagotti, Policlinico A. Gemelli Foundation, Rome, Italy*

Survival analyses from a randomized trial of primary debulking surgery versus neoadjuvant chemotherapy for advanced epithelial ovarian cancer with high tumor load (SCORPION trial). Background: Previous randomized multicenter trials determined that neoadjuvant chemotherapy (NACT) was non-inferior to primary debulking surgery (PDS) for both progression-free (PFS) and overall survival (OS) in advanced epithelial ovarian cancer (AEOC). We investigated whether NACT was superior to PDS in terms of PFS and postoperative morbidity in AEOC patients, endowed with high tumor load (HTL), in a single Institution committed toward maximal surgical effort. **Methods:** This was a superiority, randomized phase III trial registered on clinicaltrials.gov (No. NCT01461850). Tumor load was assessed by a laparoscopy predictive index (PI; Fagotti score). Women included had stage IIIC-IV disease and PI between 8 and 12 (HTL). They were randomly assigned (1:1 ratio) to undergo either PDS followed by adjuvant chemotherapy, or NACT followed by interval debulking surgery (IDS) and chemotherapy. Carbo-taxol based chemotherapy was performed in both arms. Co-primary outcome measures were PFS and postoperative complications; secondary outcomes were OS, and quality of life (QoL). Results on postoperative complications and QoL were previously published. Survival analyses were performed on intention-to-treat analysis (ITT), using Kaplan-Meier method. **Results:** From October 2011 to November 2016, 171 women were randomly assigned to PDS (n = 84) vs. NACT (n = 87). All were included in the ITT analysis. Overall median FU was 42 months (95% CI: 30-50 months). As of March 11, 2018, 137 (80.1%) disease progressions and 74 deaths (43.3%) had occurred. There was no significant difference for PFS between patients who underwent PDS vs. NACT (15 vs. 14 months) (HR = 1.06, 95%CI: 0.77-1.46; p = 0.72 log-rank test). Median OS was 41 months in the PDS arm and not reached in the NACT arm. Eighty-four women had PDS and 74 had IDS. Optimal residual tumor (≤ 1 cm) was obtained in 78 (92.8%) vs. 74 (100%) patients, respectively (p = 0.02). Seven (8.3%) deaths for post-operative complications were registered in the PDS vs. 0 in the NACT arm (p = 0.01). **Conclusions:** NACT was not superior to PDS in terms of PFS for AEOC patients endowed with HTL receiving maximal surgical effort. Clinical trial information: NCT01461850.

5517 Poster Discussion Session; Displayed in Poster Session (Board #244), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Final overall survival (OS) analysis of an international randomized trial evaluating bevacizumab (BEV) in the primary treatment of advanced ovarian cancer: A NRG oncology/Gynecologic Oncology Group (GOG) study. *First Author: Robert Allen Burger, Department of Obstetrics & Gynecology, Division of Gynecologic Oncology, University of Pennsylvania, Philadelphia, PA*

Background: GOG 0218 is a double-blind, placebo-controlled, phase 3 randomized trial studying chemotherapy with and without concurrent BEV, and with concurrent BEV followed by maintenance BEV for advanced stage ovarian carcinoma. In 2010, at a median follow-up of 17.4 months (m), the trial met its primary endpoint demonstrating improvement in progression-free survival (PFS) for patients receiving BEV with and following chemotherapy compared to chemotherapy alone: median PFS 14.1 vs 10.3m, respectively; HR 0.717; 95% CI, 0.625-0.824; $p < 0.001$ [Burger RA, et al N Engl J Med 2011]. With extended follow-up, we report on the key secondary endpoint, final OS. **Methods:** 1,873 women with newly diagnosed, incompletely resected stage III or stage IV ovarian cancer received six 21-day cycles of carboplatin (AUC 6) IV and paclitaxel (175 mg/m^2 BSA) IV chemotherapy alone (control) vs chemotherapy plus BEV (15 mg/kg body weight) IV cycles 2-6 (BEV-initiation) vs chemotherapy plus BEV cycles 2-22 (BEV-throughout). OS was analyzed in the intention-to-treat (ITT) population. The database was locked on Jan. 17, 2018 at a median follow-up of 102.9m. **Results:** After 1,491 (79.6%) deaths, 204 patients (10.9%) are alive with a progression event, and 178 (9.5%) are alive without progression. Comparing BEV-throughout to control, the hazard of death (HR) is 0.96; 95% CI, 0.85-1.09; p = 0.53. For BEV-initiation vs control, HR is 1.06; 95% CI, 0.94-1.20; p = 0.34. The relative HR for stage IV patients was reduced for BEV-throughout compared to control (HR 0.774). While the median survival times for stage IV control and stage IV bevacizumab-initiation were 32.6 and 34.5 mos., respectively, the median OS (42.8m) for stage IV BEV-throughout patients was similar to the median OS (control, 44.3m; BEV-initiation, 42.9m; BEV-throughout, 44.2m) of stage III patients. **Conclusions:** In the ITT analysis, there were no survival differences between patients receiving BEV compared to chemotherapy alone. Patients with FIGO stage IV disease may derive a survival advantage from BEV when administered with and following front-line chemotherapy. Clinical trial information: NCT00262847.

5518 Poster Discussion Session; Displayed in Poster Session (Board #245), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

AGO-OVAR 16: A phase III study to evaluate the efficacy and safety of pazopanib (PZ) monotherapy versus placebo in women who have not progressed after first line chemotherapy for epithelial ovarian, fallopian tube, or primary peritoneal cancer—Overall survival (OS) results. *First Author: Ignace Vergote, BGOG & University Hospital Leuven, Leuven, Belgium*

Background: AGO-OVAR 16 study investigated PZ, an oral multi-kinase inhibitor of VEGFR-1, -2, -3, PDGFR-α and -β and c-Kit. This study was designed to test efficacy, safety and tolerability of PZ maintenance after first-line chemotherapy in newly diagnosed advanced ovarian cancer (AOC). The results of final analysis of OS following last patient last visit (LPLV) after prespecified futility criteria were met during 3rd OS interim analysis (IA) are reported. **Methods:** Inclusion criteria: Patients with histologically confirmed AOC; prior treatment of surgical debulking and at least five cycles of platinum-taxane chemotherapy with no evidence of progression; and no bulky disease or disease requiring imminent therapy. Nine hundred and forty patients were randomized in a 1:1 ratio to receive either 800 mg PZ once daily or placebo for up to 24 months unless disease progression, toxicity, withdrawal of consent, or death. The Primary endpoint (investigator assessed progression-free survival (PFS) was met (J Clin Oncol. 2014 Oct 20; 32: 3374-82). The 3rd IA of OS (key secondary endpoint) confirmed futility (conditional power $< 1\%$), and led to study closure and a final analysis after LPLV. **Results:** The final OS analysis was conducted after 494 (89.7% of the planned 551) events occurred. No difference was observed in OS between PZ and placebo. The HR was 0.960 (95% CI: 0.805, 1.145), and the median OS was 59.1 months in PZ and 64.0 months in placebo. For the East Asian patients, similar to the first three OS IA, a numerical negative trend was observed favoring placebo (HR = 1.332, 95% CI: 0.863, 2.054). Exploratory analyses showed a trend for a longer time to first subsequent anticancer therapy or death with PZ over placebo (HR = 0.829, 95% CI: 0.713, 0.965) with a median estimate of 19.0 and 14.5 months, respectively, suggesting that the PFS benefit remained with additional data maturity. **Conclusions:** Although PZ prolonged PFS, OS benefit was not demonstrated. Clinical trial information: NCT00866697.

A phase 2 biomarker trial of combination cediranib and olaparib in relapsed platinum (plat) sensitive and plat resistant ovarian cancer (ovca). *First Author: Joyce F. Liu, Dana-Farber Cancer Institute, Boston, MA*

Background: The combination of cediranib (ced) and olaparib (olap) improves progression-free survival and overall response rates (ORR) in women with recurrent plat sensitive high-grade serous (HGS) ovca compared to olap alone. However, the activity of this combination in plat resistant disease has not been characterized and biomarkers of response are poorly understood. We conducted a Phase 2 study to assess the activity of ced/olap in plat resistant ovca and to identify biomarkers of response (NCT02345265). **Methods:** Patients (pts) across 11 centers were enrolled to two cohorts (plat sensitive or resistant ovca). All pts received ced 30mg daily and olap tablets 200mg BID. Eligibility included pts with recurrent HGS or *BRCA*-related ovca. Pts had measurable disease by RECIST 1.1, the ability to take POs, available archival tissue, and biopsiable disease. No prior anti-angiogenics in the recurrent setting or prior PARP inhibitor was allowed. All pts underwent mandatory pre-treatment and on-treatment biopsies and had the option of undergoing a post-progression biopsy. **Results:** 72 pts were enrolled, with 70 pts receiving treatment (35 plat sensitive and 35 plat resistant). The ORR in plat sensitive pts was 77% (90%CI 63-88%), with 3 confirmed CRs and 24 confirmed PRs. 22 of 27 responders remain progression free with a median follow-up of 7 months. Ten of the plat sensitive responders had a germline *BRCA* mutation, 8 were wild type, and 9 had not been tested. Disease control rate (DCR; SD at 16wks + CR + PR) was 91%. The ORR in plat resistant pts was 20% (90% CI 11-38%) with 7 confirmed PRs. Median duration of response was 6 months and DCR 43% in plat resistant patients. Among the 7 pts with confirmed response in the plat resistant cohort, 3 had germline *BRCA* mutation, 3 were wild type, and 1 had not been tested. **Conclusions:** Ced/olap demonstrated clinical activity in women with recurrent plat sensitive and plat resistant ovarian cancer. While the presence of germline *BRCA* mutation was correlated with increased likelihood of response, confirmed responses were observed in *BRCA* wild type pts with plat resistant disease. Molecular studies are ongoing to investigate additional predictive biomarkers. Clinical trial information: NCT02345265.

Significant overall survival improvement in proliferative subtype ovarian cancer patients receiving bevacizumab. *First Author: Stefan Kommoss, Department of Women's Health, Tuebingen University Hospital, Tuebingen, Germany*

Background: We previously demonstrated that bevacizumab may differentially improve ovarian cancer progression-free survival (PFS) depending on TCGA molecular subtypes. Despite recent progress in the molecular biology of epithelial ovarian cancer, results have not yet translated into individualized treatment options or improved disease outcome. In the current study we correlated mature overall survival data with TCGA molecular subtypes in ovarian cancer patients from the AGO-OVAR11 (ICON7) trial. **Methods:** Whole genome DASL gene expression arrays were performed on FFPE tissues from the AGO OVAR11 (ICON7) trial. Patients were stratified into four TCGA molecular subtypes. Correlation between molecular subtype and the efficacy of randomly assigned therapy with bevacizumab was assessed. **Results:** Among all four TCGA suptypes, only patients with tumors of the proliferative subtype had a statistically significant benefit from the addition of bevacizumab to standard chemotherapy. Median PFS and OS of proliferative subtype patients was 22.17 and 52.43 months respectively if bevacizumab was added to standard chemotherapy but only 12.0 and 35.27 months in the control arm group of patients. Thus anti-angiogenic therapy resulted in a median improvement of PFS of 10.2 months (HR 0.48 [95%CI 0.3-0.76], p = 0.002) and in a median improvement of overall survival (OS) of 17.2 months (HR 0.54 [95%CI 0.3-0.9], p = 0.021) among TCGA proliferative subtype patients. The remaining three non-proliferative subtypes showed no statistically significant improvement of PFS or OS after addition of bevacizumab. **Conclusions:** We demonstrate for the first time significant OS benefit in patients with TCGA proliferative molecular subtype. Our findings may help to develop molecularly stratified treatment strategies and hold potential to ultimately improve outcome in patients with ovarian cancer.

Genomic mutation profiles of paired ovarian cancers (OC) across time. *First Author: Julia Fehniger, NYU Langone Medical Center, New York, NY*

Background: Prior studies demonstrate the clonal heterogeneity of ovarian tumors but do not address the relationship between genomic alteration profiles and treatment selection. We analyzed comprehensive genomic profiling (CGP) results from paired recurrent OC tumor samples to identify changes in somatic mutations over time. **Methods:** DNA from two or more FFPE tumor samples collected serially during the course of clinical care from 49 OC patients in the Clearity Foundation Data Repository was analyzed for genomic mutations (Mut), microsatellite instability (MSI), tumor mutation burden (TMB), and loss of heterozygosity (LOH) by hybrid-capture, next-generation sequencing of up to 315 genes (Foundation Medicine, Cambridge, MA). Genomic profiles were compared between samples from the same patient excluding sub-clonal mutations and genes/biomarkers not assessed across assays. 5 pairs were excluded due to poor quality metrics. **Results:** 22 sample pairs compared primary tumor to recurrence (PR) and 22 pairs compared two or more recurrences (RR). The majority of patients had stage III/ IV (34/77%) and primary platinum-sensitive disease (30/68%). OC was diagnosed at a median age of 57.3 yrs (range 34.5-76.9 yrs). Most tumors demonstrated serous histology (31/70%). Between sample pairs the median number of treatments was 3 for the PR (range 1-13) and 2 for the RR (range 1-7) groups. There was a median of 2 Mut/per OC sample (range 0-5), with a minority (12/27%) of pairs with any discordant mutations (dMut; 9 gains; 5 losses). 36 (82%) OC had *TP53* Mut and all were concordant. Four *BRCA1* Mut were identified (9% of OC) and all four were conserved between sample pairs. dMut were identified in *ARID1A* for 4 (9%) patients and *RB1* for 2 (5%). No dMut were targetable with FDA-approved therapies, but could impact enrollment in clinical trials. We found no significant clinical associations for patients with discordant alterations. **Conclusions:** The majority of targetable mutations from CGP of paired OC specimens are concordant over time, despite inter-current chemotherapy and associated clonal selection. For those genes with discordant findings, attention to specimen selection may be warranted in the clinical development of drugs targeting associated pathways.

Pembrolizumab treatment of advanced cervical cancer: Updated results from the phase 2 KEYNOTE-158 study. *First Author: Hyun Cheol Chung, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, Korea, Republic of (South)*

Background: The KEYNOTE-158 study (NCT02628067) is a phase II basket study investigating the antitumor activity of pembrolizumab, an IgG4 anti-PD-1 monoclonal antibody, in 11 cancer types. An updated analysis of all 98 patients (pts) included in the cervical cancer cohort is presented. **Methods:** Key eligibility criteria for this cohort included histologically or cytologically confirmed advanced cervical cancer, progression on or intolerance to ≥1 line of standard therapy, ECOG PS 0 or 1, and provision of a tumor sample for biomarker analysis. Pts received pembrolizumab 200 mg Q3W for 2 y or until progression, intolerable toxicity, or physician or patient decision. Tumor imaging was performed every 9 wks for the first 12 mo, and every 12 wks thereafter. PD-L1 positivity, defined as a combined positive score (CPS) ≥1, was evaluated retrospectively by IHC. Primary endpoint was ORR assessed per RECIST v1.1 by independent central radiology review. Secondary endpoints included DOR, PFS, OS, and safety. **Results:** 98 pts were treated. Median age was 46.0 (range, 24-75) y, 65.3% had ECOG PS 1, and 93.9% had stage M1 disease. 83% of enrolled pts had PD-L1+ tumors. As of the August 23, 2017 data cutoff, the median follow-up duration was 10.3 mo (range, 0.6 to 18.0 mo). ORR was 13.3% (95% CI, 7.3%-21.6%), with 3 CR and 10 PR. 17 pts had SD, and the DCR was 30.6%. All 13 responses were in pts with PD-L1+ tumors, and the ORR was 16.0% (95% CI, 8.8%-25.9%) in the PD-L1-positive cohort (N = 81). 9 of 13 responses were ongoing after ≥9 mo follow-up. Median DOR had not been reached (range, 3.7+ to 12.4+). Median (95% CI) PFS and OS were 2.1 mo (2.0-2.2 mo) and 9.4 mo (7.9-13.4 mo), respectively. Treatment-related AEs occurred in 65.3% of pts, and the most common were hypothyroidism (10.2%), decreased appetite (9.2%), fatigue (9.2%), and diarrhea (8.2%). 11.2% of pts had treatment-related grade 3-4 AEs. **Conclusions:** Similar to the initial report, durable antitumor activity and manageable safety were demonstrated with pembrolizumab in advanced cervical cancer. Clinical trial information: NCT02628067.

Neoadjuvant chemotherapy with cisplatin and gemcitabine followed by chemoradiation with cisplatin in locally advanced cervical cancer: A phase II, prospective, randomized, trial. *First Author: Samantha Silva, Instituto do Cancer do Estado de São Paulo, São Paulo, Brazil*

Background: Chemoradiation with cisplatin (CRT) is the standard treatment for patients (pts) with locally advanced cervical cancer (LACC). However, 40% of pts has disease relapse. Adjuvant chemotherapy with gemcitabine plus cisplatin improves overall survival, with high toxicity. The role of the addition of neoadjuvant chemotherapy (NAC) to definitive CRT is still a matter of debate. We conducted a trial to investigate if NAC with cisplatin and gemcitabine followed by CRT would improve outcomes. **Methods:** LACC pts (FIGO IIB-IVA) were randomized to 3 cycles of NAC with cisplatin 50 mg/m^2 D1 and gemcitabine 1000mg/m^2 D1 and D8 followed by standard CRT with weekly cisplatin 40mg/m^2/w/6w plus pelvis radiotherapy (50.4Gy) followed by brachytherapy (BCT) or to the standard CRT and BCT alone. Progression-free survival (PFS) in 3 years was the primary endpoint. Secondary endpoint were response rate (RR), overall survival (OS) and toxicity. Kaplan-Meier method was used for survival analysis and curves were compared using log-rank test. RR was evaluated using chi-square test **Results:** Between July 2012 and July 2017, 107 pts were randomized. Pts characteristics were similar between groups. Median age was 47 years. The majority of the patients had squamous cell carcinoma (87.8%), and FIGO stage IIB (42.9%) or IIIB (44.8%). Median follow up was 25.5 months. PFS rates at 3 years were 41.1% (CI 95% 26.5-55.2%) in NAC group and 59.6% in the CRT alone group (CI 95% 42.5-73.1%), with an absolute difference of 18% (HR 1.48, CI 95% 0.86-2.82, p = 0.13). OS rates in 3 years were 74.2% (CI 95% 58.4-84.7%) and 81.9% (CI 95% 65.2-91.1%), respectively (HR 1.64, CI 95% 0.71-3.77, p = 0.23). CRT alone had superior complete RR (54% NAC vs 82% CRT alone, p = 0.002). No difference was seen in overall RR (92.7% NAC vs 94% CRT alone, p = 0.77). QoL improved after treatment in both groups when compared with baseline. **Conclusions:** This study showed that NAC is associated with inferior complete RR in comparison with standard CRT alone in the treatment of LACC, which is probably associated with the trend towards inferior PFS in NAC group. There was no statistically significant difference in OS. Clinical trial information: NCT01973101.

5524 Poster Discussion Session; Displayed in Poster Session (Board #251), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

PARAGON: A phase 2 study of anastrozole (An) in patients with estrogen receptor(ER) and / progesterone receptor (PR) positive recurrent/metastatic granulosa cell tumors/sex-cord stromal tumors (GCT) of the ovary. *First Author: Susana N. Banerjee, The Royal Marsden NHS Foundation Trust, London, United Kingdom*

Background: GCTs occur predominantly in postmenopausal women and arise from sex cord stromal cells of the ovary. They generally have a good prognosis but can metastasize / recur after surgery. Patients (pts) are commonly treated with antiestrogens as GCTs frequently express high ER and/or PR. The pooled response rates with a range of hormonal therapies in the literature are ~ 70 % based on case reports and small retrospective series which form the evidence base for clinical practice. Aromatase inhibitors (AIs) are reported to be particularly active. There are no reported phase 2 studies of antiestrogens in GCT. We report the results of a phase 2 trial of anastrozole, an AI in recurrent / metastatic GCT. To our knowledge this is the first prospective trial of hormonal therapy in GCTs. **Methods:** Postmenopausal women with ER/PR +ve metastatic GCT measurable by RECIST v1.1 and/or elevated Inhibin were eligible for inclusion. Pts received An 1 mg daily until progression or unacceptable toxicity. The primary endpoint was clinical benefit rate (CBR) at 12 weeks. **Results:** There were 41 pts entered. 3 pts without measureable disease had an elevated Inhibin. 1 pt received prior tamoxifen. 1 pt was not evaluable for 3-month (m) CBR. The CBR at 3m was 80.0% which included 1 (2.5%; 95% CI: 0.4 – 12.9%) partial response (PR) and 77.5% stable disease. 8 (20%) had progressive disease by 3m. Median PFS was 8.6 m (95% CI 5.5 – 13.5m). There were delayed responses beyond 3 m with a total 4 pts (9.8%; 95% CI 3.9% – 22.5%) with a RECIST PR. 23 (59%) pts were progression free at 6m (1 pt was censored at 3 m and 16 had progressed by 6 m). 2 pts remain on treatment at 14.8 m and 53.5 m. An was well-tolerated with only 1 grade 3 toxicity – arthralgia. 1 pt stopped An due to side effects. **Conclusions:** This is the first prospective trial of hormonal therapy in GCTs. Although there was a high CBR, the objective response rate to An was much lower than the pooled results of the response rate to hormonal therapy reported in retrospective series. Translational research on tumor specimens is underway for predictors of response/resistance to An which will inform future studies. Clinical trial information: 12610000796088.

5525 Poster Session (Board #252), Mon, 1:15 PM-4:45 PM

A phase 1/2A trial of synthetic DNA vaccine immunotherapy targeting HPV-16 and -18 after chemoradiation for cervical cancer. *First Author: Yasmin Hasan, Department of Radiation and Cellular Oncology, The University of Chicago Hospitals, Chicago, IL*

Background: DNA immunotherapies targeting HPV oncogenes, E6 and E7, have demonstrated clinical efficacy in pre-invasive cervical lesions. Here, we assessed the feasibility of chemoradiation and adjuvant MEDI0457 (INO-3112), a DNA-based immunotherapy targeting HPV-16 and HPV-18 E6 and E7 oncogenes, followed by electroporation (EP) with the CELLECTRA device, in locally advanced and recurrent cervical cancer patients. **Methods:** Safety and immunogenicity of MEDI0457 were assessed in HPV-16- or HPV-18-positive newly-diagnosed inoperable (Cohort 1, C1) or persistent and/or recurrent disease (Cohort 2, C2) cervical cancer patients treated with standard therapy. MEDI0457 was delivered with EP on day 0, weeks 4, 8, and 12. The primary endpoint was to evaluate safety and tolerability. Secondary objectives included clinical response (PET-CT, clinical exam) and immune responses against HPV antigens as measured by Interferon-g (IFNg) secretion by peripheral blood mononuclear cells and anti-E6/E7 antibody titers. **Results:** As of Jan 23, 2018, 10 patients (7 C1, 3 C2) with stage IB1-IV HPV 16 (n = 7) or 18 (n = 3) cervical cancers received MEDI0457 after conventional therapy. Treatment-related adverse events were all Grade 1, primarily injection site related. At up to 60 weeks of follow-up, all C1 patients remain alive with no evidence of disease clinically and on PET/CT. Of 3 C2 patients, 1 died, 1 had persistent disease and one remains free of disease. Antibody responses against HPV oncoproteins were detected in up to 60% of patients (anti-HPV16 E6 response: 5/10 patients, anti-HPV18 E6 response: 3/10 patients, anti-HPV16 E7 response: 4/10 patients, anti-HPV18 E7 response 6/10 patients). IFN-g responses were detected in 4/7 C1 patients while no IFN-g response was detected in C2 patients. **Conclusions:** Adjuvant MEDI0457 is feasible after chemoradiation for locally advanced and/or recurrent cervical cancer. More than half of the patients developed detectable immune responses to HPV antigens after treatment. These results support further study into the efficacy of adding DNA therapy with CELLECTRA EP to chemoradiation for HPV-related cancers. Clinical trial information: NCT02172911.

5526 Poster Session (Board #253), Mon, 1:15 PM-4:45 PM

Phase II clinical trial of eribulin (E) in advanced/recurrent cervical cancer. *First Author: Jocelyn Garcia, Los Angeles County Hospital/ University of Southern California, Los Angeles, CA*

Background: Eribulin (E), a Halichondrin B analog from the marine sponge H. okadai has clinical efficacy in pretreated metastatic breast cancer patients (pts) and preclinical antitumor activity in squamous cell carcinoma (SCC). We conducted a 2-stage Phase 2 study of E in pts with advanced/recurrent CC to examine its clinical activity and evaluate potential predictors of response. **Methods:** Pts with advanced/recurrent CC after ≤1 prior CT regimens, measurable disease and ECOG performance status ≤2 were treated with E (1.4mg/m^2 IV day 1 and 8, every 21 days) with tumor assessments every 2 cycles. Primary endpoint was 6-month progression-free survival PFS_6; secondary were best overall response (RECISTv1.1), toxicity (CTCAEv4.03) and overall survival (OS); and exploratory were associations of tumor and serum GRP78 as well as apoptosis/proliferation markers, unfolded protein response markers and tubulin sub-types with clinical activity. 30 evaluable pts would ensure 80% power when the true PFS_6= 26% with a 1-sided α ≤0.1 (H_o: PFS_6= 10%). A prespecified futility analysis gating stage 2 was set if 0/15pts showed at least SD at 6 months. Immunohistochemistry was performed on archival tumor samples and serial serum GRP78 levels were quantified by ELISA. **Results:** 32 pts were enrolled, median age 51 years (range 29-76), 22 had SCC, the median number of cycles was 4 (range 1-29). 26 pts had received prior pelvic irradiation. 29 pts had received prior CT with cisplatin/gemcitabine (12) and cisplatin/paclitaxel/bevacizumab (12) as the most common regimens. 6/32 pts (18.8%) achieved > PFS_6; median PFS is 2.6 months (95%CI: 1.2, 4.2). Median OS is 6.6 months (95% CI: 4.4, 12.7). Two pts were inevaluable for response having received less than 2 cycles. Among the 30 evaluable pts, 6 (20%) had a partial response and 11 (37%) had stable disease (clinical benefit rate 57%). 2 pts remain on study having received 21 and 29 cycles. Grade 3/4 adverse events occurring in > 10 % of pts are anemia (12pts), neutropenia (7pts) and leukopenia (6pts). 1 pt was removed from study due to paresthesia after 7 cycles. Analysis of correlative predictors of response is ongoing. **Conclusions:** Eribulin shows evidence of activity in recurrent/advanced CC with a favorable toxicity profile. Clinical trial information: NCT01676818.

5527 Poster Session (Board #254), Mon, 1:15 PM-4:45 PM

Propensity score-matched analysis of systemic chemotherapy versus hysterectomy for patients with residual cervical disease after definitive radiotherapy/concurrent chemoradiotherapy. *First Author: Munetaka Takekuma, Department of Gynecology, Shizuoka Cancer Cener Hospital, Shizuoka, Japan*

Background: Patients with persistent cervical cancer after definitive radiotherapy/concurrent chemoradiotherapy (RT/CCRT) have a poor prognosis. Salvage hysterectomy (HT) is considered curative treatment; however, very little data exists showing the survival advantage of HT over standard therapy. **Methods:** Patients with persistent cervical cancer treated with definitive RT/CCRT at 35 institutions from 2005–2014 were reviewed retrospectively. Those who underwent a HT for residual cervical disease after definitive RT/CCRT were matched (histology, FIGO stage at initial treatment, brachytherapy application, age and performance status at diagnosis of residual tumor, diameter and parametrial invasion by residual tumor, and the number of lymph node tumors at diagnosis, etc.) with propensity scores for patients who underwent systemic chemotherapy (CT). Oncologic outcomes between the two groups using a propensity score matched–cohort analysis were compared. **Results:** A total of 142 patients with residual cervical disease after definitive RT/CCRT were included after matching (HT: 71, systemic CT: 71). A difference in all background factors between HT and CT groups was not observed. At a median follow-up of 4.6 years, 33 (46.5%) and 47 deaths (66.2%) occurred in HT and CT groups, respectively. Median overall survival was 3.8 and 1.5 years in HT and CT groups, respectively (p= 0.0019, hazards ratio [HR] 2.438, 95% confidence interval [CI] 1.362–4.361), and median progression-free survival was 2.7 and 0.7 years, respectively (p= 0.0046, HR 2.235, 95% CI 1.262–3.960). Increasing tumor size was significantly associated with a high incomplete resection rate (p= 0.0385, Odds Ratio 0.941, 95% CI 0.888–0.997). The cut-off value for the residual tumor diameter regarding complete resection after receiver operating characteristic (ROC) analysis was 11 mm (sensitivity 70%, specificity 86.9%). **Conclusions:** Salvage HT may be considered curative treatment for patients with residual cervical disease after definitive RT/CCRT. The diameter of residual tumor is important in selecting appropriate candidates for HT.

5528 Poster Session (Board #255), Mon, 1:15 PM-4:45 PM

Preliminary results from CECILIA, an open-label global safety study of bevacizumab (BEV), carboplatin (C) and paclitaxel (P) therapy for metastatic, recurrent or persistent cervical cancer (CC). *First Author: Andres Redondo, Medical Oncology Department, Hospital Universitario La Paz, Madrid, Spain*

Background: Adding BEV to chemotherapy (cisplatin + P or topotecan + P) for advanced (a)CC significantly improved overall and progression-free survival (PFS) in the overall population in GOG240. The CECILIA study (NCT02467907) is evaluating BEV with more widely used CP. **Methods:** The primary objective is to determine the safety of BEV + CP for aCC, defined by the frequency and severity of gastrointestinal (GI) perforation/fistula, GI-vaginal fistula and genitourinary (GU) fistula. Eligible patients (pts) have metastatic/recurrent/persistent CC not amenable to curative surgery and/or radiotherapy (RT). Pts with ongoing bladder/rectal involvement, prior cobalt RT, history of fistula/GI perforation, or bowel resection ≤6 weeks or chemoRT ≤3 mo before the first dose are excluded. Pts receive BEV 15 mg/kg, P 175 mg/m^2 and C AUC 5 q3w until progression, unacceptable toxicity or consent withdrawal. If BEV, C or P are stopped for adverse events (AEs), the remaining drug(s) can be continued alone. We report preliminary findings after ≥6 mo follow-up in all pts. **Results:** Between Jul 2015 and Dec 2016, 150 pts in Europe, South/Central America and South Africa began treatment. At study entry, 20% had persistent disease, 54% recurrent disease and 26% stage IV at diagnosis; 73% had squamous cell carcinoma, 71% had received prior RT (as part of chemoRT in 58%) and 59% prior platinum. At the data cutoff (12 Jun 2017), median follow-up was 11.2 mo. Median BEV duration was 9 cycles (range 1–28; 42 pts still on therapy). Grade 3/4 AEs occurred in 67% of pts, most often hematologic AEs and hypertension; 5 AEs (3%) were fatal. GI perforation/fistula occurred in 4.0% of pts (95% CI 1.5–8.5%), GI-vaginal fistula in 4.0% (1.5–8.5%) and GU fistula in 4.0% (1.5–8.5%), giving an overall rate of 18 fistula/GI perforations in 15 pts (10.0% [95% CI 5.7–16.0%]). All but 1 pt with fistula/GI perforation had received prior RT. PFS results are immature. **Conclusions:** These preliminary results suggest that BEV can be combined with CP in carefully selected pts. The fistula/GI perforation incidence was in line with GOG240. Final results are expected in 2019. Clinical trial information: NCT02467907.

5529 Poster Session (Board #256), Mon, 1:15 PM-4:45 PM

Comparison of different adjuvant therapy after radical surgery in early stage cervical carcinoma: A 3-arm randomized control study. *First Author: He Huang, Sun Yat-sen University Cancer Center, Guang Zhou, China*

Background: To determine whether the addition of concurrent chemotherapy (CCT) or sequential chemotherapy (SCT) to adjuvant pelvic radiotherapy (RT) will improve prognosis of patients with early-stage cervical carcinoma who had adverse pathological factors. **Methods:** After radical surgery, patients with FIGO stage IB1 to IIA2 cervical cancer who had one or more of the following pathological factors were recruited: lymph node metastases (LNM), positive parametrium or margins (PPM), lymphatic vascular space involvement (LVSI), deep invasion of cervical stroma (DIS). Eligible patients were randomized to the three groups. Group A underwent 50 GY pelvic RT alone. Group B received concurrent weekly cisplatin and RT (CCRT). Group C received paclitaxel and bolus cisplatin every three weeks for two cycles before RT, followed by two cycles of chemotherapy (SCRT). **Results:** From February 2008 to August 2015, a total of 1055 cases were randomized and eligible for evaluation, with 352 cases in group A, 348 in group B and 355 in group C. The disease-free survival (DFS) was 132.3 month in group C versus 94.4 month in group A and 92.3 month in group B ($P = 0.047$), and the corresponding overall survival (OS) were 140 month, 105.4 month and 99.5 month ($P = 0.20$). In the intergroup analysis, a better DFS was found in group C (87 months) than the other two groups (79 month in group B and 69 months in group A, $P < 0.05$) among patients with LNM or/and PPM (high risk). While there was no significant difference in DFS was found between three groups in the patients with DIS and/or LVSI (intermediate risk), or in those patients who had indications for adjuvant treatment according to Sedlis Criteria. Alopecia (87.1%, $P < 0.05$) and pelvic lymph cyst (14.1% $P < 0.05$) were significantly higher in group C. There is no significant difference of grade 3/4 hematologic and gastrointestinal toxicities between group B and C. **Conclusions:** SCRT brought a better DFS in patients especially with high-risk cervical carcinoma. The sequential strategy may constitute an alternative treatment for the high-risk patients. However, CCRT and SCRT did not show survival benefit in patients with intermediate risk factors. Clinical trial information: NCT00806117.

5530 Poster Session (Board #257), Mon, 1:15 PM-4:45 PM

Association between pap abnormalities and HPV infection in participants in HPV vaccine clinical trials. *First Author: Evan Meyers, Duke University, Durham, NC*

Background: Few studies have reported the burden of Pap abnormalities associated with the specific HPV types targeted by HPV vaccines. The purpose of this analysis is to estimate prevalence of HPV anogenital infection, by baseline Pap results, in participants of 3 worldwide trials of the quadrivalent HPV vaccine (placebo and vaccine groups, FUTURE I, II, III), and to estimate incidence of Pap abnormalities by HPV infection status at enrollment (placebo only, FUTURE I, III). **Methods:** Among 16,949 young women (YW) age 15-26 years (FUTURE I, II) and 3,674 adult women (AW) age 24-45 (FUTURE III), HPV prevalence (measured with PCR for 14 HPV types) was estimated at enrollment for women with: atypical squamous cells of undetermined significance (ASC-US) (n = 781 YW, 115 AW), low-grade squamous intraepithelial lesion (LSIL) (n = 993 YW, 115 AW), and high-grade squamous intraepithelial lesion or atypical squamous cells- cannot exclude HSIL (HSIL/ASC-H) (n = 157 YW, 30 AW).

Cumulative incidence of high-grade Pap abnormalities (HSIL/ASC-H) over 4 years (placebo only), by baseline HPV status, was estimated for 1,481 (YW) and 1,701 (AW). **Results:** Prevalence of any 9-valent (9v) vaccine type (6/11/16/18/31/33/45/52/58) among women with ASC-US, LSIL, or ASC-H/HSIL at enrollment was 47%, 67%, and 89%, respectively (YM), and 29%, 55%, and 93%, respectively (AW). Prevalence of any non-vaccine type (35/39/51/56/59) among women with ASC-US, LSIL, or ASC-H/HSIL was 32%, 64%, and 47%, respectively (YM), and 24%, 54%, 38%, respectively (AW). Over 48 months, cumulative incidence of high-grade Pap abnormalities (HSIL/ASC-H) among women with any high-risk 9v HPV type at enrollment was 8% (YW) and 6% (AW); cumulative incidence among women with no measured HPV infection at enrollment was 2% (YW) and 0.4% (AW). **Conclusions:** While the 9-valent vaccine will substantially reduce Pap abnormalities associated with HPV types that cause 90% of cervical cancers, non-vaccine HPV types also contribute to Pap abnormalities. These findings underscore the need for vaccination to protect against 9 HPV types, as well as the ongoing need for cervical cancer screening. Clinical trial information: NCT00090220.

5531 Poster Session (Board #258), Mon, 1:15 PM-4:45 PM

The clinical utility of prospective molecular characterization in advanced cervical and vulvovaginal cancer. *First Author: Claire Frances Friedman, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The molecular landscape of recurrent cervical and vulvovaginal cancers is undefined. We sought to determine the clinical impact of performing next generation sequencing (NGS) in these patients (pts). **Methods:** 82 pts consented to an IRB-approved protocol for the prospective sequencing of tumor and matched normal with MSK-IMPACT (NCT01775072), a NGS assay of up to 468 cancer-associated genes. Hotspot mutations were annotated using the OncoKB knowledge base (OncoKB.org). **Results:** We analyzed 90 samples. There was no significant difference in the incidence of mutations between primary (45%) and metastatic (mets) (55%) specimens. In the 5 pts with paired mets and 2 with matched primary and mets, the molecular profiling was identical in all but one pt that gained a TP53 mutation. We identified likely therapeutically actionable mutations in 44% of pts. Using OncoKB, we found that 8.5% of patients had a level 2B oncogenic alteration (See Table). Other alterations that have a lower level of clinical evidence included mutations in PIK3CA, ERBB2, AKT, and FGFR3 (n = 29, 35%). In this cohort, 32 pts (39%) enrolled in at least one clinical trial, half of which (n = 15) were genotype-matched. Among these pts, 11 (73%) had stable disease or partial responses (PR). Overall, 24% of patients received checkpoint blockade; two patients without evidence of somatic hypermutation achieved a PR. **Conclusions:** Prospective NGS of cervical and vulvovaginal cancer informs management of patients through the identification of potentially actionable mutations.

Age at Dx (med, range)	46 (22-86)
Histology (n, %)	
Cervical Adenosquamous	7 (9%)
Cervical Squamous	25(30%)
Endocervical Adenocarcinoma	26 (32%)
Gastric Type	7 (9%)
Other Cervical	8 (10%)
Vulvovaginal carcinoma	9 (11%)
Sample Type (n, %)	
Primary	40 (45%)
Metastatic	50 (55%)
Hotspot Mutations (n, %)	
OnkoKB Level 2B: Biomarker to an FDA approved drug in another indication BRCA2, ERBB2 amp, KIT	7 (8.5%)
OncoKB Level 3B: Biomarker is likely predictive of response to a drug in another indication, but neither FDA approved PI3K, AKT1, ERBB2 mut, FGFR3	29 (35%)
OncoKB Level 4: Biomarker is likely predictive of response to a drug, but neither FDA approved BRAF, HRAS, NF1, PTEN	9 (11%)

5532 Poster Session (Board #259), Mon, 1:15 PM-4:45 PM

Unexpected lymphatic drainage pathways of cervical cancer: Insights of the sentinel lymph node biopsy. *First Author: Vincent Balaya, Hopital Européen Georges Pompidou, Paris, France*

Background: Sentinel lymph nodes (SLNs) can be observed in various territories. An intraoperative surgical strategy is needed to find all relevant SLNs and limit the risk of missed SLN. The aim of this study was to define an anatomically based surgical algorithm to identify sentinel lymph nodes (SLNs). **Methods:** We analyzed the data of two prospective multicentric trials on SLN biopsy for cervical cancer (SENTICOL I and II) in women undergoing surgery for early-stage cervical cancer. SLN detection was realized with a combined labeling technique (Patent blue and radioactive tracer). **Results:** A total of 377 patients with 1186 intraoperative detected SLNs were analyzed. 201 SLNs were only blue, 291 SLNs were only hot and 685 SLNs were blue and hot. The SLNs were located in the ilio-obturator or extern iliac area in 82.1 % of cases (974/1186) corresponding to the upper parametrial pathway (UPP) and 362 patients (96%) had at least one SLN in these areas. The SLNs were located in other unexpected areas in 17.9% of cases (212/1186). 130 patients (34.5%) had at least one SLN in an unexpected area and 14 (3.7%) patients had SLNs only in in an unexpected area. 176 SLNs (14.8%) were located in the lower parametrial pathway (LPP) with 45 in the parametrium (3.8%), 109 in the common iliac area (9.2%), 22 in the promontory area (1.9%)) whereas 36 SLNs (3%) were located in the infundibulo-pelvic pathway (IPP) with 26 in the paraaortic area (1.9%), and 13 in other areas (1.1%). The lymphatic drainage was exclusively through the UPP in 57.2% of cases (679/1186), through the UPP and another pathway in 40.8% of cases (484/1186) and exclusively through the LPP or the IPP in 1.9% of cases (23/1186). **Conclusions:** The SLNs search should begin in the ilio-obturator and external iliac area. Other territories should be explored in the absence of SLNs in this first level or as a complement. Pelvic dissection should be done only in case of absence of SLN in all territories.

AMPATH Oncology: Baseline HPV detection in Kenyan women enrolled in a longitudinal study of modifiable factors predicting cervical dysplasia. *First Author: Darron R. Brown, Indiana University School of Medicine, Indianapolis, IN*

Background: Cervical cancer is caused by oncogenic HPV types. Kenyan women, HIV-infected or uninfected were studied to define modifiable factors predicting incidence and persistence of HPV and cervical dysplasia. **Methods:** From 9/21/2015 to 10/4/2016, 223 women ages 18 to 45 years old with normal VIA at enrollment were enrolled in a longitudinal study in Kenya. Cervical swabs, behavioral data, and other data were collected. HPV typing was performed on clinician-obtained cervical swabs using the Roche Linear Array. **Results:** Analysis of 219 evaluable participants was done, including 115 HIV-infected (median age 36 years) and 104 HIV-uninfected women (median age 33 years) (p = .0009). Among HIV-infected women, 86.8% were receiving antiretroviral therapy (ART); median duration between HIV diagnosis and enrollment was 7.2 years (IQR 4.1-10.3); median CD4 count was 471 (IQR 310-612). There was a significant difference in number of lifetime sex partners between HIV-infected (median 4, IQR 3-8) and HIV-uninfected women (median 3, IQR 1.5-4), p = .0001. HPV detection is shown in Table 1. **Conclusions:** Oncogenic HPV types, including types preventable by vaccination were prevalent in Kenyan women. HIV-infected women were more likely to have detection of HPV 16, other oncogenic HPV types, and multiple types in spite of ART. In this longitudinal study, other factors will be included such as behaviors, the effect of HIV viral load, CD4 count, and details of ART.

HPV detection in 115 HIV-infected and 104 HIV-uninfected women.

HPV Types	HIV Infected	HIV Uninfected	P value

Dose dense neoadjuvant chemotherapy (NACT) with carboplatin-paclitaxel in locally advanced cervical cancer. *First Author: Domenica Lorusso, Fondazione IRCCS Istituto Nazionale dei Tumori, Milano, Italy*

Background: NACT followed by radical surgery is considered a valid therapeutic approach in locally advanced cervical cancer (LACC). The standard neoadjuvant treatment has not yet been identified. The most widely used regimen is the TIP (Cisplatin-Paclitaxel-Ifosfamide) combination which is effective but highly toxic. The aim of the study is to evaluate clinical (CR) and pathologic (PR) response to carboplatin-paclitaxel dose dense regimen as NACT in LACC. **Methods:** Consecutive patients with stage FIGO IB2-IIB were prospectively enrolled and treated with 3 cycles of neoadjuvant Carboplatin (AUC5) d1 and Paclitaxel (80 mg/m^2) d1, 8, 15 q21 chemotherapy. After 4 weeks from completion of NACT, patients were submitted to radical hysterectomy and pelvic lymphoadenectomy. Abdomino-pelvic MRI and gynaecological evaluation were performed at baseline and after 3 cycles in order to evaluate CR. PR was defined as follows: PR0: no residual disease, PR1: residual disease $\leq$ 3 mm stromal invasion, PR2: residual disease $>$ 3 mm. A two-stage optimal Simon design was applied in order to detect a 60% of PR0+PR1: if at least 7 responses were registered among the first 16 patients, the trial would continue the enrolment. **Results:** 67 patients were enrolled in 40 months. After the enrollment of the first 16 patients, at least 7 responses were detected, so the trial proceed to the second step of enrolment. 11 patients (16%) went out from the study because of allergic reaction to the first paclitaxel administration and were not evaluable. 4 of the 56 patients experienced stable or progression disease and did not underwent surgery. The only grade 3-4 registered toxicity was neutropoenia in 10.7% of patients. Patients characteristics and responses are reported in the table below. **Conclusions:** Combination of dose dense Carboplatin-paclitaxel resulted in encouraging clinical and pathologic responses and in a favourable toxicity profile. This scheme merits further evaluation in randomized clinical trials versus TIP.

Evaluation of capecitabine in patients with platinum-pretreated advanced or recurrent cervical carcinoma: A retrospective study of the IRCCS National Cancer Institute of Milan. *First Author: Domenica Lorusso, Fondazione IRCCS Istituto Nazionale dei Tumori, Milano, Italy*

Background: Cervical cancer is underrepresented in the gynecological clinical research. The objective of this retrospective study was to evaluate the activity and the safety of capecitabine in patients with platinum-pretreated recurrent cervical carcinoma. **Methods:** We performed a retrospective review of medical records from patients with advanced or recurrent cervical carcinoma pretreated with platinum-based therapy who received oral capecitabine at the Gynecological Units of the IRCCS National Cancer Institute of Milan (Italy). We used Response Evaluation Criteria In Solid Tumors (RECIST) version 1.1 to evaluate response to therapy and Common Terminology Criteria for Adverse Events (CTCAE) version 4.0 to evaluate adverse events. **Results:** From October 2013 to August 2017, we treated with oral capecitabine dose 29 patients with advanced or recurrence cervical carcinoma, already exposed to platinum. All patients receive a combination of carboplatin plus paclitaxel as first-line therapy for advanced/recurrent disease. At first capecitabine administration the median of previous treatments was 2 (range from 1 to 5). After three cycles of oral capecitabine the clinical benefit rate (CBR) was 62% with 41.3% of PR and 20.7% of SD. Grade 3 reported toxicity were 10% neutropenia and 3% hypertransaminasemia. CBR was 83.3% in adenocarcinomas versus 47% in squamous cell carcinomas. The most frequent grade 1 or 2 adverse events were fatigue (55%), hand-foot syndrome (38%) and diarrhea (24%). **Conclusions:** Our study suggests that oral capecitabine should be considered an active and safe treatment in patients with platinum-pretreated advanced or recurrent cervical carcinoma.

5536 Poster Session (Board #263), Mon, 1:15 PM-4:45 PM

A phase II evaluation of nivolumab, a fully human antibody against PD-1, in the treatment of persistent or recurrent cervical cancer. *First Author: Alessandro Santin, Yale University School of Medicine, New Haven, CT*

Background: Despite current treatments patients with persistent/recurrent cervical cancer (CC) after platinum-based chemotherapy have limited therapeutic options with a median survival limited to only ~7 months. Most of CC are infected with high-risk Human Papillomavirus (HPV) making these tumors potentially highly immunogenic. However, upregulation of the PD-1/PD-L1 pathway on CC or infiltrating immune cells may negatively regulate immunity and contribute to CC progression. We present the results of NRG-GY002, a 2-stage, phase II study with Nivolumab, an anti–PD-1 antibody, in patient with persistent or recurrent CC. **Methods:** Key eligibility criteria included persistent/recurrent CC, failure of prior systemic therapy and ECOG PS 0-1. Nivolumab 3 mg/kg was given every 2 wk for up to 46 doses over 92 wk or until disease progression, intolerable toxicity, death, or withdrawal of consent. Response was assessed every 8 wk for the first 6 mo and every 12 wk thereafter. The primary end point was objective tumor response by RECIST v1.1. **Results:** 26 pts with persistent/recurrent CC were enrolled (25 eligible and evaluable for response and toxicity); median age was 45 years old, 36.0% had an ECOG PS of 1, and 100% had received one prior systemic chemotherapy regimen for metastatic disease. As of February 5, 2018, all patients have been off study treatment; median follow-up for vital status was 18.7 months (range, 2 – 28.1). 21 (84%) pts experienced a treatment-related adverse event (TRAE), most of which were grade 1 and 2. Six (24 %) pts had grade 3 TRAEs, 1 of whom discontinued nivolumab (type I diabetes). No grade 5 TRAEs occurred, and grade 4 TRAEs occurred in 2 pts. There was 1 confirmed PR (4%; 90% CI, 0.4%-22.9%), duration of response 3.8 months. The proportion of patients with stable disease (SD) was 36% (9/25; 90% CI, 20.2%-54.4%); the median duration of SD was 5.7 months (range, 3.5-12.7). The estimated PFS and OS at 6 months was 16% and 78.4%, respectively. **Conclusions:** Single agent nivolumab exhibited low antitumor activity and an acceptable safety profile in pts with persistent or recurrent CC previously treated with platinum-based chemotherapy. (ClinicalTrials.gov NCT #02257528) Clinical trial information: NCT02257528.

5537 Poster Session (Board #264), Mon, 1:15 PM-4:45 PM

Evaluation of rucaparib in platinum-sensitive recurrent ovarian carcinoma (rOC) in patients (pts) with or without residual bulky disease at baseline in the ARIEL3 study. *First Author: Carol Aghajanian, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: In ARIEL3, pts were randomized 2:1 (oral rucaparib 600 mg or placebo). Rucaparib significantly improved progression-free survival (PFS) vs placebo in all primary analysis groups (Coleman et al. *Lancet*. 2017;390:1949-61). An exploratory subgroup analysis of ARIEL3 pts with or without bulky residual disease (> 2 cm per blinded independent central review [BICR]) at baseline is reported. **Methods:** Pts were assigned to 2 analysis subgroups: with or without bulky residual disease at baseline. PFS was assessed in 3 predefined cohorts: *BRCA* mutant; homologous recombination deficient (HRD) (*BRCA* mutant or *BRCA* wild type/high loss of heterozygosity); and intent-to-treat (ITT) population. **Results:** PFS data for each subgroup (visit cutoff date 15 Apr 2017) by status of bulky disease at baseline are summarized in the Table. Safety data were consistent with data reported previously. In the rucaparib arm, the most common grade ≥3 treatment-emergent adverse event in pts with and pts without bulky disease was anemia (20.0% and 18.5%, respectively). Clinical trial information: NCT01968213. **Conclusions:** Rucaparib improved PFS vs placebo in all 3 predefined cohorts for both pts with and without bulky residual disease. PFS benefit with rucaparib was largest in pts with *BRCA*-mutant rOC.

53BP1 as a predictor of response in PARP inhibitor-treated homologous recombination-deficient ovarian cancer. *First Author: Rachel M Hurley, Mayo Medical School, Rochester, MN*

Background: Poly(ADP-ribose)polymerase (PARP) inhibitors have shown substantial activity in homologous recombination (HR) deficient ovarian cancer and are undergoing testing in other HR-deficient tumors. For reasons that are poorly understood, not all patients with HRD cancers respond to these agents. Preclinical studies have demonstrated that changes in alternative DNA repair pathways affect PARP inhibitor (PARPi) sensitivity. As this has not previously been assessed in the clinical setting, we examined the relationship between HRD score, *BRCA1* and *BRCA2* mutation status, expression of NHEJ pathway repair proteins, and response of ovarian cancers treated with single agent PARPi. **Methods:** Archival biopsies from ovarian cancer patients undergoing treatment on a single-agent PARPi trial were stained for PARP1, RAD51, and multiple components of the nonhomologous end-joining (NHEJ) pathway, including 53BP1, KU70, KU80 and DNA-PK_{CS}. Assays were validated by showing that the IHC signal was markedly attenuated with gene knockout or highly effective siRNA. Histochemistry-(H-) scores were determined for each repair protein in each sample. HRD score was determined from tumor DNA. **Results:** Responses to the PARPi ABT-767 were observed exclusively in ovarian cancers with an HR-deficiency. In this HR-deficient subset, 7 of 18 patients (39%) had objective responses, however actual HRD score did not further correlate with change from baseline tumor volume ($r = 0.0499$; $p = 0.87$). Conversely, in the HR-deficient subset, 53BP1 H-score showed a strong correlation with change from baseline tumor volume ($r = -0.69$, $p = 0.004$), followed by KU80 ($r = -0.46$; $p = 0.08$). **Conclusions:** Differences in complementary repair pathways, particularly in the NHEJ pathway, correlate with PARPi response of HR-deficient ovarian carcinomas. Among HR-deficient ovarian carcinomas, 53BP1 H-score demonstrated a strong correlation with the percent change of tumor volume.

5539 Poster Session (Board #266), Mon, 1:15 PM-4:45 PM

The impact of health related quality of life (HRQoL) on short term survival of recurrent ovarian cancer patients: Analysis of pooled data from the North-Eastern German Society of Gynecological Oncology (NOGGO) meta data base. *First Author: Jalid Sehouli, AGO and Charité Campus Virchow-Klinikum, Berlin, Germany*

Background: The goal of this analysis is a predictive score (recurrent ovarian cancer survival score, NOGGO-ROCSurv score) using HRQoL and other risk factors to estimate the risk of 1-year mortality in recurrent ovarian cancer patients. **Methods:** The data of recurrent patients with baseline HRQoL assessment using the European Organization for Research and Treatment of Cancer (EORTC) QLQ-C30 were selected from the NOGGO data base. ROC analysis were used to evaluate the predictive value of the risk factors and to find cut off values. Multivariable stepwise logistic regression models for 1-year mortality were performed to identify risk factors and their weights for a risk score. **Results:** Out of 972 patients 808 (83.1%) had 1st, 145 (14.9%) 2nd, and 19 (2.0%) 3rd recurrence, most patients (814, 83.8%) with advanced tumor stage at first diagnosis, 918 (94.4%) with good performance status (PS). The median age was 61 years (range 25-84 years). 1-year survival rate was 67.1%. Nearly all HRQoL scales except cognitive functioning, sleep disturbance, financial difficulties and diarrhea showed predictive value for short term survival with an area under the curve (AUC) up to 62.6% for global quality of life (gQoL). The risk score included chemo therapy free interval (CTFI) < 1 year, PS > 1, gQoL < 25, fatigue > 70, Nausea > 25, age ≥ 75 years, appetite loss > 25 and pre-existing cardiovascular disease (ordered from most to least important). The AUC for the risk score was 0.744 (95% CI 0.708 – 0.780), and the high risk group showed a positive predictive value of 84.5%, a negative predictive value of 72.5%, a sensitivity of 22.3%, and a specificity of 98.0%. **Conclusions:** HRQoL combined with other risk factors is predictive for 1-year survival. This risk score may help decision making for therapy and may be useful for stratification in randomized trials. But the identified patient group under risk is only small. So an improvement of the score is reasonable and a validation necessary.

5540 Poster Session (Board #267), Mon, 1:15 PM-4:45 PM

Methylated circulating tumor DNA as a potential marker of PARP inhibitor efficiency in BRCA mutated ovarian cancer patients. *First Author: Karina Dahl Steffensen, Department of Oncology, Vejle Hospital, Institute of Regional Health Research, University of Southern Denmark, Vejle, Denmark*

Background: The liquid biopsy has proven to be an excellent material for analysis of different circulating tumor markers, among which mutated tumor DNA (ctDNA) ranks high. Cancer specific ctDNA methylation can be used to quantitate tumor DNA and is a promising new approach for monitoring changes in tumor burden in response to therapy. Homeobox genes (*HOX*) constitute a family of transcription factors that involved in regulating differentiation and are expressed in normal adult reproductive tissue and methylation of the *HOXA9* gene has been observed in 95% of patients with high grade serous ovarian carcinoma. Treatment with PARP inhibitors has demonstrated considerable benefit in ovarian cancer (OC) patients but stratification of patients for PARP inhibitor (PARPi) treatment by BRCA status has proved suboptimal. The primary aim of the present study was to investigate if methylated *HOXA9* already at baseline, before initiation of single agent PARPi treatment could predict treatment efficacy in OC patients with platinum resistant or intermediate resistant relapse. **Methods:** Plasma from OC patients were retrieved at baseline before initiation of daily oral single agent Veliparib as part of a phase II investigator initiated trial. DNA was purified from 4 ml plasma, bisulfite converted and analysed by droplet digital PCR with methylation specific assay for HOXA9 and Albumin as reference. The fractional abundance of methylated HOXA9 was calculated. CA125 was analysed according to international standard. **Results:** The phase II trial enrolled 32 patients of which 23 patients had methylated *HOXA9* at baseline. Patients with methylated *HOXA9* showed a worse progression-free survival ($p = 0.046$) compared to patients with non-methylated *HOXA9*. In multivariate analysis *HOXA9* showed borderline significance ($p = 0.056$, HR 2.53 (95%CI: [0.98-6.54]) when correcting for age, performance status and platinum sensitivity. Baseline CA125 was not a predictor of PFS. **Conclusions:** The data presented suggests circulating methylated *HOXA9* as a potential marker for prediction of efficacy of PARPi treatment. Clinical trial information: NCT01472783.

5541 Poster Session (Board #268), Mon, 1:15 PM-4:45 PM

Potential impact of dietary intervention/counseling on survival in ovarian cancer patients: Results from an observational study. *First Author: Jessica Michalak, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Ovarian cancer is the fifth leading cause of cancer death in women, and survival rates remain largely unchanged within the past forty years. Previous research suggests that dietary intervention may impact cancer development, prognosis, and survival. The purpose of this study was to determine if dietary intervention was associated with improved survival rates in ovarian cancer patients. **Methods:** A total of 183 women were enrolled in the cohort study at MD Anderson. Clinical data collected on a cohort of patients who received the dietary intervention including counseling and supplementation were compared to a cohort of contemporary controls and summarized using descriptive statistics. Survival was computed from the time of admission to time of death or loss to follow-up. The method of Kaplan-Meier was used to provide overall survival estimates at select points in time, and the Log-rank test was used to compare survival distributions between cohorts. **Results:** Estimates of overall survival for intervention (49) and control (125) patients were: 95.9% and 66.8% at 5-years; 87.1% and 34.0% at 10-years; and 76.7% and 22.9% at 15-years, respectively (Log-rank test P-value $< .001$). Control patients had over four times the risk of death relative to patients receiving intervention after adjusting for age at admission. **Conclusions:** Dietary intervention/counseling with supplementation may positively impact survival in women diagnosed with ovarian cancer. Although our findings inspire interest, a weakness was the study's observational nature and the strong potential for confounding. A prospective, appropriately powered randomized clinical trial is warranted to validate these results.

5542 Poster Session (Board #269), Mon, 1:15 PM-4:45 PM

A first-in-human study of monoclonal antibody GM102 in patients with anti-Mullerian-hormone-receptor II (AMHRII) positive gynecological cancers. *First Author: Alexandra Leary, Gustave Roussy Cancer Campus, Villejuif, France*

Background: AMH and its membrane receptor AMHRII induce regression of Müllerian ducts in the male embryo. AMHRII is constitutively expressed in ovarian granulosa tumors (GCT) and re-expressed in ~70% of gynecological tumors. GM102, a low-fucose IgG1 antibody, binds AMHRII and acts through macrophage engagement via CD16 high affinity binding, resulting in enhanced tumor phagocytosis. **Methods:** In the completed escalation part, AMHRII-positive ovarian, cervical and endometrial cancer patients (pts), with measurable disease, Performance Status ≤ 1 and adequate organ function, received GM102 1 to 20mg/kg every 2 weeks (q2w) then 7 and 10mg/kg weekly (qw) in 8 successive cohorts. Expansion phase will include granulosa, epithelial ovarian and cervical cancers. The objective was to determine a recommended dose (RP2D) from safety, pharmacokinetics, pharmacodynamics (PD) and GM102 anti-tumor activity (RECIST) and change in tumor growth rate (TGR = % change in tumor volume/month pre-treatment vs. after 2 cycles). PD included circulating immune cells (CIC) (ICOS, CD14, CD16, CD64, CD69) and in paired biopsies, macrophage (CD68, CD163, CD16) and T cell (CD3, CD4, CD8, FoxP3, Granzyme B) markers. **Results:** 27 pts with AMHRII+ gynecological tumors (including 4 GCTs) received 1 to 21 GM102 infusions. Terminal half-life was 130-200hrs. No dose limiting toxicity was observed. Treatment-emergent toxicities were mostly grade 1-2 (including rash, influenza-like symptom, 1 pt each). One pt had grade 3 anorexia and weight loss. 8/17 (47%) evaluable pts exhibited a decrease in TGR [45%-169%] under GM102. Among 4 GCT pts, 2 had a partial response and inhibin B decreased in 3. In CIC, T cell, monocyte and neutrophil activation was observed, and circulating CD16+ monocytes decreased suggesting possible recruitment to tumor site. In paired biopsies, CD16 expression increased in macrophages as well as Granzyme B suggesting GM102-induced cellular cytotoxicity. **Conclusions:** GM102 was well tolerated at all doses and schedules. RP2D includes 7mg/kg qw and 15mg/kg q2w. The encouraging PD and anti-tumor activity warrants further development of GM102, especially in the rare subtype of GCT. Clinical trial information: NCT02978755.

5543 Poster Session (Board #270), Mon, 1:15 PM-4:45 PM

Role of primary surgery for persistent residual disease after more than 5 cycles of chemotherapy for primary advanced ovarian cancer. *First Author: Philipp Harter, Kliniken Essen Mitte, Essen, Germany*

Background: The standard of care in patients with advanced ovarian cancer is upfront surgery followed by chemotherapy. An interval debulking after 3 chemotherapy cycles might be an alternative in selected patients. However, some patients attend a referral center after having received 5 or more cycles of neoadjuvant chemotherapy with persistent disease. So far, the role of a "delayed" interval surgery is poorly defined. **Methods:** Retrospective analysis of the KEM hospital database 2011-2017 of patients with newly diagnosed advanced epithelial ovarian cancer and delayed cytoreductive surgery for persistent disease after a minimum of 5 cycles of chemotherapy. **Results:** 39 patients underwent delayed interval debulking. 92.3% had a serous high grade ovarian cancer. The median number of pre-OP cycles was 6 (range 5-8). Intra-operatively, the median Peritoneal Cancer Index was 11. 53.8% underwent a bowel resection (5.1% had a protective stoma) and the median surgical complexity score was 7 (2-16). The median duration of surgery was 285 minutes (range 80-510), complete resection was achieved in 84.6%. The rate of severe complications (Clavien Dindo grade 3 or 4) was 23.1%; we observed no post-operative mortality. The median number of chemotherapy cycles after surgery was 2 (range 0-4). 15 (38.5%) patients received bevacizumab before cytoreductive surgery and 16 (41.0%) patients received maintenance therapy with bevacizumab post-operatively. The median PFS and OS in patients with complete resection was 17.2 and 49 months in contrast to only 6.4 and 14 months in patients with incomplete resection. **Conclusions:** Delayed interval surgery might be restricted to selected pts in whom the probability for achieving a complete resection is high. Patients in whom a complete resection could not be achieved show a very poor prognosis and it is likely that they rather experience harm than any benefit from surgery.

5544 Poster Session (Board #271), Mon, 1:15 PM-4:45 PM

Identification of outcome-correlated serum cytokine and chemokine clusters in ovarian clear cell carcinoma. *First Author: Akira Yabuno, Department of Gynecologic Oncology, Saitama Medical University International Medical Center, Hidaka, Japan*

Background: With the progress of immune-oncology, the immunological background of epithelial ovarian carcinoma (EOC) is gradually becoming understood. However, most of the studies have been focused on the local tumor-immune microenvironment, and the systemic immunological background in patients with EOC has not been well studied. Serum cytokines and chemokine networks may reflect the complex systemic immunological interactions in cancer patients. Studying groups of cytokines and their networks may help in improving immunotherapy for EOC patients. **Methods:** A total of 178 cases of EOC were analyzed in this study, including 73 high-grade serous (HGSC), 66 clear cell (CCC) and 39 endometrioid (EMC) subtype cases. Suspension cytokine arrays, which enable measurement of the levels of 27 cytokines and chemokines, were performed with the patients' sera taken before the primary surgery. Levels of all cytokines were log (x+1) transformed and normalized. Associations between each cytokine and clinocopathological factor were analyzed in all EOC patients using multivariate linear regression models. Cluster analyses were performed for all EOC and each histotype. **Results:** In the multivariate analyses, eleven of 27 cytokines were correlated with histotypes. In contrast, no correlations were found between each cytokine and FIGO stage. Cluster analysis of all EOC patients revealed distinct cytokine profiles in HGSC and CCC, but not in EMC. Cluster analyses in each histotype revealed 2 cytokine clusters in both HGSC and CCC. Interestingly, 22 of 27 cytokines (81.5%) were commonly clustered in HGSC and CCC. Cluster 1 included IL-2, 6, 8, 15, chemokines and angiogenic factors, whereas Cluster 2 included IL-4, 5, 9, 10, 13, TNFalpha and G-CSF. We classified the tumors into 4 subgroups based on a high or low level for each cluster in both HGSC and CCC, and this cluster-based classification demonstrated significantly different progression-free and overall survivals for CCC patients ($p = 0.00097$ and $p = 0.017$). **Conclusions:** Serum-based cytokine clusters determine the histotypes of EOC and their prognosis in patients with CCC. Further study of cytokine networks may provide new strategies for cancer immunotherapy.

5545 Poster Session (Board #272), Mon, 1:15 PM-4:45 PM

Exploratory analysis of percentage of genomic loss of heterozygosity (LOH) in patients with platinum-sensitive recurrent ovarian carcinoma (rOC) in ARIEL3. *First Author: Ana Oaknin, Vall d'Hebron University Hospital, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain*

Background: In ARIEL3, rucaparib significantly improved progression-free survival (PFS) vs placebo in all randomized patients, including patients with *BRCA*-mutant, *BRCA* wild-type/high-LOH (prespecified as ≥16% genomic LOH), or *BRCA* wild-type/low-LOH (< 16% genomic LOH) rOC (Coleman et al. *Lancet*. 2017;390:1949-61). This exploratory analysis evaluated the optimal cutoff for percentage of (%) genomic LOH in *BRCA* wild-type rOC in ARIEL3. **Methods:** Genomic LOH of archival tumor tissue DNA was centrally assessed using Foundation Medicine's next-generation sequencing-based assay (Cambridge, MA, USA). Treatment effect for investigator-assessed PFS (invPFS) was analyzed in *BRCA* wild-type rOC for the prespecified cutoff (16%) and across a range of cutoffs for % genomic LOH (5%–30%). Hazard ratios (HRs) were estimated using a stratified Cox proportional hazards model. Prognostic and predictive utility of % genomic LOH was assessed by comparing invPFS between and within the treatment arms. **Results:** In ARIEL3, 564 patients were randomized. Of the 368 patients with *BRCA* wild-type associated rOC, LOH was calculable for 319. Rucaparib significantly improved invPFS vs placebo between the 5% and 23% cutoffs for % genomic LOH. Using the prespecified cutoff (16%), the HR (rucaparib vs placebo) was 0.44 (95% confidence interval [CI], 0.29–0.66; $P< 0.0001$) for patients with high-LOH rOC. To further assess the % genomic LOH cutoff, we compared patients with high- vs low-LOH rOC within the rucaparib arm and found a statistically significant benefit for invPFS at the prespecified cutoff of 16% (HR, 0.70; 95% CI, 0.50–0.97; $P= 0.0338$). In the placebo arm, no statistically significant benefit was observed for invPFS in patients with high- vs low-LOH rOC at any cutoff tested. **Conclusions:** Rucaparib improved invPFS vs placebo across the range of cutoffs tested for % genomic LOH, including the prespecified cutoff of 16% for high LOH. The observance of significant differences between patients with high- vs low-LOH rOC in the rucaparib but not placebo arm suggests that genomic LOH is a predictive but likely not prognostic biomarker. Clinical trial information: NCT01968213.

5546 Poster Session (Board #273), Mon, 1:15 PM-4:45 PM

Effect of hypertension (HTN) on progression-free survival (PFS) in patients (pts) receiving front-line bevacizumab (BEV) for primary advanced ovarian cancer (OC) in the NOGGO single-arm OTILIA study: A post hoc analysis in 808 pts. *First Author: Robert Armbrust, Campus Charité Mitte, Charité Centrum 17, Klinik f. Geburtsmedizin, Berlin, Germany*

Background: The efficacy and safety of front-line BEV-containing therapy for OC were demonstrated in two phase III trials. At the 3rd interim analysis of OTILIA (NCT01697488) evaluating front-line BEV in German clinical practice, median PFS was 21.3 months. The potential association between HTN and PFS was explored in the present analysis. **Methods:** Pts with newly diagnosed FIGO stage IIIB–IV OC received the EU-approved BEV-containing regimen. In exploratory analyses, outcomes were analyzed according to the presence or not of HTN at baseline (BL). Cox regression models in each subgroup explored the effect on PFS of HTN developing (no HTN subgroup) or worsening (pre-existing HTN subgroup) during treatment in a time-dependent manner. **Results:** Of 808 evaluable pts, 406 had BL HTN and 402 did not. Pts in the HTN subgroup were generally older (median 71.8 vs 61.8 years in the subgroup without HTN) with a higher BMI (median 25.7 vs 23.1 kg/m^2) and more likely to have diabetes (16% vs 5%). Median BEV duration was similar in the two subgroups (13.5 vs 13.3 months, respectively). As of 31 Jan 2017, PFS events had been recorded in 364 pts (45%). Median PFS was 21.3 months in both subgroups. HTN worsened in 291 (72%) of 406 pts with pre-existing HTN and developed in 132 (33%) of 402 pts without BL HTN. Cox regression analysis suggested an association between onset of HTN and PFS in pts without BL HTN (hazard ratio [HR] 0.69, 95% CI 0.50–0.96) but not between worsening of HTN and PFS in those with pre-existing HTN (HR 1.18, 95% CI 0.82–1.70). Residual tumor burden was associated with worse PFS in both subgroups (HR 2.04; 95% CI 1.39–3.00 in pts without BL HTN; HR 2.42, 95% CI 1.56–3.74 in pts with pre-existing HTN). **Conclusions:** These exploratory analyses suggest no detrimental effect of HTN on PFS in BEV-treated pts. Based on these observations, in pts with HTN and ongoing clinical benefit, it seems reasonable to continue BEV therapy if HTN is managed appropriately. As this was an exploratory interim analysis, the observed more favorable PFS in pts with HTN developing during BEV should be validated in further prospective trials. Clinical trial information: NCT01697488.

5547 Poster Session (Board #274), Mon, 1:15 PM-4:45 PM

Tumor regression grading after neoadjuvant chemotherapy predicts long-term outcome of stage IIIC epithelial ovarian cancer. *First Author: Mingyi Zhou, Cancer Hospital of China Medical University, Liaoning Cancer Hospital and Institute, Shenyang, China*

Background: Prognostic value of tumor regression grading (TRG) after neoadjuvant chemotherapy (NAC) in patients with FIGO stage IIIC epithelial ovarian cancer (EOC) is controversial. **Methods:** A total of 55 stage IIIC EOC patients who underwent interval debulking surgery (IDS) after NAC at the Department of Gynecology of Liaoning Cancer Hospital and Institute between January 2003 and September 2016 and had full information were involved this retrospective study. All the pathological sections were individually reviewed by two pathologists. TRG was determined by the ratio of viable tumor versus fibrosis, ranging from TRG 0 when no viable tumor, to TRG 5 when fibrosis was absent. TRG 1 was defined as regression more than 75%, TRG 2 was defined as regression more than 50% but less than 75%, TRG 3 was defined as regression more than 25% but less than 50%, and TRG 4 was defined as regression less than 25%. Patients were stratified into TRG 0-1-2 group and TRG 3-4-5 group according to cut-off values calculated through receiver operating characteristic (ROC) curves. Progression-free survival (PFS) and overall survival (OS) were analyzed using Kaplan-Meier method. Univariate analyses were performed using log-rank tests. Multivariate analyses were performed using Cox regression analysis to assess the prognostic factors of TRG, which were expressed as hazard ratios (HRs). **Results:** Univariate and multivariate analyses suggested that TRG and residual disease (RD) were independent predictive factors of PFS, and TRG, RD and CA125 change were independent predictive factors of OS. TRG was a better prognostic factor compared with CA125 value change after NAC (area under curves [AUC] of the ROC of TRG 0.93 versus AUC of the ROC of CA125 change 0.69). The median PFS of the patients in TRG 0-1-2 group was 14.0 months longer than TRG 3-4-5 group (26.0 months versus 12.0 months, HR 2.19, 95% confidence interval [CI] 1.17-4.07, $P = 0.014$). The median OS of the patients in TRG 0-1-2 group was 28.6 months longer than TRG 3-4-5 group (50.4 months versus 21.8 months, HR 3.10, 95%CI 1.49-6.42, $P = 0.002$). **Conclusions:** TRG after NAC was an independent prognostic factor of patients with FIGO stage IIIC EOC.

5548 Poster Session (Board #275), Mon, 1:15 PM-4:45 PM

Incidence of myelodysplastic syndrome (MDS) and acute myeloid leukemia (AML) in patients (pts) with a germline (g) *BRCA* mutation (m) and platinum-sensitive relapsed ovarian cancer (PSR OC) receiving maintenance olaparib in SOLO2: Impact of prior lines of platinum therapy. *First Author: Jacob Korach, Sheba Medical Center, Tel Aviv University, Tel Hashomer, Israel*

Background: Olaparib has been investigated and subsequently approved as maintenance treatment after response to platinum-based chemotherapy in pts with relapsed OC. A relationship between increasing dose and duration of platinum therapy and an increased risk of MDS/AML has been reported (Travis *et al. N Engl J Med* 1999). Events of MDS/AML have been reported in pts treated with olaparib, but a causal relationship has not been established. The results of a *post hoc* analysis evaluating the incidence of MDS/AML by prior lines of platinum therapy in pts with g*BCRA*m PSR OC receiving maintenance olaparib or placebo in the Phase III SOLO2 trial (ENGOT Ov-21; NCT01874353; Pujade-Lauraine *et al. Lancet Oncol* 2017) are reported here. **Methods:** The safety analysis set comprised 195 pts who received olaparib tablets (300 mg twice daily) and 99 pts who received placebo. The median duration of follow-up in the olaparib and placebo groups (pts censored at time of primary analysis) was 25.3 and 25.1 months, respectively. **Results:** The overall incidence of MDS/AML was similar in the olaparib and placebo groups (2.1% vs 4.0%; Table). With both olaparib and placebo, the incidence of MDS/AML appeared to increase with an increasing number of lines of prior platinum therapy. This trend did not appear to be driven by pt age. This trend was also observed in a larger pooled analysis of olaparib clinical studies. Clinical trial information: NCT01874353. **Conclusions:** Olaparib did not increase the risk of MDS/AML vs placebo in SOLO2. Rather, a trend was seen for a higher incidence of MDS/AML with an increasing number of prior lines of platinum therapy. A limitation of this analysis is the small number of events that occurred in each group; however, results of a separate, larger pooled analysis of trial data support these findings.

MDS/AML incidence and pt age by number of prior lines of platinum therapy.

	MDS/AML incidence, n/N (%)		Median pt age, years	
	Olaparib	Placebo	Olaparib	Placebo
2	1/110 (0.9)	2/62 (3.2)	56.0	55.0
3	1/60 (1.7)	1/20 (5.0)	56.5	58.5
≥4	2/25 (8.0)	1/17 (5.9)	57.0	61.0
Overall	4/195 (2.1)	4/99 (4.0)	56.0	56.0

5549 Poster Session (Board #276), Mon, 1:15 PM-4:45 PM

Mirvetuximab soravtansine, a folate receptor alpha (FRα)-targeting antibody-drug conjugate (ADC), in combination with bevacizumab in patients (pts) with platinum-resistant ovarian cancer: Maturing safety and activity profile from the FORWARD II phase 1b study. *First Author: David M. O'Malley, The Ohio State University College of Medicine, Columbus, OH*

Background: Mirvetuximab soravtansine is an ADC, comprising a FRα-binding antibody linked to the tubulin-disrupting maytansinoid DM4, currently being evaluated in combination with bevacizumab as part of an ongoing Phase 1b trial (FORWARD II; NCT02606305) in pts with platinum-resistant ovarian cancer. **Methods:** Pts were administered mirvetuximab soravtansine (6 mg/kg; adjusted ideal body weight) in combination with bevacizumab (15 mg/kg) on Day 1 of a 21-day cycle. Responses were assessed according to RECIST 1.1 and adverse events (AEs) evaluated by CTCAE v4.0. **Results:** To date, a total of 51 pts have received combination therapy at this dose level: 11 in dose escalation; 40 during the expansion stage. Pts had a median age of 64 years and received a median of 3 prior lines of systemic therapy (range 1-8); 51% and 29% of pts had received prior therapy with bevacizumab or a PARP inhibitor, respectively. The four most commonly reported AEs were nausea, fatigue, diarrhea, and blurred vision (45-57% of pts), which were primarily grade 1 or 2. The most frequent grade 3 AE was hypertension (8 pts - 16%). For the efficacy evaluable population (49 pts), objective tumor responses were observed in 19 pts for a confirmed overall response rate (ORR) of 39% and a median progression-free survival (mPFS) interval of 9.5 months (95% CI, 4.6, -). In a subset analysis of pts (n = 20) with ≤ 3 prior therapies and medium to high FRα levels (i.e., ≥ 50% of cells with ≥ 2+ staining intensity) the ORR was 55% with mPFS not yet reached, with a median follow-up of 5.7 months (range 1.3-11.7). Updated results will be presented. **Conclusions:** The mirvetuximab soravtansine-bevacizumab combination continues to display a manageable safety profile in pts with platinum-resistant ovarian cancer. The encouraging efficacy results justify further exploration of this novel therapeutic combination in this difficult to treat population. Clinical trial information: NCT02606305.

5550 Poster Session (Board #277), Mon, 1:15 PM-4:45 PM

Prediction of post-operative residual disease in advanced-stage ovarian cancer (AOC) using whole transcriptome expression: An exploratory analysis of the AGO-OVAR 11 (ICON7) trial. *First Author: Florian Heitz, Department of Gynecologic Oncology, Kliniken Essen-Mitte, Essen, Germany*

Background: Complete resection (CR) at primary debulking surgery is the single most important prognostic factor in AOC. It has been demonstrated, that suboptimal debulking (residual disease > 1cm) might be associated with TCGA molecular subtypes and de novo generated gene expression (GE) signatures. The aim of this study was to validate previous findings and to investigate the impact whole transcriptome GE analyses might have on postoperative residual tumor prediction in a phase III ovarian cancer frontline trial. **Methods:** Core biopsies from formalin fixed paraffin embedded tumor tissue of FIGO stage IIIC/IV AGO-OVAR 11/ICON7 pts were used to generate whole-genome DASL GE data. TCGA molecular subtype and two previously published GE debulking signatures (7 genes and 11 genes) were correlated with size of residual disease (CR vs. any residual disease). Logistic Regression (LR), support vector machine with polynomial kernel, and random forest were used as classifiers. We built models with all GE features as well as gene selected with HITON-PC, a method that select the markov blanket of the outcome. **Results:** 283 pts met inclusion criteria, of those 114 (40.3%) had complete resection. Previous reported debulking signatures using 7 and 11 genes respectively did not predict residual disease in this cohort. Best Area under the Curve (AUC) for 7 gene signature was generated using LR 0.50 ± 0.05, while 11 gene signature had an AUC of 0.53 ± 0.04. Similarly, TCGA molecular subtypes (AUC = 0.56 ± 0.04), an independent de novo developed signature (AUC = 0.51 ± 0.04) and the total gene expression data set using all 21,000 genes (AUC = 0.55 ± 0.03) were not able to predict residual disease status. **Conclusions:** In contrast to previous findings, we were not able to predict residual disease using GE in tumor samples from the AGO-OVAR11/ICON7 phase III trial. A standardized radical surgical approach resulting in a higher frequency of complete resection might allow detection of biologic factors responsible for sub-optimal debulking. The ongoing AGO-OVAR TRUST trial might be able to address this important clinical question.

5551 Poster Session (Board #278), Mon, 1:15 PM-4:45 PM

METRO-BIBF: Phase II, randomised, placebo controlled, multicentre, trial of low dose (metronomic) cyclophosphamide (MCy) with or without nintedanib in relapsed ovarian cancer (ROC). *First Author: Marcia Hall, Mount Vernon Cancer Centre, Middlesex, United Kingdom*

Background: ROC patients (pts), heavily pretreated with IV chemotherapy (CT) are a heterogenous group, median OS 3-9 mo. Oral MCy is well tolerated, avoids IV CT and has been shown to have clinical benefit. MCy has anti-angiogenic properties, inhibiting growth of tumour, endothelial and host vasculature. Augmentation with bevacizumab showed encouraging results in single arm studies. METRO-BIBF evaluates a novel combination of MCy with either placebo (P) or nintedanib (N)- oral inhibitor VEG/PDG/FGFR tyrosine kinases. **Methods:** Eligible pts received ≥2 lines of CT; platinum-resistant/intolerant, ECOG PS 0-2, life-expectancy of > 6 weeks. MCy (100mg/d) was given continuously with either N or P, to progression / toxicity. No prior TKI permitted; pts stratified for prior bevacizumab. Priamry aim to increase median OS by 2 mo. PFS, toxicity and QoL also measured. **Results:** 117 pts were randomised 08/14 – 10/16, median age 64, 87% HGS ROC, 39% pts ≥ 5 lines prior CT. Dose of N/P was reduced from 200 to 150 mg bd after planned review of N/P/MCy in first 46 pts. 96 patients have died. N had no effect on OS (HR 1.08, p = 0.72). Table shows OS/PFS by arm. Combining MCy pts from both arms, median OS was 6.4 mo and 26 patients (23%) took MCy for ≥ 6 mo. Pts without prior bev treatment (69%) stayed longer on MCy than pts with prior bev (31%) (mean diff: 53 days, p < 0.01). Grade 3-4 toxicity as expected in 64.4% pts on N/MCy vs. 54.5% pts on P/MCy; more N/MCy pts had neutropenia and diarrhoea. Two treatment-related deaths: 1 bowel perforation, possibly disease-progression (N), 1 liver failure (P). QoL did not differ between arms. **Conclusions:** Adding N to MCy did not improve OS/PFS. But in this large study of MCy in heavily pre-treated ROC, almost one quarter remained on therapy for > 6 months, suggesting either more indolent disease and/or MCy has longer-term cytostatic or immunological benefits requiring further investigation. Clinical trial information: NCT01610869.

	Placebo (N = 55*) *3 pts did not start M/Cy	Nintedanib (N = 59)
Median OS (95% CI) mo	6.4 (5.0-10.1)	6.8 (4.5-9.5)
OS: 6 mo	50.9%	55%
OS: 12 mo	31.3%	20%
Median PFS (95% CI) mo	2.7 (2.5-4.7)	2.9 (2.7-4.6)
PFS: 6 mo	22.8%	29.6%
PFS: 12 mo	5.7%	5.9%

5552 Poster Session (Board #279), Mon, 1:15 PM-4:45 PM

Facilitated referral pathway for genetic testing at the time of ovarian cancer diagnosis: Uptake of genetic assessment and testing and impact on patient-reported stress, anxiety and depression. *First Author: Sarah S. Lee, New York University Langone Medical Center, New York, NY*

Background: To determine if a patient-centered, facilitated genetics referral pathway whereby all women with newly-diagnosed ovarian cancer are proactively contacted by a genetics navigator (GN) for genetic assessment (GA) increases rates of GA and genetic testing (GT) uptake without increased patient-reported stress, anxiety or depression **Methods:** Patients with epithelial ovarian cancer were referred for GA by their gynecologic oncologist within six weeks of diagnosis. Patients were contacted by a GN and offered an appointment for GA and GT within six weeks of contact. English-speaking patients completed quality of life (QoL) instruments (Impact of Events Scale, State-Trait Anxiety Questionnaire, Hospital Anxiety and Depression Scale) immediately pre-and post-GA and 6-9 months later. Primary outcome was feasibility of this pathway as defined by presentation for GA or declining GA within 6 weeks of contact by a GN. **Results:** From 10/2015-12/2017, 88 patients were enrolled. Seventy-one (81%) patients had GA and 62 (70%, 87% of those who had GA) underwent GT. Median time from diagnosis to GA was 28 days (range 9-75). Among patient who underwent GT, 11 (18%) had a pathogenic mutation (BRCA1-6, BRCA2-4, MSH2-1) and 25 (40%) had a variant of uncertain significance. Forty-one patients completed QoL assessments which demonstrated mild to moderate stress, normal to clinically significant anxiety and borderline levels of depression. QoL assessments were not associated with the GT result and with no significant changes in stress, anxiety or depression when comparing QoL measurements for each patient obtained pre/post-GA and 6-9 months later. **Conclusions:** A facilitated referral to genetic counselors at time of ovarian cancer diagnosis is effective and efficient, resulting in GA in 81% of patients within 4 weeks of diagnosis, GT in 70% of patients and discovery of pathogenic mutations in 18% of those tested, and does not demonstrate a psychologic toll. Concern about emotional distress should not deter clinicians from early genetics referral as GT in this population can yield important prognostic and therapeutic information.

5553 Poster Session (Board #280), Mon, 1:15 PM-4:45 PM

A phase I study of concomitant galinpepimut-s (GPS) in combination with nivolumab (nivo) in patients (pts) with WT1+ ovarian cancer (OC) in second or third remission. *First Author: Roisin Eilish O'Cearbhaill, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY*

Background: WT1 is highly expressed in serous ovarian cancer. GPS is WT1-targeting heteroclitic peptide tetravalent non-HLA-restricted vaccine, and has shown promising phase 2 activity in AML, mesothelioma and myeloma. Efficacy of GPS may be enhanced through checkpoint blockade, providing a rationale for combining it with anti-PD1 antibody, nivo. We conducted a phase I study to evaluate the safety and immunogenicity of the combination in WT1+ OC in remission. **Methods:** Pts with WT1+ OC in $\geq 2^{nd}$ remission were enrolled from 06/16-07/2017, and received GPS (800 mcg) x 6 total doses mixed with adjuvant (0.5 ml) and 70 mcg GM-CSF (all s.c. in extremities) and nivo 3 mg/kg IV q2wks over 12 weeks. DLTs were assessed using CTCAE criteria, with detection of $>$ 2/10 DLTs deeming the combination unsafe. Treatment was continued until disease progression or toxicity. Immune responses (IgG & IgM WT1 antibody, T cell assays) induced by the combination were evaluated. The 1-year progression-free survival (PFS) rate, defined as the interval from start of preceding chemo to date of progression or death, is an exploratory objective. **Results:** n=11; Median age 61 yrs (41-76). 7 pts in 2^{nd} and 4 pts in 3^{rd} remission. 1 DLT (gr 3 myositis with myocarditis post GPS and nivo #2). Most common AEs were Gr $\leq$2 fatigue and injection site reactions. Immune Response Results: n=9; Serum levels of antigen-specific IgG (against both individual WT1 peptides in GPS and the full-length WT1) significantly increased in 86% of evaluable pts between study wks 6-27. Antigen-specific T cell responses to individual WT1 peptides were observed between 6-15 wks, primarily CD4 and to a smaller extent, CD8 T cells. 1yr PFS rate was 64% in the ITT analysis (7/11) and 70% (7/10) in pts who had $>$ 2 GPS/nivo doses. **Conclusions:** Administration of GPS in combination with nivo was safe, well tolerated and induced high frequency of T- and B-cell immune responses, warranting further evaluation. The 1yr PFS rate compares favorably to historic rates of approximately 50% in comparable populations. Additional cohorts are planned to receive the current combination along with vaccination against additional tumor-associated antigens. Clinical trial information: NCT02737787.

5554 Poster Session (Board #281), Mon, 1:15 PM-4:45 PM

A phase I dose-escalation of hyperthermic intraoperative intraperitoneal chemotherapy (HIPEC) carboplatin for the frontline treatment of advanced ovarian cancer. *First Author: Leslie M. Randall, University of California, Irvine, Orange, CA*

Background: Hyperthermic intraperitoneal chemotherapy (HIPEC) at the time of frontline ovarian cancer surgery has shown preliminary overall survival benefit, but selection of chemotherapy agent and dose is mostly arbitrary. **Methods:** For this prospective study, women with peritoneal carcinomatosis of suspected ovarian, tubal, or peritoneal origin with optimal (R1 or R0) primary or interval debulking were eligible. Those with non-gynecologic primary, suboptimal surgery, or intraoperative complications were excluded. Dose for a pre-planned sample size (n = 30) was escalated according to a Bayesian continual reassessment schedule. The simulated maximum tolerated dose (MTD) estimate was 970 mg/m^2. Closed-technique HIPEC was administered at 41^{o}C for 60 minutes. Serum and perfusate samples were collected at time 0 and every 15 minutes for PK. Adverse events (AEs) were assessed every other day until discharge and weekly for 30 days according to NCI CTCAE v4.03. **Results:** We enrolled 52 subjects to reach n = 30 (attrition rate 42% for non-gynecologic primary or suboptimal surgery). Median age was 63 (range 33-78) with 15 Caucasian, 6 Hispanic, 7 Asian, and 2 other. Any AE was observed in 26 (87%) of subjects with 15 (50%) experiencing grade 3 or greater AEs. The most common grade 1-2 AEs were anemia (40%) and nausea (13.3%). Grade 3 AEs included anemia (10%), pancreatic leak (3.3%), wound dehiscence (3.3%), and sub diaphragmatic abscess (3.3%). One patient had grade 4 neutropenia and thrombocytopenia and grade 5 *C. difficile* colitis and sepsis; this was the only patient death. The post-trial MTD was 1115 mg/m^2. PK analysis is ongoing. **Conclusions:** HIPEC with carboplatin was well tolerated at the protocol-specified doses in this cohort. The majority of AEs were attributable to surgery. Intraoperative protocol assignment is associated with a significant attrition rate that should be accounted for in sample size calculations and reported in clinical trials of HIPEC therapy. Clinical trial information: NCT02199171.

5555 Poster Session (Board #282), Mon, 1:15 PM-4:45 PM

Inter and intra-observer variability with the assessment of RECIST in ovarian cancer. *First Author: Michelle K. Wilson, Auckland City Hospital, Auckland, New Zealand*

Background: Measurement of response with RECIST is central to the interpretation of trial outcomes and relies upon accurate and reproducible unidimensional tumor measurements. This study assessed intra and inter-observer variability with assessment and selection of target lesions for RECIST in patients with ovarian cancer. **Methods:** Eight international radiologists measured 30 lesions at 2 discrete time points. Lesion measurements between radiologists were compared to assess inter-observer variability. Percentage difference between lesions was calculated. Measurements of the same lesion at two time points by each radiologist were used to assess intra-observer variability. Radiologists were also asked to select 2 target lesions for RECIST. Reproducibility of lesion selection based on site (peritoneal vs nodal vs visceral) was calculated. **Results:** 80 lesions were measured with a median size of 2.6cm (range 0.8-9.5cm). Seventy-one lesions (89%) were 1.5cm or larger. Assessments at two time points were performed by 7 radiologists. Inter-observer assessment of a single lesion varied on average by 22% (range 5 to 68%). Measurements differed by $\geq$20% in 28% of visceral, 79% of nodal and 60% of peritoneal lesions. When measured by the same radiologist only 10% of lesions differed by $\geq$20%. Intra-observer measurements were less likely to vary by $\geq$20% (10 vs 54%; $p < 0.0001$). Radiologists were more likely to measure the same lesion with visceral (7/7 lesions; 100%; $p = 0.01$) and nodal (9/10; 90%; $p = 0.01$) lesions versus peritoneal lesions (5/14; 36%). When selecting 2 lesions for RECIST, the largest lesion was most consistently chosen (35/38 target lesions; 92%). When this was repeated, 5 of 7 radiologists (71%) chose the same lesions each time. **Conclusions:** RECIST underpins trial outcomes yet significant variability in tumor measurements was found in this study. These results suggest RECIST assessments by the same radiologist should improve consistency. Peritoneal lesions are a key site of disease progression in ovarian cancer yet these were the most inconsistent to select and had significant inter-observer variability in measurements. These factors need consideration as we strive to improve response assessment in clinical trials.

5556 Poster Session (Board #283), Mon, 1:15 PM-4:45 PM

Characterization and predictors of long term ($\geq$ 10 years) survivors in NRG/GOG randomized clinical trials of intraperitoneal and intravenous chemotherapy in stage III ovarian cancer patients. *First Author: Michael Friedlander, Department of Medical Oncology, Prince of Wales Hospital, Sydney, New South Wales, Australia*

Background: ~25% of patients with stage III OC are reported to be alive $\geq$ 10 years after diagnosis in registry studies[1]. Some have long term disease-free survival (LTDFS) without recurrence and others have recurrent active disease but the proportions of each is unclear. We propose to determine the proportion, characteristics, and predictors of long term survival in patients with stage III ovarian cancer (OC) enrolled in clinical trials who are $\geq$ 10 years LTDFS . **Methods:** Data from 3 NRG/GOG trials (104, 114, and 172) which enrolled patients to intraperitoneal (IP) vs. intravenous (IV) chemotherapy were analysed. Demographics and clinic-pathologic characteristics of patients living $\geq$ 10 years were tabulated. Using a landmark approach at 10 years, Cox regression survival analysis was performed to evaluate independent prognostic factors that predict LTDFS. **Results:** Of 1,229 stage III OC patients, 18.8% (232/1229) were alive $\geq$ 10 years. Of these, 13.7% (n = 168) had LTDFS $\geq$ 10 years and 5.2% (n = 64) had recurrent disease. Compared to the overall study group, the LTDFS $\geq$10 years patient had a median age of 54.8 vs. 57.2 years ($p < 0.001$), gross residual disease after primary surgery 42.3% vs. 45.8% ($p = 0.027$); serous cell type 62.5% vs. 68.4%; endometrioid 14.3% vs. 9.4% ($p = 0.035$), well differentiated cancers 12.5% vs. 8.5% ($p < 0.001$), respectively. Of the LTDFS patients, 45.2% were treated with IP and 54.8% with IV chemotherapy ($p = 0.3$). Age (HR = 1.077; 95% CI = 1.03–1.12; $p < 0.001$) was the only independent prognostic factor for LTDFS $\geq$10 years on multivariate Cox analysis. **Conclusions:** Approximately 14% of stage III ovarian cancer patients were in LTDFS at $\geq$10 years and an additional 5% were alive with recurrent disease. Younger age at diagnosis was the only independent prognostic factor for LTDFS $\geq$10 years. Further work is needed to understand characteristics and predictors of exceptional responders and whether they could be identified at initial diagnosis. 5558 Poster Session (Board #285), Mon, 1:15 PM-4:45 PM

Predictive factors for prolonged response to olaparib as maintenance therapy in ovarian cancer patients with *BRCA* mutations. *First Author: Sana Intidhar Labidi-Galy, Hopitaux Universitaires de Geneve, Geneve, Switzerland*

Background: To investigate clinical factors predictive for prolonged progression-free survival (PFS) in ovarian cancer (OC) patients carrying *BRCA* mutations and receiving olaparib as a maintenance therapy. **Methods:** Multicentric (7 cancer centers) international (France and Switzerland) retrospective study of OC patients having germline or somatic mutations of *BRCA1/BRCA2* genes and treated with olaparib as maintenance therapy after platinum-based chemotherapy. **Results:** One hundred and fifteen patients were included. Median age was 60 years. There were 92 *BRCA1* carriers, 22 *BRCA2* carriers and one patient had double mutation of *BRCA1* and *BRCA2* genes. Ninety-two percent had serous carcinomas. Six patients had somatic mutations (all *BRCA1*) and 109 had germline mutations. Median follow-up was 9.8 months. Ninety percent of the patients were platinum-sensitive: 24% had platinum-free interval (PFI) at 6-12 months and 65% had PFI $>$ 12 months. Responses to platinum-based chemotherapy before olaparib as maintenance therapy were: SD (15.7%), PR (52.2%) and CR (32.2%). In multivariate analysis, factors predictive for prolonged PFS under olaparib were: CR (HR = 0.13; 95%CI 0.06-0.28; $p< 10^{-3}$), PFI $>$ 12 months (HR = 0.43; 95%CI 0.26-0.73; p= 0.002) and *BRCA2* mutations (HR = 0.42; 95%CI 0.24-0.94; p= 0.033). **Conclusions:** Complete response to platinum before olaparib, PFI $>$ 12 months, and *BRCA2* mutations are predictive for prolonged PFS in *BRCA* carriers who received olaparib as maintenance therapy.

5559 Poster Session (Board #286), Mon, 1:15 PM-4:45 PM

Cost-effectiveness of niraparib versus routine surveillance, olaparib, and rucaparib for the maintenance treatment of adult patients with ovarian cancer in the United States. *First Author: Mark Fisher, FIECON, St Albans, United Kingdom*

Background: To estimate the cost-effectiveness of niraparib, a poly (ADP-ribose) polymerase (PARP) inhibitor, compared with routine surveillance (RS), olaparib and rucaparib for the maintenance treatment of patients with recurrent ovarian cancer. **Methods:** A decision-analytic model estimated the cost per quality-adjusted life-year gained for niraparib versus RS, olaparib and rucaparib from a US payer perspective. Recurrent ovarian cancer patients with or without germline *BRCA* mutation, who were responsive to their last platinum-based chemotherapy regimen, entered the model (non-g*BRCA*mut, g*BRCA*mut). The model had three health states; progression-free disease, progressed disease and dead. For non-g*BRCA*mut and g*BRCA*mut, mean progression-free survival (PFS) was estimated for niraparib and RS, and rucaparib using parametric survival distributions based on ENGOT-OV16/NOVA (Niraparib Phase III trial) and ARIEL3 (Rucaparib Phase III trial), respectively. For non-g*BRCA*mut, olaparib PFS was estimated from Study 19 (Olaparib Phase II trial). For g*BRCA*mut, a cost-minimisation analysis was conducted versus olaparib. Due to immature overall survival (OS) data in ENGOT-OV16/NOVA and ARIEL3, mean OS benefit was estimated as double the mean PFS benefit for niraparib, olaparib and rucaparib versus RS. Costs included; drug, chemotherapy, monitoring, adverse events, and terminal care. EQ-5D captured quality-of-life. A 3% annual discount rate was used. **Results:** Treatment with niraparib increased costs and QALYs versus RS, with an incremental cost-effectiveness ratio of \$94,186 and \$58,804, for non-g*BRCA*mut and g*BRCA*mut. Niraparib had lower costs and higher QALYs compared to olaparib and rucaparib in both populations, with a cost difference of -\$57,575 and -\$60,400 versus olaparib, and a cost difference of -\$117,916 and -\$261,950 versus rucaparib for non-g*BRCA*mut and g*BRCA*mut. **Conclusions:** These estimates indicate that niraparib was cost-effective compared to olaparib and rucaparib. Additionally, the cost-effectiveness ratio falls within an acceptable range versus RS. Mature OS data is required to validate these results.

5560 Poster Session (Board #287), Mon, 1:15 PM-4:45 PM

Nanoparticle micellar formulation of paclitaxel in combination with carboplatin for women with recurrent platinum sensitive ovarian cancer (OAS07-OVA): Overall survival results of a phase 3 randomized trial. *First Author: Nina Heldring, Oasmia Pharmaceutical AB, Uppsala, Sweden*

Background: The primary objective in the pivotal trial OAS-07OVA was reached and it was demonstrated that Paclical, a nanoparticle micellar formulation of paclitaxel (Oasmia Pharmaceutical AB) is non-inferior to Cremophor-EL Paclitaxel in terms of progression free survival (PFS) in the treatment of recurrent platinum-sensitive ovarian, fallopian tube or peritoneal carcinoma. Paclical is given as 1-h infusion without standard use of premedication. The follow-up analyses presented here includes overall survival (OS) and subgroups of PFS and OS. **Methods:** In this open 1:1 randomized 2-armed phase 3 study, 789 patients were included 2009 - 2012 in 81 centers. Non-inferiority in terms of OS was included as a secondary objective, anddefined as the time between date of randomization and death. Following the end of study, information of the death of participating patients was collected on a special form until August 2016. The upper non-inferiority limit of the one-sided confidence interval of the hazard ratio of the two treatment arms was set to 1.185. **Results:** Non-inferiority of OS was showed as the hazard ratio estimated based on a Cox proportional hazards model stratified by CA125 and relapse was 0.95 (95% CI: 0.78; 1.16) in the PP population. The median overall survival time was 25.7 months in the Paclical arm and 24.8 months in the Taxol arm. Non-inferiority of OS was also seen in patients experiencing their first relapse, and patients with serous adenocarcinoma at diagnosis. In addition, sensitivity analyses as well as subgroup analyses showed a consistent tendency of favor for Paclical in terms of PFS. **Conclusions:** Paclical is non-inferior to Taxol with respect to OS and PFS for patients with recurrent platinum-sensitive ovarian cancer. Even though the pivotal study was not designed to show superiority, subgroup analyses show a consistent tendency of favor for Paclical in terms of OS and PFS indicating a benefit for the Paclical group. Clinical trial information: NCT00989131, Eudra CT: 2008-002668-32 Clinical trial information: 2008-002668-32.

5561 Poster Session (Board #288), Mon, 1:15 PM-4:45 PM

Tumor molecular profiling to differentiate extreme responses to first-line platinum-based chemotherapy in suboptimally debulked serous ovarian cancer patients. *First Author: Johanne I Weberpals, Ottawa Hospital Research Institute, Ottawa, ON, Canada*

Background: Patients with advanced high grade serous ovarian cancer (SOC) who undergo a suboptimal debulking primary surgery typically have adverse clinical outcomes. However, a spectrum of sensitivity to first line platinum-based chemotherapy is observed but poorly understood. In this study, we perform molecular characterization of two groups of responders (extreme versus poor) to first line carboplatin/taxol chemotherapy in suboptimally debulked SOC patients. **Methods:** Suboptimally debulked SOC patients with advanced disease (stage III-IV) were grouped by response to first-line chemotherapy and clinicopathologic data collected. Extreme platinum-sensitive (PS) responders had a PFI (progression-free interval) $>$ 12 months (mo) and platinum-resistant (PR) responders had a PFI $<$ 6mo. Tissue specimens were used to interrogate the molecular features of both PS and PR cohorts using whole exome and transcriptome sequencing. Sequence alignment and variant calling were performed using GATK and annotation was performed using Variant Effect Predictor for assessment of non-synonymous tumor mutation burden (TMB) and discovery of novel mutational signatures to predict platinum response. **Results:** There were 39 patient samples analyzed from primary surgery (PS group = 20; PR group = 19). Median PFI for PS and PR patient cohorts was 30 mo and 3 mo ($p < 0.001$), respectively. In all tumors, in addition to BRCA and TP53 mutations, additional oncogenic mutations were noted in genes associated with PI3K/AKT/mTOR signaling and in epigenetic regulation. The PS samples were characterized by mutations in BRCA1/2 and the PR samples by mutations in MGA. Compared to tumors in the PR cohort, PS tumors had a significantly higher non-synonymous mutation rate using TMP analysis ($p < 0.05$) with a trend towards increased immune response. Additional bioinformatics analysis is ongoing and will include copy number variation analysis, immune inference using ESTIMATE and Gene Set Enrichment Analysis. **Conclusions:** Contracting a mutational signature is feasible from patient tumors at primary surgery and helps to elucidate extreme responses to platinum-based chemotherapy.

5562 Poster Session (Board #289), Mon, 1:15 PM-4:45 PM

Integrated molecular analysis of Asian ovarian cancer: Gene expression and whole exome sequencing analyses from the iPocc Translational Research study (TriPocc). *First Author: Ruby Huang, Cancer Science Institute of Singapore, National University of Singapore, Singapore*

Background: iPocc is a randomized, multicenter international study comparing the efficacy of first line intravenous (IV) dose-dense paclitaxel and intraperitoneal (IP) carboplatin with standard IV dose-dense paclitaxel and carboplatin in women with epithelial ovarian, fallopian tube or primary peritoneal cancer. TriPocc is the translational research protocol evaluating the molecular and predictive biomarkers for differences in treatment outcome. **Methods:** Fresh frozen (FF) biopsies (N = 123) collected during surgeries from participating institutions in Japan and Singapore were included into TriPocc. Briefly, DNA and RNA were extracted from FF biopsies and paired germline DNA were extracted from the peripheral blood mononuclear cells (PBMC). Whole-transcriptome profiling (WTP) was done by Affymetrix Human Transcriptome Array (HTA) 2.0 (N = 120) for gene expression molecular subtypes (GEMS). Whole-exome sequencing (WES) was done by Nextera Rapid Capture Custom Enrichment Kit for library preparation followed by Illumina NextSeq 500 for paired somatic and germline sequencing (N = 116). The Broad Institute Genome Analysis Tool Kit (GATK) V3.7 was used for variant calling. **Results:** High grade serous carcinoma (HGSC) was the most frequent histotype (N = 72; 60%), followed by endometrioid (N = 18; 15%) and clear cell carcinoma (N = 16; 13.3%). Mes was the dominant GEMS (N = 43; 35.8%), followed by Epi-B (N = 29; 24.2%), Stem-A (N = 27; 22.5%), Stem-B (N = 17; 14.2%), and Epi-A (N = 4; 3.3%). Unique mutations were discovered in HGSC. Top significant mutations identified (q-value lower than 1xE-9) included *ITGA4, UCN3, COL4A3, ACP2, SEH1L, AGL, FAM26F, OR5H15, EXO1, TEKT3, ZNF720, IFI44L, MERTK, TP53, DHX57, TTC31,* which were not reported previously in the TCGA cohort. BRCA1/2 mutations (26.1% of all samples) were found in 35.2% of HGSC and 13.5% of non-HGSC, which is higher than previously reported. **Conclusions:** The integrated genomic analysis from TriPocc has enabled the discovery of potentially novel molecular alterations in Asian ovarian cancers. The predictive value of these molecular alterations will be assessed once the iPocc outcome data are mature.

5563 Poster Session (Board #290), Mon, 1:15 PM-4:45 PM

Locus-specific loss of heterozygosity (LOH) in *BRCA1/2* mutated (mBRCA) ovarian tumors from the SOLO2 (NCT01874353) and Study 19 (NCT00753545) clinical trials. *First Author: Kirsten Timms, Myriad Genetics, Salt Lake City, UT*

Background: The PARP inhibitor olaparib is approved in the US for patients with mBRCA (germline) advanced ovarian cancer, and in the EU for platinum-sensitive relapsed mBRCA (germline or somatic) ovarian cancer. A recent study reported retention of a normal allele in 7% of germline *BRCA1* mutant ovarian tumors and 16% of germline *BRCA2* ovarian tumors, and suggested that absence of locus-specific LOH may be a biomarker of primary resistance to DNA damaging agents (Maxwell KN et al, Nature Commun. 2017;22:319). **Methods:** mBRCA tumors were identified from two trials with patients with platinum sensitive relapsed ovarian cancer: SOLO2 (NCT01874353), Study 19 (NCT00753545). Analysis was performed on tissue obtained at the time of diagnosis. LOH status was assigned using a genomic instability algorithm, and confirmed via human review. Both processes evaluated relative read count and allele dosage data from 54,000 independent SNPs. **Results:** 210 mBRCA tumors (144 *BRCA1*, 66 *BRCA2*) were identified in the SOLO2 cohort. 103 mBRCA (70 *BRCA1*, 33 *BRCA2*) were identified in the study 19 cohort. There was lack of locus-specific LOH observed in 1 *BRCA2* mutant in each trial. There was no statistically significant difference in the frequency of locus-specific LOH between the two cohorts. The frequencies of locus-specific LOH in the combined SOLO2 and Study 19 cohort were statistically significantly different to that reported by Maxwell et al (Table) for *BRCA1*, *BRCA2*, and combined *BRCA1/2* mutants (p = 0.001, 0.01, 0.00002, respectively). **Conclusions:** Locus-specific LOH in mBRCA tumors from the SOLO2 and Study19 cohorts was almost universal; however it is possible that selection for platinum sensitivity enriched for tumors with loss of both alleles. These data support the use of germline or tumor *BRCA1/2* testing as a means of identifying patients likely to respond to olaparib treatment in platinum-sensitive ovarian cancer. Further analysis of this phenomenon in additional cohorts will be presented. Clinical trial information: SOLO2 (NCT01874353), Study 19 (NCT00753545).

5564 Poster Session (Board #291), Mon, 1:15 PM-4:45 PM

Assessing delay and barriers to risk-reducing surgery in women with BRCA mutations. *First Author: Anne Olsen, NYU School of Medicine, New York, NY*

Background: The NCCN recommends risk-reducing salpingo-oophorectomy (RRSO) for women with BRCA mutations by age 35-40 or upon completion of childbearing. We previously reported that RRSO was being performed at age 43-44; and age 46-47 when fertility considerations were excluded. Since these ages are past the NCCN guidelines, our objective was to elucidate the timing between genetic testing (GT) and risk-reducing surgery (RRS) and reasons for delay. **Methods:** We conducted a retrospective chart review to identify women with BRCA mutations who underwent RRSO between 2012-2017. We analyzed demographics, date of GT and RRS and reasons for delay in RRS. **Results:** We identified 187 patients with mutations who underwent RRS: 93 with *BRCA1* and 94 with *BRCA2*. Median age at RRS was 44 (28-77); 43 (31-77) and 45 (28-71), for *BRCA1* and *BRCA2*, respectively. The median time between GT and RRS was 9 (1-171) months (m). Fifty-six percent of patients (n = 105) had a documented reason for delay in RRS: 39 (37%) for future fertility; 25 (24%) for breast cancer (BC) treatment; 14 (13%) due to fear of surgical menopause; 10 (10%) to coordinate with simultaneous breast surgery; 17 (16%) miscellaneous. The median time of delay from mutation diagnosis to RRS among groups was: fertility, 29 (3-171) m; BC, 9 (2-36) m; menopause, 12 (4-76) m; and surgical coordination, 8 (4-13) m. Median age at RRS among groups was: fertility, 39 (31-46) years (y); BC, 45 (28-70) y; menopause, 42 (32-44) y; and surgical coordination, 52 (37-71) y. In patients undergoing RRS after diagnosis of BC, 30 of 36 (83%) had a family history that qualified them for earlier genetic testing by NCCN guidelines. Two of these BC patients had ovarian cancer at the time of RRS. **Conclusions:** Overall, patients underwent RRS within a year of mutation diagnosis. Patients comprised two distinct groups: those with fertility or menopause concerns who underwent RRS at 39-42 y, close to the NCCN recommended age; and those with BC who underwent RRS at 45-52 y. Over 80% of patients in the BC group qualified for earlier genetic screening. Obtaining a family history, referral for GT, and earlier diagnosis of mutations, prior to development of BC, will be an important step to better comply with NCCN guidelines and prevent ovarian cancer.

5565 Poster Session (Board #292), Mon, 1:15 PM-4:45 PM

PF-06647020 (PF-7020), an antibody-drug conjugate (ADC) targeting protein tyrosine kinase 7 (PTK7), in patients (pts) with advanced solid tumors: Results of a phase I dose escalation and expansion study. *First Author: Jasgit C. Sachdev, Scottsdale Healthcare, Paradise Valley, AZ*

Background: PF-7020 is an ADC comprising of a humanized monoclonal antibody against PTK7, a cleavable valine-citrulline linker and auristatin payload that is being investigated in an ongoing Phase I clinical trial in pts with advanced solid tumors resistant to standard of care (SoC). Here we report safety results and clinical activity of PF-7020. **Methods:** Eligible patients received PF-7020 intravenously once every three weeks (Q3W) in doses ranging from 0.2 - 3.7 mg/kg (mpk) in sequential dose escalation cohorts. Dose limiting toxicity (DLT) evaluation period was 21 days (cycle 1). Dose expansion cohorts of pts with advanced ovarian cancer (OVCA), non-small cell lung cancer (NSCLC), and triple negative breast cancer (TNBC) were treated with PF-7020 at recommended phase 2 dose (RP2D). PTK7 expression was assessed by immunohistochemistry. Adverse events (AEs) were assessed by CTCAE v4.03 and best objective response per RECIST v1.1. **Results:** As of 24 OCT 2017, 112 pts were treated with PF-7020 in dose escalation and expansion cohorts. The pharmacokinetic exposure of PF-7020 increased in a dose related manner, with a terminal half-life of 3 days at 2.8 mpk. 2 DLTs (Grade (Gr) 3 headache, Gr3 fatigue) were observed in the 3.7 mpk cohort, and a RP2D of 2.8 mpk was established. Toxicities were manageable, most AEs limited to Gr1 or 2 (no Gr5). Common treatment-related AEs were nausea, alopecia, fatigue, headache, neutropenia, and vomiting. Antitumor activity irrespective of PTK7 expression is summarized below and further enriched in PTK7 medium/high pts (not shown). **Conclusions:** Promising antitumor activity and manageable safety profile of PF-7020 were observed in pts with advanced OVCA, NSCLC and TNBC resistant to SoC. Further investigation of PF-7020 is ongoing. Clinical trial information: NCT02222922.

Inhibition of the Wnt/β-catenin pathway to promote T-cell immunity and survival in a syngeneic mouse model of ovarian cancer. *First Author: David W Doo, University of Alabama at Birmingham, Birmingham, AL*

Background: The Wnt/β-catenin pathway downregulates protective immunity mediated by intra-tumoral CD8+T cells, resulting in immune exclusion across cancer types. WNT974 inhibits the enzyme porcupine, which controls Wnt ligand secretion. Our objective was to evaluate the effects of Wnt inhibition on tumor growth, immune response, and survival in a syngeneic mouse model of ovarian cancer (OVCA). **Methods:** C57BL/6 mice were injected subcutaneously (SC) or intraperitoneally (IP) with 7 x 10^6 ID8 mouse OVCA cells. After 28 days, WNT974 or vehicle control was administered by oral gavage for up to 28 days. SC tumors were measured with calipers and tumors were harvested for NanoString gene expression profiling. Mice with IP tumors were kept to evaluate survival, or sacrificed after 14 days of treatment and omental tumor weights and ascites volume were measured. Flow cytometry was used to evaluate the immune response in IP tumors. **Results:** In the SC model, treatment with WNT974 reduced tumor size compared to vehicle control at day 60 (22.4 vs. 41.0 mm^2, p = 0.0001). A gene signature of T cell infiltration was upregulated in SC tumors of WNT974-treated mice (p = 0.038). In the IP model, ascites volume (0.06 vs. 5.95 mL, p = 0.019) and number of ascites cells (2.60 x 10^7 vs. 7.45 x 10^7 cells, p = 0.019) were decreased after treatment with 14 days of WNT974. Analysis of the omental tumors revealed an increased ratio of CD8+ T cells to T regulatory cells in the WNT974-treated mice (2.90 vs. 1.67, p = 0.024), as well as an increased number of dendritic cells (23,613 vs. 8,332 cells, p = 0.045). A higher frequency of CD8+ T cells were found to express granzyme B (91.8 vs. 26.6%, $p < 0.0001$) and TNF-α (31.1 vs. 0.84%, $p < 0.0001$) after treatment with WNT974. Survival was significantly improved in the WNT974-treated group (p = 0.007). **Conclusions:** Using a syngeneic OVCA mouse model, treatment of ID8 tumor-bearing mice with WNT974 decreased tumor growth and ascites and prolonged survival. This effect coincided with an upregulated anti-tumor immune response, suggesting that the Wnt/β-catenin pathway may be an important immunomodulatory target in ovarian cancer.

5567 Poster Session (Board #294), Mon, 1:15 PM-4:45 PM

Phase II results of GANNET53: A European multicenter phase I/randomized II trial of the Hsp90 inhibitor Ganetespib (G) combined with weekly Paclitaxel (P) in women with high-grade serous, high-grade endometrioid, or undifferentiated, platinum-resistant epithelial ovarian, fallopian tube or primary peritoneal cancer. *First Author: Nicole Concin, Medical University of Innsbruck, Innsbruck, Austria*

Background: Stabilized mutant p53 protein (mutp53) is a novel target in ovarian cancer. Mutp53 proteins depend on folding support by the Hsp90 chaperone. Hsp90 blockade induces degradation of mutp53, resulting in anti-tumor cytotoxicity and increased sensitivity to chemotherapeutics. The GANNET53 trial (EUDRACT 2013-003868-31, FP7 project funded by the European Union) tests the combination of Ganetespib (G) with Paclitaxel (P) in platinum-resistant epithelial ovarian cancer (PROC) patients (pts). **Methods:** Eligible pts had PROC, ≤ 4 prior chemotherapy lines, high-grade histology, disease measurable according to RECIST 1.1 or assessable according to GCIG CA-125 criteria. Pts were randomized in a 2:1 manner to receive weekly P (80 mg/m^2) + G (150 mg/m^2) or weekly P alone. Treatment was given i.v. on days 1, 8, 15 in a 28 day cycle until disease progression. Primary endpoint was PFS, secondary endpoints were OS, ORR, PFS2, safety, PRO and PK. **Results:** A total of 133 pts (median age 61 years, range 40-81) were enrolled. Median follow-up was 10.0 months in the ITT population. The study was prematurely closed for active recruitment due to unsecured drug supply with G (initially planned 222 pts). In the ITT population, median PFS was 3.5 and 5.3 months for P+G and P, respectively (p = 0.16; HR 1.3, 95%CI: 0.897-1.895). OS was 11.0 and 14.9 months, respectively (p = 0.13; HR 1.4, 95%CI: 0.902-2.171). The most frequent related gr 1/2 AEs in the P+G arm were typical transient (1-2 days) diarrhea (79% of pts), anemia (46%), nausea (41%), and peripheral neuropathy (36%), and in the P arm anemia (51%), peripheral neuropathy (47%), nausea (40%) and diarrhea (26%). Most frequent related > gr 2 AEs in the P+G arm were neutrophil count decrease (12% of pts), diarrhea (11%), and anemia (8%) and in the P arm anemia (9%), neutrophil count decrease (9%) and diarrhea (5%). ORR, PFSII and detailed safety data and analyses in PP population will be presented. **Conclusions:** The addition of G to weekly P did not improve survival in PROC patients. Clinical trial information: EUDRACT 2013-003868-31.

5568 Poster Session (Board #295), Mon, 1:15 PM-4:45 PM

Comparing the impact of dose reductions and delays on ovarian cancer patient outcomes with three-weekly versus dose dense carboplatin and paclitaxel regimens in the national prospective OPAL cohort. *First Author: Tharani Sivakumaran, Peter MacCallum Cancer Centre, Melbourne, Australia*

Background: To determine if chemotherapy dose reductions and delays in the adjuvant setting impact ovarian cancer pt outcomes. Secondary objective is comparing deliverability of three weekly and dose dense chemotherapy. **Methods:** OPAL is a national prospective study involving 958 pts with newly diagnosed epithelial ovarian (or peritoneal, fallopian tube) cancer. All pts who commenced 3 weekly Carboplatin (AUC 5/6) and Paclitaxel 175mg/m^2 (3CP) or Carboplatin (AUC 5/6) and weekly Paclitaxel 80mg/m^2(CddP) were identified from the OPAL study database. Information regarding patient demographics, treatment doses, adverse effects and clinico-pathological characteristics had been collated from medical records were identified. **Results:** Five hundred and fifty-two pts were identified from the database with 262 commencing 3CP and 290 commencing CddP. The median age at diagnosis was 62 yrs (range 21-79). The most common pathology was serous (74%) with most high grade (77%). Six cycles of chemotherapy were completed by 200 (76%) and 128 (44%) pts ($p < 0.001$) in the 3CP and CddP groups respectively. There was at least one treatment delay in 125 (48%) and 143 (49%) pts in the 3CP and CddP groups respectively. The 3CP and CddP groups had 46 (18%) and 91 (31%) pts respectively requiring at least a 15% dose reduction for Carboplatin; and 47 (18%) and 94 (32%) patients for Paclitaxel respectively. Severe haematological toxicity was experienced in 8% and 16% of pts in the 3CP and CddP group respectively and 7% experienced severe neurological toxicity in both groups. Mean relative dose intensities of Carboplatin was 93% and 85% for the 3CP and CddP group respectively; and for Paclitaxel was 86.5% and 75.5%. The median progression free survival (mPFS) was 23.3 mo vs 20.1 mo for 3CP and CddP groups (p = 0.0012). The mPFS in 3CP was 23.7 mo vs 26.5 mo in the dose reduction and no dose reduction group respectively; and for CddP group was 20.1 mo vs 20.4 mo. **Conclusions:** Dose reductions did not have an impact on mPFS. CddP had more treatment delays, dose reductions, haematological toxicities and lower completion rates than the 3CP group.

5569 Poster Session (Board #296), Mon, 1:15 PM-4:45 PM

Gene expression profiling using Nanostring technology to predict surgical outcome in advanced primary high grade serous ovarian cancer (HGSOC) patients (pts). Study of the Tumor Bank Ovarian Cancer (TOC). *First Author: Elena Ioana Braicu, Charité Universitätsmedizin Berlin, Department of Gynaecology, European Competence Center for Ovarian Cancer, Charité Campus Virchow-Klinikum, Berlin, Germany*

Background: Ovarian cancer has the highest mortality rates among gynecological cancer. Residual tumor mass after primary debulking surgery (PDS) is one of the most important prognostic factors. There are no accurate predictive tools to identify pts who won't benefit from upfront surgery. Aim was to discover and validate a debulking signature to predict surgical outcome in advanced HGSOC. **Methods:** Using *in silico* data analysis of publicly available data, we developed a 200 gene signature to differentiate between optimal vs. suboptimal debulked pts. Optimal debulking was defined as no macroscopical residual mass after PDS. The mRNA expression levels of the top 25% genes were validated in an independent cohort of 246 HGSOC pts, using Nanostring nCounter Analysis System. Only advanced stage, chemonaive HGSOC pts were included in the study. FFPEs and clinical data were provided by TOC (www.toc-network.de). Residual mass and clinical-histological parameters were documented prospectively. Surgery was performed by an experienced gynecological oncologist, between 2002-2013. The validation was performed using unsupervised hierarchical clustering (distance metric:1-correlation, complete linkage). Pts stratification in the two main clusters was assessed by Pearson's Chi-squared test with Yates' continuity correction. **Results:** 152 (61.7%) pts presented no residual mass after PDS. Median age at diagnosis was 59 years. The own generated data showed 29 differentially expressed genes between suboptimal and optimal debulked pts (Mann-Whitney U-test, $p < 0.05$). MYCN, PTCH1, MMP11, GREM1, PMEPA1, FABP4, ASPN and TGFB3 were the top differentially expressed genes ($p < 0.05$ and abs(log2FoldChange) > 0.5) between the two cohorts. Unsupervised hierarchical clustering of all measured genes, the 29 genes and the 8 top genes, showed significant phenotypical separation (p = 0.04, p = 0.00011 and p = 0.00022, respectively). **Conclusions:** Our debulking signature predicts macroscopical residual mass after PDS in advanced HGSOC. This will more likely allow pts selection for primary vs. interval debulking surgery.

5570 Poster Session (Board #297), Mon, 1:15 PM-4:45 PM

Differences in survival between Caucasians and Asians. *First Author: John K. Chan, Palo Alto Medical Foundation, San Francisco, CA*

Background: To compare the difference in the presentation and survival of Asian subgroups and whites with epithelial ovarian cancer. **Methods:** Data were extracted from the National Cancer Database between 2004-2013. Chi-squared tests, Kaplan-Meier methods, and Cox-proportional hazard models were used for statistical analyses. **Results:** Of the 81,355 women, 78,531 (96.5%) were White and 2,824 (3.5%) were Asians. Of Asians, 495 (23.5%) were Chinese, 487 (23.1%) Indian/Pakistani, 476 (22.6%) Filipino, 207 (11%) Vietnamese, 224 (10.6%) Japanese, and 219 (10.4%) Korean. Compared to Whites, Asians were younger (54 vs. 61 years: $p < 0.001$) had more early stage disease (47.8% vs. 35.0%; $p < 0.001$), non-serous histology (56.7% vs. 44.5%; $p < 0.001$), and better survival (63.9% vs. 50.6%; $p < 0.001$). Of the Asians, Korean and Vietnamese were younger at 53 years compared to Chinese, Indian/Pakistani, Filipino, and Japanese (54, 54, 55, and 59 years) Vietnamese presented with 38.2% of stage I disease compared to 37.8%, 28.8%, 36.6%, 33.8%, and 34.8% in Chinese, Indian/Pakistani, Filipino, Korean, and Japanese. The 5 years disease specific survivals for Vietnamese, Chinese, Indian/Pakistani, Korean, Filipino, and Japanese were 74%, 67.6%, 67.5%, 60.3%, 59.3%, and 53.4%, respectively ($p < 0.001$). On multivariate analysis, Chinese (HR: 0.78, 95%CI: 0.65-0.95, $p = 0.01$), Vietnamese (HR: 0.64, 95%CI: 0.47-0.87, $p = 0.005$), Indian/Pakistani (HR: 0.70, 95%CI: 0.57-0.85, $p < 0.001$) race predicted for better survival compared to whites. In addition. younger age at diagnosis (HR: 1.03, 95%CI: 1.027-1.029, $p < 0.001$), advanced stage of disease (HR: 1.98, 95%CI: 1.95-2.01), and endometrioid cell type (HR:0.72, 95%CI: 0.69-0.75, $0 < 0.001$) predicted for survival. **Conclusions:** Our data suggest that asians presented at a younger age, had more early stage disease with better survival compared to whites. More specifically, the subgroups of Chinese, Vietnamese and Indian/Pakistani have better survival compared to whites.

5571 Poster Session (Board #298), Mon, 1:15 PM-4:45 PM

Phase Ib study of anti-mesothelin antibody drug conjugate anetumab ravtansine in combination with pegylated liposomal doxorubicin in platinum-resistant ovarian, fallopian tube, or primary peritoneal cancer. *First Author: Iurie Bulat, ARENSIA Exploratory Medicine Research Unit, Institute of Oncology, Chisinau, The Republic of Moldova*

Background: Anetumab ravtansine (AR) comprises a novel fully human anti-mesothelin IgG1 antibody conjugated to the maytansinoid tubulin inhibitor DM4. A phase Ib dose escalation was conducted in patients with platinum-resistant ovarian cancer to assess overall safety, pharmacokinetics (PK) and clinical activity. **Methods:** Eligible pts with histologically confirmed, locally invasive or metastatic platinum-resistant ovarian cancer, and ECOG performance status ≤ 1 were enrolled. Pegylated liposomal doxorubicin (PLD) at 30 mg/m^{2}IV every 21 days (q3w) was administered with AR in two IV dosing schedules: 5.5 or 6.5 mg/kg q3w in 9 pts (Part I dose escalation) and at 6.5 mg/kg q3w in 12 patients (Part II expansion cohort). Tumor response was assessed based on RECIST v1.1 q6w C1-C9 and q12w thereafter. Determination of mesothelin expression in archival or fresh biopsy tumor samples by IHC (SP74, Ventana) was highly encouraged. PK of AR and PLD was performed. **Results:** A total of 21 pts were evaluable in Part I and II: mean age 61.5 yrs (range 42-77), PS 0/1 66.7%/33.3%, median prior lines of therapy 3 (range 1-10). The maximally tolerated dose (MTD) in combination was AR at 6.5 mg/kg and PLD at 30 mg/m^2 q3w. Adverse events (AEs) were similar to previously reported AEs for of each agent as monotherapy, including reversible corneal disorders, neutropenia, liver function test increases and gastrointestinal disorders. Drug-related (DR) serious AEs were low (2 pts, 9.5%). Most common grade 3-4 AEs were neutrophil count decreased (5, 23.8%) and platelet count decreased (2, 9.5%). A total of 11 pts (52%) had confirmed partial responses (PR) and 7 (33%) had stable disease for a disease control rate of 86%. Six pts (29%) had a durable PR (> 250 days). No PK interaction was observed. **Conclusions:** AR in combination with PLD showed preliminary efficacy with durable PRs in pts with platinum-resistant ovarian cancer. The safety profile was manageable. Further study of this combination is warranted. Clinical trial information: NCT02751918.

5572 Poster Session (Board #299), Mon, 1:15 PM-4:45 PM

Toxicity profile of patients with gynecological cancers (Gyne) enrolled in phase I trials. *First Author: Yeh Chen Lee, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Gyne patients enrolled in Phase I trials may be at increased risk of certain toxicities given their extent of abdominal disease and prior treatments (surgery, chemo and radiotherapy). This study aims to assess the toxicity profile of patients with and without gyne cancers enrolled in Phase I trials. **Methods:** A retrospective review of the National Cancer Institute Phase I database was conducted with trials enrolling at least 1 gyne patient over a 16-year period (1995-2015). Eligible patients required complete data collection from baseline to end of trial participation. Adverse events (AEs) were categorized by CTCAE. Each AE was counted one time and analyzed based on highest grade and drug attribution. **Results:** 4,269 eligible patients enrolled in 150 Phase I trials were identified and divided into 3 groups: 1) females with gyne cancer (n = 685); 2) females with non-gyne cancer (n = 1698); 3) males (n = 1886). Median age in each group was 56 *vs* 56 *vs* 60 years, respectively. Mean total AEs reported during treatment was highest for females with gyne cancer [mean (standard error of mean [SEM]): 17.1 (0.4) *vs* 14.7 (0.2) *vs* 13.5 (0.2)], despite being similar at baseline [mean (SEM): 7.0 (0.2) *vs* 7.4 (0.1) *vs* 7.0 (0.1)]. Differences were predominantly due to greater abdominal-related AEs, infection and myelosuppression in females with gyne cancer. Drug-related AEs were also highest for females with gyne cancer [mean (SEM): 8.3 (0.2) *vs* 6.9 (0.1) *vs* 6.2 (0.1)]. Grade 3-5 AEs were similar [mean (SEM): 2.3 (0.1) *vs* 2.3 (0.1) *vs* 2.1 (0.1)]. Discontinuations due to AEs were similar (9% vs 9% vs 10%) and deaths during treatment were higher in males (2% vs 2% vs 4%). Regarding study outcomes, females with gyne cancer remained on treatment marginally longer (4.3 *vs* 3.3 *vs* 3.1 cycles) and achieved higher objective response rates (11% *vs* 6% *vs* 3%). **Conclusions:** Gyne patients enrolled in Phase I trials experienced greater abdominal-related AEs and infection, thus warranting specific consideration. However, grade 3-5 AEs and discontinuations were similar in all groups, suggesting that toxicities were low-grade and did not compromise outcomes.

5573 Poster Session (Board #300), Mon, 1:15 PM-4:45 PM

Determinants of severe chronic fatigue among epithelial ovarian cancer survivors: A GINECO VIVROVAIRE study. *First Author: Florence Joly, GINECO and Regional Centre Control Against Cancer Francois Baclesse, Caen, France*

Background: Vivrovaire was a large case-control study comparing patients reported outcomes (PROs) between 318 Epithelial Ovarian Cancer Survivors (EOCS) without relapse ≥ 3 years after 1st line treatment and age matched controls. Severe chronic fatigue (SCF), the main end point, (26% of EOCS) was one of the most frequent reported late side effects (Joly et al, abstr 940PD, ESMO 2017). The aim of this exploratory study was to assess determinants of SCF among EOCS. **Methods:** EOCS were recruited in 27 centers. Patients filled-in PROs questionnaires: quality of life, neurotoxicity and fatigue (FACT-G, FACT-O, FACT/GOG-Ntx, FACT-F), anxiety/depression (HADS), sleep disturbance (ISI) and physical activity (IPAQ). SCF was defined as FACT-F score < 37. Variables associated with SCF ($p < 0.01$) were included in a multivariate logistic regression. **Results:** EOCS were: Median age 65[20-86] years, high level of education (52%), FIGO stage I/II (50%), III/IV (48%). Histologic subtypes were: serous 49%, endometrioid 15%, clear-cell 8%, mucinous 4%. BRCA1/2 mutations: n = 23 (15%). 98% of EOCS had surgery and 99% received platinum and taxane chemotherapy, associated with antiangiogenic agent (13%). Median follow-up was 5[2-24] years. Current treatments included psychotropic (12%) and pain medications (3%). 26% of EOCS reported SCF, 63% poor quality of sleep, 53% and 22% anxiety/depression, and 27% neurotoxicity. Only 18% of EOCS had high physical activity. Results of univariate and multivariate analysis appear in table. **Conclusions:** Depression, persistence of neurotoxicity, and sleep disturbance are the main determinants of SCF among EOCS. These symptoms should be early detected and treated.

First results of a prospective national controlled study: Prophylactic Radical Fimbriectomy (NCT01608074), in women with a hereditary familial risk of breast/ovarian cancer—Tolerance and pathological findings. *First Author: Eric Leblanc, Centre Oscar Lambret, Lille, France*

Background: Risk-reducing salpingo-oophorectomy is the gold standard to prevent the development of a pelvic high grade serous carcinoma (HGSC) in women at risk of breast/ovarian cancer. However, some are reluctant to perform this surgery due to significant related adverse effects. Most of HGSCs stem from the distal fimbrial part of fallopian tubes. Thus we suggested a new prophylactic procedure called radical fimbriectomy (RF), which consists of the resection of both tubes along with the fimbrio-ovarian junction (attached ovarian fragment), completed at 50 years-old or menopause by a bilateral oophorectomy. We present the first results of this operation focused on perioperative morbidity and pathological observations. **Methods:** BRCA1/2 carriers or any women with a documented familial risk of breast/ovarian cancer were first counseled to perform a classical laparoscopic RRSO. If they denied, they were offered to enter the RF controlled study. All pathological specimens were examined using the SEE-FIM protocol. Intra- and 30-day post-operative events and pathological data were recorded according to protocol. **Results:** From January 2012 to June 2014, 121 laparoscopic RF were performed. Intraoperative complications were: 1 laparo-conversion for adhesions and 2 grade I procedural hemorrhages. 20 patients (16.5%) complained of Clavien grade I, and 2 (1.7%) grade II adverse effects. Pathologically, we found one (0.8%) invasive HGSC, two (1.7%) Serous Tubal Intraepithelial Carcinoma (STIC), one (0.8%) Serous Tubal Intraepithelial Lesion (STIL) and 21 (17.7%) p53 signatures. All lesions were located at the fimbria, except the HGSC found at a tubal isthmus. **Conclusions:** In this cohort, 2.5% of patients had a diagnostic of occult tubal neoplasia, as observed in the literature. Tubal examination by a trained pathologist, using SEE-FIM protocol, is necessary to detect precancerous lesions. A longer time is still necessary to report the efficacy of RF in terms of cancer prevention. Meanwhile, we can conclude that RF is safe, well tolerated and effective in term of occult neoplasia detection. Clinical trial information: NCT01608074.

5575 Poster Session (Board #302), Mon, 1:15 PM-4:45 PM

LION-PAW: Lymphadenectomy in ovarian neoplasm-pleasure ability of women—Prospective substudy of the randomized multicenter LION study. *First Author: Annette Hasenburg, University of Mainz, Mainz, Germany*

Background: There is limited information regarding the impact of radical surgery including pelvic and para-aortic lymphadenectomy (LNE) and subsequent chemotherapy on sexuality in patients (pts.) with advanced ovarian cancer (AOC). We addressed this question within the prospectively randomized LION trial, evaluating the role of LNE in AOC. **Methods:** The Sexual Activity Questionnaire (SAQ) was used to assess sexual function in terms of its subscales activity, pleasure, and discomfort. Additionally we added the "orgasm" subscale from the Female Sexual Function Index. The questionnaire was administered together with the EORTC QLQ-C30 questionnaire at baseline before surgery, after 6, 12 and 24 months. Primary endpoint was changes in sexual function. **Results:** 495 pts. received the questionnaires. 254 pts. responded at baseline (55 sexually active, 182 sexually inactive,17 data not available (na)), 55 at 6 months, 139 at 12 and 81 at 24 months (22 active, 56 inactive, 3 data na). Median age was 60.5 years (range 21.4 – 75.8 yrs.). Discomfort evaluated as dryness of the vagina and pain during sexual intercourse was significantly worse at 12 months compared to baseline ($p < 0.001$), however, the surgical variable LNE did not show any impact on this. In contrast, the orgasm subscale showed diverging results with a deterioration from baseline to 12 months in the LNE group, but slightly improving in the no-LNE group. This difference was significant ($p = 0.02$). None of the other subscales showed significant differences between arms at any time point. **Conclusions:** A significant difference in pts. with or without LNE after 12 months regarding the ability to get an orgasm was observed in sexually active patients with AOC. This domain should be addressed when sexually active pts. are informed about the potential sequelae of systematic LNE. However, the majority of pts. in this LION substudy were sexually inactive and furthermore the compliance to respond to the sexuality questionnaire was limited. Clinical trial information: NCT00712218.

5576 Poster Session (Board #303), Mon, 1:15 PM-4:45 PM

Progression free survival (PFS) as a surrogate endpoint for overall survival (OS) in first-line advanced ovarian cancer (AOC) therapy: A Gynecologic Cancer InterGroup individual (GCIG) patient-level (IPD) analysis of multiple randomized trials. *First Author: Xavier Paoletti, Gustave Roussy Institute, Villejuif, France*

Background: OS is considered the gold standard endpoint for controlled clinical trials but it requires extended follow-up (median OS > 40 months for first line therapy) and large sample sizes. Our objective was to evaluate whether PFS based on CA125 measurements confirmed by radiological exam or on combined GCIG criteria is a surrogate endpoint for OS in AOC. **Methods:** Using the meta-analytic approach on trials published after 2000, correlations between PFS and OS at the individual level, and between treatment effects on PFS and on OS at the trial level, were estimated using Kendall' tau and copula bivariate (R^2_{Copula}) models respectively. Criteria for PFS surrogacy required $R^2_{Copula} \geq 0.80$. **Results:** We analyzed IPD from 8,973 patients enrolled in 15 randomized first line trials of standard (n = 7), intensification (n = 5) and maintenance (n = 3) chemotherapies or targeted treatments. No heterogeneity in the treatment effects across trials was detected. High correlations were found at the individual level (tau = 0.69) but low correlation at the trial level ($R^2_{Copula} = 0.03$). Sub-group analyses led to similar results. **Conclusions:** This large IPD meta-analysis did not establish PFS as a surrogate endpoint for OS in first line treatment of AOC, but the analysis was limited by the narrow range of treatment effects observed and post study treatment. Additional trials are being collected that will enable us to refine the sub-groups analyses. Table of results

Endpoint / Trial type	Trials N (pts)	tau[a]	R^2_{Copula}
Overall	15 (8973)	0.69	0.03
CA125 confirmed by radiological exam	9 (5126)	0.67	0.16
GCIG criteria	4 (2548)	0.7	0.14
Carbo-Tax as control	9 (5807)	0.72	0.05
Standard or intensification	12 (7703)	0.71	0.10
Maintenance	3 (1270)	0.64	0.14

[a]tau and R^2 values range from 0 (no association) to 1 (perfect correlation).

5577 Poster Session (Board #304), Mon, 1:15 PM-4:45 PM

Phase 1b study of oncolytic vaccinia virus GL-ONC1 in recurrent ovarian cancer (ROC). *First Author: Robert W. Holloway, Gynecologic Oncology Program, Florida Hospital Cancer Institute, Orlando, FL*

Background: Immunotherapy can trigger immune activation including tumor-infiltrating CD8+ T cells, leading to antitumor response and survival benefits. Immunotherapeutic GL-ONC1 (modified vaccinia virus) causes oncolysis, immune activation and durable anti-cancer memory. **Methods:** Intraperitoneal infusion of GL-ONC1 monotherapy was given at higher repeated doses compared to a previous Ph1 trial in patients (pts) with platinum refractory/resistant disease. Primary endpoint: adverse events; Secondary endpoints: anti-tumor response by RECIST1.1 & survival. Eleven heavily pretreated pts with end-stage ROC were enrolled: 3-4 prior lines (n = 3), ≥ 5 lines (n = 8), ECOG 0 (n = 7) or 1 (n = 4), ascites/pleural effusion (n = 9) & progressive disease (PD) at baseline (n = 10). There were two dose cohorts: 3×10^9 (n = 6) or 1×10^{10} (n = 5) plaque forming units/day on 2 consecutive days. **Results:** (1) Adverse reactions included Grade 1-2 chills (n = 7), nausea (7), fever (6), abdominal pain/distention (4), & vomiting (3). There were no differences in toxicity for the two dose levels. (2) GL-ONC1 colonized and replicated in the tumor, as indicated by a virus-encoded glucuronidase assay. (3) Clearance of tumor cells in ascites with induction of lymphocyte infiltration was shown in 5 pts with ascites. (4) Reduction of circulating tumor cells (CTC) was identified in 6/8 (75%) pts who had baseline CTC, ranging 1-42 per 7.5 mL blood. (5) Enhanced infiltration of CD8+ T cells into tumor tissue was demonstrated by repeat biopsy. (6) Disease Control Rate (DCR = partial response (PR) + stable disease (SD) ≥ 15 weeks) was 6/11 (55%). (7) Extended progression-free survival (PFS) of 23, 35, 59 (with confirmed PR) & 71 weeks were observed in 4 pts, respectively. (8) A tumor-specific T cell response was absent at baseline but confirmed at Week-30 in the PR patient by IFN-γ ELISPOT assay. (9) More than doubling of PFS compared to the last chemotherapy regimen was recognized in 4/11 (36%) pts. **Conclusions:** Promising safety data, anti-tumor activity, and immune activation mechanisms were documented in this Ph1b trial, and a Ph2 trial (VIRO-15) is currently enrolling. Future studies combining GL-ONC1 and other immune therapies and/or chemotherapy are under consideration. Clinical trial information: NCT02759588.

5578 Poster Session (Board #305), Mon, 1:15 PM-4:45 PM

Platinum based chemotherapy selects for PDGFRα dependent angiogenesis. *First Author: Nuala McCabe, Almac Diagnostics, Craigavon, United Kingdom*

Background: Patients with High Grade Serous Ovarian Cancer (HGSOC) initially respond to SOC platinum based treatment but most will eventually relapse with platinum resistant disease. Angiogenesis is known to be an integral pathological feature of HGSOC and anti-angiogenic agents have been trialed in this population, but have failed to demonstrate a significant impact on overall survival (OS). Here, we asked if platinum resistance could be associated with an improved response to anti-angiogenic therapies. **Methods:** A meta-analysis of 14 phase II and III clinical trials in EOC were used to investigate the association between platinum resistance and response to anti-angiogenic agents. In addition we analysed gene expression in 12 matched pre-and post-chemotherapy samples. Novel cisplatin-resistant HGSOC cell lines and novel ascites-derived primary cell lines from HGSOC patients with known outcomes following platinum-based chemotherapy were developed to investigate the relationship between angiogenesis and platinum resistance. **Results:** The meta-analysis revealed an OS benefit for anti-angiogenics in platinum-resistant disease ($p = 0.029$), whilst platinum-sensitive disease derived only PFS benefit ($p = < 0.0001$). In the matched pairs of patient samples, post-platinum samples had a higher micro-vessel density (MVD) relative to their paired treatment-naïve sample ($p = 0.0001$). Additionally, an *in vivo* angiogenesis matrigel plug assay demonstrated that cisplatin-resistant EOC cell lines were associated with an increase in MVD ($p = < 0.0001$). MVD was reduced in the platinum-resistant cells following treatment with bevacizumab ($p = 0.001$). Ascites-derived cells established from platinum-resistant patients demonstrated overexpression of VEGF-A through increased PDGFRa and PDGFRb expression. **Conclusions:** We have demonstrated that previous platinum therapy for EOC is associated with an increase in tumour PDGFα and VEGF-A expression, correlating with a response to anti-angiogenic therapies. This data suggests that platinum therapy resistance may inform the selection of EOC patients for novel anti-angiogenic therapies in future clinical trials.

5579 Poster Session (Board #306), Mon, 1:15 PM-4:45 PM

Paired somatic and germline genetic testing for ovarian cancer patients: Observations, benefits and implications for treatment. *First Author: Daniel Chen, Ambry Genetics, Aliso Viejo, CA*

Background: Germline and somatic genetic testing have traditionally been offered separately; however, the clinical applications of these tests are now converging with continued FDA approval of targeted therapies for both germline and somatic mutation carriers. This study aims to describe the findings of a paired testing (germline and somatic) approach among ovarian cancer (OC) patients. **Methods:** Study participants consisted of 95 consecutive OC patients undergoing paired testing at a clinical diagnostic laboratory. Eleven OC predisposition genes in the homologous recombination (HR) repair pathway were targeted by capture-based NGS: *ATM, BARD1, BRCA1, BRCA2, BRIP1, CHEK2, MRE11A, NBN, PALB2, RAD51C,* and *RAD51D*. Paired analysis of sequence data from both tumor (minimum of 20% neoplastic cellularity) and blood specimens was performed to differentiate variants of somatic vs. germline origin. Customized NGS pipelines and/or microarray were used to detect gene copy number variants. Additional test results included hypermethylation analysis of *BRCA1* and *RAD51C* promoter regions by methylation-specific PCR, when available. **Results:** In total, 41 patients (43.2%) were eligible for PARP-inhibitor therapy based on the presence of a germline (n = 3, 7.3%), somatic (n = 34, 82.9%) or germline and somatic (n = 4, 9.8%) *BRCA1* or *BRCA2* pathogenic mutation. Of 38 (40.0%) patients with somatic alterations, 3 (7.9%) had sequencing mutations, 32 (84.2%) had whole gene deletions of *BRCA1* and/or *BRCA2*, and 3 (7.9%) had both alteration types. Somatic whole gene deletions of *BRCA1* or *BRCA2* were often accompanied by gains or losses of other genes in the tumor. Twenty-nine patients (30.5%) were germline and tumor *BRCA1/2*-negative, but tested positive for germline or somatic pathogenic mutations in other HR genes or tumor promoter methylation in *BRCA1* or *RAD51C*. **Conclusions:** Our findings highlight the benefits of paired testing over germline and/or somatic testing alone, such as concurrent confirmation of germline mutations and maximizing detection of patients who would benefit from therapy. Further research is needed to determine the impact of paired testing on healthcare costs and patient outcomes.

5580 Poster Session (Board #307), Mon, 1:15 PM-4:45 PM

Phase I study of carboplatin (C), pegylated liposomal doxorubicin (PLD) and everolimus (E) in platinum-sensitive epithelial ovarian, Fallopian tube or primary peritoneal cancer in first relapse (NCT01281514). *First Author: Lainie P. Martin, Fox Chase Cancer Center, Philadelphia, PA*

Background: The PI3K/AKT/ mTOR pathway may play an important role in chemotherapy resistance in ovarian cancer. (E) is an orally administered mTOR inhibitor approved for multiple indications. This Phase I trial evaluated the feasibility of combining E with C and PLD in women with recurrent, platinum sensitive ovarian cancer. **Methods:** Patients were administered C AUC 5 with PLD 30 mg/m2 on 28 day cycles, and escalating doses of E, starting at 2.5 mg/day. Planned Phase I doses of E were 2.5 mg/d, 5 mg/d, 7.5 mg/d and 10 mg/d. The study used a modified TITE-CRM design with a requirement that cohort 1 complete 6 cycles of chemotherapy with E at 2.5 mg/d prior to dose escalation. The primary endpoint was safety and tolerability. **Results:** 21 patients were treated on study. There was a DLT of rash at dose level(DL) 1, 2.5 mg/d; patient discontinued treatment on trial after cycle 1. 5 additional patients completed 6 cycles at DL1 without DLT. 3 patients completed 6 cycles of treatment at DL3, 7.5 mg/d, but 2 experienced DLT and required dose reduction. 12 patients were enrolled at DL2; no DLTs were seen at DL2. 7 patients completed 6 cycles without dose modification. 1 patient required dose modification of E for thrombocytopenia. 2 patients stopped treatment early due to disease progression. 2 patients experienced hypersensitivity reactions to Doxil, and failed desensitization. They were permitted to remain on study with C and E, but were considered inevaluable. DLTs included rash,(n = 1 at DL1), headache (n = 1 at DL3) and thrombocytopenia (n = 1 at DL3). The most common AEs included neutropenia, anemia, stomatitis, rash, nausea, vomiting, diarrhea and constipation (42-90%). Grade 3 AEs included neutropenia (n = 3), thrombocytopenia (n = 2), stomatitis (n = 1), rash (n = 1) and PE/DVT (n = 2). The MTD of E in combination with C and PLD was determined to be 5 mg/d. 3 patients experienced a CR and 11 patients experienced a PR, for a RR of 67%. 3 patients experienced stable disease and 3 experienced disease progression. **Conclusions:** C with PLD and E at 5 mg/day is tolerable with intriguing activity in women with platinum sensitive relapsed ovarian cancer. Clinical trial information: NCT01281514.

5581 Poster Session (Board #308), Mon, 1:15 PM-4:45 PM

Clear cell ovarian cancer (CCOC): 115 patient (pt) series showing access to experimental therapy may improve response rates in recurrent disease. *First Author: Michael-John Devlin, University College London Hospitals, London, United Kingdom*

Background: 10 year survival for ovarian cancer (OC) in the UK has improved from 18% (1971) to a predicted survival of 35% (2011). Historical data show pts with advanced CCOC have worse survival compared to other histological subtypes of epithelial OC. We sought to determine treatment type and outcome of CCOC pts at 2 UK gynaecological cancer centres. **Methods:** Medical records of pts with CCOC treated between 2002 and 2017 were reviewed. Data collected comprised pt and tumour characteristics, treatment and outcome. **Results:** 115 pts, median age 56 (29-86) years (y) with CCOC were identified: stage (S) I (62), II (16), III (23), IV (8) and unknown (6). 91 pts had pure CCOC and 24 had mixed histopathology: endometrioid (83%), serous (12%), other (5%). Endometriosis co-existed in 43 (37%) pts; 34 pure CCOC, 8 mixed endometrioid. BRCA mutations were present in 4/19 tested and MMR loss in 2/8 tested. 21/23 pts with a thromboembolic event and 9/10 pts with hypercalcaemia (2.72-3.63mmol/L) had advanced or recurrent disease. 19 pts had a prior or synchronous malignancy, most commonly endometrial (8) or breast (6). Primary refractoriness to first line treatment occurred in S I (3%), III (13%) and IV (100%) CCOC with median overall survival (OS) of 224 days (d). Recurrence rates were 22% (S I), 38% (S II) and 61% (S III). Molecular targeted agents (MTA) were used in 29 treatments; bevacizumab (45%), nintedanib (17.5%), PARP combination (10%), PI3K/mTOR inhibitor (10%), other novel agent (17.5%).33pts had 2nd line treatment with overall response rate (ORR) of 30% and progression free survival (PFS) 258d. 12/33pts treated with a regimen containing a MTA had PFS 358d vs 228d for those without. ORR in the 3rd line was 14% with PFS 185d. The OS rate at 1y was 98% (S I), 100% (S II), 86% (S III) and 0% (S IV) and at 5y was 81% (S I), 50% (S II) and 23.5% (S III). **Conclusions:** Late stage CCOC has a phenotype distinct to early stage with a propensity to be treatment resistant, recur, have paraneoplastic manifestations and poor survival. The 2nd line ORR of 30% in our cohort is higher than expected and may reflect increased MTA use. 21% and 25% pt had a BRCA variant or MSI loss suggesting benefit of testing CCOC.

5582 Poster Session (Board #309), Mon, 1:15 PM-4:45 PM

Efficacy and immune modulation of the tumor microenvironment with the combination of the PARP inhibitor rucaparib and CD122-biased agonist NKTR-214. *First Author: Andrew Simmons, Clovis Oncology, San Francisco, CA*

Background: NKTR-214 is a biased agonist of the IL2Rbg (CD122) pathway that activates and mobilizes CD8 T and NK cells into the tumor microenvironment. The PARP inhibitor rucaparib has demonstrated activity in *BRCA* mutant deficient tumors through synthetic lethality. We hypothesized that PARP inhibition in a *BRCA* syngeneic model would lead to immunogenic cell death and synergize with NKTR-214 through antigen priming and enhanced activation of newly infiltrated intratumoral T and NK cells. **Methods:** Mice (n = 10/group) were inoculated with the murine ovarian tumor cells (BR5FVB1) harboring genetic alterations (TP53-/-, BRCA1-/-, myc and Akt) frequently present in human ovarian carcinomas. Tumors were grown to 125 mm^3 prior to treatment with vehicle, rucaparib (150 mg/kg BID x 28 days), NKTR-214 (0.8 mg/kg q9d x 3), or the combination and tumor volumes were measured. Immune modulation was evaluated by IHC and gene expression. **Results:** Treatment with the combination resulted in 88.5% tumor growth inhibition (day 22; $p < 0.0001$), and tumors were monitored for regrowth after 28 days of dosing. Tumor volume nadir was 94.5 mm^3 on day 38 for rucaparib treated animals and progressed to > 1000 mm^3 by day 59. In contrast, 50% of mice treated with NKTR-214 and rucaparib combination were tumor free on day 113, suggesting development of immune memory. The combination of NKTR-214 and anti-PD1 in the same model did not provide tumor-free mice. An increase in infiltrating T cells, NK cells, dendritic cells, and neutrophils, as well as the induction of interferon-gamma induced chemokines was observed with the combination of rucaparib and NKTR-214 by expression profiling. IHC staining also showed significant increases in CD3, CD4 and CD8 T cells with the combination ($p < 0.05$). **Conclusions:** The novel combination of NKTR-214 plus rucaparib results in durable complete responses in a genetically-relevant ovarian tumor model. Profiling of tumors suggested the activity of this combination is through antigen priming of infiltrating memory T cells, increased NK cell numbers, and enhanced cytotoxicity of immune infiltrates into the tumor.

5583 Poster Session (Board #310), Mon, 1:15 PM-4:45 PM

A gene expression prognostic signature for overall survival in patients with high-grade serous ovarian cancer. *First Author: Joshua Millstein, Department of Preventive Medicine, USC Norris Comprehensive Cancer Center, Keck School of Medicine, Los Angeles, CA*

Background: Median survival for high-grade serous ovarian cancer (HGSOC) patients is 3-4 years with a wide range of outcomes. Gene expression patterns have been reported to be predictive of outcome, but results have been inconsistent. The aim of this study was to assess the predictive utility of genes previously associated with outcome and to develop a clinically useful predictor for overall survival (OS). **Methods:** We identified 200 genes associated with prognosis from a meta-analysis of previously published gene expression profiling studies in HGSOC and selected an additional 313 candidate genes. Expression in formalin fixed paraffin embedded (FFPE) HGSOC tumor tissue was measured with Nanostring for 3770 women with known OS. Regression-based and machine learning methods were used to develop a prognostic signature for OS. These approaches included stepwise regression, elastic net penalized regression, random survival forests, and component-wise gradient boosting. Models were trained and tested on approximately 2/3 of the data and the best performing model was evaluated on the remaining 1/3. **Results:** In single gene Cox models for OS adjusted for age and stage, there were 275 significant associations (false discovery rate (FDR) < 0.05). The two most significant genes were *TAP1* ($p = 2.2e\text{-}17$; hazard ratio (HR) = 0.84 (0.81, 0.87)) and *ZFHX4* ($p = 1.3e\text{-}15$; HR = 1.19 (1.14, 1.25)). Elastic net yielded the best performing signature in the training data, and in the validation data it was substantially more prognostic than any individual gene (HR = 2.42 (2.09, 2.81), scaled to 1SD). The area-under-the-curve (AUC) for the signature combined with age and stage for 5yr OS was 0.74, substantially larger than the AUC for age and stage alone (0.62). **Conclusions:** These data confirm previously reported or hypothesized associations between gene expression in HGSOC tumor tissue and overall survival. Our signature could be useful in designing clinical trials for patients who are destined to have poor survival, thereby delivering new agents to the patients who are in the most urgent need. Identification of genes associated with the outcome also provides the opportunity to develop targeted therapeutic approaches.

5584 Poster Session (Board #311), Mon, 1:15 PM-4:45 PM

Phase III randomized trial of maintenance pegylated liposomal doxorubicin (PLD) / carboplatin versus without in patients with advanced ovarian cancer: An Asian Gynecologic Oncology Group study. *First Author: Chyong-Huey Lai, Department of OB/GYN, Chang Gung Memorial Hospital, Taoyuan, Taiwan*

Background: An Asian Gynecologic Oncology Group (AGOG) phase III randomized trial was conducted to determine whether maintenance chemotherapy after complete remission could improve progression-free survival (PFS) in FIGO stages III/IV ovarian cancer. **Methods:** Between June 2007 and September 2014, 45 patients were enrolled and randomized (1:1) with stratification factor of residual tumor and stage. One patient was found ineligible shortly after registration and randomization and was excluded without treatment. Twenty-three patients were randomized to arm A (4-weekly carboplatin AUC4 and liposomal doxorubicin 30 mg/m^2) for six cycles and 21 patients were randomized to arm B (observation). The primary endpoint was PFS. Overall survival (OS) was calculated as secondary end-point. **Results:** Enrollment was slow, therefore a decision of closing accrual was made by the AGOG Board meeting when 7+ years had lapsed. We ended the study after the last enrolled patient had completed 3-year follow-up. With a median follow-up of 80.1 months, 30 patients experienced cancer progression (14 [60.9%] for arm A and 16 [76.2%] for arm B). The median PFS was significantly better in arm A (38.9 months) than arm B (9.2 months) (log-rank p = 0.038), and the median OS was marginal better in arm A (not applicable, > 50 % of patients were alive at study end) than arm B (42.8 months) (log-rank p = 0.117). Overall rates of grade 3/4 adverse events were 60.9 % for arm A and 0.0 % for arm B ($p < 0.001$). Grade 3/4 including neutropenia were more frequent in arm A than arm B with 30.4% and 0.0%, respectively (p = 0.0094). **Conclusions:** Despite limitation in small sample size, it suggests that maintenance chemotherapy after complete remission could be beneficial significantly improving PFS in stages III/IV ovarian cancer. Clinical trial information: ACTRN12607000329460.

5585 Poster Session (Board #312), Mon, 1:15 PM-4:45 PM

Histone deacetylase inhibition alters tumor phenotype and stimulates a productive anti-tumor immune response in preclinical models of ovarian cancer. *First Author: Tyler McCaw, University of Alabama, Birmingham, Birmingham, AL*

Background: Ovarian cancer remains the most deadly gynecologic malignancy. Chemotherapy and surgical reduction are initially effective but most patients relapse with chemoresistant disease. Immunotherapy is currently being evaluated in multiple clinical trials as a treatment modality for ovarian cancer, but response rates as a single agent have been disappointing. Because an altered epigenetic framework contributes to malignant transformation and immune escape in ovarian cancer, our objective was to evaluate whether histone deacetylase (HDAC) inhibition could reorient the suppressive tumor microenvironment and stimulate a productive anti-tumor immune response. **Methods:** Syngeneic ovarian cancer cells (ID8 or ID8 p53-/-) were injected into the peritoneal cavity of C57BL/6 mice and treated daily with 20mg/kg entinostat or vehicle, starting on day 21. First, we assayed transcript-level changes in gene expression of whole tumor lysates using the NanoString PanCancer Immune Profiling Panel. Next, we used flow cytometry to assess the number and function of T cells in the tumor and ascites. **Results:** HDAC inhibition increased expression of genes associated with T and NK cell infiltration, cytolytic functions, major histocompatibility class I and class II, as well as other genes associated with immune recognition. In addition, entinostat significantly reduced the number and suppressive capacity of regulatory T cells in both the tumor and ascites. Notably, HDAC inhibition led to infiltration of higher quality CD8 cytotoxic T cells with superior effector functions. These CD8 T cells expressed lower levels of the exhaustion-associated transcription factor Eomes, suggesting they will remain highly functional for a longer amount of time and are less susceptible to exhaustion. **Conclusions:** Our results suggest entinostat could dramatically increase tumor immunogenicity and help turn a "cold" (non-inflamed) tumor into a "hot" (T cell inflamed) tumor, while potentiating anti-tumor T cell functions. Thus, inclusion of HDAC inhibition may increase the frequency of patients responding to checkpoint blockade and/or other immunotherapies.

5586 Poster Session (Board #313), Mon, 1:15 PM-4:45 PM

Genomic profiling of lymph node metastases in endometrial cancer and association with volume of metastasis. *First Author: Stephanie Sullivan, University of North Carolina, Chapel Hill, NC*

Background: Lymph node (LN) metastasis and genomic profiles are important prognostic factors in endometrial cancer (EC). However, the prognostic significance of the volume of metastatic disease found in sentinel lymph node (SLN) specimens is unknown. We sought to determine if particular genomic mutations were associated with LN metastasis and volume of LN metastasis. **Methods:** Surgically staged women with EC at a single institution were enrolled in a genetic sequencing institutional protocol. Relevant targets were enriched by a custom designed Agilent SureSelect hybrid capture enrichment library using standard protocols. A subset of the EC population underwent SLN biopsy with completion lymphadenectomy and hysterectomy as part of the FIRES study. SLN specimens underwent ultrastaging to detect low volume disease such as isolated tumor cells (ITCs). **Results:** 345 patients with EC completed surgical staging and tumor sequencing between 3/2007 and 9/2016; median age 63 yrs and median BMI 34.2 kg/m^2. 55 patients (16.0%) were LN positive (LN+) while 290 (84.0%) were LN negative (LN-). The LN+ group were less likely to have endometrioid histology than the LN- group (54.5% vs 77.2%) and more likely to have grade 3 disease (65.5% vs 33.1%) ($p < 0.001$ for both). LN+ patients were more likely than LN- patients to have p53 mutations (44.4% vs 27.0%, $p = 0.02$), and less likely to have PTEN mutations (38.9% vs 59.1%, $p = 0.01$). Polyclonality of PIK3CA mutations (defined as > 2 mutations in the same tumor) was only observed in the LN- patients ($p = 0.08$). 44 patients had a staging with SLN biopsy. Of these, 8 (18.2%) had ITC's as their only metastatic disease. All ITC patients with p53 mutations were of non-endometrioid histology (3/8). PTEN (80.0%) and PIK3CA (60.0%) mutations were observed in the endometroid ECs. No patients with ITCs had a recurrence. **Conclusions:** Primary tumors associated with LN metastases have both genomic mutations and histologic features consistent with more aggressive disease. In patients with low volume (ITC's) metastases, genomic mutations aligned with histology. More work is needed to better define the relationship between genomic mutations, histology, metastatic volume and prognosis.

5587 Poster Session (Board #314), Mon, 1:15 PM-4:45 PM

Adjuvant therapy may decrease disparities in outcomes for black endometrial cancer patients. *First Author: Fan Zhu, Presence St. Joseph Hospital, Chicago, IL*

Background: Prior literature reports worse survival in Black (B) endometrial cancer patients compared to White (W) counterparts. This study compares outcomes between B and W patients after accounting for clinicopathologic (CP) factors and treatment. **Methods:** From 2006-2014, 305 (169 B and 136 W) patients with endometrial cancer treated at a single hospital were identified. CP features, treatment, and outcome data were collected. 201 (117 B and 84 W) with surgery and follow up were included in analysis. KM curves and log-rank test were performed to compare survival. Multivariable analysis (MVA) with Cox model was fitted for outcomes accounted for patient features, tumor details and treatment. To assess the stability of parameters and significance, an imputation analysis was performed. **Results:** Analysis showed that B and W patients had similar BMI, Charlson Comobidity Index (CCI), smoking history, stage, depth of invasion, and nodal involvement. B patients were older ($P < 0.06$) and had more non-endometrioid histology ($P < 0.005$) and lymphovascular invasion (LVI) ($P < 0.05$). Radiotherapy (RT) was used in 43% B and 30 % W ($P = 0.069$), and chemotherapy in 38% B and 27% W ($P = 0.08$), respectively. On MVA, non-endometrioid histology (HR = 10; $P < 0.05$), smoking (HR = 4.18; $P < 0.05$) and higher CCI (HR = 1.39; $P < 0.05$) were associated with worse OS. Race was not a predictor of OS. G3 endometrioid histology (HR = 16.14; $P < 0.05$), non-endometrioid histology (HR = 22.78; $P < 0.005$), smoking (HR = 3.32; $P < 0.05$) and higher CCI (HR = 1.41; $P < 0.05$) portended worse DFS. Early-stage improved DFS (HR = 0.16; $P < 0.005$). The 5-yr OS for B and W were 37% (SE 0.08) and 44% (SE 0.13) ($p = 0.164$) and the 2-yr DFS for B and W were 77% (SE 0.05) and 91% (SE 0.04), respectively ($p = 0.215$). For patients with known recurrence (N = 35), smoking (HR = 11; $P < 0.005$) and higher CCI (HR = 1.45; $P < 0.05$) portended worse OS; EBRT (HR = 0.07; $P < 0.05$) and W race (HR = 0.123; $P < 0.05$) predicted longer time to recurrence. **Conclusions:** While high risk CP features were associated with worse outcomes as expected, the more high risk features in B patients did not lead to worse outcomes. One explanation for this could be adjuvant therapy, which was implemented at least similarly between races in this study.

5588 Poster Session (Board #315), Mon, 1:15 PM-4:45 PM

Differences in survival outcomes in advanced endometrial cancer due to variation in adjuvant therapy and histology. *First Author: Emily Meichun Ko, University of Pennsylvania, Philadelphia, PA*

Background: To determine the impact on overall survival (OS) of the sequence-order of adjuvant radiation (RT) and chemotherapy (CT) on different advanced endometrial cancer (EC) histologies. **Methods:** Stage 3 endometrioid (EAC), serous (SER), clear cell (CC), and carcinosarcoma (CS) patients who underwent primary surgical staging from 1999-2011 were identified in SEER-Medicare. Sequence, timing, and modality of RT and CT were analyzed using Kaplan-Meier estimates, log rank tests, and multivariable cox modeling. Treatment groups with $n < 10$ were excluded in cox modeling. **Results:** Of 2375 cases identified (1537 EAC, 485 SER, 96 CC, 257 CS), 31.3% received no AT. The remainder received RT or CT alone, concurrent RT-CT, serial or sandwich modalities (table 1). OS differed by receipt of AT overall as well as within each histologic subtype (log rank $p < 0.05$, all). After adjusting for age, race, substage, region, and histology, all patients receiving AT except for concurrent RT-CT followed by CT, had improved OS over no treatment (all $p < 0.05$). However, differences by histology were seen. For EAC the sandwich arm had the greatest reduction in death (72%), whereas for SER and CC the concurrent RT-CT arms fared best. For CS receipt of any CT improved OS, whereas above RT alone did not. (Table1). **Conclusions:** OS for advanced EC significantly differs by histology and mode of adjuvant therapy. Future studies should evaluate whether sandwich therapy for EAC, concurrent RT-CT for SER and CC, and CT alone for CS may most effectively improve OS.

Adjuvant therapy: adjusted HR for OS.

Type of AT	(%)	All histology	EAC	SER	CC	CS
None	31.3	ref	ref	ref	ref	ref
RT	26.2	0.80 (0.71, 0.91)	0.78 (0.67, 0.92)	0.96 (0.67, 1.36)	0.90 (0.45, 1.81)	0.73 (0.49, 1.09)
CT	24.8	0.60 (0.52, 0.70)	0.60 (0.48, 0.74)	0.69 (0.53, 0.90)	0.60 (0.26, 1.36)	**0.45 (0.30, 0.67)**

5589 Poster Session (Board #316), Mon, 1:15 PM-4:45 PM

Analysis of patient-reported outcomes (PROs) for GOG-258, a randomized phase III trial of cisplatin and tumor volume directed irradiation followed by carboplatin and paclitaxel (Cis-RT+CP) vs. carboplatin and paclitaxel (CP) for optimally debulked, locally advanced endometrial carcinoma: A Gynecologic Oncology Group/NRG study. *First Author: Ursula A. Matulonis, Dana-Farber Cancer Institute, Boston, MA*

Background: Protocol GOG-258 randomized Cis-RT+CP or CP for 6 cycles to patients (pts) with stage III/IVA endometrial carcinoma (Matei et al, ASCO 2017). Recurrence-free survival was the primary endpoint and was not increased by addition of RT. PRO analyses evaluated the impact of treatment (tx) on quality of life (QOL) during tx and up to 1 year. **Methods:** PROs were assessed at baseline prior to tx, 6 weeks (wks) after starting tx (corresponding to 1-wk post completion of RT (Cis-RT+CP) or prior to cycle 3 (CP)), and 18 and 70 wks after tx start. The analysis used FACT-En TOI, FACT/GOG-neuropathy (Ntx) subscale, and FACT-C items C3, C5 combined with En1, O1, O3, Cx6 in TOI of FACT-En for gastrointestinal (GI) symptoms (exploratory). **Results:** Questionnaire compliance was 95% at baseline, 90% at 6 wks, 87% at 18 wks, and 78% at 70 wks after tx start. Pts (332 on Cis-RT +CP and 349 on CP) with valid baseline and ≥ 1 follow-up PRO assessments were evaluable for analysis. After adjusting age and baseline scores, pts receiving Cis-RT+CP reported 5.2 points (97.5% CI: 2.7~7.8; adjusted $p < 0.001$) lower TOI scores on average at 18 wks (end of tx) compared to CP. The tx difference remained statistically significant at 70 wks (3.4 points lower on Cis-RT+CP group; 97.5% CI: 0.7~6.2; adjusted $p = 0.022$); none exceeded the 6 point difference pre-set as "clinically meaningful." Pts in both groups reported increased chemo-induced Ntx symptoms since tx start, but pts on CP reported 2.0 points lower (worse Ntx symptoms) (97.5% CI: 1.4~2.6; adjusted p-value < 0.001) in the Ntx subscale score at 6 wks (post 2 cycles of chemo) than those receiving RT. Pts on Cis-RT+CP reported significantly worse GI symptoms compared to CP arm pts at all assessments. **Conclusions:** The Cis-RT+CP group experienced overall worse QOL and GI toxicity; both groups reported neuropathy which did not return to baseline by 1 year. PRO differences observed with Cis-RT+CP and CP may influence choice of treatment for locally advanced endometrial cancer. Clinical trial information: NCT00942357.

5590 Poster Session (Board #317), Mon, 1:15 PM-4:45 PM

Assessment of activating estrogen receptor 1 (*ESR1*) mutations in gynecologic malignancies. *First Author: Stephanie Gaillard, Duke Cancer Institute, Durham, MD*

Background: Endocrine therapy is often considered to treat hormone-responsive gynecologic (gyn) malignancies. Mutations in *ESR1* leading to constitutive transcriptional activity have been reported in estrogen receptor positive (ER+) breast cancers and may contribute to acquired resistance to endocrine therapy. Using comprehensive genomic profiling (CGP) we assessed the frequency of *ESR1* activating genomic alterations (GA) in gyn malignancies. **Methods:** DNA from FFPE tumor tissue obtained during routine clinical care for 9645 gyn malignancies (ovary, fallopian tube, uterus, cervix, vagina, vulvar, and placenta) was analyzed for all classes of GA [base substitutions (muts), indels, rearrangements, and amplifications] in *ESR1* by hybrid capture, next generation sequencing. **Results:** 295 ESR1 GA were identified in 285 (3.0%) cases; 10 cases contained 2 ESR1 GA each. *wtESR1* amplifications were identified in 80 (0.8%) cases and *mutESR1* were present in 86 (0.9%) cases. *mutESR1* were more common in uterine compared to other cancers (2.0% vs $< 1\%$, $p < 0.001$). *mutESR1* were also enriched in carcinomas with endometrioid histology: 4.2% in uterine endometrioid vs 0.2% in uterine serous carcinomas ($p < 0.001$) and 3.5% in ovarian endometrioid compared to 0.3% in ovarian serous carcinomas ($p < 0.001$). The Y537S, D538G, L536P, and S463P mut comprised 35%, 17%, 13%, and 12%, respectively, of all *mutESR1*. Clinical data for multiple gyn malignancy patients demonstrate that *mutESR1* may be a *de novo* or acquired endocrine resistance mechanism. Low-grade serous ovarian cancer (LGSOC) samples obtained at diagnosis and after recurrence in a patient treated with letrozole demonstrated an acquired mutESR1 Y537S. Another LGSOC patient had a *mutESR1* Y537N at diagnosis and has attained prolonged clinical benefit (> 4 years) with fulvestrant. **Conclusions:** *ESR1* GA are present at a low frequency in gyn malignancies, are enriched in endometrioid histologic subtypes, and may occur either de novo or as a resistance mechanism to prior endocrine therapy. CGP identified clinically relevant *ESR1* GA that may be useful in directing therapy of gyn malignancies.

5591 Poster Session (Board #318), Mon, 1:15 PM-4:45 PM

A 12 multigene NGS panel to characterize molecular biotypes in endometrial cancer. *First Author: Ignacio Romero, Instituto Valenciano de Oncología (IVO), Valencia, Spain*

Background: The Cancer Genome Atlas (TCGA) study for endometrial carcinomas (EC) defined four prognostic molecular biotypes based on *POLE* status, Microsatellite instability (MSI) and Copy Number (CN) analysis. The aim of this study was to develop a prognostic EC molecular classifier, based on the analysis of a small multi-gene NGS panel, as a tool that supports the therapeutic decision making for EC patients. **Methods:** Serous (S) and endometrioid (E) EC (stages I, II and III from FIGO 2009) were identified from a prospective EC database of 187 patients. DNA from FFPE blocks was obtained and sequenced following the NGS TruSeq Custom Amplicon low input (Illumina) protocol interrogating a 12 multi-gene panel, including: *POLE, PTEN, TP53, ARID1A, ARID5B, FBXW7, PPP2R1A, CTCF, CTNNB1, RPL22, PIKRCA y PIK3R1*. MSI analysis was carried out using eight specific microsatellite markers. Random Forest classification algorithm (RFA) including the NGS results of the 12-gene panel, histology, stage and grade was developed from TCGA EC data. Validation was performed in our independent cohort of EC cases. **Results:** A total of 96 cases (13 S and 83 E) fulfilled histology, stage and DNA quality assessment criteria for the analysis. Most of the cases were Stage I (77); stage II and III being 2 and 17 respectively. Median age at diagnosis was 62 years (36-87) with a median follow-up of 33 months (2– 88). A RFA to classify patients in the four EC molecular biotypes was developed using a training set from TCGA EC dataset. The accuracy of this RFA (99 %) was confirmed in an independent set of the TCGA cohort, and then independently validated in our series with the following results by biotype: POLE, 17/96 (17.7 %); MSI-H, 15/96 (15.6 %); CN High (CNH), 22/96 (22.9 %); and CN Low (CNL), 42/96 (43.7 %). Progression-free and Overall survival analysis revealed that POLE and CNH biotypes constitute the best and worst prognostic groups respectively (PFS, $p = 0.038$; OS, $p = 0.029$). **Conclusions:** We have defined a prognostic model to classify EC molecular biotypes on the basis of the analysis of a 12 multi-gene NGS panel; which could be easily implemented as molecular diagnostic tool.

5592 Poster Session (Board #319), Mon, 1:15 PM-4:45 PM

Patterns of care and survival outcomes of stage IIIA endometrial cancer: An analysis of the National Cancer Database. *First Author: Sherry Yan, Department of Radiation Oncology, NYU Langone Health, New York, NY*

Background: Stage IIIA endometrial cancer with serosal or adnexal involvement has a better prognosis than other advanced uterine cancers and likely behaves differently compared to those with vaginal, parametrial or lymph node involvement. We performed a population-based analysis of Stage IIIA endometrial cancer from the National Cancer Database (NCDB) to evaluate survival outcomes by treatment regimens. **Methods:** Patients with FIGO stage IIIA endometrioid endometrial cancer treated with hysterectomy and bilateral oophorectomy and receiving adjuvant treatment between 2004 and 2014 were identified. Treatments evaluated include chemotherapy alone (CT), pelvic radiation ± brachytherapy (RT±BT), chemotherapy with brachytherapy (CT+BT), chemotherapy with pelvic radiation (CT+RT), or chemotherapy with pelvic radiation and brachytherapy (CT+RT+BT). Treatment trends over time were analyzed. Multivariate Cox proportional hazard models were developed to examine treatment outcomes. **Results:** Of 6,760 patients who met study criteria, 1842 (27.2%) received adjuvant CT; 2,732 (40.4%) received RT±BT; 702 (10.4%) received CT+BT; 871 (12.9%) received CT+RT; and 613 (9.1%) received CT+RT+BT. The practice of RT±BT declined from 56% to 16%, while CT alone rose from 18% to 36% and CT+BT rose from 4% to 14% over the study period ($p < 0.001$). Median follow-up was 69.0 months. Five-year overall survival was 83.7%, 69.7%, 73.6%, 63.6% and 78.0% for CT+BT, CT, CT+RT, RT±BT, and CT+RT+BT, respectively. Older age, black race, higher Charlson-Deyo comorbidity score, higher tumor grade, lymphovascular invasion, and having Medicare/uninsured were negative predictors of survival on multivariate analysis. CT+BT was significantly associated with improved survival over CT (HR 1.89, 95% CI 1.53-2.33; $p < 0.001$), CT+RT (HR 1.72, 95% CI 1.36-2.18; $p < 0.001$), RT±BT (HR 2.46, 95% CI 2.01-3.01; $p < 0.001$), and CT+RT+BT (HR 1.38, 95% CI 1.07-1.79; $p < 0.001$). **Conclusions:** While pattern of care shows an increase in use of adjuvant chemotherapy alone in Stage IIIA endometrial cancer, our findings demonstrate that chemotherapy should be combined with vaginal cuff brachytherapy to decrease mortality.

5593 Poster Session (Board #320), Mon, 1:15 PM-4:45 PM

Quality of life (QoL) in a phase III trial of pelvic external beam radiation therapy (PXRT) versus vaginal cuff brachytherapy followed by paclitaxel/carboplatin chemotherapy (VCB/C) in patients with high risk, early stage endometrial carcinoma: An NRG Oncology/Gynecologic Oncology Group study. *First Author: Vivian Vongruenigen, Summa Health, Akron, OH*

Background: In GOG Study 249, VCB/C was not superior to PXRT in overall survival or treatment failure rate (Randall et al, ASTRO, 2017). Here we compare QoL, fatigue, neurotoxicity, and gastrointestinal (GI) symptoms between patients randomized to VCB/C versus PXRT, and examine the association between primary comorbid illness plus obesity on QoL. **Methods:** The Functional Assessment of Cancer Therapy (FACT) – Endometrial Trial Outcome Index (FACT-En TOI) for QoL, FACIT-Fatigue subscale, FACT/GOG-Neurotoxicity subscale, and 6 items from the FACT-En for gastrointestinal (GI) symptoms were measured at baseline, 4 and 11 weeks, 8 and 14 months post-enrollment. Treatment differences were assessed with a linear mixed model adjusting for pretreatment score, assessment time, and age at enrollment. **Results:** 540 of 601 eligible patients provided evaluable patient-reported assessments. QOL was not statistically significantly different between treatment arms. However, fatigue and neurotoxicity were significantly worse in the VCB/C group compared to the PXRT group ($p < 0.001$) especially at 11 weeks. Patients in the PXRT arm, however, reported significantly ($p < 0.001$) worse GI symptoms when compared with those in VCB/C. Patients with ≥3 comorbid illnesses reported 7.1 points lower (95% CI: 12.0~-2.3; $p = 0.004$) QOL scores than those with ≤ 2 comorbid illnesses, and 6.5 points lower (95% CI: 2.8~102; $p < 0.001$) fatigue scores than those with ≤1 comorbid illness. Although obesity status was not associated with the QOL score, patients with morbid obesity (BMI≥40) reported worse fatigue (4.1 points lower; 95% CI: 0.8~7.5; $p = 0.008$) than other patients. **Conclusions:** VCB/C was associated with substantially more fatigue and neuropathy; however, PXRT resulted in more GI symptoms. Absent any survival or disease control benefit of VCB/C over PXRT, PXRT remains an effective and appropriate treatment for this patient population. In addition, patients with three or more comorbidities at study entry are likely to have worse QoL and fatigue. Clinical trial information: NCT00807768.

5594 Poster Session (Board #321), Mon, 1:15 PM-4:45 PM

Efficacy and safety of nivolumab (Nivo) in patients (pts) with advanced or recurrent uterine cervical or corpus cancers. *First Author: Kosei Hasegawa, Saitama Medical University International Medical Center, Hidaka, Japan*

Background: Recent advances in immuno-oncology provide evidence for the efficacy of PD-1/PD-L1 blockade therapy for a variety of cancers. However, the clinical activity of Nivo, an anti-PD-1 monoclonal antibody, in the treatment of advanced/recurrent uterine cervical (CVC) and corpus cancers (CC) is not yet clear. **Methods:** Phase 2, multicenter, multicohort, open-label study evaluating the efficacy and safety of Nivo in pts with advanced/recurrent CVC or CC (JapicCTI-163212). Patients received Nivo 240 mg every 2 weeks until progression or unacceptable toxicity. Primary end point was overall response rate (ORR; complete or partial response [PR]); an ORR ≥19.2% was considered efficacious. Secondary end points included progression-free survival (PFS), overall survival (OS), and safety. PD-L1 immunohistochemical staining, microsatellite instability (MSI) testing, and HPV typing (CVC only) were evaluated for biomarker analysis. **Results:** A total of 20 CVC (14 squamous, 5 adenocarcinoma [AC], 1 adenosquamous) and 23 CC (15 endometroid AC, 6 other endometrial cancer, 2 carcinosarcoma) pts were enrolled. Most pts had ≥2 prior chemotherapy regimens (CVC 13/20; CC 14/23). ORR was 25% (5/20) and 23% (5/22 evaluable), median PFS was 5.6 and 3.4 months, 6-month OS was 84% and 73%, and 12-month OS (preliminary) was 73% and 49% in CVC and CC, respectively. One pt with CVC AC had PR. Most of the pts who responded had a durable response (4/5 CVC, 5/5 CC) at data cut-off (Aug 18, 2017). Drug-related adverse events were seen in 63% (Grade 3-4, 19%) of pts. There were no drug-related deaths. In CVC, ORR was higher in pts with PD-L1^{+} tumors (33%; 5/15) than in pts with PD-L1^{-} tumors (0%; 0/5) based on a PD-L1 expression level of ≥1%; HPV status did not affect ORR (33% in both HPV^{+} [3/9] and HPV^{-} [1/3]). In CC, ORRs were similar, regardless of PD-L1 status (PD-L1^{+}, 25% [2/8] vs PD-L1^{-}, 21% [3/14]). All CC pts with MSI-High (n = 2) had PRs that were durable; no pts with CVC had MSI-High. **Conclusions:** This study demonstrates that Nivo has acceptable toxicity with evidence of clinical activity (primary end point met) in pts with CVC and CC. PD-L1 expression in CVC and MSI-High in CC may predict the clinical activity of Nivo. Clinical trial information: JapicCTI-163212.

5595 Poster Session (Board #322), Mon, 1:15 PM-4:45 PM

Immune profile and outcomes of patients (pts) with gynecological malignancies (GYN) enrolled in early phases immunotherapy (IO) trials. *First Author: Victor Rodriguez Freixinos, Vall d'Hebron University Hospital, Barcelona, Spain*

Background: Immune checkpoint inhibitors have shown promising activity in multiple tumor types. However, there are no approved IO for GYN. **Methods:** We identified GYN pts treated with IO from 2014-2017 in phase I/II trials at Vall d´Hebron. Tumor infiltrating lymphocites *(TILs)*; PD-L1 expression by immunohistochemistry (IHC) (SP263 antibody); microsatellite instability (MSI) by IHC and Gynecological Immune Prognostic Index (GIPI) (baseline derived NLR (dNLR) (neutrophils/(leucocytes-neutrophils)) > 3 and LDH > upper limit of normal) were correlated with outcomes. **Results:** Sixty GYN cases (32 ovarian (OC); 8 endometrial(EC);15 cervical(CC) and 5 vulvar (VC)) were selected. Median number of metastatic sites and prior lines were 2 (1-4) and 2 (0-8) respectively. Median TILs was 10% (1%-90%); 10% of pts had high TILs (≥ 50%) and CC showed higher TILs (p = 0.007). PD-L1 > 1% was shown in 60% of pts (46% OC, 43% CC, and 11% EC). Single agent IO involved 47% of cases. Median follow-up was 69m. Overall response rate was 15%. Median progression-free survival (PFS) and clinical benefit rate (CBR) (complete/partial response or stable disease ≥ 6 months (m)) were 2.63m [95% CI 2.07-5.13] and 32% respectively, without differences in any subgroup (4 EC pts with CBR are ongoing). Two EC pts (14%) from the population with CBR had MSI. dNLR and > 3 metastatic sites correlated with worse PFS (p = 0.035 and p < 0.0007 respectively). PD-L1 expression as continuous variable (p = 0.017) but not TILs (p = 0.37) correlated with improved outcomes. PD-L1≥20% associated with longer mPFS (NR (95% CI 5.13-NA) vs. 2.47m (95% CI 1.9-3.77); HR = 0.08, p = 0.017). "Hyperprogression" (HPD) (≥40% tumor burden increase or ≥20% plus multiple new lesions) was shown in 23% of pts without differences in any subgroup. Poor GIPI group (2 factors (+)) had a trend for worse overall survival (4.43 vs. 18.23m; HR = 2.63 (95% CI 0.9-7.5), p = 0.07). **Conclusions:** Although IO drug development is slowly evolving in GYN, we found encouraging activity in a significant proportion of GYN pts. HPD is not a rare event in GYN. Further work is needed to better characterize pts at risk of HPD and optimize immune-related biomarkers, particularly PD-L1 assessment.

5596 Poster Session (Board #323), Mon, 1:15 PM-4:45 PM

Lenvatinib + pembrolizumab in patients with advanced endometrial cancer: Updated results. *First Author: Vicky Makker, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Lenvatinib (LEN) is an inhibitor of VEGFR 1−3, FGFR 1−4, and other kinases. Pembrolizumab (PEM) is an anti-PD-1 antibody. We report updated interim results from a phase 1b/2 study evaluating LEN + PEM in patients (pts) with advanced endometrial cancer (EC) (NCT02501096). **Methods:** In this multicenter, open-label study, pts with histologically confirmed EC irrespective of microsatellite instability (MSI) or mismatch repair (MMR) status and measurable disease per immune-related RECIST (irRECIST) received LEN (20 mg PO QD) plus PEM (200 mg IV Q3W). Tumor assessments were performed by investigators using irRECIST. The primary phase 2 endpoint was objective response rate at 24 weeks (ORR_{WK24}), calculated only for evaluable pts who had 24 weeks of follow up or discontinued treatment or died prior to 24 weeks. Secondary endpoints included ORR (full analysis set), progression-free survival (PFS), and duration of response (DOR). **Results:** At data cutoff of Aug 1 2017, 54 pts were enrolled [endometrioid: Gr 1 (7), Gr 2 (12), Gr 3 (5); serous (18); others (8); unknown (4)]. Three (6%) pts were MSI-high (MSI-H); 43 (80%) were non-MSI-H/proficient MMR (MMRp); 8 (15%) were not done/unknown. Median follow-up for PFS was 4.0 months (95% confidence interval [CI], 2.7–7.6). ORR_{WK24} was 50.0% (95% CI, 32.4–67.6), and all responses were confirmed. ORR was 36.7% (95% CI, 23.4–51.7), which reflects the short follow-up time for pts with later enrollment. Median DOR has not yet been reached (not estimable [NE], 95% CI, 4.1–NE) and median PFS was 10.1 months (95% CI, 5.3–NE). Of the 3 MSI-H pts, 1 achieved partial response, 1 had stable disease, and 1 had progressive disease. For non-MSI-H/MMRp pts, ORR_{WK24} was 50.0% (95% CI, 29.9–70.1). Grade 3 treatment-related adverse events (TRAEs) occurred in 32 (59%) pts; there were no Grade 4 TRAEs. 3 (6%) pts discontinued treatment due to a TRAE. The most common TRAEs were hypertension (59%), fatigue (50%), diarrhea (44%), hypothyroidism (35%), and stomatitis (33%). **Conclusions:** Combination LEN + PEM demonstrated encouraging activity in advanced EC regardless of MSI/MMR status, with no new safety signals identified. A randomized, international, 2-arm, phase 3 study in recurrent EC is planned. Clinical trial information: NCT02501096.

5597 Poster Session (Board #324), Mon, 1:15 PM-4:45 PM

Biomarker results and preclinical rationale for combination lenvatinib and pembrolizumab in advanced endometrial carcinoma. *First Author: Vicky Makker, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Lenvatinib (LEN) is a multikinase inhibitor of VEGFR 1−3, FGFR 1−4, and other targets; pembrolizumab (PEM) is an anti–PD-1 antibody. We report biomarker analyses from a phase 1b/2 trial in advanced endometrial cancer (EC) and preclinical rationale for the activity of combination LEN + PEM. **Methods:** In an exploratory analysis, 41 candidate serum biomarkers for LEN and PEM were assessed using immunoassay panels in 38 patients with EC receiving LEN + PEM at baseline, cycle 1 day 15 (C1D15), and C2D1. Data cutoff: May 31, 2017. Tumor-associated macrophages (TAM) were assessed in mouse syngeneic tumor models by flow cytometry and immunohistochemistry. RNAseq transcriptomes of tumors from mice treated with LEN, anti–PD-1, or LEN + anti–PD-1 were subjected to weighted gene coexpression network analysis for pathway enrichment analyses. **Results:** At C1D15 and C2D1 of LEN + PEM, significant changes were seen in the levels of 16 and 18 of 41 biomarkers, respectively, including increased levels of interferon (IFN)-γ and IFN-γ–regulated chemokines (CXCL9, CXCL10, CXCL11; all $P < 0.05$). Of these, significant associations were found between increases in CXCL9 and CXCL10 levels and patients with compete, partial, or unconfirmed partial responses (all $P < 0.05$). Preclinical model experiments *in vivo* showed that LEN alone significantly depleted the TAM population in excised tumors ($P < 0.01$). Transcriptome analyses of tumors from mice treated with LEN + anti–PD-1 showed that genes specifically regulated by the combination were significantly enriched for genes involved in signaling pathways associated with immune modulation, including IFN signaling (FDR P as low as 1.50×10^{-9}). **Conclusions:** In patients with advanced EC, LEN + PEM was associated with changes in several biomarkers, including IFN-γ–regulated chemokines, some of which may be associated with clinical response. *In vivo* preclinical experiments suggest that LEN monotherapy may modulate tumor microenvironment by decreasing the local TAM population, whereas LEN + anti–PD-1 may act via a mechanism that includes the IFN signaling pathway. Overall, these findings provide preclinical rationale for the activity of combination LEN + PEM. Clinical trial information: NCT02501096.

5598 Poster Session (Board #325), Mon, 1:15 PM-4:45 PM

Preoperative olaparib in early-stage endometrial cancer (EC): A phase 0, window of opportunity trial to evaluate the PARP inhibition effect, targeting cell cycle-related proteins (POLEN study). *First Author: Ignacio Romero, Instituto Valenciano de Oncología (IVO), Valencia, Spain*

Background: Olaparib (AZD2281, KU-0059436) is a poly ADP ribose polymerase (PARP) inhibitor. Biomarkers that predict a response to olaparib in EC are not fully established. The aim of this study is to identify pharmacodynamic and pharmacogenetic biomarkers associated with a short term exposure to olaparib in type I primary EC surgical patients (pts). **Methods:** In this phase 0, multicenter, single arm, window of opportunity trial, women diagnosed with type I primary EC received olaparib tablets (oral 300mg/BID; 4 weeks) before surgery. Biological effects were evaluated by comparing the initial biopsy and the tumor tissue at surgery. The primary endpoints were the significant inhibition of cyclin D1, Ki67 and active caspase 3 activity. Secondary objectives included the correlation between PARP inhibition and cell proliferation, angiogenesis and tumor-tissue biomarkers. The predictive role of PTEN, PMS2 and MSH6 mutations were evaluated. We control multiple testing issues with a false discovery rate (FDR) of 10%. **Results:** From March 2016, 41 pts have been screened, 36 included, 23 treated and 19 could be studied in biomarker analysis. Median age was 63y (51-82); 100% were endometrioid and clinical stage was I (17, 89.5%) and stages II, III and IV (2, 10.5%). Median time of olaparib exposure was 21 days (13-32). Significant inhibition was declared for cyclin D1 ($p = 0.01$), but not for Ki67 and active caspase 3 immunostaining. Differences in PARP1 baseline and post-treatment immunostaining correlates (Rho > 0.45; $p < 0.05$) with differences in pre-post cyclin D1, Ki67, phosphohistone H3, p50, VEGF and HIF1α measures. However, only cyclin D1 (Rho = 0.771, $p < 0.001$) showed a significant correlation under FDR criterion. Genetic alterations did not show differences in pre-post treatment measures. The most common AEs were nauseas (31.6%), vomiting (21.1%) and fatigue (21.1%) grade 1 and 2. No surgery was delayed due to toxicity. **Conclusions:** The study has identified some potential biomarkers associated with olaparib exposure in cell proliferation/apoptosis pathways that might help select best candidates. Clinical trial information: NCT02506816.

5599 Poster Session (Board #326), Mon, 1:15 PM-4:45 PM

Variability in Medicare utilization and payment among gynecologic oncologists. *First Author: Stephanie Lim, Duke University School of Medicine, Durham, NC*

Background: The Medicare Provider Utilization and Payment Data: Physician and Other Supplier Public Use File (POSPUF) for 2015 is a publicly available file from the CMS that includes all direct payments to providers who care for fee-for-service Medicare recipients. The objective of this study was to analyze variability in gynecologic oncologists' Medicare utilization and reimbursements, with attention to differences based on provider gender and time spent in practice. **Methods:** The POSPUF 2015 was analyzed with respect to Gynecologic Oncology specialty providers. We used publicly available data to confirm gynecologic oncology subspecialty and to determine each provider's total number of years in gynecologic oncology practice. Evaluation, management, and procedure/surgery codes were analyzed; drug delivery codes were excluded due to variability in billing these by facility/hospital. **Results:** The POSPUF file included 824 gynecologic oncologist providers receiving a total of $28,772,739 in payments. The majority of providers practiced in large metropolitan areas (66%) or mid-sized metro areas (27%). While females composed 38.5% of gynecologic oncologists, they accounted for only 28.1% of Medicare reimbursements. The median Medicare reimbursement to a Gynecologic Oncologist was $24,828 (IQR $11,564, $45,412), but this was significantly different by gender; female $19,394 (IQR $10,913, $34,894) compared to male $29,395 (IQR $13,903, $52,941). Overall, female providers receive 30.4% of evaluation and management reimbursements and 22.5% of surgical reimbursements. During the first ten years in practice, women composed 47.0% of providers and accounted for 52.3% of the services reimbursed, compared to 36.25% of providers/26.6% of the reimbursed services (11-20 years in practice), and 18.11% of providers/16.4% of services ($>$ 20 years in practice). **Conclusions:** While male gynecologic oncologists receive higher median reimbursements than females, there is a trend toward equal services and reimbursements between genders among younger providers, suggesting a trend toward gender equity over time.

TPS5600 Poster Session (Board #327a), Mon, 1:15 PM-4:45 PM

GOG 3016/ENGOT-cx9: An open-label, multi-national, randomized, phase 3 trial of cemiplimab, an anti-PD-1, versus investigator's choice (IC) chemotherapy in ≥2 line recurrent or metastatic cervical cancer. *First Author: Krishnansu Sujata Tewari, The Division of Gynecologic Oncology at the University of California, Irvine, Orange, CA*

Background: Patients with recurrent and metastatic cervical carcinoma experience modest survival benefit with first-line platinum-based chemotherapy with or without bevacizumab. Those with platinum-refractory disease have a median survival of only 7 months. Cemiplimab, a human monoclonal anti-PD-1, has exhibited antitumor activity and an acceptable safety profile in a phase 1 trial of solid tumors including recurrent cervical cancer. **Methods:** GOG 3016/ENGOT-cx9 is an open-label, randomized (1:1), phase 3 trial of cemiplimab versus IC chemotherapy in women ≥18 years with platinum-refractory recurrent and/or metastatic cervical cancer that has progressed within 6 months of the last dose of platinum-containing chemotherapy (NCT03257267). Patients will be stratified for the primary efficacy analysis by histology and geographic region. Patients will receive cemiplimab every 3 weeks (Q3W) or IC chemotherapy, ie, pemetrexed 500 mg/m^2 Q3W; topotecan 1 mg/m^2 daily x5 days, every 21 days; irinotecan 100 mg/m^2 days 1, 8, 15, and 22, followed by 2 weeks rest, for a 42-day (6-week cycle); gemcitabine 1000 mg/m^2 days 1 and 8, every 21 days; or vinorelbine 30 mg/m^2 days 1 and 8, every 21 days. Treatments will be given IV for up to 96 weeks. The primary objective is overall survival (OS). Key secondary objectives include the assessment of overall response, progression-free survival, and the frequency and severity of adverse events. Stratification factors include prior bevacizumab, histology, and ECOG status. Assuming duration of study enrollment and follow-up of 20 months and 12 months, respectively, we calculated we would need to enroll approximately 436 patients, with 330 deaths expected, to provide the study with 90% power to detect a reduction in the risk of death of at least 20% with cemiplimab, with the 1-sided type 1 error rate limited to 2.5%. An independent data monitoring committee (IDMC) will monitor the data during the study conduct. Clinical trial information: NCT03257267.

TPS5601 Poster Session (Board #327b), Mon, 1:15 PM-4:45 PM

A single arm, phase 2, multicenter, international trial of tisotumab vedotin (HuMax-TF-ADC) in previously treated, recurrent or metastatic cervical cancer. *First Author: Robert L. Coleman, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Cervical cancer treatment options are limited for patients with recurrent and/or metastatic cervical cancer. Tisotumab vedotin (TV) is an antibody-drug conjugate (ADC) composed of a human antibody targeted to tissue factor (TF), a protease-cleavable linker and the potent microtubule-disrupting agent monomethyl auristatin E (MMAE). The phase 1/2 GEN701 trial (NCT02001623) initially enrolled 34 patients with recurrent or metastatic cervical cancer in the cervical expansion cohort. Treatment with intravenous TV at 2 mg/kg every 3 weeks resulted in an overall response rate of 32% (confirmed and unconfirmed responses) by investigator review per RECIST v1.1 as a part of preliminary analysis. Furthermore, TV was safe and tolerable with a safety profile generally consistent with other MMAE-based ADCs **Methods:** This is an international, multicenter, open-label, non-randomized phase 2 trial evaluating efficacy of TV in approximately 100 patients with recurrent and/or metastatic cervical cancer who have progressed on a standard 1st line therapy and who have not received more than 2 prior systemic treatment regimens for recurrent or metastatic disease. Response will be assessed every 6 weeks for the first 30 weeks, and then every 12 weeks thereafter. The primary objective is to assess the confirmed objective response rate (ORR) by an independent review committee (IRC) using RECIST v1.1. Secondary efficacy endpoints include: duration of response (DOR), ORR by investigator review, time to response (TTR), progression free survival (PFS), overall survival (OS), and safety and tolerability. For the ORR analyses, a 2-sided 95% exact confidence interval will be calculated using the Clopper-Pearson method. PFA and OS will be analyzed using the Kaplan-Meier method. Adverse events (AEs) will be monitored and graded using CTCAE v5.0.

TPS5602 Poster Session (Board #328a), Mon, 1:15 PM-4:45 PM

SENTICOL III: International validation study of sentinel node biopsy in early cervical cancer: A GINECO, ENGOT and GCIG study. *First Author: Fabrice Lecuru, GINECO, Paris, France*

Background: Sentinel node biopsy (SLN) is an alternative to pelvic lymphadenectomy (PLN). The false negative rate is < 1%) when "MSKCC Algorithm" is fulfilled. The technique can detect isolated tumor cells (ITC) or micrometastases in 15 – 20 % of N0 patients, reveal SLN in unexpected areas in up 30% of cases and reduce short term lymphatic morbidity. However, the long-term prognosis of SLN negative patients is unknown. In 2014, the GCIG brainstorming on cervical cancer pointed out the need for a validation study, taking survival into account, giving birth to SENTICOL III. **Methods:** SENTICOL III is an international prospective multicenter randomized trial. We use a « co-primary » objective regarding Disease Free Survival (DFS) and Health Related Quality of Life. The hypothesis is that SLN biopsy alone provides similar DFS and better quality of life. Secondary objectives are outcome of patients with ITC and micrometastases, evaluation of mapping with indocyanine green (ICG), overall survival, recurrence free survival. A cost analysis will be undertaken and a tumor tissue bank will be established. Patients with an early stage cervical cancer defined as FIGO stage Ia1 with lymphovascular invasion to IIa1, maximum diameter ≤40mm on MRI and node negative on imaging will be eligible to participate. SLN biopsy will be performed using isotopic detection +/- blue dye or ICG. SLN of patients with an "optimal" mapping will be analyzed by frozen section. SLN negative patients will be randomized intraoperatively 1:1 to SLN only or SLN + PLN. All SLN will be submitted to ultrastaging (200 microns levels). All centers will follow a quality assurance program to ensure surgical competency and a standardized pathological evaluation 900 patients will be recruited in 3 years, with 4 years of follow-up. (3 years-disease free survival of 85%, with a non-inferiority margin of 5% (80 vs 85%, HR = 1.373), a unilateral alpha error of 5%, and a power of 80%) The trial has started in France, and an international collaboration has been developed through GCIG and ENGOT. (NCT03386734). CHU Besançon is the sponsor for France Clinical trial information: ID-RCB : 2017-A00945-48.

TPS5603 Poster Session (Board #328b), Mon, 1:15 PM-4:45 PM

A randomized phase II/III trial of conventional paclitaxel and carboplatin (cTC) versus dose-dense paclitaxel and carboplatin (ddTC), with or without bevacizumab (Bmab), for stage IVb, recurrent, or persistent cervical cancer (CC): Japan Clinical Oncology Group study (JCOG1311). *First Author: Ryo Kitagawa, Department of Gynecology and Obstetrics, Tohoku Medical and Pharmaceutical University, Miyagi, Japan*

Background: Patients with metastatic or recurrent CC who are not amenable to curative treatment with surgery or radiation have a poor prognosis, and systemic chemotherapy is regarded as a standard treatment. Based on the JCOG0505, we considered tri-weekly cTC as the standard regimen. We subsequently focused on dose-dense, weekly administered paclitaxel, which was more effective than conventional administration for breast cancer and, in Japan, ovarian cancer. The efficacy and safety of ddTC have not been evaluated for CC. Therefore, we designed JCOG1311 to confirm the superiority of ddTC to cTC in metastatic or recurrent CC. However, Bmab was approved in Japan for treatment of metastatic or recurrent CC on May 2016. We amended the protocol to add the criteria by which patients would receive Bmab. **Methods:** Major eligibility criteria are stage IVB, persistent, or recurrent CC patients including SCC or adenocarcinoma histology. We enroll patients according to institution, PS, and platinum-free interval as adjustment factors, whether they receive carboplatin (AUC of 5) on day 1 plus either paclitaxel (175 mg/m^2) on day 1 (cTC), or paclitaxel (80 mg/m^2) on day 1, 8, 15 (ddTC). Both treatments are repeated every 3 weeks. They can receive Bmab (15 mg/kg) every 3 weeks if not contraindicated. 14 of planned 56 with measurable lesion receiving Bmab in phase II part, of which the primary endpoint is response rate (RR), have been enrolled until January 2018. If the RR of ddTC + Bmab arm is greater than that of cTC + Bmab arm plus 5%, the study will proceed to phase III part, which has OS as the primary endpoint. We hypothesize that the 2-year OS of ddTC arm will be greater than that of the cTC arm (i.e., ≥ 45% compared to 35%). According to the Schoenfeld and Richter method, the required sample size is total 420 patients, with one-sided α of 0.05 and β of 0.20 during 3.5 years of accrual and 2 years of follow-up. This trial is supported by the Japan Agency for Medical Research and Development. And, this trial was registered at the UMIN Clinical Trials Registry as UMIN000019191. Clinical trial information: 000019191.

TPS5604 Poster Session (Board #329a), Mon, 1:15 PM-4:45 PM

A phase 2, multicenter study to evaluate the efficacy and safety using autologous tumor infiltrating lymphocytes (LN-145) in patients with recurrent, metastatic, or persistent cervical carcinoma. *First Author: Amir A. Jazaeri, University of Virginia, Charlottesville, VA*

Background: Adoptive cell therapy (ACT) with tumor-infiltrating lymphocytes (TIL) has demonstrated efficacy in the treatment of immunogenic tumors with high mutation loads, such as melanoma, and virally-associated tumors, such as HPV-mediated cervical cancer. As outcomes for patients with recurrent, metastatic or persistent cervical cancer remain extremely poor, there is an enormous need for the development of novel immunotherapeutic approaches with curative potential such as ACT with TIL. **Methods:** Clinical trial C-145-04 (NCT03108495) is a prospective, phase 2 multicenter, open-label study evaluating the efficacy of a single autologous TIL infusion (LN-145) followed by IL-2 after a non-myeloablative lymphodepletion (NMA-LD) regimen in patients with recurrent, metastatic, or persistent cervical cancer who have failed at least one prior systemic therapy. Patients undergo surgical resection of a tumor from which TIL are extracted and expanded at a central GMP manufacturing facility that prepares a cryo-preserved TIL (LN-145) product for infusion. One week prior to LN-145 infusion, patients undergo NMA-LD consisting of cyclophosphamide (60 mg/kg) daily x 2 days followed by fludarabine (25 mg/m^2) daily x 5 days. LN-145 is infused 24 hours after NMA-LD and followed by up to 6 doses of IL-2 (600,000 IU/kg) every 8-12 hours. The primary endpoint is the objective response rate (ORR) per RECIST v1.1. Secondary endpoints include safety and efficacy parameters such as complete response, duration of response, disease control rate, progression free- and overall survival. In addition to the tumor resected, patients must have an additional measurable lesion for response assessment. Other major eligibility criteria include adequate bone marrow, liver, pulmonary, cardiac and renal function; ECOG performance status of 0 or 1. Clinical trial information: NCT03108495.

TPS5605 Poster Session (Board #329b), Mon, 1:15 PM-4:45 PM

EDMONd: A feasibility study of elemental diet as an alternative to parenteral nutrition for ovarian cancer patients with inoperable malignant bowel obstruction. *First Author: Agnieszka Michael, University of Surrey, Guildford, United Kingdom*

Background: Inoperable bowel obstruction (IBO) occurs in up to 50% of patients diagnosed with ovarian cancer. Nutrition support for patients with IBO is challenging. Parenteral feeding (PN) is the recommended route for patients with a prognosis of > 2 months, however there is little evidence that it improves quality of life and the cost of it is very high . If PN is not available patients are frequently discharged home from hospital with sips of clear fluids only. Management of inoperable bowel obstruction remains a major challenge and clear guidelines are needed. Elemental diet (ED) is a liquid diet that contains proteins in the form of amino acids, fats in the form of medium chain triglycerides, vitamins and trace minerals. EDs are almost completely absorbed in the upper small intestine **Methods:** The primary objective of the study is to establish if ED can be used as an alternative to home PN in patients with IBO by providing a 'proof of concept' of ED as an acceptable and useful feeding option. The secondary aim is to examine the impact of ED on quality of life. The primary endpoints of the study are taste acceptability (graded 1-5 on a purposely designed Elemental Diet data collection chart), incidence of vomiting and incidence of pain. The secondary endpoints include the number of women who can tolerate ED and can subsequently be treated with palliative chemotherapy (as per standard of care), the number of patients alive at the end of the study, quality of life and nutritional intake. This is a mixed-method single arm feasibility study of 34 patients diagnosed with IBO and who can tolerate 500ml of liquid. Patients are provided with ED and followed-up for 2 weeks. Patients' symptoms and quality of life are assessed using the Memorial Symptoms Assessment Scale (MSAS) and EORTC Quality of Life QLQ-C30 questionnaire. As this is a feasibility study to evaluate whether ED is an acceptable intervention for patients with IBO, recruiting 25 patients into the study will provide an answer to the question. As the prognosis is poor in this cohort we assumed 25% attrition rate 8 out of 34 patients have been recruited and the recruitment continues. Clinical trial information: ISRCTN16862540.

TPS5606 Poster Session (Board #330a), Mon, 1:15 PM-4:45 PM

OVARIO: The phase 2, single-arm, open-label study of maintenance therapy with niraparib + bevacizumab in patients with advanced ovarian cancer following response on frontline platinum-based chemotherapy. *First Author: Joanie M. Hope, Alaska Women's Cancer Care, Anchorage, AK*

Background: Niraparib (Zejula) a selective poly(ADP-ribose) polymerase (PARP) 1/2 inhibitor, significantly improved progression-free survival (PFS) as a single agent for patients with recurrent ovarian cancer (OC) relative to placebo in the ENGOT-OV16/NOVA trial, regardless of *BRCA* or HRD status. The ongoing AVANOVA trial (NCT02354131) has shown that niraparib can be safely combined with bevacizumab (bev). This combination is being explored in AVANOVA, as a strategy to increase tumor sensitivity to PARP inhibition. As an anti-angiogenic agent, bev can induce tumor hypoxia, leading to downregulation of *BRCA* and *RAD51,* which could sensitize tumors to PARP inhibition, and lead to apoptosis via contextual synthetic lethality. While *BRCA* and HRD status was insufficient to predict responders to niraparib in NOVA, a longer median PFS was observed for the cohorts with these biomarkers. In the phase 2 OVARIO study (NCT03326193), niraparib plus bev will be evaluated as a maintenance treatment in patients with advanced OC who have recovered from primary debulking surgery and have responded to frontline platinum-based chemotherapy with bev. **Methods:** Target enrollment is 90 patients, regardless of *BRCA or* HRD status, with stage 3b and 4 epithelial ovarian, fallopian tube, or peritoneal cancer. Patients must achieve complete response, partial response or no evidence of disease after the frontline platinum-based chemotherapy. The primary objective for OVARIO will be PFS at 18 months landmark. Secondary objectives include evaluation of PFS, overall survival, time to first subsequent therapy, and safety and tolerability. Exploratory objectives will be PFS at 6 and 12 months and patient-reported outcomes. The starting dose of niraparib will be based on the patient's baseline body weight and/or platelet count. Patients weighing $\geq$77 kg with a platelet count of $\geq$150,000/μL will receive 300 mg qd. Patients weighing $<$ 77 kg or with a platelet count of $<$ 150,000/μL will receive 200 mg qd. The bev dose will be 15 mg/kg q3w up to 15 months. Patients will be treated continuously until disease progression or unacceptable toxicity. Clinical trial information: NCT03326193.

TPS5607 Poster Session (Board #330b), Mon, 1:15 PM-4:45 PM

ATALANTE (ENGOT-ov29): A randomized, double-blinded, phase III study of atezolizumab versus placebo in patients with late relapse of epithelial ovarian, fallopian tube, or peritoneal cancer treated by platinum-based chemotherapy and bevacizumab. *First Author: Jean Emmanuel Kurtz, GINECO, Strasbourg, France*

Background: The immunosuppressive environment is increased in Ovarian Cancer (OC) by the expression of T cell inhibitory receptors on tumor cells and immune cells. Targeting PD-1/PD-L1 pathway (an inhibitory immune pathway exploited by cancer) may restore CD8+ anticancer response from exhausted Tumor Infiltrating Lymphocytes (TILs). Bevacizumab (bev) is an anti-VEGF monoclonal antibody approved in the EU in first line or relapse for the treatment of advanced OC in combination with platinum-based chemotherapy (Cx) and in maintenance. VEGF has immunosuppressive properties, decreasing tumor access by TILs, increasing both PD-L1 expression on tumor cells and Treg activity. Hence there is evidence that anti-VEGF therapy and immunotherapy act synergistically. **Methods:** ATALANTE is a randomized (2:1), double blinded, phase III trial evaluating the efficacy and safety of adding the anti-PD-L1 monoclonal antibody atezolizumab (At) to Cx and bev in 405 OC patients (pts) in platinum-sensitive relapse. Main eligibility criteria include: ECOG $\leq$1, first or second platinum-sensitive relapse ($>$6 months), ECOG 0 or 1, normal organ function, absence of auto-immune disease or of chronic corticosteroid therapy. All patients must have a tumor biopsy at study entry for PD-L1 testing (stratification factor). Pts are treated with 6 cycles of platinum-based Cx (q3 or q4 weeks) plus bev + At (1200mg q3 weeks)/placebo followed by bev (15 mg/kg q3 weeks) plus At/placebo maintenance until progression or prohibitive toxicity. The primary endpoint is PFS based on RECIST v1.1 according to investigator assessment. The final PFS analysis will be performed when the number of predefined events is reached. The latest review by the Independent Data Monitoring Committee in July 2017 did not identify any safety issue and suggested that the trial can continue as planned. The study is currently recruiting internationally. Clinical trial information: NCT02891824.

TPS5608 Poster Session (Board #331a), Mon, 1:15 PM-4:45 PM

An open-label phase 1 trial of the safety and efficacy of daily subcutaneous SPL-108 injections when used in combination with paclitaxel in patients with platinum-resistant, CD44+, advanced ovarian epithelial cancer. *First Author: Eugenia Girda, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ*

Background: Ovarian cancer often presents in advanced stages and is treated with platinum-based chemotherapy. However, many patients develop platinum-resistant disease with either failing to achieve clinical response or progressing within 6 months after completion of treatment. Our laboratory has shown that CD44 contributes to the development of chemotherapeutic resistance, through MDR1-dependent/P-glycoprotein mediated efflux of chemotherapeutic agents. Targeting CD44 or related signaling pathways inhibits tumor growth and relapse, and increases sensitivity to cytotoxic agents. SPL-108 is an 8-amino-acid peptide derived from single chain urokinase plasminogen activator that binds to CD44. In vitro and in vivo experiments showed that SPL-108 has therapeutic activity in models of ovarian and other cancers. Phase I trials with SPL-108 in healthy volunteers demonstrated no systemic adverse events; phase Ib trials in women with gynecologic cancers showed self-limited, mild or moderate adverse events with several subjects showing stable disease. Phase II trials in ovarian cancer patients showed improved time to disease progression with no grade 4 toxicity, 6.5% had grade 3 all of which were constitutional. In the current trial, SPL-108 would be used in combination with paclitaxel in an attempt to reverse efflux-mediated resistance to chemotherapy. Due to positive safety profile of SPL-108, the goal is to achieve improved efficacy without enhanced toxicity. **Methods:** Open-label 2-arm phase I trial. Arm I includes 6-12 patients, with a 3+3 design with 2 cohorts. Cohort 1 will receive daily 150-mg SPL-108 SQ, cohort 2 will receive twice-daily 150-mg SPL108; both cohorts will have concurrent administration of weekly paclitaxel of 80 mg/m2, on Days 1,8,15 of a 28 day cycle. Safety will be assessed and subjects without dose-limited toxicity continue 6 cycles, unless disease progression or unacceptable toxicity occurs. Arm II is the Exploratory Expansion Phase: 12 subjects receive SPL-108 daily dose determined in the Arm I Safety phase with concurrent 80 mg/m2 paclitaxel. Clinical trial information: NCT03078400.

TPS5609 Poster Session (Board #331b), Mon, 1:15 PM-4:45 PM

Clinical trial in progress: A study of VB-111 combined with paclitaxel vs. paclitaxel for treatment of recurrent platinum-resistant ovarian cancer (OVAL, VB-111-701/GOG-3018). *First Author: Richard T. Penson, Harvard Medical School, Boston, MA*

Background: Ofranergene obadenovec (VB-111) is a targeted anti-cancer gene therapy with a dual mechanism: an antiangiogenic broad effect and induction of a tumor directed viral immune response. Over 400 cancer patients have been treated with VB-111, with evidence of anti-tumor activity across three phase 2 studies and a favorable safety profile. A phase 2 trial in patients with platinum resistant ovarian cancer treated with VB-111 in combination with weekly paclitaxel was conducted. In a population with 50% platinum refractoriness and 52% prior antiangiogenics, CA-125 response was observed in 60% of patients with a dose response pattern and a significant increase in overall survival (OS) at therapeutic vs. low dose level (median 810 vs. 172 days, p = 0.042) as well as evidence of an immunotherapeutic effect. Based on these observations, a phase 3 study of VB-111 in combination with weekly paclitaxel in patients with recurrent platinum-resistant ovarian cancer was initiated (NCT03398655) in collaboration with The GOG Foundation, Inc. **Methods:** This is a multicenter, randomized, double-blind, placebo-controlled, phase 3 study of patients with platinum-resistant ovarian cancer, a deadly indication with significant unmet need. Patients with recurrent epithelial ovarian cancer, who have platinum-resistant and measurable disease (RECIST 1.1) previously treated with no more than 5 treatment lines are randomized 1:1 to receive VB-111 ($1x10^{13}$ VPs) combined with paclitaxel (80mg/m^2) or placebo combined with paclitaxel (80mg/m^2). Randomization is stratified by number of prior treatment lines and prior antiangiogenic therapy. Treatment beyond RECIST progression is allowed in the absence of significant deterioration. The primary endpoint is OS; secondary endpoints include objective response rate, progression free survival (both by RECIST 1.1), combined CA-125 and RECIST 1.1 response, and CA-125 response (GCIG). The sample size calculation of 350 patients (event driven) provides 88% power to detect a difference in survival at the two-sided 5% significance level using the logrank test. To date, 2 patients have been randomized. Clinical trial information: NCT03398655.

TPS5610 Poster Session (Board #332a), Mon, 1:15 PM-4:45 PM

A multicentric single-arm phase II clinical trial to evaluate safety and efficacy of the combination of olaparib and PLD for platinum resistant ovarian primary peritoneal carcinoma and fallopian tube cancer patients: The GEICO-1601 ROLANDO trial—A trial in resistant ovarian cancer with olaparib and pegylated liposomal doxorubicin. *First Author: Jose Alejandro Perez-Fidalgo, Hospital Clínico Universitario de Valencia; INCLIVA; Centro de Investigación Biomédica en Red de Oncología; CIBERONC-ISCIII; GEICAM Spanish Breast Cancer Group, Valencia, Spain*

Background: Olaparib is a PARP-inhibitor that has demonstrated efficacy in ovarian cancer in both platinum-sensitive and platinum-resistant relapse. *BRCA* mutations have been identified as an important predictive factor for response to olaparib, however in Study 19 progression free survival (PFS) was also improved in BRCA wildtype (*BRCA*wt) patients (1). A preclinical study showed synergism between doxorubicin and olaparib in 2D and 3D models of ovarian cancer (2). The combination of pegylated liposomal doxorubicin (PLD) 40 mg/m2 and olaparib 400 mg bid (capsule formulation) was considered tolerated and suitable in a phase I trial (3). **Methods:** This is a multicenter single arm phase II trial in women with platinum-resistant relapsed ovarian cancer. Patients receive Pegilated liposomal doxorubicin (PLD) 40 mg/m2 every 28 days and olaparib 300 mg bid tablets for 6 cycles followed by olaparib 300 mg bid maintenance until toxicity or disease progression. Primary endpoint is progression-free survival at 6 months (PFS6m). Secondary endpoints are PFS, overall-survival, response rate, quality of life, and growth modulation index. Key inclusion criteria are: 1) Serous or endometrioid ovarian cancer 2) Platinum-resistant relapse (between 28 days and 6 months after last platinum-containing chemotherapy (CT)) 3) Previous PLD is allowed if administered as part of a platinum-sensitive recurrence and $>$ 6 months before inclusion 4) *BRCA* mutant patients are eligible after only 1 previous CT line, 5) *BRCA*wt or unknown are eligible after at least 2 previous platinum sensitive lines 6) no more than 3 CT lines are allowed, 7) Hemoglobin $>$ 10 g/dl and 8) left ventricle ejection fraction $>$ 50%. Sample size calculation assumed that PFS6m 40% or higher would be of interest for further investigation; with 90% power and a 2-sided alpha error 0.05 the number of patients needed will be 32 patients. Enrolment was initiated in December 2017 and the first patient has been enrolled. Clinical trial information: NCT03161132.

TPS5611 Poster Session (Board #332b), Mon, 1:15 PM-4:45 PM

A phase Ib trial of pembrolizumab (Pembro) following adoptive cell therapy (ACT) in patients with platinum-resistant ovarian cancer; The ACTIVATE (Adoptive Cell Therapy InVigorated to Augment Tumor Eradication) trial. *First Author: Josee-Lyne Ethier, Cancer Centre of Southeastern Ontario, Kingston, ON, Canada*

Background: ACT is based on the in vitro expansion of T cells with anti-tumor activity, followed by transfer of large numbers of T cells back to the patient. T cells for ACT can be obtained from tumor-infiltrating lymphocytes (TILs), which represent a source of tumor-specific T cells. Evidence supports that epithelial ovarian carcinoma (OC) is immunogenic and has the potential to respond to immunotherapy. Pembro, a PD-1 monoclonal antibody, was shown to have activity in metastatic ovarian cancer with a response rate of 11.5% (Varga, ASCO 2015;33:5510). There is limited data regarding the efficacy of combining ACT with PD-1/PD-L1 inhibitors. However, ACT may synergize with checkpoint inhibitors to overcome immunosuppression within the tumor microenvironment, and dramatic clinical responses have been observed anecdotally. Based on these observations, a Phase 1b study of ACT followed by Pembro in advanced OC was initiated. **Methods:** This is a single-centre, non-randomized trial of Pembro following ACT using TILs in platinum-resistant OC. Key inclusion criteria include progression within 6 months of last platinum dose and tumor suitable for harvest. Patients undergo preparative lymphodepleting chemotherapy, followed by a single TIL infusion. Therapy with Pembro 200 mg q3 weeks is initiated once toxicities grade 2 or higher have resolved. The primary objective is safety, and the regimen will be deemed feasible if at least 80% of enrolled patients receive ACT with TILs and $\geq$2 doses of Pembro without unacceptable toxicity. Secondary objectives include evaluation of response rate, overall and progression free survival. The study will enroll 12 patients to determine whether the proportion of patients in whom the treatment regimen is tolerable, P, is less than or equal to 0.50 or is greater than or equal to 0.80. If the number of patients for whom treatment is feasible is 8 or more, the hypothesis that P $\leq$ 0.50 is rejected with a target error rate of 0.20. Enrollment is currently ongoing, with TIL preparation underway for 10 patients and plan to initiate treatment in 3 of these over the next 3 months. Clinical trial information: NCT03158935.

TPS5612 Poster Session (Board #333a), Mon, 1:15 PM-4:45 PM

PRO-105, a phase II open-label study of NUC-1031 in patients with platinum-resistant ovarian cancer. *First Author: Charlie Gourley, University of Edinburgh Cancer Research UK Centre, MRC IGMM, Edinburgh, United Kingdom*

Background: Patients with platinum-resistant ovarian cancer, following $\geq$3 lines of chemotherapy have limited treatment options. NUC-1031, a phosphoramidate transformation of gemcitabine, is designed to overcome the three key resistance mechanisms associated with gemcitabine: transport, activation and breakdown. By overcoming these resistance mechanisms, NUC-1031 achieves $>$ 200-times higher intracellular concentrations of the active anti-cancer metabolite, dFdCTP, compared to gemcitabine. NUC-1031 was well tolerated and demonstrated anti-tumor activity in ovarian cancer patients (Blagden *et al,* ASCO 2015; Blagden *et al,* ESMO 2017). Based on these data, a Phase II dose-confirming study was initiated to investigate NUC-1031 in patients with platinum-resistant ovarian cancer. **Methods:** PRO-105 is a randomized open-label, two-part clinical study designed to determine the optimal dose of NUC-1031 in patients with platinum-resistant ovarian cancer who have received $\geq$3 lines of chemotherapy. The primary endpoint is Objective Response Rate at the selected dose level (500 mg/m^2 or 750 mg/m^2), assessed by a blinded independent central reviewer. Secondary endpoints include duration of response, progression-free survival, overall survival, PK/PD and patient-reported outcomes. In Part I, up to 40 patients will be randomized to NUC-1031 at 500 mg/m^2 or 750 mg/m^2 on days 1, 8 and 15 of a 28-day cycle. Randomization is stratified for BRCA 1/2 mutation status and number of prior chemotherapy lines. One dose level will be selected for further evaluation in Part II based on safety, PK, dosing intensity and clinical activity. Enrollment will continue in Part II until 44 response evaluable patients are recruited at the selected dose. To date, 22 patients with platinum-resistant ovarian cancer have been randomized into Part I of the study, which is currently recruiting across 15 US and 8 UK sites. Clinical trial information: NCT03146663.

TPS5613 Poster Session (Board #333b), Mon, 1:15 PM-4:45 PM

Phase II study of neoadjuvant IGFBP-2 vaccination with neoadjuvant carboplatin and paclitaxel in advanced ovarian cancer. *First Author: William Rayford Gwin, University of Washington, Seattle, WA*

Background: Patients with advanced ovarian cancer not amenable to primary debulking surgery are candidates for neoadjuvant chemotherapy (NACT). Patients achieving a complete pathologic response (cPR) with NACT have superior overall survival; however, the rate of cPR is only 7.5%. In ovarian cancer, tumor infiltrating lymphocytes (TIL) are critically important in prognosis. Paclitaxel and carboplatin augment Type I immunity and decrease MDSCs and Tregs. A Phase I study of an IGFBP-2 vaccine designed to augment Type 1 immunity in Stage III/IV ovarian cancer patients was safe and induced IGFBP-2 specific immunity. Vaccination during the myeloid nadir after platinum/taxane chemotherapy has shown robust Th1 immune responses. We hypothesize that vaccination against IGFBP-2 during the myeloid nadir can synergize with NACT to improve the rate of cPR through Th1 immunity, antigen specific T cells, and TIL. **Methods:** *Trial Design*: Phase II single arm study of concurrent IGFBP-2 vaccination with carboplatin and paclitaxel. Patients receive NACT IV on day 1 of each 3 week cycle and receive the IGFBP-2 vaccination on day 14. Study treatment includes 3 vaccinations, evaluations at 1 week and 6 months post vaccine and yearly follow-up for 5 years. Toxicity is assessed at baseline and through end of study. Blood and tumor tissue will be collected for immunologic monitoring and evaluation. *Eligibility:* Patients with newly diagnosed advanced stage ovarian cancer who will receive NACT with subsequent planned cytoreductive surgery. *Specific aims*: (1) Determine the rate of pCR, (2) Determine the level of TIL in residual tumor (2) Determine whether IGFBP-2 induces IGFBP-2 specific T cells, (3) Explore if there is a predictive signature for pCR when IGFBP-2 vaccination is used with NACT. *Statistical Methods*: (1) The sample size of 38 will provide 80% power to detect a significant increase in pCR to 20% when compared to NACT alone, (2) Tumor tissue will be evaluated for TIL, (3) IGFBP-2 specific INF-g/IL-10 ratios by ELISPOT will be evaluated, (4) Whole exome sequencing will be performed to correlate expression profiles with response to vaccination. *Targeted Accrual:* 7 of the planned 38 patients have been enrolled. Clinical trial information: NCT03029611.

TPS5614 Poster Session (Board #334a), Mon, 1:15 PM-4:45 PM

INNOVATE-3: Phase 3 randomized, international study of tumor treating fields (200 kHz) concomitant with weekly paclitaxel for the treatment of platinum-resistant ovarian cancer. *First Author: Eilon David Kirson, Novocure, Haifa, Israel*

Background: Tumor Treating Fields (TTFields) are a non-invasive, regional antimitotic treatment modality FDA-approved for glioblastoma. TTFields act by disrupting mitotic spindle formation during metaphase. In multiple preclinical models of ovarian cancer, TTFields (200 kHz) reduced viability of cell lines via apoptosis. TTFields has demonstrated synergistic effects with taxanes *in vitro* and *in vivo*. The Phase 2 INNOVATE clinical study [NCT02244502] demonstrated the safety of TTFields combined with weekly paclitaxel in 31 PROC (platinum-resistant ovarian cancer) patients. Patients had a median of 4.1 prior chemotherapy regimens (range: 1-11). Most patients had CTCAE grade 1-2 TTFields-related dermatitis; 6.4% had grade 3 toxicity. Median progression-free survival was 8.9 months. The INNOVATE-3 is a phase 3 study in PROC of TTFields combined with weekly paclitaxel. **Methods:** Patients with PROC (progression per RECIST V1.1) within 6 months of last platinum therapy with a maximum of two lines following the diagnosis of PROC and maximum total of five prior lines of systemic therapy will be enrolled. Patients (ECOG score 0-1) will have no peripheral neuropathy. Patients with primary refractory disease (progression during first line therapy) will be excluded. Patients will be randomized in a ratio of 1:1 to receive either weekly paclitaxel alone or weekly paclitaxel in combination with TTFields (200 kHz). Weekly paclitaxel will be administered at standard starting of dose 80 mg/m^2 weekly for 8 weeks, and then on Days 1, 8, and 15 for each subsequent 28-day cycle. TTFields will be applied in the experimental arm for at least 18 hours/day on average, and maybe continued as long as there is no progression in the abdominal or pelvic regions ("in-field region") per RECIST V1.1. Clinical follow up will be performed q4w, with radiological follow up (CT or MRI scans of the abdomen and chest) q8w. The primary endpoint will be overall survival. Main secondary endpoints include progression-free survival, objective response rate, severity and frequency of adverse events and quality of life based on EORTC QLQ-C30 with the QLQ-OV28 questionnaire.

TPS5615 Poster Session (Board #334b), Mon, 1:15 PM-4:45 PM

STATEC: A randomised trial of non-selective versus selective adjuvant therapy in high risk apparent stage 1 endometrial cancer. *First Author: Tim Mould, University College London Hospital, London, United Kingdom*

Background: The benefit of lymphadenectomy on survival in stage 1 endometrial cancer remains uncertain. STATEC is a surgical trial designed to evaluate the use of nodal status after lymph node dissection to tailor adjuvant treatment in patients with high risk apparent stage I endometrial cancer. **Methods:** DESIGN: Randomised (1:1), controlled, two-arm, phase III, multicentre, international, non-inferiority trial. ELIGIBILITY: High risk apparent FIGO stage I endometrial cancer on diagnostic endometrial sampling OR hysterectomy. If randomisation occurs after hysterectomy and BSO: FIGO grade 3 endometrioid or mucinous carcinoma, high grade serous, clear cell, undifferentiated or dedifferentiated carcinoma or mixed cell adenocarcinoma or carcinosarcoma. STRATIFICATION: participating site, histology, lymphovascular space invasion, timing of hysterectomy and bilateral salpingo-oophorectomy (BSO). TREATMENT: Arm 1: Hysterectomy and BSO, plus intraoperative bilateral pelvic and para-aortic lymph node dissection + adjuvant therapy if node positive or stage III. Arm 2: Hysterectomy and BSO+ adjuvant therapy based on stage and uterine factors. ENDPOINTS: Overall survival (primary), disease-free, endometrial cancer-event free and endometrial cancer-specific survival, pelvic and extra-pelvic relapse-free survival, cost-effectiveness, surgical adverse events, quality of life and performance of sentinel lymph node assessment (secondary). QUALITY ASSURANCE: surgical specimen processing and microscopy to local specialist gynaecological oncology site pathologists, central pathology (10% of UK patients) and surgical imaging of all Arm 1 patients. Recruitment: 4 years, with 5 years follow up. STATISTICS**:** Using the exponential parameter of 0.0040, allowable hazard ratio of 1.272, a sample size of 2000 (500 deaths) will provide 85% power, and 5% two-sided statistical significance. With 80% power, the minimum sample size is 1720 patients (430 deaths). CURRENT ENROLMENT (as of February 2018): STATEC is open in the UK, Australia and New Zealand. 7 patients have been enrolled. STATEC is registered with. Clinical trial information: NCT02566811.

6000 **Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

Results of a randomized phase III study of nimotuzumab in combination with concurrent radiotherapy and cisplatin versus radiotherapy and cisplatin alone, in locally advanced squamous cell carcinoma of the head and neck. *First Author: Vijay Maruti Patil, Tata Memorial Centre, Mumbai, India*

Background: We conducted an investigator-initiated, phase 3 randomized study to evaluate the efficacy and toxicity of addition of Nimotuzumab during concurrent chemoradiation in locally advanced squamous head and neck cancer (LASHNC). **Methods:** Adult subjects (age ≥ 18 years), with stage III-IV, LASHNC, Karnofsky performance status of ≥ 70 and adequate organ function were randomized 1:1 into either radical radiotherapy (66-70 Gy) with weekly cisplatin (30 mg/m2) (CRT arm) or the same schedule of chemoradiation along with weekly Nimotuzumab (200 mg) (NCRT arm). The primary endpoint was progression free survival (PFS) and the other key secondary endpoints were disease free survival (DFS), duration of locoregional control (LRC) and overall survival (OS). Intent to treat analysis was performed. The planned sample size was 536 for superiority margin of 12%, assuming PFS of 60% with 80% power and alpha of 0.05. **Results:** 536 patients were equally allocated between both arms. The median follow up was 33.0 months (95%CI 30.7-35.2 months). The PFS was significantly longer in the patients treated in the NCRT arm (2 year PFS 58.9% versus 49.5%, HR = 0.74; 95% CI 0.56-0.95; P = 0.022). The median duration of PFS was 60.3 months (95% CI 29.4-NA) in the NCRT arm (P = 0.023) and 21 months (95% CI 15.1-NA) in the CRT arm. Addition of Nimotuzumab improved the LRC (HR = 0.75; 95% CI 0.57-0.97, P = 0.030), DFS (HR = 0.75; 95% CI 0.57-0.97, P = 0.030) and had a trend towards improvement in OS (HR = 0.85, 95% CI 0.65-1.10, p = 0.222). Grade 3-5 adverse events (CTCAE version 4.03) were similar between the 2 arms except for the higher incidence mucositis in the NCRT arm (66.7% versus 55.8%, p = 0.010). **Conclusion:** In conclusion, Nimotuzumab in combination with cisplatin and radiotherapy was superior to cisplatin and radiotherapy in improving the PFS, LRC and DFS. This combination provides a new therapeutic option in the armamentarium against LASHNC. Clinical trial information: CTRI/2014/09/004980.

6001 **Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

Definitive cetuximab-based (CRT-CX) vs. non-cetuximab based chemoradiation (CRT) in older patients with squamous cell carcinoma of the head and neck (HNSCC): Analysis of the SEER-Medicare linked database. *First Author: Dan Paul Zandberg, University of Maryland, Marlene and Stewart Greenebaum Comprehensive Cancer Center, Baltimore, MD*

Background: Overall survival (OS) after definitive CRT-CX vs. definitive CRT has not been adequately evaluated outside of younger more highly selected clinical-trial populations with locally advanced HNSCC. **Methods:** We used the SEER-Medicare linked database to evaluate OS in HNSCC patients diagnosed over 2005-2011, following FDA approval of cetuximab in combination with radiation therapy (RT) in March 2006. **Results:** 2135 beneficiaries were identified. Median age was 73 (66-104) years. Primary subsites were oropharynx (61%), hypopharynx (15%), nasopharynx (5%), and larynx (19%). CRT-CX was associated with worse OS compared to CRT (P < 0.005), and similar OS to RT (P = 0.21); 5-year OS was 46% for CRT, 35% for CRT-CX, 32% for RT. Median survival was 4.5(3.8-4.9), 2.5(2.2-3.0), and 2.2 (2.0-3.0) years after CRT, CRT-CX, RT, respectively. Patients were more likely to receive CRT-CX vs. CRT if they had oropharyngeal vs nasopharyngeal primary, Charlson comorbidity index 2 vs 0, older age at diagnosis. Multivariable Cox regression showed that CRT-CX was associated with a higher risk of death compared to CRT (HR = 1.23, 1.07- 1.42; p = 0.005), after stratifying by stage and primary site, and adjusting for gender, race, age, income, Charlson comorbidity index, marital status, hospital type, and year of diagnosis. Regarding treatment-related toxicity, CRT was associated with significantly higher hearing loss within the first 3 months compared to CRT-CX (9.3% vs. 4.1%, p < 0.001), but there were no differences in dysphagia, gastrostomy tube placement, pneumonia, and weight loss over the first 12 months after diagnosis. **Conclusions:** Definitive treatment with CRT-CX was associated with inferior OS compared to CRT even after adjustment for established prognostic factors, and with similar toxicity, in the SEER-Medicare patient population. Survival after CRT-CX was not significantly different from RT alone. Despite the limitations to comparative effectiveness evaluation in population-based registries, our data suggest that non-cetuximab based chemoradiation should be used for eligible older HNSCC patients.

LBA6002 **Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

Are women with head and neck cancer undertreated? *First Author: Annie Park, Kaiser Permanente, Santa Clara, CA*

The full, final text of this abstract will be available at abstracts.asco.org at 2:00 p.m. ET on Friday, June 1, 2018, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2018, issue of the *Journal of Clinical Oncology*. On site at the Meeting, this abstract will be printed in the Sunday edition of *ASCO Daily News*.

6003 **Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

Treatment deintensification to surgery only for stage I human papillomavirus-associated oropharyngeal cancer. *First Author: John David Cramer, University of Pittsburgh School of Medicine, Pittsburgh, PA*

Background: Human papillomavirus-associated (HPV+) oropharyngeal cancer (OPC) is an emerging entity with improved prognosis and distinct staging system. We assessed if deintensificaiton to surgery only decreased survival for stage I patients at low or intermittent risk compared with surgery with adjuvant radiation (RT) or chemoradiation (CRT). **Methods:** From the National Cancer Data Base (2010-2014), we identified patients with stage I HPV+ OPC (after restaging with eighth edition guidelines) treated with surgery only or with adjuvant RT or CRT. We compared survival for low risk patients (≤1 metastatic lymph nodes with no adverse features) and intermediate risk patients (2-4 metastatic lymph nodes, microscopic extranodal extension (ENE) or lymphovascular invasion). We excluded high risk patients with positive margins or macroscopic ENE. **Results:** We identified 2,463 patients with median follow-up of 44.3 months. In the low risk group 4-year overall survival was 93.0% with surgery only versus 95.6% with surgery + RT and 93.0% with surgery + CRT. In the intermediate risk group, 4-year overall survival was 92.2% with surgery only versus 93.3% with surgery + RT and 93.2% with surgery + CRT. On multivariate analysis, we observed no difference in survival with treatment between surgery only versus surgery + RT or surgery + CRT for both the low risk group (hazard ratio (HR) 0.75; CI 0.32-1.79 and HR 1.03; CI 0.42-2.51 respectively) or the intermediate risk group (HR 0.78; CI 0.42-1.46 and HR 0.85; CI 0.47-1.53 respectively). **Conclusions:** This offers retrospective evidence that surgery only for stage I patients at both low and intermediate risk provides equivalent survival to surgery and adjuvant therapy. This offers clinical equipoise for randomization to surgery only for stage I patients in future deintensification trials.

Overall survival based on treatment and risk level.

Group	1-y	2-y	3-y	4-y	Log Rank
Low Risk					
Surgery Only (n = 308)	96.7%	95.0%	94.2%	93.0%	0.59
Surgery + RT (n = 167)	99.4%	97.0%	95.6%	95.6%	
Surgery + CRT (n = 171)	99.4%	96.9%	94.9%	93.0%	
Intermediate Risk					
Surgery Only (n = 228)	97.8%	96.8%	94.1%	92.2%	0.77
Surgery + RT (n = 589)	99.3%	97.6%	96.2%	93.3%	
Surgery + CRT (n = 1,000)	99.0%	97.6%	95.8%	93.2%	

6004 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Phase II study: Induction chemotherapy and transoral surgery as definitive treatment (Tx) for locally advanced oropharyngeal squamous cell carcinoma (OPSCC): A novel approach. *First Author: Robert S. Siegel, George Washington University School of Medicine, Washington, DC*

Background: The standard of care for OPSCC includes chemoradiation (CRT) or surgery with adjuvant radiation (RT). However, RT is associated with significant life long morbidity. We assessed the efficacy of a two-drug induction regimen, followed by transoral robotic assisted surgery (TORS) & neck dissection for locally advanced OPSCC. **Methods:** This is an IRB approved single-arm phase II study for untreated stage III or IVA (AJCC 7th edition) OPSCC patients (pts) with an ECOG < 2 and GFR >50 cc. Induction chemotherapy consisted of cisplatin 75 mg/m2 and docetaxel 75 mg/m2 every 21 days for 3 cycles. Tumor shrinkage was examined after each cycle. If the primary tumor was $\geq$ 80% smaller, pts underwent TORS and neck dissection(s). At post-op visits, flexible laryngoscopy, blood tests, and imaging with PET/CT and/or MRI were done. Short and long term toxicity, progression-free survival, overall survival, and quality of life (QOL) were evaluated. **Results:** Twenty pts were treated, nineteen were male, 17 were Caucasian, and 19 were HPV+. Median age at diagnosis was 57. Tumors involved the tonsil (13 pts) and base of tongue (7 pts). Three pts were stage III, and 17 were stage IVA. Tumor size was reduced by 53.4%, 80% and 90.5% after the 1st, 2nd and 3rd induction cycles respectively. Pathologic CR of the primary site occurred in 15 pts and CR among LN neck dissections occurred in 13 pts. Four pts were given dose-reduced chemo and one pt was changed to carboplatin per protocol because of renal dysfunction. Pre vs post tx QOL scores did not change. At a mean follow-up of 21 months (range 7.6 to 32.1), 18 pts are alive and NED. Three pts recurred a mean of 2.2 months after surgery, and were treated with salvage CRT. Two pts died of metastatic disease, the third is alive and well. All 3 pts had positive LN (9 LN, 3 LN and 1 LN) at surgery. **Conclusions:** Cisplatin + docetaxel followed by TORS & neck resections appears to be an effective model for the definitive treatment for OPSCC, while avoiding the adverse effects of RT. Clinical trial information: NCT02760667.

6005 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Survival outcomes by HPV status in non-oropharyngeal head and neck cancers: A propensity score matched analysis of population level data. *First Author: Sibo Tian, Department of Radiation Oncology, Winship Cancer Institute of Emory University, Atlanta, GA*

Background: The impact of HPV status in non-oropharynx (OPX) cancers is unclear. Limited sample sizes, and unadjusted comparisons have confounded interpretation. Our goal was to evaluate the prognostic value of HPV status in non-OPX cancers using an administrative database. **Methods:** The National Cancer Data Base was queried to capture patients diagnosed between 2010-2013 with invasive cancers of OPX, hypopharynx (HPX), larynx (LX), and oral cavity (OC). HPV positivity was defined by high-risk subtypes, i.e. 16 & 18. Patients with HPV status, survival outcomes and non-metastatic disease were analyzed. Survival was estimated using the Kaplan-Meier method, and log-rank tests were used to compare distributions. Propensity matched methods were utilized by reweighting patients using the inverse probability of treatment weighting (IPTW) approach; included variables were: age, sex, Charlson-Deyo score, treatment with surgery, chemotherapy, radiotherapy, group stage, and subsite where appropriate. Analyses were stratified by AJCC 7th edition stage I-II vs III-IVB. **Results:** A total of 27,954 patients were included: 1,140 cases of HPX, 5,074 cases of LX, 4,540 cases of OC, and 17,200 cases of OPX. The proportion of HPV positive cases were: 20.9% in HPX, 14.2% in LX, 12.2% in OC, and 67.5% in OPX. HPV positivity was associated with superior overall survival (OS) in multiple non-OPX groups. In HPX, actuarial OS by HPV status were at 2-yr 75.9% vs 59.6%; at 5-yr 60.2% vs 33.6% (HPV+ vs HPV-); survival was significant with IPTW (HR 0.56, $p < 0.001$). HPV-positivity was associated with superior OS for stage III-IVB LX cancer; OS at 2-yr was 75.3% vs 66.2% (IPTW HR 0.81, $p = 0.029$). HPV status was not prognostic overall in OC. HPV status in stage III-IVB OC patients trended towards significance (IPTW HR 0.82, $p = 0.059$); OS at 2-yr was 64.9% vs 59.1%. Survival outcomes by HPV status in OPX were: stage I-II IPTW HR 0.45 ($p < 0.001$); stage III-IVB HR 0.42, ($p < 0.001$). **Conclusions:** HPV positivity was associated with improved survival in HPX, locally-advanced LX, and potentially locally-advanced OC patients. These finding, if prospectively validated, may have implications for future risk stratification.

6006 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Results of a randomized, placebo (PBO) controlled, double-blind P2b trial of GC4419 (avisopasem manganese) to reduce duration, incidence and severity and delay onset of severe radiation-related oral mucositis (SOM) in patients (pts) with locally advanced squamous cell cancer of the oral cavity (OC) or oropharynx (OP). *First Author: Carryn M. Anderson, University of Iowa Hospitals and Clinics, Iowa City, IA*

Background: Intensity-modulated radiotherapy (IMRT) plus cisplatin is established treatment for locally advanced OC/OP cancer, but appx. 70% of patients develop SOM, defined as WHO Grade 3 or 4, which limits patients' ability to eat solids (Gr 3) or liquids (Gr 4, requiring artificial nutrition). An RT-induced burst of superoxide initiates oral mucositis (OM) development. GC4419, a superoxide dismutase mimetic, interrupts this process by potently converting superoxide to H_2O_2. It showed promising reductions of SOM in a published open-label Phase 1b/2a trial (IJROBP 1 Feb 2018). **Methods:** 223 pts with OC or OP cancer receiving 70 Gy IMRT ($\geq$50 Gy to $>$ 2 oral sites) plus cisplatin (qwk or q3wk), were randomized 1:1:1 to PBO, 30 or 90 mg of GC4419, by 60-minute IV infusion, M-F before each RT fraction. OM by the WHO scale was assessed by trained evaluators biw during RT & qwk for up to 8 wks post RT. Primary endpoint was duration of SOM. Secondary endpoints included incidence & time to onset of SOM. Analyses (each active dose v PBO, ITT) proceeded by a sequential, conditional approach; 2-sided $\alpha = 0.05$. **Results:** 90 mg GC4419 reduced SOM across endpoints, including a statistically significant reduction in the primary endpoint of duration. Efficacy results with 30 mg were intermediate and did not reach significance. Baseline patient & tumor characteristics, & treatment delivery, were well-balanced. Safety was comparable across arms with no significant GC4419-specific toxicity or increased toxicity of IMRT/cisplatin. **Conclusions:** GC4419 provides a clinically meaningful reduction of SOM in terms of duration, incidence and severity (Grade 4), with a safety profile comparable to placebo. Clinical trial information: NCT02508389.

6007 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Phase II trial of high-dose melatonin oral gel for the prevention and treatment of oral mucositis in H&N cancer patients undergoing chemoradiation (MUCOMEL). *First Author: Alicia Lozano, Institut Català d'Oncologia, Barcelona, Spain*

Background: Severe Oral Mucositis (SOM) is one of the most significant adverse events (AE) in H&N cancer patients undergoing concurrent chemo/bio-radiotherapy. The objective of the trial is to evaluate the safety and efficacy of melatonin (MLT) oral gel in the prevention and treatment of oral mucositis (OM) in H&N cancer patients. **Methods:** Multicenter, prospective, randomized, double-blind, placebo-controlled study. Eligible patients were randomly assigned (1:1 ratio) to receive 3% MLT or matching placebo (PLC) oral gel. Patients received once daily (5 days/week) IMRT radiation therapy (total dose $\geq$ 66 Gy). Concurrent systemic treatments were cisplatin Q3W or cetuximab Q1W. All patients received concomitant standard symptomatic treatment for OM. Efficacy analyses were performed on a mITT population (patients receiving at least one medication dose) or ITT. Efficacy endpoints were either RTOG or NCI CTCv4, G3-4 oral mucositis (SOM) and G2-4 ulcerative oral mucositis (UOM). Comparison of incidence rates of SOM/UOM: Fisher exact test; comparison of duration of SOM/UOM: U Mann-Whitney test. **Results:** 84 patients (ITT: 42 MLT/42PLC; mITT: 40 MLT/39 PLC) were included. Most frequent tumor sites were oropharynx (n = 38; 45%) and oral cavity (n = 24; 29%). Concurrent systemic treatments were cisplatin (n = 54; 64%) or cetuximab (n = 30; 36%). Efficacy results in the mITT population (incidence) and ITT (duration) Clinical trial information: NCT02630004. No relevant differences for AEs between groups or for overall response rate after 2 months of IMRT completion. **Conclusions:** Treatment with MLT oral gel resulted in a consistent trend to a lower incidence and shorter duration of SOM as well as a significantly shorter duration of UOM. These benefits were more marked in the subgroup of patients receiving cisplatin. These results warrant further clinical development.

6008 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Multicenter phase II trial of palbociclib, a selective cyclin dependent kinase (CDK) 4/6 inhibitor, and cetuximab in platinum-resistant HPV unrelated (-) recurrent/metastatic head and neck squamous cell carcinoma (RM HNSCC). *First Author: Douglas Adkins, Washington University School of Medicine in St. Louis and Siteman Cancer Center, St. Louis, MO*

Background: In platinum-resistant RM-HNSCC, the efficacy of cetuximab is modest with a tumor response rate of 13%, median time to progression of 2.3 months and median overall survival (OS) of 6 months (Vermorken *JCO* 2007). In HPV (-) HNSCC, p16 inactivation and/or CCND1 (cyclin D1) amplification are ubiquitous events that result in hyperactivation of the CDK/cyclin D regulatory complex and Rb inactivation. Deregulated cyclin D1 expression is a mechanism of resistance to EGFR inhibitors. In a phase I trial, palbociclib, a potent CDK4/6 inhibitor, given with cetuximab, was safe and tumor responses were observed in RM HNSCC (Adkins *Oral Oncology* 2016). **Methods:** In a phase II trial, patients with platinum-resistant, cetuximab-naive HPV (-) RM HNSCC were treated with palbociclib 125 mg po/d Days 1-21 of 28 day cycles and weekly cetuximab. Platinum-resistance was defined as: progression on platinum in the RM setting; cetuximab-naïve was defined as: no prior cetuximab for RM disease. HPV (-) disease was defined as SCC of the oral cavity, larynx, hypopharynx or p16 negative SCC of the oropharynx. Tumor response assessments (RECIST 1.1) were performed every 2 cycles. We hypothesized that palbociclib and cetuximab would increase the tumor response rate from 13% (historical data with cetuximab) to $>$ 26%. Futility assessments of response and toxicity occurred after every 6 patients (sample size: 30) using a Bayesian monitoring method. **Results:** 30 patients were enrolled. Median age 67 years (range: 26-84). Sites of recurrence: local/regional (6), distant (8), or both (16). Tumor response occurred in 35% (8 of 23 evaluable to date). Decrease in target lesions occurred in 57% (13 of 23 evaluable). Median progression free survival (PFS) was 6.4 months and median OS was 12.1 months. Immunotherapy was given to three patients before and eight after study participation. **Conclusions:** Palbociclib and cetuximab resulted in a robust tumor response rate and prolongation of PFS and OS in platinum-resistant HPV (-) RM-HNSCC. The median OS of 12.1 months is the longest reported for patients with platinum-resistant RM HNSCC. Clinical trial information: NCT02101034.

6009 Clinical Science Symposium, Fri, 4:30 PM-6:00 PM

A phase II randomized trial of nivolumab with stereotactic body radiotherapy (SBRT) versus nivolumab alone in metastatic (M1) head and neck squamous cell carcinoma (HNSCC). *First Author: Sean Matthew McBride, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: A minority of patients with metastatic HNSCC respond to the anti-programmed death (PD-1) monoclonal antibody, Nivolumab (Nivo). We sought to determine whether targeted radiation to a single lesion combined with Nivo would enhance tumor regression in non-irradiated lesions (abscopal response) and improve outcomes. **Methods:** Patients with M1 HNSCC (including nasopharynx) with at least two RECIST 1.1 measurable lesions were randomized with stratification for viral status (EBV/HPV pos vs. neg) 1:1 to either Nivo alone q 2 weeks or Nivo with SBRT to a single lesion (9 Gy x 3) between the 1st and 2nd doses of Nivo. The primary end-point was objective response rate (ORR) in non-irradiated lesions using RECIST 1.1. Secondary analyses included overall survival (OS), progression free-survival (PFS), and duration-of-response (DOR). We hypothesized that SBRT added to Nivo would increase ORR from 15% to 45%. Enrolling 53 patients thus provides a one-sided alpha of 0.10 and a power of 0.80. **Results:** 53 patients were randomized, 26 to Nivo alone and 27 to Nivo+SBRT; the lung was the most common irradiated site (59%). There were no significant differences between arms in terms of age ($p = 0.12$), viral status (pos vs neg; $p = 0.786$), primary site (oropharynx vs. nasopharynx vs other; $p = 1.0$), or median lines of prior chemotherapy (1; $p = 0.73$). ORR in the Nivo alone arm was 26.9% (95% CI: 13.7, 46.1%) vs 22.2% (95% CI: 10.6%, 40.8%) in the Nivo+SBRT arm ($p = 0.94$). Median DOR with Nivo alone was not reached (NR) vs 9.3 months (95% CI: 5.52, NR) with Nivo+SBRT ($p = 0.21$). Median follow-up amongst surviving patients was 12.8 mos; OS at 1 year was 64% (95% CI: 47%, 88%) in the Nivo alone arm vs 53% (95% CI: 36%, 79%) in the Nivo+SBRT arm ($p = 0.79$); median PFS was 1.9 mos (95% CI: 1.78, NR) with Nivo vs 2.4 mos (95% CI: 1.0, 11.4) with Nivo+SBRT ($p = 0.8$). Treatment-related $\geq$ Grade 3 toxicities in the Nivo alone vs Nivo+SBRT arms occurred in 15% vs. 11% of patients ($p = 0.96$). **Conclusions:** While safe, the addition of SBRT to Nivo in M1 HNSCC failed to improve ORR, PFS, or OS. This is the first randomized evaluation of the abscopal response in any tumor histology. Biomarker analyses are near completion. Clinical trial information: 02684253.

6010 Clinical Science Symposium, Fri, 4:30 PM-6:00 PM

Safety evaluation of nivolumab (Nivo) concomitant with cetuximab-radiotherapy for intermediate (IR) and high-risk (HR) local-regionally advanced head and neck squamous cell carcinoma (HNSCC): RTOG 3504. *First Author: Robert L. Ferris, University of Pittsburgh Medical Center and University of Pittsburgh Cancer Institute, Pittsburgh, PA*

Background: Nivolumab, which inhibits the programmed death-1 (PD-1) receptor, improved survival for patients (pts) with platinum-refractory recurrent/metastatic HNSCC compared with standard therapy. This trial evaluates the safety of adding nivo to 4 standard radiotherapy (RT) regimens for pts with newly diagnosed IR/HR HNSCC (Table). Safety data for cohort 3 (cetuximab) are reported. Efficacy data for cohorts 1, 2, and 3 will be reported at the presentation. **Methods:** Eligibility includes IR (p16+, oropharynx (OP) T1-2N2b-N3/T3-4N0-3, $>$10 pack-years (pys) or T4N0-N3, T1-3N3 $\leq$10 pys) and HR HNSCC (oral cavity, larynx, hypopharynx, or p16(-) OP, stage T1-2N2a-N3 or T3-4N0-3). 10 pts are enrolled to obtain 8 evaluable pts. Primary endpoint is dose-limiting toxicity (DLT), defined as nivo-related: $\geq$grade 3 adverse event (AE) unresolved to $\leq$grade 1 in $\leq$28 days; RT delay $>$2 wks; incomplete RT; or inability to receive $\geq$70% of cetuximab. DLT window was from first nivo dose (day -14) to 28 days post RT. $>$2 DLTs in 8 evaluable pts is unacceptable. **Results:** Of 10 enrolled pts for cohort 3: median age 61.5, 80% male, 70% Caucasian, 70% PS 0, 80% $>$10 pys, 60% p16(+) OP cancer, 60% T3-4 and 100% N2-3 disease. 1 pt was inevaluable for DLT due to withdrawal of consent and 1 pt has not yet completed the DLT observation period. 1 DLT (mucositis) was reported in 8 evaluable pts; 1 other grade 3 AE attributed to nivo was reported (lipase increase) but was not a DLT. 11 SAEs in 3 pts, but none nivo-related. 7/8 pts completed RT, 7/8 pts completed cetuximab; 5 pts completed 10 concurrent doses of nivo, 1 pt received 6 doses, 1 pt 7 doses, and 1 pt is ongoing after 8 doses. **Conclusions:** Nivo is safe and feasible to administer concomitant with a cetuximab-RT regimen for patients with newly diagnosed IR/HR HNSCC. Clinical trial information: NCT02764593.

Neoadjuvant anti-OX40 (MEDI6469) prior to surgery in head and neck squamous cell carcinoma. *First Author: Richard Bryan Bell, Earle A. Chiles Research Institute at Robert W. Franz Cancer Center, Providence Cancer Institute, Portland, OR*

Background: This phase Ib clinical trial was performed to investigate an agonistic murine antibody to OX40 (MEDI6469) at various dose intervals prior to definitive surgical resection in patients with head and neck squamous cell carcinoma (HNSCC). **Methods:** 17 patients with resectable stage III-IVA HNSCC (11 = HPV-; 7 = HPV+) received MEDI6469 0.4mg/kg x 3 doses administered on day 1, day 3-4 and day 5-6 of the study, followed by definitive surgical excision and neck dissection either 2 days, 1 week or 2 weeks after infusion of anti-OX40. Primary tumor, lymph nodes and peripheral blood (PB) were obtained at baseline and at the time of surgery to characterize the circulating and tumor infiltrating lymphocyte (TIL) cell populations based on flow cytometry (FC) and multiplex immunohistochemistry (mIHC) as well as whole transcriptome analysis via RNA-sequencing (seq). **Results:** MEDI6469 administration was well tolerated, surgery was not delayed, and there were no grade 3 or 4 adverse events related to MEDI6469 treatment. With a median follow up of 20 months, 13/17 patients are alive without disease. 4 patients had evidence of an immunological response to treatment on FC and mIHC that peaked between 12 and 19 days after MEDI6469 infusion and was characterized by: 1) increased Ki67+CD38+ICOS+ CD4+ and CD8+ memory T-cell populations in both the TME and PB, 2) increased expression of CD39, ICOS and PD-1 on CD4+ TIL (N = 10), and 3) increased frequency of tumor-reactive, tissue resident CD39+CD103+CD8+ T cells (N = 5). RNA-seq analysis of the primary tumor in a subset of patients (N = 7) revealed significant differences between immunological responders and non-responders in genes associated with MHC I-mediated antigen processing and presentation. Subsequent immune-subtype deconvolution analysis of the RNA data revealed all responders segregated with above median levels of CD39+CD103+CD8+ T cells, consistent with flow and mIHC. **Conclusions:** Preoperative MEDI6469 administration is safe and resulted in increased activation and proliferation of T cells within the tumor, peaking two weeks following infusion. Immunologic changes are associated with MHC I-mediated antigen processing machinery. Clinical trial information: NCT02274155.

6013 Poster Discussion Session; Displayed in Poster Session (Board #1), Sat, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Sat, 4:45 PM-6:00 PM

Health-related quality of life (HRQoL) of pembrolizumab (pembro) vs standard of care (SOC) for recurrent/metastatic head and neck squamous cell carcinoma (R/M HNSCC) in KEYNOTE-040. *First Author: Ezra E.W. Cohen, Moores Cancer Center at UC San Diego Health, University of California, San Diego, La Jolla, CA*

Background: In KEYNOTE-040 (NCT02252042) (N = 495), pembro 200 mg Q3W for 24 mo yielded a clinically meaningful improvement in overall survival over SOC choice of methotrexate (Mtx), docetaxel (Dtx), or cetuximab (Ctx) in patients (pts) with R/M HNSCC, with fewer grade 3-5 drug-related adverse events. We present results of prespecified exploratory HRQoL analyses. **Methods:** The EORTC QLQ-C30, EORTC QLQ-H&N35, and EQ-5D were administered electronically at baseline; wks 3, 6, 9; then every 6 wk up to 1 y or end of treatment; and at 30-day safety follow-up visit. HRQoL was analyzed in pts who received ≥1 dose of study drug and had ≥1 HRQoL assessment. Mean change from baseline to wk 15 was compared using a constrained longitudinal data analysis model. Time to deterioration (TTD) (defined as ≥10-point decline from baseline) was estimated by Kaplan-Meier method and Cox regression model. **Results:** The HRQoL population included 469 pts (241 pembro; 228 SOC). HRQoL compliance at wk 15 was 75.3% for pembro and 74.6% for SOC. From baseline to wk 15, global health status (GHS)/QoL scores were stable for pembro (least-squares [LS] mean, 0.39; 95% CI, –3.00, 3.78) but worsened for SOC (LS mean –5.86; 95% CI, –9.6 8, –2.04); difference in LS mean between arms was 6.25 points (95% CI, 1.32, 11.18; nominal 2-sided *P*= 0.013). Subgroup analyses by SOC choice identified a greater difference in LS mean for GHS/QoL scores with pembro vs Dtx (10.23; 95% CI, 3.15, 17.30) compared with pembro vs Mtx (6.21; 95% CI, –4.57, 16.99) or Ctx (–1.44; 95% CI, –11.43, 8.56). Median TTD in GHS/QoL with pembro vs SOC was 4.8 and 2.8 mo (HR, 0.79; 95% CI, 0.59, 1.05; nominal 1-sided *P*= 0.048). Pts in the pembro arm generally had stable functioning and symptom scores at wk 15; no notable between-group differences were seen. **Conclusions:** Over 15 wks, pembro-treated pts had stable GHS/QoL; those receiving SOC generally showed a decline. This effect was more marked for Dtx-treated pts. Additional HRQoL analyses by SOC choice will further assess trends. Along with previously presented efficacy and safety results, these data support the clinically meaningful benefit of pembro in R/M HNSCC. Clinical trial information: NCT02252042.

Association of immune-related adverse events (irAEs) with improved response, progression-free survival, and overall survival for patients with metastatic head and neck cancer receiving anti-PD-1 therapy. *First Author: Corey Christian Foster, Department of Radiation & Cellular Oncology, The University of Chicago Medicine, Chicago, IL*

Background: Anti-programmed death receptor-1 (PD-1) therapies are approved for recurrent/metastatic head and neck (H&N) cancer progressing on or after platinum-based chemotherapy, and immune competence may modulate anti-tumor response. We hypothesized that developing immune-related adverse events (irAEs) while receiving anti-PD-1 therapy for metastatic H&N cancer would be associated with improved outcomes. **Methods:** 114 patients with metastatic H&N cancer unselected for PD-ligand 1 (PD-L1) status received anti-PD-1 therapy. Adverse events (AEs) were prospectively graded using CTCAE v4.0. irAEs were any possibly immune-mediated AE regardless of attribution. Univariate and multivariate logistic regression analyzed the relationship between irAEs and overall response rate (ORR) measured by RECIST v1.1. Progression-free survival (PFS) and overall survival (OS) were analyzed using Kaplan-Meier methods and Cox proportional hazard regression. **Results:** Median follow-up was 8.6 months, and follow-up did not significantly differ between irAE+/- groups (p = 0.72). Baseline characteristics including known PD-L1+ (53.1% irAE+ vs. 49.2% irAE-, p = 0.76) were comparable. 59 irAEs occurred in 49 patients. irAEs were classified as dermatologic (n = 20), pulmonary (n = 1), GI (n = 1), endocrine (n = 14), musculoskeletal (n = 15), ophthalmologic (n = 2), or hepatic (n = 6). 5 patients (10.2%) experienced grade ≥3 irAE. ORR was higher for the irAE+ (30.6%) compared to the irAE- (12.3%) group (p = 0.02). Median PFS was 6.9 months for irAE+ and 2.1 months for irAE- patients (p = 0.0004), while median OS was 12.5 months and 6.8 months (p = 0.007), respectively. On multivariate analyses, irAE+ was independently associated with improved ORR (p = 0.03), PFS (p = 0.009), and OS (p = 0.003). **Conclusions:** Developing irAEs while receiving anti-PD-1 therapy is associated with superior ORR, PFS, and, in particular, OS in this cohort of H&N cancer patients unselected for PD-L1 status. The ability to develop irAEs may be an indicator of immune competence and further investigation of biomarkers of immune competence is warranted.

Response to salvage chemotherapy after progression on immune checkpoint inhibitors in patients with squamous cell carcinoma of the head and neck. *First Author: Khalil Saleh, Departemnt of Head and neck, Gustave Roussy Cancer Campus, Villejuif, France*

Background: Immune checkpoint inhibitors (ICI) have shown efficacy in patients with recurrent/metastatic squamous cell carcinoma of the head and neck (R/M SCCHN) with an overall response rate (ORR) ranging from 13 to 17%. Recent data suggest that exposure to ICI potentially improves ORR to salvage chemotherapy (SCT) in advanced non-small cell lung carcinoma. We evaluated responses to chemotherapy in R/M SCCHN patients after progression on ICI. **Methods:** A retrospective study was conducted at 4 French referral centers. Eligibility criteria were patients treated with ICI for R/M SCCHN, who progressed after treatment with ICI (primary or secondary resistant to ICI) and received SCT between September 2014 and January 2018 and for whom efficacy data were available. Clinical and radiological data were collected from review of medical records. **Results:** Of 232 patients treated with ICI (anti-PD-1, anti-PD-L1, anti-CTLA-4 and anti-KIR), 82 met eligibility criteria: 84% were male, median age was 60 years old. ICI was given as monotherapy in 45% of patients or as combination in 55%. SCT included taxane-based regimen (56%), platinum-based regimen (37%), and methotrexate (7%). Cetuximab was administered in combination with taxanes or platinum in 50% of patients. The median number of treatment lines prior to SCT was 2 (range 1-6). The ORR to SCT was 30% (95% confidence interval: 21%-40%). Three patients (4%) presented complete response and 22 patients (27%) had partial response. The disease control rate was 57%. The age at initiation of SCT, initial tumor location, number of prior chemotherapy regimens, type of chemotherapy prior to ICI, best response to ICI, site of relapse and ECOG at SCT were not significantly associated with response to SCT on univariate analysis. **Conclusions:** In R/M SCCHN pretreated with ICI, the ORR to SCT was 30% higher than figures of historical cohorts in this setting. This suggests that exposure to ICI may increase tumor sensitivity to chemotherapy. Further investigations are warranted.

A phase 1b/2 trial of lenvatinib plus pembrolizumab in patients with squamous cell carcinoma of the head and neck. *First Author: Matthew H. Taylor, Knight Cancer Institute, Oregon Health and Science University, Portland, OR*

Background: Lenvatinib (LEN) is a multikinase inhibitor of vascular endothelial growth factor receptor 1−3, fibroblast growth factor receptor 1−4, platelet-derived growth factor receptor α, RET, and KIT. Pembrolizumab (PEM) is an anti-PD-1 antibody approved for the second-line treatment of recurrent or metastatic squamous cell carcinoma of the head and neck (SCCHN) based on durable responses and an objective response rate (ORR) of 16% (Bauml J et al, *J Clin Oncol* 2017). We report initial results of the SCCHN cohort from a phase 1b/2 trial of the LEN + PEM combination (NCT02501096). **Methods:** In this multicenter, open-label study, patients (pts) with measurable, confirmed metastatic SCCHN and ECOG performance status ≤1 received LEN (20 mg/day orally) + PEM (200 mg Q3W, IV). Pts were not preselected based on PD-L1 status. Tumor assessments were performed by study investigators using immune-related RECIST (irRECIST). The phase 2 primary endpoint was ORR at 24 weeks (ORR_{WK24}). Secondary endpoints included ORR, progression-free survival (PFS), and duration of response (DOR), which is calculated for pts with complete or partial responses. **Results:** At data cutoff of August 1, 2017, 22 pts with SCCHN (regardless of PD-L1 status) were enrolled. 86% of pts had ≥1 prior anticancer therapy. Median follow-up for PFS was 7.6 months (95% confidence interval [CI], 4.2–12.6) per irRECIST. Efficacy outcomes are summarized in the table. Grade 3 or 4 AEs occurred in 91% of pts (grade 4 AEs in 14%). However, 4 (18%) discontinued study treatment due to AEs. The most common AEs were fatigue (55%), decreased appetite (41%), hypertension (41%), diarrhea (36%), and nausea (36%). Updated data will be presented. **Conclusions:** LEN + PEM demonstrated promising clinical activity and manageable toxicities, supporting further evaluation of the LEN + PEM combination in pts with SCCHN. Clinical trial information: NCT02501096.

Outcome	irRECIST (N = 22)
ORR_{WK24}, n (%)*	8 (36.4)
95% CI	17.2–59.3
ORR, n (%)†	8 (36.4)
95% CI	17.2–59.3
Median DOR, months (95% CI)‡	8.2 (2.2–not estimable)
Median PFS, months (95% CI)	8.2 (4.3–not estimable)
PFS rate at 12 months, % (95% CI)	37.2 (12.8–62.2)

*8 partial responses (PR). †7 PRs, 1 complete response. ‡4 of the 8 (50%) responders achieved a DOR of > 6 months.

Phase II multi-site investigation of neoadjuvant pembrolizumab and adjuvant concurrent radiation and pembrolizumab with or without cisplatin in resected head and neck squamous cell carcinoma. *First Author: Trisha Michel Wise-Draper, University of Cincinnati Cancer Institute, Cincinnati, OH*

Background: 2Despite aggressive adjuvant treatment, locally advanced HNSCC patients undergoing primary surgical resection with high risk [HR] features (extracapsular extension of lymph nodes (LN) and/or positive margins) have 3 year disease free survival (DFS) of 47-57%. Pre-clinically, radiation upregulates the immune checkpoint PD-L1 and importantly PD-L1 blockade concurrently with radiation resulted in improved overall survival (OS) in mice bearing HNSCC tumors. Therefore, we initiated a window of opportunity study "Phase II Investigation of Adjuvant Combined Cisplatin and Radiation with Pembrolizumab in Resected HNSCC" (NCT02641093) supported by Merck. **Methods:** Clinically high risk (T3/4 stage and/or ≥2 + LNs) patients received the PD-1 antibody, pembrolizumab (200 mg I.V. x 1), 1-3 weeks before resection. Adjuvant concurrent pembrolizumab (q3 wks x 6 doses) and radiation (60-66Gy) were administered, along with weekly cisplatin (40mg/m2) for those with HR features. Pre- and post-surgical specimens were archived for H&E, immunohistochemistry, RNAScope and Nanostring. Safety lead-in included first 8 patients of each arm and dose limiting toxicity (DLT) was determined by delay in surgery, radiation and/or cisplatin. **Results:** Twenty-eight of 80 planned patients have been enrolled with 23 evaluable for efficacy. Characteristics included median age of 52 (range, 27-80), 32% female, T3-21%, T4- 46% and 64% ≥ N2b. The lead-in safety period is near completion (15/16) without DLT with 9/19 (47%) patients demonstrating a pathological response (> 10% tumor effect [TE]) and 6/19 (32%) achieving major response (> 70% TE), one of which had a pathological complete response after 1 dose. Pathological response was associated with robust immune cell infiltration, increased PD-L1 and PD-L2. Two patients (neither attaining pathological response) have recurred. **Conclusions:** Pathological response was seen after one dose of pembrolizumab in HNSCC. Increased tumor immune cell infiltration predicted pathological response. Adjuvant combination treatment with pembrolizumab has an acceptable safety profile. Clinical trial information: NCT02641093.

6018 Poster Discussion Session; Displayed in Poster Session (Board #6), Sat, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Sat, 4:45 PM-6:00 PM

A phase II randomized trial of pembrolizumab versus cetuximab, concomitant with radiotherapy (RT) in locally advanced (LA) squamous cell carcinoma of the head and neck (SCCHN): First results of the GORTEC 2015-01 "PembroRad" trial. *First Author: Xu Shan Sun, CHRU Jean Minjoz, Besancon Cedex, France*

Background: Based on the hypothesis of a potential synergistic effect of the anti-PD1 pembrolizumab when combined with RT, this new combination was tested in a phase II randomized trial against the SoC cetuximab-RT in LA-SCCHN. **Methods:** Patients (pts) were randomized between cetuximab (Arm A : 400 mg/m^2 loading dose and 250 mg/m^2 weekly) and Pembrolizumab (Arm B : 200 mg Q3W during RT). In both arms, patients received IRMT (69.96 Gy in 33 fractions). Main Inclusion criteria were : pts unfit for high dose cisplatin, non operable stage III-IVa-b SCC of oral cavity, oropharynx, hypopharynx and larynx. Treatment allocation was performed by randomization 1:1, stratified on N stage (N0-1 vs N2-3) , tumor location and p16 status. To detect a difference between arms of 60% to 80% in locoregional control at 15 months (primary endpoint), inclusion of 66 pts per arm was required to achieve a power of at least 0.85 at 2-sided significance level of 0.20, with less than 15% unevaluable pts. **Results:** from 05/16 to 10/17, 133 pts were randomized in 27 centers, 66 in Arm A and 67 in Arm B. Median age was 65 years, 92% were smokers, 60% of oropharynx, 28% p16+ and 26%, 56% and 19% of stage III, IVa and IVb respectively. Both arms were well balanced. At the time of the abstract writing, full and cleaned safety and compliance data were available for 77 pts (58%). Data for all the randomized pts will be presented at the meeting. In Arm A and B, 25 and 18 Serious Adverse Events (SAE) occurred and 94% and 78% pts had at least one CTCAE v4 grade 3 AE in arm A and B respectively. The compliance to RT was not different (full total dose received by 86% and 88% pts in Arm A and B respectively). Mucositis >= grade 3 was observed in 57% (Arm A) versus 24% (Arm B) of pts (p = 0.004) (but no difference in dysphagia, 34% versus 39%). In radiation field dermatitis >= grade 3 occurred more frequently in Arm A (49% versus 17%) (p=0.003). **Conclusions:** Preliminary data indicate that tolerance of pembrolizumab-RT was good when compared to cetuximab-RT in LA-SCCHN. Updated and complete safety results will be presented at the meeting. Clinical trial information: NCT02707588.

6019 Poster Discussion Session; Displayed in Poster Session (Board #7), Sat, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Sat, 4:45 PM-6:00 PM

Discovery of a reliable and robust methylome classifier of HPV driven head and neck cancer with favorable response to chemoradiation: A multicenter study of the German Cancer Consortium Radiation Oncology Group (DKTK-ROG). *First Author: Bouchra Tawk, German Cancer Research Center (DKFZ), Heidelberg and German Cancer Consortium (DKTK), core center Heidelberg, Heidelberg, Germany*

Background: Human Papilloma Virus (HPV)-driven head and neck cancer (HNSCC) is associated with good prognosis. The prognostic value of HPV-DNA and p16 IHC was recently reported by this consortium. Discordance between HPV and p16 status is consistently observed impacting patient stratification and treatment outcome. We sought to overcome this limitation by developing a next-generation methylome-based classifier of HPV-driven HNSCC. **Methods:** HPV-DNA and p16 status of a DKTK-ROG multicenter retrospective cohort of patients (n = 194) with oropharynx cancer (OPC), oral cavity- and hypopharynx cancer (non-OPC), homogenously treated with surgery and adjuvant cisplatin-based radiochemotherapy (RCHT), was employed as a training set. Five validation cohorts were utilized including DKTK-ROG patients with definitive RCHT (n = 110), three additional RCHT cohorts from Heidelberg, Dresden, Munich (n = 222) and The Cancer Genome Atlas – HNSCC cohort (TCGA, n = 206). Overall methylome data from 732 samples including two different sources (FFPE/FrFr) and platforms (Illumina 450K and EPIC 850K) were studied. **Results:** A 24-probe set methylome-based classifier of HPV-driven HNSCC was discovered (HPV-M) to significantly correlate with improved clinical outcomes: HR for local recurrence (range 0.11-0.19), disease progression (range 0.16-0.29) and overall survival (OS, range 0.19-0.42) were significant in all cohorts ($p < 0.05$). Notably, HPV-M+ classification was superior to HPV-DNA+ status or p16+ IHC in predicting OS in all cohorts independent of tumor localization (OPC/non-OPC). Likewise, HPV-M showed a strong correlation with HPV-DNA and p16 status ($p < 0.0001$). Across cohorts ~ 10% discordance between HPV-M and HPV-DNA or p16 status was found, respectively. Among these patients (n = 71), OS was significantly reduced in patients with HPV-M negative vs. positive tumors ($p < 0.009$). **Conclusions:** We present a novel robust and independent methylome-based classifier of HPV-driven HNSCC that could be instrumental for accurate patient stratification in the era of de-escalation trials.

6020 Poster Discussion Session; Displayed in Poster Session (Board #8), Sat, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Sat, 4:45 PM-6:00 PM

High-accuracy HPV testing versus p16 IHC using multiple clinically relevant outcomes: The University of Chicago Experience. *First Author: Sara Kochanny, Section of Hematology/Oncology, Department of Medicine, The University of Chicago Medicine, Chicago, IL*

Background: The current most widely used standard for HPV status testing in head & neck cancer is p16 IHC. However, p16 IHC is a surrogate method which does not test directly for HPV genetic material and p16 expression is known to occur in HPV- tumors also. Furthermore, HPV strain identification can influence prognosis necessitating HPV typing. We have developed a dual testing method using both p16 IHC in combination with multiplex HPV PCR to accomplish the high sensitivity HPV testing with overall high specificity, sensitivity, and overall accuracy. **Methods:** As part of our clinical experience, we evaluated the HPV status of 317 patients with head & neck cancer suspicious for HPV involvement using a dual testing method with both p16 IHC and multiplex PCR. For discrepant cases where p16 and PCR do not agree, we confirmed status by performing genetic profiling (OncoPlus). The sensitivity and specificity of the method was tested with a combined validation cohort of 87 HPV negative (n = 48) and HPV positive (n = 39) tumor samples. **Results:** In our clinical experience with oropharyngeal HPV testing, including as part of de-escalation trials, we identified that 5% of oropharynx cases have false positive p16, where the PCR does not support HPV. 8% of PCR confirmed HPV positive cases were non-HPV16, which were associated with poorer prognosis. In the combined HPV- and HPV+ validation cohort, sensitivity was 97.4%, specificity 93.75%, PPV was 95%, NPV = 97.8%, with an overall accuracy of 95.4%. **Conclusions:** Dual testing by p16 and PCR is feasible, and increases accuracy. Using p16 alone results in a 5% false positive and 8% misclassification rate for HPV(-) and non-HPV16 cancers, respectively. In the era of de-escalation where treatment decisions are based on HPV status, it is critical to identify patients who are actually HPV(-) or non-HPV16. Such patients likely should not be treated on de-escalation trials unless appropriate safeguards are in place.

6021 Poster Discussion Session; Displayed in Poster Session (Board #9), Sat, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Sat, 4:45 PM-6:00 PM

A randomized doubled blind phase II study exploring the safety and efficacy of nintedanib (BIBF1120) as second line therapy for patients (pts) with differentiated thyroid carcinoma (DTC) progressing after first line therapy: EORTC 1209. *First Author: Martin Schlumberger, Department of Nuclear Medicine and Endocrine Oncology, Gustave Roussy and University Paris-Sud, Villejuif, France*

Background: Radioiodine refractory advanced DTC may benefit from treatment with TKI. Most DTC pts will ultimately progress after treatment with a TKI and those in good general condition are candidates for further treatment lines. Nintedanib (N) is an oral triple angiogenesis inhibitor of VEGF, FGF and PDGF receptors. We conducted a randomized phase II trial of N vs placebo (P) in pts with locally advanced or metastatic DTC who received 1 or 2 lines of prior TKI. **Methods:** Eligible pts had documented RECIST v1.1 progression on a prior treatment with TKI. The primary endpoint was progression free survival (PFS) using RECIST v1.1 according to local radiologist. Tumor assessment occurred every 8 weeks. With a 1-sided alpha 10%, the study was powered at 90% level to detect a Hazard Ratio (HR) of 0.6 in PFS. **Results:** Between July 2014 and December 2016, 70 pts were randomized 2:1 to N (45 pts starting dose 400 mg/d) or matching P (25 pts). Pt characteristics were similar in both arms. Median (med) age was 65.8 years, 56 % female, all had distant metastases, 76% received 1 prior line of TKI and 24% received 2 lines. At the time of database lock, 2 N pts and 1 P pt were still receiving study treatment. Among pts who completed treatment, med duration of treatment was 17.7 weeks (W) in N and 10.4 W in P. Med relative dose intensity was 100% in N. AEs led to decrease N treatment dose in 21 pts and to permanent discontinuation in 5 pts. Grade ≥3 AEs occurred 50% in N and 36% in P, among others hypertension (9 vs 4%), diarrhea (9 vs 4%), abdominal pain (2.3% vs 0), nausea (4.5% vs 0), anorexia (11.4% vs 0), weight loss (2.3% vs 0), fatigue (6.8 vs 4%), anemia (2.3 vs 4 %) and lymphopenia (6.8% vs 0). Based on 53 events observed in 56 per protocol population pts (37 in N and 19 in P), med PFS was significantly prolonged from 2.86 months in P to 3.71 in N (HR [80% CI]: 0.65 [0.42, 0.99], stratified logrank test p = 0.095). **Conclusions:** N as second line therapy for pts with DTC progressing after 1st or 2nd line therapy was well tolerated. Based on per protocol population, N slightly prolonged med PFS compared to P. Clinical trial information: NCT01788982.

A phase II study of lenvatinib in patients with progressive, recurrent/metastatic adenoid cystic carcinoma. *First Author: Vatche Tchekmedyian, Memorial Sloan Kettering Cancer Center, NY, NY*

Background: Recurrent/metastatic adenoid cystic carcinoma (R/M ACC) is a malignant neoplasm of salivary gland origin with no standard treatment. The majority of ACCs are characterized by MYB over-expression which correlates to upregulation of several genes, including lenvatinib-relevant targets such as vascular endothelial growth factor A, the receptor tyrosine kinase *KIT* and fibroblast growth factor 2. We hypothesize that the multi-tyrosine kinase inhibitor (TKI) lenvatinib could be an effective therapy for R/M ACC. **Methods:** In a minimax two stage phase II study, patients with R/M ACC were treated with lenvatinib 24mg orally once daily. The protocol required new or progressive lesions radiographically and/or new or worsening disease related symptoms within 6 months of enrollment. The primary endpoint was overall response rate (ORR) (ORR= complete response (CR)+partial response (PR)) as documented by RECIST v1.1. The objective was to detect a difference in ORR of 5% versus 20% (with a one-sided type I error of 10% and power of 90%). ≥4 responses out of 32 patients was the pre-specified target for a positive study. **Results:** From 6/2/2016-5/22/2017, 33 patients were enrolled and 32 were evaluable for the primary endpoint (1 screen fail). The ORR was 15.6%. For best overall response (BOR), 5 patients (15.6%) had confirmed PR, 24 (75%) had stable disease (including 16 (50%) with tumor regression), and 1 (3.1%) had progression of disease (POD); 2 (6.3%) were removed prior to re-imaging. Five patients remain on therapy (range 11.0-19.9m). Reasons for discontinuation included POD (7), withdrawal of consent (9), physician discretion (6), and protocol-mandated removal for toxicity (5: myocardial infarction, posterior reversible encephalopathy syndrome, proteinuria, oral cavity fistula, and intracranial hemorrhage). 20 patients underwent at least one dose reduction.Median progression free survival (PFS) was 16.4 months (95% CI 7.2-not reached). **Conclusions:** The trial reached its primary endpoint, demonstrating impressive efficacy with the highest ORR and longest PFS of any phase II multi-TKI ACC study published in the literature to date. Clinical trial information: NCT02780310.

Facilitating rapid precision oncology in anaplastic thyroid cancer: Clinical implications of next generation sequencing (NGS) mutation testing and impact on survival. *First Author: Jennifer Rui Wang, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Anaplastic thyroid cancer (ATC) is a rare malignancy characterized by rapid progression and median overall survival (OS) of less than 6 months. With the goal of improving ATC outcomes, a multi-disciplinary program ("FAST") was developed at our institution, which provides rapid access to care, mutation testing, and personalized treatment. The objective of this study was to examine whether results of mutation testing are associated with OS in ATC patients. **Methods:** ATC patients seen between 2012-2017 at our institution who had adequate tumor samples for NGS testing were included. DNA was extracted from pre-treatment core biopsies or surgical specimens of primary ATC. Targeted mutation testing was performed using NGS platforms for 46-158 genes. Cox proportional hazards models were used to assess the associations between mutation status and OS. **Results:** A total of 101 pts were included (median age: 65.7 years, 55.5% male). 84% presented with T4b disease. 50% were M1 at presentation. Median OS at 1 and 2 years was 52% and 29%. The most common mutations detected were p53 (54%), BRAFV600E (50%), RAS (21%), PIK3CA (23%), and CDKN2A (7%). RAS and BRAFV600E mutations were mutually exclusive. In univariate analysis, BRAFV600E was associated with better OS (HR 0.59, 95% CI 0.35-0.98, p = 0.043) while RAS mutation was associated with worse OS (HR 3.41, 95% CI 1.94-5.99, p < 0.001). P53 mutation was not significantly associated with OS. After adjustment for additional clinical variables, RAS mutation was most significantly associated with OS (adjusted HR 3.03, 95% CI 1.45-6.33, p = 0.03). Twenty-four of 51 (47%) BRAFV600E+ pts were treated with a BRAF inhibitor. In BRAFV600E+ patients, BRAF inhibitor treatment was significantly associated with improved OS at 1 year (HR 0.25, 95% CI 0.08-0.78, p = 0.018). **Conclusions:** This is the largest study of mutation status and survival outcome in ATC to date. BRAFV600E and RAS are mutually exclusive drivers that impact prognosis in ATC. Mutation analysis at diagnosis offer prognostic evaluation and may lead to improvement in outcome by facilitating treatment with targeted therapies and enrollment in clinical trials.

Phase I/II study of spartalizumab (PDR001), an anti-PD1 mAb, in patients with anaplastic thyroid cancer. *First Author: Lori J. Wirth, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Spartalizumab, a humanized IgG4 mAb, binds programmed death-1 (PD-1) with subnanomolar affinity and blocks interaction with PD-L1/PD-L2. Anaplastic thyroid cancer (ATC) is an aggressive tumor, with nearly 100% disease-specific mortality (NCCN Guidelines 2018) and few treatment options. **Methods:** This Phase I/II, open-label, dose escalation/expansion study (NCT02404441) characterized the safety and efficacy of spartalizumab in patients (pts) with advanced solid tumors. The recommended Phase II dose was 400 mg once every 4 weeks (Q4W). **Results:** During the dose escalation phase of the study, a patient with ATC treated at 3 mg/kg Q2W experienced a mixed response with overall stable disease (SD) for 7 months before developing progressive disease. Based on this encouraging patient, an expansion cohort was opened in ATC. At the safety cut-off of Nov 13, 2017, 26 pts with ATC had been treated in the spartalizumab 400 mg Q4W expansion group. The median age was 62 (46–79), 54% were men, and ECOG performance status was 0 (42%) or 1 (58%). 77% of pts had received prior treatment for ATC, with 19% of pts receiving ≥2 prior therapies. AEs suspected to be related to treatment (> 5% of pts) were diarrhea, pruritus, and asthenia (8% each). G3/G4 AEs suspected to be related to treatment were anemia, hypophosphatemia, lymphopenia, and oncologic complication (inflammation around the tumor; 1 pt each). At the efficacy cut-off of Jan 23, 2018, 37 pts had been treated and 30 pts were evaluable for efficacy. The overall response rate (ORR) by RECIST 1.1 (confirmed + unconfirmed PRs) was 5/30 (17%), with four confirmed responses and one patient awaiting a confirmatory scan. At the efficacy cut-off, all responses were ongoing, and PFS and OS data were immature. The ORR by irRC was 6/30 (20%). Three additional pts had RECIST and/or irRC SD ongoing after 5, 5, and 12 months of treatment. The overall disease control rate was 8/30 (27%) by RECIST and 10/30 (33%) by irRC. **Conclusions:** Spartalizumab showed encouraging response rates, clinical benefit, and durability in pts with ATC, with no unexpected safety concerns. Clinical trial information: NCT02404441.

6025 Poster Session (Board #13), Sat, 1:15 PM-4:45 PM

Phase I/II trial of pembrolizumab(P) and vorinostat(V) in recurrent metastatic head and neck squamous cell carcinomas (HN) and salivary gland cancer (SGC). *First Author: Cristina P. Rodriguez, Division of Medical Oncology, University of Washington, Seattle, WA*

Background: Epigenetic modification is increasingly recognized as a mechanism for tumor immune evasion. This clinical trial explored the activity of P with the HDAC inhibitor V in HN and SGC. **Methods:** Patients(pts) with progressing incurable HN and SGC with ECOG ≤1, no prior immunotherapy, RECIST 1.1 measurable disease, and normal organ function were eligible. Controlled brain metastases were permitted. PDL1 expression was not an eligibility criterion. P 200mg was given IV q21 days (d) , with V 400mg QD PO, 5d on and 2d off, both started on d1 of each cycle. The primary endpoint was safety according to CTCAE v. 4.03. Secondary endpoints were RECIST 1.1 objective response rates and biomarker collection. **Results:** From 11/2015 to 8/2017, 25 HN and 25 SGC pts were enrolled. Among all 50 pts, median age was 61 (range 33-86) yrs, 39 (78%) were male, 21(62%) were never smokers, 27 (54%) had ECOG 0. In HN, primary sites were oropharynx 17 (68%), nasopharynx 4 (16%), oral cavity 1(4%), skin 2 (8%) and unknown 1 (4%). Thirteen(52%) were p16+ oropharynx HN. SGC histologies were adenoid cystic (ACC) 12(48%), acinic cell (AciC) 3(12%), mucoepidermoid 3(12%), ca ex. pl. adenoma 2(8%). There was 1(4%) pt each with adenocarcinoma, salivary duct, epithelial-myoepithelial, clear cell, parotid lymphoepithelioma-like(LEL-C) carcinoma. The median (range) treatment cycles received in HN was 6 (1-33), and SGC 9 (1-34). Adverse events regardless of cause (AEs) in all pts were: 27 (54%) Grade ≥1, 18(36%) Grade≥ 3. Nine(18%) pts required V dose reductions. The most common AEs in all pts were renal insufficiency in 7 (14%), fatigue 6 (12%) and nausea 3 (6%). There were 3 (12%) deaths on study, 1 aspiration pneumonia, 1 myocardial infarction, and 1 presumed pneumonitis from P. Responses in HN were: complete response (CR) 0, partial response(PR) 8 (36%), stable disease(SD) 5 (20%). Efficacy in SGC:CR 0, PR 4 (16%) in 1 LEL-C, 2 AciC and 1 ACC, SD 14(56%). With a median follow up of 8.7 mos for all pts, in HN median PFS was 4.5 mos, median OS, 12.6 mos; in SGC median PFS was 7 mos, and median OS 13 mos. **Conclusions:** P+V demonstrated activity in HN, with fewer responses in SGC. Serum and tissue biomarker analyses are ongoing. Clinical trial information: NCT02538510.

6026 Poster Session (Board #14), Sat, 1:15 PM-4:45 PM

Phase II trial of apatinib in patients with recurrent and/or metastatic adenoid cystic carcinoma of the head and neck: Updated analysis. *First Author: Guopei Zhu, Department of Oral and Maxillofacial Head & Neck Oncology, Shanghai Ninth People's Hospital, Shanghai JiaoTong University School of Medicine, Shanghai, China*

Background: There is no specific therapy, including targeted agents, has consistently improved clinical outcomes in recurrent/metastatic adenoid cystic carcinoma of the head and neck (ACCHN). Recently, anti-angiogenic targeted therapy represents a potential effective strategy. We conducted a single-arm, phase II trial to evaluate apatinib, a small-molecule inhibitor of VEGFR-2, in ACCHN, and promising response was observed (2018 Multidisciplinary Head and Neck Cancers Symposium Abstract: 20160). Here we report the updated efficacy and safety data. **Methods:** Pathologically confirmed recurrent and/or metastatic ACCHN patients (pts) who had evidence of disease progression within 3 months or had failed at least 1 line of systemic chemotherapy were eligible. All pts received continuous apatinib 500 mg qd until disease progression, death, or intolerable toxicity. **Results:** Between Apr 2016 and Dec 2017, 59 pts were recruited, including 22 (37.3%) males and 37 (62.7%) females. The median age was 47.5 years. 61.0% cases had metastases, and the main metastatic site was lung. All pts were evaluable for efficacy and safety analyses. At the cutoff date of 12/31/2017, 9 progression-free survival (PFS) events and 2 deaths after progression occurred. The median PFS and overall survival (OS) had not been reached; however, the median time of apatinib treatment was already 6.4 (IQR, 3.8–9.9) months. The 6-month PFS rate was 87.9% (95%CI, 76.6%–99.1%), and the 12-month PFS rate was 50.7% (95%CI 21.8%–79.7%). The 12-month OS rate was 96.3% (95% CI, 91.3%–101.3%). Moreover, the objective response rate and disease control rate was 47.1% and 98.1%, respectively. 34 (57.6%) pts experienced dose reduction. The incidence of drug-related adverse events (AEs) was 88.1% (52/59). 22.0% (13/59) pts developed AEs of Grade ≥3. Main AEs were hypertension (54.2%), hand-foot syndrome (33.9%), and proteinuria (23.7%). **Conclusions:** This updated analysis further confirmed that apatinib appears to be effective and safe for recurrent/metastatic ACCHN. It did achieve the best reported response rate and long duration of disease control with a good safety profile. Further investigation is warranted. Clinical trial information: NCT02775370.

6028 Poster Session (Board #16), Sat, 1:15 PM-4:45 PM

Nivolumab (nivo) vs investigator's choice (IC) in patients (pts) with recurrent or metastatic (R/M) squamous cell carcinoma of the head and neck (SCCHN): Analysis of CheckMate 141 by age. *First Author: Nabil F. Saba, Winship Cancer Institute, Emory University, Atlanta, GA*

Background: Nivo is the only immunotherapy to significantly improve overall survival (OS) in pts with platinum (plt)–refractory R/M SCCHN. In the randomized, open-label, phase 3 CheckMate 141 trial (NCT02105636), nivo significantly improved OS vs IC (HR [95% CI] = 0.68 [0.54, 0.86]) in pts with R/M SCCHN who had progressed on or within 6 mo of plt-based therapy. The safety profile of nivo in the overall pt population was favorable compared with IC. With conventional treatments, there has been concern regarding efficacy and tolerability in elderly patients owing to age-related factors and comorbidities. Here we describe efficacy and safety of nivo compared with IC, by age. **Methods:** Eligible pts were randomized 2:1 to nivo 3 mg/kg every 2 weeks (n = 240) or IC (methotrexate, docetaxel, or cetuximab, n = 121). The primary endpoint was OS. Outcomes were analyzed by age < 65 and ≥65 yrs. Data cut: September 2017 (minimum follow-up: 24.2 mo). **Results:** At baseline, 68 pts (28.3%) in the nivo arm and 45 pts (37.2%) in the IC arm were ≥65 yrs old. Baseline characteristics and relative nivo dose intensity were generally similar across age groups. OS and tumor response benefits with nivo vs IC were maintained regardless of age (Table). The 30-mo OS rates of 11.2% (< 65 yrs) and 13.0% (≥65 yrs) with nivo were more than tripled vs corresponding IC rates of 1.4% and 3.3%, respectively. As in the overall pt population, the nivo arm had a lower rate of treatment-related adverse events (TRAEs) vs IC (Table). **Conclusions:** Nivo improved OS and objective response rate (ORR) vs IC in pts < 65 yrs and ≥65 yrs in CheckMate 141, with a manageable safety profile in both age groups. OS benefit with nivo was maintained through 2 yrs of follow-up for both groups. These data support the use of nivo, regardless of age, in pts with R/M SCCHN who progress within 6 mo of plt therapy. Clinical trial information: NCT02105636.

	< 65 yrs		≥65 yrs

6029 Poster Session (Board #17), Sat, 1:15 PM-4:45 PM

Comparison between lobaplatin and cisplatin plus 5-fluorouracil combined with intensity-modulated radiotherapy for locoregionally advanced nasopharyngeal carcinoma: A multicenter randomized phase III clinical trial. *First Author: Kuiyuan Liu, Sun Yat-Sen University Cancer Center, Guangzhou, China*

Background: Cisplatin-based chemoradiotherapy(CRT) has been widely applied as a first-line regimen in patients with locoregionally advanced nasopharyngeal carcinoma (LA-NPC). However, cisplatin can induce severe side effects .Our previous phase II trial revealed that lobaplatin combined with 5-fluorouracil (5-FU) followed by concurrent chemoradiotherapy (CCRT) showed encouraging anti-tumor effects with tolerable toxicities for LA-NPC. Here, we assess the efficacy and toxicities of a regimen of lobaplatin versus cisplatin plus 5-FU as induction chemotherapy (ICT) followed by concomitant lobaplatin versus cisplatin with intensity-modulated radiotherapy (IMRT). **Methods:** Stage III-IVB NPC patients were randomly assigned to receive lobaplatin or cisplatin plus 5-FU as ICT followed by CCRT. In the lobaplatin arm, patients received lobaplatin at a dose of 30 mg/m^2 on days 1 and 22 combined with a continuous 120-h intravenous injection of 5-FU at a dose of 4 g/m^2 followed by lobaplatin at a dose of 30 mg/m^2 on days 43 and 64 concomitant with IMRT. Lobaplatin was replaced by cisplatin (100mg/m^2) in the cisplatin arm. The primary end-point was progression-free survival (PFS). **Results:** Of the 494 eligible patients, 250 were assigned to lobaplatin arm and 244 to cisplatin arm. No difference was observed in overall tumor response between two arms (98.6% vs. 97.7%, P= 0.459). After a median follow-up of 42.6 months, no statistically significant differences in 3-year PFS rate was observed between two arms (PFS: 78.9% vs. 82.0%, P= 0.985). During ICT, more patients suffered grade 3-4 leucopenia, neutropenia, nausea and vomiting in cisplatin arm (all P< 0.001). During CCRT, grade 3-4 anemia, nausea and vomiting were more common in cisplatin arm (all P< 0.001). **Conclusions:** The regimen of ICT with lobaplatin plus 5-FU followed by concomitant lobaplatin and IMRT achieved similar survival outcomes with less acute toxicity compared to cisplatin-based CRT in LA-NPC. Long-term follow up is required to determine whether lobaplatin-based systemic chemotherapy should be the first line of therapy for LA-NPC. Clinical trial information: ChiCTR-TRC-13003285.

6030 Poster Session (Board #18), Sat, 1:15 PM-4:45 PM

Anti-VEGF treatment to modulate tumor microenvironment (TME) prior to chemotherapy in EBV-positive nasopharyngeal carcinoma (NPC). *First Author: Wan Qin Chong, National University Cancer Institute, National University Health System, Singapore, Singapore, Singapore*

Background: EBV-related NPC is chemosensitive but stage 4 disease has high relapse rate and short progression free survival (PFS). Almost all NPCs overexpress VEGF.We hypothesized that anti-VEGF (bevacizumab) prior to chemotherapy could promote vascular normalisation, improve tumor perfusion, and enhance immune response in NPC. **Methods:** We conducted a study using bevacizumab in 2 doses, 7.5mg/kg (Arm A) or 2.5mg/kg (Arm B), starting 7 days prior to 3 weekly cycle of cisplatin 75mg/m^2 (Day 1) and gemcitabine 1g/m^2 (D1, D8), for 3 cycles followed by concurrent chemoradiotherapy in stage 4A/B (locally advanced) patients, and for 6 cycles in stage 4C (metastatic) patients, with the primary objectives to determine safety and response rate (RR), and secondary objectives to evaluate PFS and effects on the TME. Immunohistochemistry studies were performed by a blinded pathologist on serial fresh tumor biopsies at baseline and 7 days post cycle 1 bevacizumab. **Results:** 20 patients were recruited to Arm A, and 10 to Arm B. 1 screen failed and 2 withdrew consent. Objective RECIST response was seen in arm A (17/18 [94.4%] partial response (PR), 1/18 [5.6%] stable disease (SD)), vs arm B (8/9 [88.9%] PR, 1/9 SD [11.1%]). Metabolic PET-CT response was seen in all 25 evaluable patients with complete response in 4/17 [23.5%] patients in arm A. EBV DNA was detectable in 17 patients at baseline, and 12 patients had undetectable plasma EBV DNA by day 1 of cycle 2. 9/13 (69.2%) in arm A vs 1/4 (25%) in arm B had undetectable plasma EBV DNA post treatment. TME response to bevacizumab included increase in stromal inflammatory infiltrate, specifically CD4 ($p = 0.0002$) and CD8 T cells ($p = 0.0069$), and reduction in hyaluronic acid binding protein score ($p = 0.0116$), indicating increased vascular permeability within the TME. 3 patients had grade 3 hypertension and no patients had tumoral bleed related to bevacizumab use. **Conclusions:** In this first evaluation of bevacizumab prior to chemotherapy for NPC, tolerability and efficacy was established, and bevacizumab enhances stromal immune infiltration, and modulates TME, potentially improving vascular permeability. Clinical trial information: 2010/00693.

6031 Poster Session (Board #19), Sat, 1:15 PM-4:45 PM

A phase I/II trial adding poly(ADP-ribose) polymerase (PARP) inhibitor veliparib to induction carboplatin-paclitaxel (Carbo-Tax) in patients with head and neck squamous cell carcinoma (HNSCC) Alliance A091101. *First Author: Michael J. Jelinek, University of Chicago, Department of Medicine, Comprehensive Cancer Center, Chicago, IL*

Background: This phase I/II study evaluates safety and efficacy of veliparib, a PARP inhibitor, with induction carbo-tax in patients (pts) with locoregionally advanced HNSCC. Since PARP is involved in DNA repair, inhibition of PARP may augment damaging effects of chemotherapy on tumor DNA. We report on the completed phase I portion of the trial. **Methods:** Eligible pts had newly diagnosed stage IVa-b non-oropharyngeal cancer (OPC) or stage IVa-b, human papillomavirus-negative OPC. The primary endpoint is the maximum tolerated dose (MTD) or recommended phase II dose using a 3+3 pt cohort design. Pts received induction carboplatin (AUC 6 day 1), paclitaxel (100 mg/m^2 day 1, 8, 15), and veliparib (days 1-7) every 21 days for 2 cycles. Veliparib doses were 200, 250, 300 and 350 mg BID. Standard chemoradiotherapy followed induction. **Results:** 20 pts enrolled. Two withdrew prior to treatment, leaving 18 pts for analysis. Median age was 62.5 years: 50% were female. Primary sites (# pts) included hypopharynx (5), larynx (5), oral cavity (4), oropharynx (3) and nasal cavity (1). The most common grade (gr) 3+ adverse events (AEs) were decreased neutrophil count (33%), decreased platelet count (33%) and anemia (11%). Gr 3+ hematologic AEs were more common at higher veliparib doses. Three pts had gr 4 AEs, all hematologic (1 pt: neutropenia, 1 pt: thrombocytopenia (dose-limiting), 1 pt: both). The recommended phase II dose and MTD for veliparib in combination with carbo-tax is 350 mg. Of 13 pts currently evaluated for response, 9 (69%) had partial or complete response. At an early median follow-up of 16.7 months (mo) across dose levels for all pts, the 12-mo overall survival was 76% (95% CI: 55-100%), and 12-mo progression-free survival was 75% (95% CI: 54-100%). Medians have not been reached. Data for 350 mg is not fully mature. **Conclusions:** Addition of veliparib 350 mg BID on days 1-7 to carbo-tax was well tolerated in pts with advanced HNSCC. This dose is higher than previously tested in other trials. Hematologic toxicities were the most common AEs. Support: U10CA180821, U10CA180882; Clinical trial information: NCT01711541.

6032 Poster Session (Board #20), Sat, 1:15 PM-4:45 PM

Randomised phase II study with cetuximab in combination with 5-FU and cisplatin or carboplatin versus cetuximab in combination with paclitaxel and carboplatin for treatment of patients with relapsed or metastatic squamous cell carcinoma of the head and neck (CETMET trial). *First Author: Signe Friesland, Dep. of Oncology, Karolinska University Hospital, Stockholm, Sweden*

Background: Platinum-based chemotherapy with cetuximab is the standard of care for relapsed or metastatic squamous cell carcinoma of the head and neck (SCCHN). The aim of this trial was to investigate whether cetuximab and paclitaxel/carboplatin can achieve similar progression free survival (PFS) with less toxicity compared to standard cetuximab and 5-FU/platinum based chemotherapy. **Methods:** In this multicentre, randomised, controlled, phase 2 trial, 85 patients with relapsed or metastatic SCCHN were randomised in a 1:1 ratio to cetuximab and 5-FU/cisplatin or carboplatin (arm A, n = 42), versus cetuximab and paclitaxel/carboplatin (arm B, n = 43). Patients without disease progression continued with cetuximab maintenance every second week until progression or toxicity. Eligibility criteria included age $\geq$18 years, Eastern Cooperative Oncology Group (ECOG) performance status (PS) of 0–1, and adequate organ functions. The primary endpoint was to investigate whether PFS in arm B is non-inferior to PFS in arm A using a liberal non-inferiority margin of 1.5 for the PFS hazard ratio (HR). **Results:** The median age for the whole study population was 60.9 years with a male predominance (69.4%). Clinically significant parameters, such as tumour localization, tumour stage, PS, HPV status and age were well balanced between the two treatment arms. Adverse events $\geq$ grade 3 were more frequent in arm A than in arm B (60% vs 40%; $p = 0.034$). Median PFS in arm A was 4.37 months (95% CI: 2.9- 5.9 m) and 6.5 months (95% CI: 4.8-8.2 m) in arm B, ($p = 0.064$). Median overall survival (OS) was 8.4 months (95% CI: 5.3-11.5 m) in arm A and 10.2 months (95% CI: 5.4-15 m) in arm B (HR = 0.71; 95% CI: 0.43-1.16). PFS HR for arm B was 0.65 (95% CI: 0.41- 1.03) and the predefined non-inferiority criterion was met. **Conclusions:** Cetuximab and paclitaxel/carboplatin was found to have similar efficacy and less toxicity compared to cetuximab and 5-FU/cisplatin or carboplatin. The experimental arm is easier to administer rendering it a favourable alternative to standard therapy in daily clinical practice. Clinical trial information: NCT01830556.

6034 Poster Session (Board #22), Sat, 1:15 PM-4:45 PM

Hyperfractionated reirradiation with cetuximab for recurrent head and neck cancer: The GORTEC 2008-01 multicentric phase II study. *First Author: Mathilde Saint-Ghislain, Centre Guillaume Le Conquérant, Le Havre, France*

Background: Most head and neck cancer (HNC) patients die of locoregional progression. Surgery is feasible in less than half the patients only and chemotherapy only offers palliation. Locoregional reirradiation of recurrent HNC or second HNC primary may achieve long-term disease control in some patients, at the expense of high rates of late sequelae. We evaluated the feasibility and tolerance of slightly accelerated hyperfractionated reirradiation and cetuximab in recurrent inoperable/unresectable HNC in a prospective GORTEC phase II study. **Methods:** Patients from 13 GORTEC centers underwent twice-daily reirradiation (1.2 Gy / fraction, 5 days a week, over 5.5 weeks) to 66 Gy. Weekly cetuximab was delivered as 400mg/m2 load dose one week before reirradiation and 250mg/m2 thereafter for 6 weeks. **Results:** From October 2010 to October 2014, 48 patients with recurrent inoperable/unresectable HNC were enrolled. Of those, 71% were in the oropharynx. Median age was 61 years (range 40-75). The median delay between the first and second irradiation was 5 years (0.5-35) years. Median tumor size was 3.5 cm (range 1.3-7.0). Acute grade 3-4 toxicities were dermatitis (15%), mucositis (49%) and dysphagia (24%). Anaphylaxis with cetuximab was observed in one patient (2%). Radiotherapy was completed in 90 %. The full cetuximab course was completed in 79%. Complete response was observed in 40% of the patients. Objective response was 53%. Median follow-up for living patients was 24 months. In 28 evaluable patients, there were 7, 1, 4 and 2 patients with late grade 3 dermatitis/fibrosis, osteoradionecrosis, xerostomia or dysphagia. There was two grade 4 toxicities, mucositis and laryngeal. There was one late grade 5 toxicity carotid blowout. Median survival was 9 months and two-year overall survival rate was 22%. Tumor size at recurrence was identified as a prognostic factor for survival with a median survival time of 11.9 months ($<$ 35 mm) vs 7.4 months ($\geq$35 mm). **Conclusions:** High dose twice-daily HNC reirradiation with cetuximab is feasible in this population. Median survival was similar to those observed in previous studies, with 22% of long survivors, especially in patients with tumor diameter $<$ 35 mm. Clinical trial information: A91168-41.

6035 Poster Session (Board #23), Sat, 1:15 PM-4:45 PM

Saline alone vs saline plus mannitol hydration for the prevention of acute cisplatin nephrotoxicity: A randomized trial. *First Author: Bradley Beeler, USAF, Fort Sam Houston, TX*

Background: Cisplatin is a widely used chemotherapeutic in treating malignancies. One of the common side effects of cisplatin is kidney injury, or nephrotoxicity. This can be a reason for discontinuation of treatment. The majority of the cisplatin is excreted by urination. Mannitol is a compound that has been thought to help negate cisplatin -induced nephrotoxicity. Mannitol is a diuretic, causing increased amount of urination, thereby enhancing excretion of cisplatin. Multiple studies have indirectly looked into the effect of mannitol in preventing kidney damage in patients receiving cisplatin. However, there are limited prospective data that evaluate the effect of mannitol in preventing cisplatin-induced nephrotoxicity. In this study, we determine the effects of pre-hydration with mannitol on reducing the risk of cisplatin-induced nephrotoxicity, as opposed to normal saline pre-hydration in patients receiving cisplatin. **Methods:** 48 patients eligible to receive IV cisplatin therapy at a dose of $\geq 50 mg/m^2$ were identified and randomized to receive 1 L saline alone (A) or saline plus mannitol (B) before and after chemotherapy. Serum creatinine and BUN were drawn on days 1, 5 and 14. **Results:** Renal function as measured by BUN/Cr ratio, GFR, creatinine, and BUN between group A and B are similar at baseline (BL), day 1, day 5, and day 14. Cisplatin caused acute decline in renal function as determined by ser Cr, BUN to ser Cr ratio and GFR, however, the addition of mannitol to NS pre-hydration did not change the outcome. The decline in renal function is limited to grade 1 and most patients recover **Conclusions:** Mannitol does not prevent acute nephrotoxicity in patients receiving cisplatin. This underscores the importance of adequate hydration in patients treated with cisplatin.

Change in mean values	A (n=23)	B (n=25)	p-value

6036 Poster Session (Board #24), Sat, 1:15 PM-4:45 PM

Safety and preliminary efficacy of talimogene laherparepvec (T-VEC) in combination (combo) with pembrobrolizumab (Pembro) in patients (pts) with recurrent or metastatic squamous cell carcinoma of the head and neck (R/M HNSCC): A multicenter, phase 1b study (MASTERKEY-232). *First Author: Kevin J. Harrington, The Institute of Cancer Research and the Royal Marsden NHS Foundation Trust, Surrey, United Kingdom*

Background: We evaluated the safety and efficacy of the combo of T-VEC, the first FDA-approved oncolytic immunotherapy that enhances systemic antitumor immune responses, and Pembro, an immune checkpoint inhibitor against programmed death receptor-1 (PD-1), in pts with R/M HNSCC. **Methods:** Pts were eligible for enrollment if they had histologically confirmed R/M HNSCC unsuitable for curative resection or radiotherapy, and platinum-refractory and injectable disease. T-VEC was injected intralesionally at a dose of up to 8.0 mL of 10^6 PFU/mL on day 1. After 3 weeks, subsequent doses of up to 8.0 mL of 10^8 PFU/mL were administered every 3 weeks (Q3W). Pembro was administered intravenously at a dose of 200 mg Q3W. The primary objective was to evaluate safety, as assessed by the incidence of dose limiting toxicity (DLT). Key secondary objectives were objective response rate (ORR), best overall response per immune-related RECIST, and long-term safety. **Results:** 36 pts were enrolled and treated: 28 (77.8%) had confirmed PD-L1-positive tumor; 5 (13.9%) were HPV-positive and 13 (36.1%) were HPV-negative, with 18 (50%) unknown. One (6.3%) DLT, fatal arterial hemorrhage, was observed among 16 DLT-evaluable pts. Overall, 24/36 (66.7%) pts had grade 3 or higher treatment-emergent adverse events (TEAEs): 5 (13.9%) and 3 (8.3%) pts had TEAEs related to T-VEC and Pembro; 2 (5.6%) and 1 (2.8%) pt discontinued treatment due to T-VEC- and Pembro-related TEAEs, respectively. The most common TEAEs were pyrexia (36.1%), dyspnea (33.3%), and fatigue (25.0%). 24/36 (66.7%) pts had serious AEs. 7 deaths were reported during the study, 1 of which was related to T-VEC (the DLT pt) and none to Pembro. The ORR was 16.7% (6/36 pts; 5 PD-L1-positive; 95% CI, 6.4–32.8), and the disease control rate (objective response/stable disease) was 38.9% (14/36 pts; 11 PD-L1-positive; 95% CI, 23.1–56.5). **Conclusions:** The combo demonstrated a manageable safety profile. Preliminary ORR showed clinical activity in R/M HNSCC. Further follow-up is ongoing for PFS/OS. Clinical trial information: NCT02626000.

6037 Poster Session (Board #25), Sat, 1:15 PM-4:45 PM

An open-label, non-randomized, multi-arm, phase II trial evaluating pembrolizumab combined with cetuximab in patients with recurrent/metastatic (R/M) head and neck squamous cell carcinoma (HNSCC): Results of the interim safety analysis. *First Author: Assuntina Gesualda Sacco, University of California San Diego Moores Cancer Center, La Jolla, CA*

Background: Pembrolizumab (a humanized monoclonal antibody blocking programmed death receptor-1), and cetuximab (a chimeric monoclonal antibody inhibiting epidermal growth factor receptor) are both FDA-approved as single agents for second-line R/M HNSCC treatment. This is the first trial to combine pembrolizumab with cetuximab to evaluate anti-tumor synergy. As this specific drug combination has not been previously tested, an interim safety analysis was completed per protocol. **Methods:** Patients (pts) with R/M HNSCC were treated with pembrolizumab at a fixed dose of 200mg IV on day 1 with cetuximab 400mg/m2 loading dose followed by 250mg/m2 weekly (21-day cycle). The first 10 pts who enrolled and completed at least 1 cycle of therapy were included in the safety analysis. A mandatory study hold and Data Safety Monitoring Committee (DSMC) review were required if at least 4 of the 10 pts developed any grade (G) 3-4 non-hematologic toxicity. **Results:** Of the 10 patients included in the analysis, median age 58y (range 47-79y), M: F 5:5. 8 pts had mucosal (6 oral cavity, 1 oropharynx, 1 nasopharynx) and 2 had cutaneous HNSCC primaries. 65 adverse events (AEs) were reported in 9 pts; G1: 39, G2: 15, ≥G3: 11. Of the 11 ≥G3 AEs, only 1 was treatment-related (see Table). There were no treatment-related deaths or dose-limiting toxicities (DLTs). 3 pts discontinued treatment, none of which were due to toxicity (2 had disease progression, 1 withdrew from study). DSMC reviewed the safety data and permitted resumption of trial accrual. Of 7 evaluable pts, 4 partial responses were noted at first radiographic assessment. Clinical trial information: NCT03082534. **Conclusions:** Pembrolizumab combined with cetuximab has a very tolerable safety profile, with no DLTs. Efficacy analysis of this combination will be performed.

6038 Poster Session (Board #26), Sat, 1:15 PM-4:45 PM

Association of a baseline neutrophil-to-lymphocyte ratio (NLR) with progression-free and overall survival in head and neck cancer patients receiving anti-PD-1 therapy. *First Author: Corey Christian Foster, Department of Radiation & Cellular Oncology, The University of Chicago Medicine, Chicago, IL*

Background: An elevated neutrophil-to-lymphocyte ratio (NLR) is associated with tumor-induced inflammation and poor prognosis in a variety of treatment settings. Moreover, tumor-derived myeloid growth factors (Seiwert *et al*. ASCO 2017) could elevate the NLR and suppress cytotoxic T-cell activity and anti-PD-1 efficacy. We hypothesized that high baseline NLR will associate with poor outcomes in patients with metastatic head and neck (H&N) cancer receiving anti-PD-1 therapy. **Methods:** 114 patients with metastatic H&N cancer unselected for PD-ligand 1 (PD-L1) status received anti-PD-1 therapy. Baseline NLRs were divided into quartiles with high NLRs being the highest quartile (> 8.77). Univariate logistic regression analyzed the relationship between NLR and overall response rate (ORR) by RECIST v1.1. Progression-free survival (PFS) and overall survival (OS) were analyzed using Kaplan-Meier methods and Cox proportional hazard regression. **Results:** Median follow-up was 8.6 months. Baseline characteristics including known PD-L1 positivity (n = 15/29 high NLR vs. n = 38/78 low NLR, p = 0.15) were comparable between groups. ORR was 22.3% with a trend towards lower ORR for the high NLR group (odds ratio: 0.42, 95% confidence interval [CI]: 0.11-1.57, p = 0.20). Median PFS was 1.7 months (95% CI: 1.0-3.6) for high NLR patients and 3.6 months (95% CI: 2.6-5.6) for low NLR patients (p = 0.02). Notably, median OS was 4.1 months (95% CI: 2.1-5.5) in the high NLR group and 12.5 months (95% CI: 9.0-17.2) in the low NLR group (p = 0.007). NLR more strongly associated with outcome than PD-L1+, which was not associated with PFS (p = 0.67) or OS (p = 0.53). On multivariate analyses, a high baseline NLR remained independently associated with reduced PFS (p = 0.04) and OS (p = 0.01). **Conclusions:** A high baseline NLR showed a strong inverse relationship with OS and PFS in patients receiving anti-PD-1 therapy for metastatic H&N cancer regardless of PD-L1 expression. Future investigation of NLR as a clinically-useful biomarker, NLR kinetics over time, and a mechanistic understanding of tumor-driven factors influencing NLR and anti-PD-1 efficacy are warranted.

6039 Poster Session (Board #27), Sat, 1:15 PM-4:45 PM

RM-1929 photo-immunotherapy in patients with recurrent head and neck cancer: Results of a multicenter phase 2a open-label clinical trial. *First Author: Ann M. Gillenwater, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Patients with recurrent HNSCC (rHNSCC) have limited therapeutic options and poor prognosis. We report promising results of a Phase 2a trial of photoimmunotherapy (PIT) for the treatment of rHNSCC using a novel targeted light activated drug RM-1929; a conjugate of the EGFR-directed monoclonal antibody cetuximab with the phthalocyanine dye, IRDye 700DX. **Methods:** A multi-institutional, open label Phase 2a study of rHNSCC patients who could not be satisfactorily treated with surgery, radiation, or platinum chemotherapy was conducted to evaluate the safety and efficacy of RM-1929. For each treatment, non-thermal red light was applied to the tumors 24 hours after intravenous infusion of RM1929. Light was applied by surface illumination for superficial disease or interstitial illumination via intratumoral placement of fiber optic diffusers for deep tumors. Therapeutic response was calculated using CT RECIST 1.1 determined by an independent blinded radiologist. **Results:** Thirty rHNSCC patients were enrolled in this Phase 2a trial. Safety data are currently evaluable from 30 subjects, outcome data from 28 subjects. There were no dose-limiting toxicities or skin photosensitivity reactions observed. SAEs reported to be possibly related to study treatment, included treatment site pain, tumor hemorrhage, and swelling. Objective response rate was 28% (8/28), complete response was 14% (4/28). Median progression free survival for 28 evaluable patients was 173 days (5.7 months). Median overall survival for the entire 30 patient cohort was 278 days (9.1 months). **Conclusions:** Photoimmunotherapy with RM1929 in patients with rHNSCC is safe and well tolerated. CT RECIST 1.1 PFS, ORR and CR response rates are improved over those of standard therapies in this heavily pretreated population. Future clinical trials are planned to evaluate the therapeutic potential of RM1929 alone or in combination with other treatment modalities. Clinical trial information: NCT02422979.

6040 Poster Session (Board #28), Sat, 1:15 PM-4:45 PM

COTI-2, a potent orally available small molecule targeting mutant p53, with promising efficacy as monotherapy and combination treatment in preclinical tumor models. *First Author: Richard T Ho, Cotinga Pharmaceuticals, Boston, MA*

Background: The p53 tumor suppressor is mutated in more than half of all cancers. COTI-2, an oral 3rd-generation thiosemicarbazone, restores the structure and function of mutant p53 proteins and inhibits growth of p53 mutant cancer cell lines. While few anticancer agents are effective as monotherapies in the clinic in part due to resistance, the COTI-2 mechanism of action to reactivate normal p53 function complements DNA-damaging radiation- or chemo-therapy. Our data demonstrate that COTI-2 has a promising role in combination treatments inducing synergistic anticancer responses. **Methods:** Cell viability was measured with crystal violet stains or indicator dye to assess IC_{50}. Xenograft studies used cancer cell lines with specified p53 mutations. Drug synergy was determined by combination-index and isobolograms generated using CalcuSyn software. **Results:** COTI-2 and chemotherapy agents were tested, singly and in combination, in carcinoma cell lines: colorectal, non-small cell lung (NSCLC), and head and neck squamous cell (HNSCC). Cell lines had wild-type p53, a variety of p53 mutations, or unknown status. COTI-2 IC_{50} for the HNSCC lines, both established and early passaged, were 9.6-370.0 nM with most p53 mutants having lower IC_{50} than wild-type. In other work, single agent and combination treatment with COTI-2 and approved anticancer agents in colorectal carcinoma, NSCLC, or HNSCC cells *in vitro* showed strong synergism against mutant p53 cell lines. In mice bearing A2780 or PCI13 tumors with mutant p53, COTI-2 and doxorubicin or cisplatin, singly and in combination, demonstrated significant enhancement of tumor growth inhibition, and combinations were well tolerated. Lastly, COTI-2 and radiotherapy were administered singly and in combination in a PCI13 tumor model and showed strong synergy against tumor growth. **Conclusions:** COTI-2 is a highly potent, orally bioavailable compound active against many tumors with p53 mutations. This work highlights the potential of combination treatment using COTI-2 with other anticancer agents to provide synergistic tumor growth inhibition with good tolerability.

6041 Poster Session (Board #29), Sat, 1:15 PM-4:45 PM

CAPTN: A nomogram for predicting survival and guiding therapy for patients with de novo metastatic head and neck squamous cell carcinoma. *First Author: Jared R. Robbins, Medical College of Wisconsin, Milwaukee, WI*

Background: Determining prognosis for de novo metastatic head and neck squamous cell carcinoma (mHNSCC) is difficult with limited data to direct clinical management. Recommendations for aggressive treatment must be measured since the duration and toxicity of treatment may exceed the projected lifespan. For this reason, tools to predict survival are needed to guide decisions like the appropriateness of radiation, standard verses experimental therapy, or supportive care alone. Purpose/Objective: To develop and evaluate a model for predicting survival for patients with de novo mHNSCC. **Methods:** We identified 8,441 patients diagnosed with de novo mHNSCC (oral cavity, oropharynx, larynx, hypopharynx, nasopharynx, and paranasal sinuses) in the National Cancer Database from 2004-2013. Test and validation cohorts were randomly generated. Univariate and multivariate Cox regression models were used to identify factors associated with overall survival. A simple scoring system based on clinically-relevant factors was used to generate the CAPTN nomogram (see table). **Results:** For all patients, the median OS was 9.5 months with 1-year OS of 43%. In both the test and validation cohorts, the CAPTN accurately predicted outcomes between each group by pairwise comparison (all $p < 0.001$, see table). A CAPTN score of 0 correlated to the best prognosis while higher score represented step-wise worse prognosis. **Conclusions:** Patients with de novo mHNSCC have heterogeneous outcomes, but the CAPTN score can accurately discriminate survival. Although further validation in other cohorts is needed, the CAPTN model is usefully clinically for tailoring treatment intensity to prognosis and may be pertinent to clinical trial design as a stratification factor.

Factor	0 points	1 point	2 points		Score	Median OS	6-m OS	1-yr OS	3-yr OS
Charlson Deyo	0	1 (mild)	2 (severe)	Test	0	16.8 m	78%	60%	29%

6042 Poster Session (Board #30), Sat, 1:15 PM-4:45 PM

Absolute lymphocyte count (ALC) during and after chemoradiation (CRT) for squamous cell carcinoma of the head and neck (SCCHN): Effect of the regimen and potential therapeutic implications. *First Author: Marit Uglane, NorthShore University HealthSystem, Evanston, IL*

Background: Radiation (RT) or (CRT) is a component of treatment (tx) for locoregionally advanced (LA) SCCHN. ALC and lymphocyte subsets are known to decrease as a result of RT for SCCHN. The changes in and variables affecting ALC during or after RT/CRT are not well described. **Methods:** We retrospectively reviewed the ALC of 298 consecutive patients (pts) treated with IMRT based therapy for LASCCHN from 7/2003-7/2015. ALC was categorized using a prespecified algorithm at day 0 of RT, weeks (wk) 1,2,3,4,5,6,7,8,9, months (mo) 3, 6, 12 and years (yr) 2,3,4,5. Chemotherapy (CT) was categorized as induction (IC) yes/no and CRT as one of 4 groups: none/weekly cisplatin/ FHX (5FU, hydroxyurea, taxol)/"other", and RT was recorded as unilateral or bilateral neck tx. Regression analysis was used to assess survival as a function of ALC. VZV (shingles) infection was noted and recorded. **Results:** ALC nadir for the entire group occurred at week 9 at a mean level of 0.4 (CTCAE 4.03 grade 3, normal range 1.0 - 4.0 10^3/uL) for CRT patients and 0.76 for RT only patients ($p = 0.016$). At yr 1, ALC ranged from 0.83-1.04 ($p = 0.2$) amongst 4 groups. By year 5, ALC had only recovered to 69% of baseline with no significant differences between groups. The use of IC did not affect nadir ALC. Pts receiving bilateral neck RT vs. unilateral had significantly lower mean ALC nadirs from wk 3-9 (wk 9: 0.38 vs. 0.88 $p < 0.001$) but not after 3 mo. ALC nadir had no effect on relapse or survival parameters. 19 pts had documented cases of shingles (VZV) occurring at a median time of 10 mo. There was no effect on nadir ALC by p16 status for oropharynx pts. **Conclusions:** Pts undergoing RT or CRT for SCCHN have a quick and severe ALC nadir which never recovers to normal. CRT compared with RT decreased the severity of the nadir but not recovery. IC does not impact ALC, but bilateral neck RT leads to a deeper nadir than unilateral. ALC nadir does not affect survival. VZV could be a related adverse event as it follows CRT in at least 6% of patients at a median of 10 mo. The severe and sustained ALC nadir may also have important effects on the timing of the use of checkpoint inhibitor therapy during RT or CRT.

6043 Poster Session (Board #31), Sat, 1:15 PM-4:45 PM

The use of exosome and immune profiling to analyze a phase 2 study on the addition of patritumab or placebo to cetuximab and a platinum agent for recurrent / metastatic head and neck cancer (R/M HNSCC) patients. *First Author: Tony Ng, King's College London, London, United Kingdom*

Background: The use of patritumab (Daiichi Sankyo), an internalizing anti-HER3 monoclonal antibody, in combination with cetuximab and cisplatin was investigated in a cohort of patients with R/M HNSCC in a Phase II trial (NCT02633800). We investigated the EGFR-HER3 dimer (an established marker of cetuximab resistance within a previous study) in the circulating exosomes from patients enrolled in this trial. The objective was to identify non-invasive treatment stratification and longitudinal monitoring markers. Since antibody-directed cytotoxicity is involved as a mechanism of action for these therapies, exosomal microRNAs (miR21 and miR142), which promote the expansion of functional myeloid-derived suppressor cells (MDSC), as well as other suppressive adaptive and innate immune cell components are postulated as potential immune monitoring parameters. **Methods:** We extracted exosomes from patient serum at 2 timepoints: pretreatment (c1) and pre-cycle 2 (c2, day 1). Exosomes were stained with fluorescently labelled antibodies for fluorescence lifetime imaging microscopy (FLIM) to assess EGFR-HER3 dimerization by FRET. Serum exosomal miRs were analyzed using ddPCR. PBMCs were analyzed by flow cytometry with antibodies against CD3, CD4, CD8, CD25, CD127, CD45RO, CCR6, CCR7, and HLA-DR (T cells panel), or CD3, CD11b, CD14, CD16, CD19, CD24, CD27, CD33, CD38, and IgD (B cells/MDSC panel). We used Bayesian multivariate survival analysis, blinded, with overfitting prevention, to prospectively determine parameter contributions to risk. **Results:** Multivariate risk scores/signatures were derived that predicted either: progression free survival (PFS), with parameters including c1 MDSC, and c2 CD27-IgD-double-negative exhausted memory B cells; or RECIST response, with parameters including suppressive transitional B cells (c1 - c2 difference predicting response), and exosomal EGFR-HER3 dimer (c1 - c2 difference negatively predicting response). **Conclusion:** This study prospectively establishes an effect of exosomal and immunological factors on the efficacy of anti-HER/chemo combination therapies, paving the way for future stratification strategies that combine with immunological therapies. Clinical trial information: NCT02633800.

6044 Poster Session (Board #32), Sat, 1:15 PM-4:45 PM

Cisplatin dose intensity (CDDP-D) in human papillomavirus-positive (HPV+) localized oropharyngeal carcinoma (OPC) treated with chemoradiotherapy (CRT). *First Author: Marc Oliva Bernal, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: CDDP-D $\leq$ 200 mg/m^2 has been shown to have a detrimental impact on overall survival (OS) in HPV negative disease with a similar trend in T4/N3 HPV+ patients (pts). We evaluated the impact of CDDP-D on OS in a larger cohort of HPV+ OPC, staged using 8th Ed. AJCC/UICC TNM staging criteria (TNM8-S). **Methods:** We performed a retrospective single institution analysis of HPV+ OPC pts treated with CRT (IMRT) between 2005-2015. HPV status was tested by p16 staining, supplemented by HPV DNA (ISH or PCR) if equivocal. All cases were re-classified using TNM8-S. Kaplan-Meier 5-year OS (5yOS) was calculated and compared by log-rank test between CDDP-D ($<$ 200, = 200 or $>$ 200 mg/m^2) stratified by stage. Significant univariate variables including TNM8-S, smoking history and CDDP-D were tested in multivariable analysis (MVA) to identify OS predictors. **Results:** A total of 506 pts were evaluated: median age 57.4 (range 31.3-80.9); smoking $\leq$ vs $>$ 10 pack-year (PY), 52% vs 48%; TNM8-S I/II/III N = 200/183/123. Median CDDP-D: 200mg/m^2. Median follow-up: 4.9 (range 0.6-12.7) years. 5yOS differed by TNM8-S I, II and III: 93 vs 82 vs 78% ($p < 0.001$). In the MVA, PY had a detrimental impact on OS (HR = 1.16, 95%CI: 1.05-1.29 $p = 0.003$); CDDP-D did not impact OS overall (HR: 0.71, 95%CI: 0.41-1.21 $p = 0.4$), but in the TNM8-S III subgroup there was a trend toward decreased OS with CDDP-D $<$ 200 mg/m^2 (table). **Conclusions:** No linear CDDP-D effect on OS was seen for HPV+ OPC overall, although $<$ 200 mg/m^2 may be detrimental in TNM8-S III. TNM8-S separated OS well in this large cohort of uniformly treated pts. Suboptimal 5yOS (78%) in TNM8-S stage III HPV+ disease suggests the need for novel strategies in this setting.

6045 Poster Session (Board #33), Sat, 1:15 PM-4:45 PM

Randomized phase 2 trial of patritumab (P) or placebo (PBO) + cetuximab (C) + cisplatin (CIS) or carboplatin (CAR) for recurrent and/or metastatic (R/M) squamous cell carcinoma of the head and neck (SCCHN). *First Author: Kevin J. Harrington, Royal Marsden Hospital/Institute of Research, London, United Kingdom*

Background: P, a fully human monoclonal antibody can block HER3 activation. HER3 activation is a resistance mechanism to C, induced by the ligand heregulin (HRG). This randomized phase 2 study in Europe evaluated first-line C + CIS or CAR + P or PBO for R/M SCCHN. **Methods:** Patients (pts) age $\geq$ 18 y with confirmed R/M SCCHN, stratified by HRG high vs low expression (via RT-PCR from tumor RNA) and human papilloma virus (HPV)+ vs HPV-, received IV P (18 mg/kg loading dose [LD]; 9 mg/kg maintenance dose [MD] every 3 weeks [q3w]) or PBO, and C (400 mg/m^2 LD; 250 mg/m^2 MD weekly) + $\leq$6 cycles of CIS (100 mg/m^2 q3w) or CAR (AUC of 5). Co-primary endpoints were progression-free survival (PFS) in the intent-to-treat (ITT) and HRG high arms. **Results:** In all, 87 pts (44 P, 43 PBO; median age 59 y; 83% male) were treated; a median 6 (1-20) P cycles were completed. Pts received CAR (70%) or CIS (34%) (median 5 [2-6] CAR and 5 [1-6] CIS cycles) in the P arm and CAR (7%) or CIS (20%) (median 5 [1–6] cycles each) in the PBO arm. Discontinuations due to adverse events (AEs) were higher with P (16%) vs PBO (5%). Treatment-emergent AEs grade $\geq$3 were more frequent with P (84%) vs PBO (58%) (most frequent: acneiform dermatitis [14% vs 7%] and rash [14% vs 0%]). Serious AEs occurred in 43% (41% grade $\geq$3) (P) and 37% (33% grade $\geq$3) (PBO) of pts. In P and PBO arms, PFS and objective response rates (ORR; complete + partial response) in ITT, HRG-high (Table), HRG low (difference in PFS: HR 1.2, 95% CI 0.6–2.6, and ORR: 11.1%, 95% CI -15.8–36.0) and HPV- (difference in PFS: HR 1.5, 95% CI 0.9–2.7, and ORR: 4.7%, 95% CI -16.6–25.3) arms were similar (HPV+ arm was too small [n = 16] to draw meaningful results). **Conclusions:** P + C + CIS or CAR was not more effective than C + CIS or CAR. Clinical trial information: NCT02633800.

6046 Poster Session (Board #34), Sat, 1:15 PM-4:45 PM

Incidence of ototoxicity in head and neck cancer (HNSCC) patients (pts) receiving concomitant chemo-radiation (CRT) with weekly or triweekly cisplatin (Cis). *First Author: Jishu Das, Ohio State University Comprehensive Cancer Center, Columbus, OH*

Background: Cisplatin (Cis) is one of the most ototoxic chemotherapy drugs, resulting in a permanent and irreversible hearing loss in up to 50% of patients. Little is known about the incidence of hearing loss when using different cisplatin schedules in patients receiving concomitant CRT. We, therefore, assessed prospectively the incidence of ototoxicity in patients receiving weekly or triweekly Cis concomitantly with radiation. **Methods:** Head and Neck Squamous Cell Cancer patients receiving definitive or adjuvant cisplatin-based CRT were included. Cisplatin was administered weekly (40 mg/m2 weekly, 7 cycles) or triweekly (100 mg/m2 every three weeks, 3 cycles). Radiation was administered to a total dose of 70 Gy as definitive treatment or 66 Gy as adjuvant treatment (2 Gy/fraction). Intensity-modulated radiation therapy was used in all cases. Pure-tone air-conduction audiometry was performed in all pts before starting and after completion of CRT. The primary endpoint of the analysis was Common Terminology Criteria for Adverse Event (CTCAE v4.0) hearing change $\geq$3 at the end of CRT. **Results:** A total of 96 pts (M:77/F:19) were included (oropharynx 56 pts, other 40). Age: 55y (26-78). 68 pts received weekly cis and 28 triweekly regimen. 58 pts received definitive treatment and 38 adjuvant treatment. Nine pts receiving weekly cis (13%) experience G3 ototoxicity vs 14 pts (50%) receiving triweekly cis ($P < 0.001$, OR = 6.4, 95% CI 2.1-20.7). Risk of ototoxicity was not associated with age, cis cumulative dose, sex, tumor primary site, or CRT modality (definitive vs. adjuvant). After adjusting for these factors in a multivariable model cis schedule remained significant (OR = 8.7, 95% CI 2.31-32.75, p = 0.001). With a minimum follow-up of three months, the complete response rate after treatment was 84% for weekly CRT and 86% for triweekly CRT. **Conclusions:** Triweekly Cis-based CRT increases the risk of irreversible severe ototoxicity. This risk should be discussed with patients that are candidates for cis-based CRT.

Interference between mutational load, immune signatures and outcome in patients with head and neck cancer treated with definitive chemoradiation: A multicenter study of the German Cancer Consortium Radiation Oncology Group (DKTK-ROG). *First Author: Inge Tinhofer, Department of Radiooncology and Radiotherapy, Charité University Hospital and German Cancer Research Center Heidelberg (DKFZ)/German Cancer Consortium (DKTK), Berlin, Germany*

Background: Mutational load and immune expression signatures have previously been established as efficacy biomarkers in immune checkpoint inhibitor (ICI) trials. It is important to know the value of these biomarkers for predicting outcome after concurrent chemoradiation (cCRTX), for defining patient subgroups likely to benefit from ICI/cCRTX combinations. **Methods:** FFPE tumor samples from 101 patients with locally advanced SCCHN from a retrospective DKTK-ROG biomarker trial were available for this study. All patients had been treated with standard definitive cCRTX. Mutation profiling was performed using a large gene panel targeting the complete coding sequence of 327 genes. Mutational load was calculated based on the number of somatic non-synonymous mutations per megabase (Mb). Immune mRNA profiles were determined using the nanoString PanCancer Immune panel. Mutational load was correlated with immune profile and outcome. **Results:** The mean number of somatic mutations per Mb was 4.9 (range 0-36), in line with previous reports from TCGA/ICGC studies. No association was found between mutational load and HPV status. Univariate Cox regression analysis revealed a significant correlation of high mutational load with reduced OS (HR for death: 1.9; 95%-CI: 1.1-3.3, P= 0.028). Conversely, detection of immune profiles linked to T-cell functions was associated with improved OS (HR: 0.3; 95%-CI: 0.1-0.9, P= 0.033). There was a significant interaction between mutational load and immune profiles in their effects on outcome ($P_{interaction}$= 0.03). High mutational load was associated with low T-cell infiltration, IFN-gamma signature scores and expression of genes involved in T-cell functions including PD-L1 and LAG3, indicative of immune dysfunctions in neoantigen-rich tumors. **Conclusions:** We established mutational load and T-cell immune signatures as interdependent predictors of the efficacy of cCRTX, thereby providing first evidence that both parameters might serve for selection of patients with benefit from combined cCRTX/ICI regimens.

6048 **Poster Session (Board #36), Sat, 1:15 PM-4:45 PM**

Cisplatin-induced ototoxicity in head and neck squamous cell carcinoma (HNSCC) patients treated with chemoradiation: The role of WFS1 and ABCC2 heritable variants. *First Author: Mary Mahler, Western Univeristy, London, ON, Canada*

Background: Ototoxicity is a common adverse drug reaction associated with cisplatin therapy and with radiation to the HN region. We evaluated the differential effect on hearing impairment in HNSCC patients by candidate polymorphisms of genes associated with either hearing loss or cisplatin function. **Methods:** In this observational study of locally-advanced HNSCC patients treated with cisplatin chemoradiation, hearing impairment attributed to treatment was defined as ≥grade 2 audiometric change from baseline to post-treatment, evaluated within 18 months of completing therapy (CTCAE v4.02). Patients were genotyped for 30 polymorphisms using Sequenom. Logistic regression evaluated associations between genetic variants and ototoxicity. Cox regression assessed relationships between genetic variants and locoregional control (LRC), distant control (DC), disease free survival (DFS) and overall survival (OS). **Results:** Of 246 patients who had audiometric testing pre- and post-chemoradiation, 79% were male; 76%, oropharyngeal cancers; 11%, oral cavity cancers; 8%, laryngeal cancer; 91%, stage IV; 58% had hearing loss. Two polymorphisms had significant associations with hearing loss post treatment: WFS1 rs62283056 and ABCC2 rs3740066. In an additive inheritance model, individuals with WFS1 variants had a significantly decreased risk of ototoxicity (P= 0.012; adjusted odds ratio (aOR) = 0.56; 95% CI, 0.4-0.9, per increase in one minor allele), while the minor allele of ABCC2 was associated with greater risk of ototoxicity (P = 0.016; aOR = 1.68; 95% CI, 1.1-2.6). In contrast, the same genetic variants were not associated with LRC, DC, DFS or OS in a larger cohort of 642 HNSCC patients. **Conclusions:** WFS1 genetic variant is associated with differential hearing loss in LA-HNSCC patients. An ABCC2 variant, involved with removal of cisplatin from cells, is associated with increased cisplatin-induced ototoxicity. The same genetic variants were not associated with any efficacy outcomes. This information could be useful in the development of predictive models for cisplatin-induced ototoxicity.

Development and validation of a combined metabolic and immune prognostic classifier for head and neck cancer. *First Author: Hisham Mohamed Mehanna, University of Birmingham, Birmingham, United Kingdom*

Background: Genomic characterisation of head and neck cancer (HNC) has identified 3-5 subgroups with distinct biological properties, including metabolic profile and immune status. Both facets could impact on response to standard and novel targeted therapies for HNC, but are not currently considered for treatment selection due to lack of validated biomarkers. **Methods:** A 54-gene metabolic-immune signature (MIGS) was constructed. Gene expression was analysed *in silico* using the TCGA HNC dataset (whole transcriptome RNA-Seq, n = 275) and validated using two independent cohorts (*Chicago* microarray [Agilent], n = 130; *Birmingham* targeted RNA-Seq [Illumina] on FFPE tissue, n = 123). We then evaluated MIGS in a cohort of anti-PD-1 treated R/M HNC patients. Immunohistochemistry (IHC) was used to investigate the utility of a surrogate protein signature. Spatial distribution of metabolic and immune markers was examined using Opal/Vectra multiplex immunofluorescent staining. **Results:** Analysis of TCGA dataset using unsupervised hierarchical clustering identified three patient subgroups with distinct metabolic-immune phenotypes and survival profiles: (1) immune^{high}/metabolic^{low}, (2) metabolic^{high}/immune^{low} and (3) intermediate, with 5-yr overall survival (OS) rates of 71%, 51% and 49% respectively (p = 0.0015). The prognostic nature of MIGS was replicated in both validation cohorts (*Table*). Protein IHC signature was not prognostic. Metabolic and immune markers showed inverse expression patterns on multiplex staining. Preliminarily, presence of metabolic^{high}/immune^{low} signature was associated with ~ 20% worse OS at 1yr in PD-1 treated R/M HNC patients. **Conclusions:** We developed and validated a prognostic molecular classifier based on metabolic profile and immune status. This classifier may have clinical application to guide use of metabolic modification and targeted immunotherapies for HNC treatment.

A study to evaluate immunological response to PD-1 inhibition in squamous cell carcinoma of the head and neck (SCCHN) using novel PET imaging with [18F]F-AraG. *First Author: A. Dimitrios Colevas, Stanford Cancer Institute, Stanford, CA*

Background: Immune checkpoint blockade has demonstrated remarkable responses in a subset of patients with head and neck squamous cell carcinoma (HNSCC). However, the response rate is only ~20% or less for HNSCC. Currently, there are no good biomarkers to predict and assess responses after patients have initiated therapy. We evaluated the ability of a PET metabolic tracer ([^{18}F]F-AraG), that preferentially accumulates in activated CD8$^+$ T cells, to assess response to anti-PD-1 ab. We hypothesize that uptake of this agent within the tumor will correlate with the accumulation and activation of T cells within the tumor. **Methods:** Locally advanced HNSCC patients undergoing surgical resection received an infusion of anti-PD-1 ab in a window-of-opportunity study. A novel radiofluorinated AraG imaging agent, [^{18}F]F-AraG (Cellsight), was used to image patients by PET/CT before and 2-3 weeks after their infusion. The tissue volume of interest (VOI) for the pre- and post-infusion [^{18}F]F-AraG PET/CT scans was defined using pre-treatment conventional FDG-PET/CT scans. To assess for correlation of the [^{18}F]F-AraG with immune response, pre- and post-infusion samples of the patients' tumors were obtained and dissociated into cell suspensions. Tumor-infiltrating T cells were evaluated by flow cytometry to determine T cell infiltration and activation. Tumor tissue also underwent whole exome sequencing to assess for potential immune mediated selection and elimination of neoantigens. **Results:** In a patient with oral cavity HNSCC, there was an approximately 50% increase in total [^{18}F]F-AraG SUV in the VOI representing the tumor volume, following anti-PD-1 ab. Concurrently we observed an approximately 4-fold increase in the proportion of CD8+ T cells and an approximately 5-fold increase in the proportion of CD4+ T cells within the tumor tissue. The CD8+ T cells exhibited an activated state based on surface marker expression. **Conclusions:** [^{18}F]F-AraG accumulation in the tumor tissue correlates with an increase in T cell infiltration and activation. Further study of this novel PET tracer is underway in HNSCC to assess its utility for predicting clinical response. Clinical trial information: NCT03129061.

6051 Poster Session (Board #39), Sat, 1:15 PM-4:45 PM

Cardiovascular disease risks among head and neck cancer survivors in a large, population-based cohort study. *First Author: Mei Wei, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT*

Background: Over 63,000 Americans develop head and neck cancer (HNC) yearly. The 5-year survival rate for HNC patients is 40-90%. HNC shares risk factors to cardiovascular disease (CVD), such as age > 60 years, male sex, low fruit and vegetable intake, tobacco and alcohol use. Our study was to investigate cardiovascular complications and risk factors for CVD among HNC survivors. **Methods:** A total of 1,901 HNC patients diagnosed between 1997 and 2012, and 7,796 age and sex matched individuals from the general population were identified. CVD diagnoses were identified in electronic medical records: statewide ambulatory surgery and inpatient visit databases linked to the Utah Population Database. Multivariate Cox proportional hazard models were used to calculate hazard ratios (HR) for cardiovascular outcomes at 0-2 years, 2-5 years and 5+ years after HNC diagnosis. **Results:** Within the first 2 years after cancer diagnosis, HNC survivors had higher risks of developing CVD than matched comparison individuals, such as heart valve disease (HR 3.33, 95% 2.60-4.28), cardiomyopathy(HR3.21, 95% 2.04-5.03), systolic heart failure (HR 3.90, 95% 3.10-4.89), conduction disorders (HR 5.73, 95% 4.02-8.16), acute myocardial infarction (HR 3.11, 95% 2.08-4.65), coronary atherosclerosis (HR 3.42, 95% 2.90-4.03) and cardiac dysrhythmias (HR 4.26, 95% 3.68-4.93). The risks persisted even 5 years after cancer diagnosis. More baseline comorbidities(HR 1.27, 95%1.01-1.58), late stage of disease (HR 2.20, 95% 1.64-2.96), age > = 65 years old (HR 1.56, 95% 1.27-1.92), radiation therapy (HR 1.33, 95% 1.07-1.65) and chemotherapy (HR 1.72, 95% 1.39-2.13) were associated with increased CVD risk. Baseline comorbidities such as diabetes (HR 3.68, 95% 2.82-4.80), hyperlipidemia (HR 4.59, 95% 3.62-5.82), hypertension (HR 2.90, 95% 1.60-2.52) and chronic kidney disease (HR 5.14, 95% 4.19-6.30) were associated with increased CVD risk. **Conclusions:** Compared to the general population, HNC survivors have higher risk of developing CVD. Older age, late stage of cancer, comorbidities, radiation therapy and chemotherapy were risk factors. Close CVD monitoring and preventive treatments should be considered in this population.

6052 Poster Session (Board #40), Sat, 1:15 PM-4:45 PM

ICR gene signature to identify differential immune landscapes in anatomic subsites of head and neck squamous cell carcinomas and implications in personalized medicine. *First Author: Sara I. Pai, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Head and neck squamous cell carcinoma (HNSCC) patients have a 16-25% response rate to single agent immune checkpoint inhibitors (ICI). Prognostic biomarkers to ICIs are needed to identify patients who may most benefit from immunotherapy and to deliver personalized treatment to patients. The Immunologic Constant of Rejection (ICR) 18-gene signature reflects activation of both innate and adaptive immune effector mechanisms required for successful host immune-mediated tissue-specific destruction. **Methods:** The ICR transcriptional signature was applied to 109 primary HNSCCs and matched tumor-involved lymph nodes (oral cavity (OC, N = 40), oropharynx (OP, N = 32), and larynx/hypopharynx (L/HP, N = 37)). **Results:** The ICR signature varied substantially across anatomic subsites, with OC and OP tumors having significantly higher ICR scores than L/HP tumors (p = 1.5e-06). The ICR signature between primary and matched metastatic lymph nodes were concordant in most cases, suggesting that sampling of either the primary or metastatic site yields concordant results in determining an immune-inflamed or immune-deserted landscape. **Conclusions:** Our data suggest that L/HP primaries are less likely to respond to ICIs based on a reduced ICR gene expression profile within the tumor microenvironment. Based on this hypothesis, we are performing a retrospective analysis of HNSCC patients treated with ICIs and will evaluate their objective clinical responses with respect to anatomical subsite. This is the first report that identifies anatomic subsites within the head and neck region to have differential immune landscapes. Correspondingly, differential responses to ICIs may be linked to the evolutionary biology of the various HNSCC primary subsites.

6053 Poster Session (Board #41), Sat, 1:15 PM-4:45 PM

Comprehensive proteomic and genomic profiling to identify therapeutic targets in adenoid cystic carcinoma. *First Author: Sheeno P. Thyparambil, NantOmics, LLC, Rockville, MD*

Background: Adenoid cystic carcinoma (ACC) is a rare cancer of secretory glands accounting for 10% of salivary gland cancers and 1% of head and neck cancers. ACC rarely responds to chemotherapy or targeted therapy and there is no standard therapy for advanced ACC. Comprehensive molecular profiling of ACC tumors could identify targets of FDA-approved or investigational therapies. **Methods:** ACC specimens (n = 24) were analyzed with the GPS Cancer test, which includes whole genome sequencing, RNA-seq, and mass spectrometry-based targeted proteomic analysis. Tumor areas of FFPE tissue sections were marked by a pathologist, microdissected and solubilized for mass spectrometric quantitation of 30 clinically relevant proteins. A subset of tumors was further analyzed by global proteomics and compared with results from squamous cell carcinoma of the head and neck (SCCHN). RNA-seq results from ACC tumors was compared with that of various solid tumor types using the k-nearest neighbors algorithm. **Results:** Targeted proteomic analysis of chemopredictive proteins suggested that 17% of patients were likely to respond to irinotecan, while 33% were likely to be resistant to taxane. The vast majority of patients (96%) did not express any target proteins of FDA-approved targeted therapies. Global proteomic analysis with unsupervised hierarchical clustering of 4,002 proteins from 8 ACC specimens and 6 SCCHN specimens revealed a clear separation between the two groups. In genomic analysis, tumor mutational burden was lower in ACC than in SCCHN (1.53 vs 3.53 per MB). In ACC, MYB-NFIB fusion and missense mutations involved in transcriptional regulation (ZNF43, ZNF519 and ZNF429) were frequent. Expression of CDK6 protein and CDK6 mRNA (transcripts per million) were 4-fold and 3-fold higher in ACC than in SCCHN, respectively. None of the ACC tumors exhibited *RB1* deficiency. Among solid tumors, breast cancer was closest to ACC based on mRNA expression. **Conclusions:** Proteogenomic analysis identified CDK6 overexpression at both protein and mRNA levels in ACC. The combination of CDK6 overexpression and *RB1* proficiency suggests that ACC patients may benefit from CDK6 targeted therapy.

6054 Poster Session (Board #42), Sat, 1:15 PM-4:45 PM

Molecular prediction of lymph node metastases using immunohistochemical analysis of primary oral tongue squamous cell carcinomas. *First Author: Furrat Amen, Addenbrooke's Hospital, Cambridge, United Kingdom*

Background: Patients that present with oral tongue squamous cell carcinoma (OTSCC) may have a clinically and radiologically N0 neck at presentation. Should we observe these patients without treatment to the neck, waiting for lymph node metastases to occur, or should they be treated with a prophylactic neck dissection or irradiation, with their associated mortality and morbidity? **Methods:** This is translational research, using a tissue microarray constructed from formalin-fixed paraffin-embedded glossectomy specimens from 186 patients with OTSCC treated in 7 cancer centers in the United Kingdom. Full clinical follow up for at least 5 years and pathology data were obtained for all patients retrospectively. Up to 3 cores were taken from the centre of the tumour, 3 from the periphery, 3 from areas of perineural or vascular invasion and 1 core from normal tissue surrounding the tumor. 30 antibodies were selected from a previous cDNA microarray study (novel antibodies) and previous research studies, for confirmation of these reports. We standardized and performed immunohistochemistry using 19 antibodies: p16, FAS, desmoglein, P4HA1, involucrin, MMP8, S100, orniithine, SRP19, MRP2, LLGL2, laminin 5, FTH1, CD44, IL22, p53, Kif2a, anticollagen V, and VEGF. **Results:** Nodal metastases were related to central cores being P4HA1 negative and p53 positive, and peripheral cores being MMP8 positive and VEGF positive. SRP19 expression in the centre (56% vs 78% 5-year survival p = 0.004) and periphery of tumor (60% vs 78% 5-year survival p = 0.015) predicted significantly worse survival. VEGF expression in the periphery of tumor predicted significantly worse survival (60% vs 80% 5-year survival p = 0.001). All other tumor and patient specific predictors of metastases and survival will also be presented. **Conclusions:** The "Amen signature" (P4HA1 central negative, MMP8 peripheral positive and VEGF peripheral positive), in the primary tumor, is highly predictive of nodal metastases (p = 0.000). This will help predict which patients need a neck dissection. Poor survival can also be predicted so that these patients can have aggressive therapies or be entered into therapeutic trials of new regimens.

6055 Poster Session (Board #43), Sat, 1:15 PM-4:45 PM

Prognostic role of pretreatment plasma EBV DNA on stage III nasopharyngeal carcinoma staged by AJCC/UICC 8th edition TNM staging classification. *First Author: Victor Lee, Department of Clinical Oncology, Queen Mary Hospital, The University of Hong Kong, Hong Kong, Hong Kong*

Background: The AJCC/UICC 8th edition TNM staging classification for nasopharyngeal carcinoma (NPC) was launched in 2018. We previously proposed new stage groups which incorporated pretreatment plasma EBV DNA and T-, N-classifications into recursive partitioning analysis. Stage III disease remains heterogeneous with different combinations of T and N-classifications. We investigated if pretreatment plasma EBV DNA can stratify stage III into high-risk vs. low-risk groups (NCT02476669). **Methods:** 518 patients with non-metastatic NPC confirmed by PET-CT and MRI scans were prospectively recruited from 2010 to 2016. They all had plasma EBV DNA measured at baseline, and then 8 weeks and 6 months following IMRT with/without concurrent +/- adjunct chemotherapy. They were treated based on 7th edition TNM but were re-staged by 8th edition TNM for subsequent analysis. Covariates including age, sex, ACE-27, pretreatment LDH and plasma EBV DNA were analyzed by Cox regression for prognostic factors of progression-free survival (PFS), cancer-specific survival (CSS) and overall survival (OS). **Results:** 234 (45.2%) patients had stage III disease (see Table). 11 (4.7%) patients received IMRT alone, 39 (16.7%) received concurrent chemoradiation alone and the remaining 184 (78.6%) received concurrent chemoradiation and adjunct chemotherapy. The median pretreatment plasma EBV DNA was 494 copies/ml (range 0-175000 copies/ml). After a median follow-up of 5.2 years, 5-year PFS, CSS and OS in this cohort were 77.1%, 90.4% and 84.4% respectively. Pretreatment plasma EBV DNA 500 copies/ml stratified patients into high-risk vs. low-risk groups (PFS: 88.9% vs. 68.2%, p = 0.009; CSS: 96.8% vs. 85.4%, p = 0.033; OS: 91.2% vs. 79.4%, p = 0.124). Cox regression with multivariable analyses demonstrated that pretreatment plasma EBV DNA 500 copies/ml was the only significant prognostic factor of PFS (p = 0.005) and CSS (p = 0.027) while no prognostic factor was found for OS. **Conclusions:** Patients with high pretreatment plasma EBV DNA had a higher risk of relapse and additional therapy may be necessitated.

	N0	N1	N2	Total

6056 Poster Session (Board #44), Sat, 1:15 PM-4:45 PM

Tracking tumor-specific mutations in plasma, saliva and para-carcinoma tissues from patients with head and neck squamous cell carcinomas. *First Author: Ping Wu, Xiangya Hospital of Central South University, Changsha, China*

Background: In this study, tumor derived Cell-free DNA (cfDNA) is detected in plasma and saliva samples in head and neck squamous carcinomas (HNSCC), as well as genomic variants in para-carcinoma tissues (PCT). The utility of cfDNA and alterations in PCT to predict tumor relapse is evaluated. **Methods:** A cohort of 27 patients with HNSCC were enrolled, plasma and saliva samples collected pro and post surgery. Tumor samples and PCT were also taken at surgery for each patient. Targeted next generation sequencing with a panel of 1021 genes was performed on all samples. **Results:** Average number of somatic mutations in each tumor was 5.86 alterations (range, 1 to 13). Tumor-specific mutations were observed in 70% patients (n = 19) in plasma and 52% patients (n = 14) in saliva. At least one somatic mutation was identified in 73% (19 of 26) of PCT. TP53 was the most common mutated gene in all categories of sample. Tumor-specific DNA was detected in 94% of stage III-IV patients, comparing 67% of stage I-II. It is more likely to identified somatic mutations in plasma in hypopharyngeal carcinoma (90% in hypopharynx versus 50% in oral cavity and 64% in larynx). Approximately, they were more likely detected in saliva in oral cancer (83% in oral cavity versus 46% in larynx and 40% in hypopharynx). Disease free survival (DFS) was 50% in patients with detectable postoperative cfDNA in plasma and 86% in patients undetectable (HR = 8.09, $P < 0.05$). Similarly, patients (n = 7) with detectable postoperative cfDNA in saliva were significantly lower DFS than those patients undetectable (n = 20) (HR = 22.18, $P < 0.01$). Interestingly, patients whose PCT harbored more than one TP53 mutations or its frequency more than 5% have more tendency to relapse ($P < 0.01$). **Conclusions:** Tumor-specific mutations can be detected in cfDNA from plasma or saliva samples, including PCT, and tracking these mutations in cfDNA and in PCT can predict disease relapse after surgery in patients with HNSCC. Patients with cfDNA positive in post-surgery samples are at higher risk of relapse and are more likely to derive benefit from adjuvant treatment.

6057 Poster Session (Board #45), Sat, 1:15 PM-4:45 PM

Association of low serum albumin concentration with reduced overall survival for patients with metastatic head and neck cancer receiving anti-programmed death receptor-1 therapy. *First Author: Sara Kochanny, Section of Hematology/Oncology, Department of Medicine, The University of Chicago Medicine, Chicago, IL*

Background: Immunotherapy efficacy is modulated by immune competence which lacks well established clinical measures. Nutritional status influences immune competence and has been associated with poor outcomes with antimicrobial and oncologic therapies. The relationship between nutritional status and outcomes with anti-PD-1 checkpoint blockade has not been reported, and we examined this association in patients with metastatic head and neck (H&N) cancer. **Methods:** 114 patients with metastatic H&N cancer unselected for PD-ligand 1 (PD-L1) status received anti-PD-1 therapy. Low baseline serum albumin concentration was < 4.0 g/dL. Univariate logistic regression analyzed the relationship between albumin and overall response rate (ORR) measured by RECIST v1.1, and the association with body mass index (BMI) was performed with Chi-square analysis. Progression-free survival (PFS) and overall survival (OS) were analyzed using Kaplan-Meier methods and Cox proportional hazard regression. **Results:** Median follow-up was 8.6 months. Baseline characteristics including known PD-L1+ (n = 27/48 high albumin vs. n = 27/60 low albumin, p = 0.38) were comparable between groups. ORR was 22.3%. Albumin status not associated with ORR (p = 0.41) but was associated with BMI (p = 0.04). There was a trend towards lower median PFS for the low albumin group (2.4 months, 95% confidence interval [CI]: 1.9-3.7) compared to the high albumin group (4.6 months, 95% CI: 2.6-7.5) (p = 0.1). OS was significantly reduced for the low albumin group (median: 5.4 months, 95% CI: 3.6-9.5) compared to the high albumin group (median: 12.5 months, 95% CI: 9.1-17.3) (p-0.03). On multivariate analysis, albumin was the strongest independent predictor of poor OS (p = 0.01). **Conclusions:** Poor nutritional status as measured by low baseline serum albumin concentration is associated with worse outcomes in patients with metastatic H&N cancer receiving anti-PD-1 therapy and is a potential measure of immune competency. Investigation of clinical measures of immune competency including albumin as a marker of nutritional status in larger patient cohorts is warranted.

6058 Poster Session (Board #46), Sat, 1:15 PM-4:45 PM

Impacts of plasma EBV DNA load during different time-points of induction chemotherapy plus radiotherapy for nasopharyngeal carcinoma. *First Author: Jin-Ching Lin, Taichung Veterans General Hospital, Taichung City, Taiwan*

Background: To investigate the prognostic impacts of plasma EBV DNA measured at different time-points in patients with advanced nasopharyngeal carcinoma who received induction chemotherapy (IndCT) plus radiotherapy (RT). **Methods:** We retrospectively review 206 previously untreated, biopsy-proven, and no distant metastasis NPC patients who received IndCT consisting of biweekly P-FL (cisplatin 60 mg/m^2, day 1 and 5-fluorouracil 2500 mg/m^2 + leucovorin 250 mg/m^2, day 8) × 10 weeks, followed by RT 70-74 Gy. Quantification of EBV DNA was done before treatment, the 5th week (during-IndCT) and the 10th week (post-IndCT) in the IndCT period, one week after RT (post-RT). We set cut-off values as > vs. < 1500 copies/ml for pretreatment, and detectable (> 0) vs. undetectable (= 0) for other time-points (during-IndCT, post-IndCT and post-RT) and analyze the relationship between the EBV DNA status at different time-points and clinical outcome. **Results:** Pretreatment EBV DNA (median, 1550 copies/ml; interquantile range, 375-5688) was detectable in 95.1% (196/206) patients. The EBV DNA load decreased markedly as treatment going- 114 (55.3%), 84 (40.8%), and 30 (14.6%) patients showing detectable results during-IndCT, post-IndCT, and post-RT with a lower copy numbers (median 37, 18, and 236 copies/ml). The pretreatment, post-IndCT, and post-RT EBV DNA levels can discriminate relapse rates between the two subgroups (47.1% vs. 21.6%, P = 0.0001; 50.0% vs. 23.8%, P < 0.0001; 83.3% vs. 26.1%, P < 0.0001) whereas during-IndCT viral load cannot (37.7% vs. 30.4%, P = 0.2741). Overall survivals were significantly affected by the pretreatment (HR = 2.26, 95%CI = 1.45-3.52, P = 0.0002), post-IndCT (HR = 2.02, 95%CI = 1.32-3.09, P = 0.0010), and post-RT (HR = 4.86, 95%CI = 3.05-7.73, P < 0.0001) but not during-IndCT (HR = 1.27, 95%CI = 0.82-1.95, P = 0.2859) EBV DNA load. Relapse-free survivals showed the same results. **Conclusions:** Pre-treatment, post-IndCT, and post-RT EBV DNA are important variables to predict outcome for NPC patients. Those who had high pre-treatment levels, detectable after IndCT and one week after RT should be searched for more intensive post-RT adjuvant therapy in future trials.

6059 Poster Session (Board #47), Sat, 1:15 PM-4:45 PM

Gene expression signature after one dose of neoadjuvant pembrolizumab associated with tumor response in head and neck squamous cell carcinoma (HNSCC). *First Author: Eejung Kim, University of Cincinnati Medical Center, Cincinnati, OH*

Background: Immune checkpoint inhibitors have been shown to induce durable tumor response in a subset of recurrent and/or metastatic HNSCC. Higher expression of PD-L1, INF-γ, and composite signatures such as "T cell-inflamed" profiles have been reported as biomarkers of response. However, prospective study of gene expression profiles after a single dose of Pembrolizumab compared to pre-treatment biopsy have not been reported. As a part of study "Phase II Investigation of Adjuvant Combined Cisplatin and Radiation with Pembrolizumab in Resected HNSCC" (NCT02641093), we have investigated gene expression changes associated with Pembrolizumab pathological response in HNSCC. **Methods:** Total RNA was extracted from 11 paired samples of pre- and post- one dose of Pembrolizumab. Total RNA was subjected to a hybridization-based digital counting assay (Nanostring®), which measures mRNAs of 770 immune-related genes and controls. RNA counts were normalized and log-transformed. Gene expression comparison analysis was performed between pre- and post- Pembrolizumab treatment and between five responders and six non-responders. Response was defined as more than 10% of pathologic treatment effect. **Results:** Higher expression of PD-L1, PD-L2, and INF-γ in pre-treatment samples were associated with tumor response after one dose of Pembrolizumab (Welch's t-test, $p = 0.015$, 0.021, 0.006). Existence of T cells, B cells, NK cells, macrophages, neutrophils in pre-treatment samples were not predictive with response. However, macrophages, T and B lymphocytes were increased in post-treatment samples of responders, implying that these were recruited effectors. There was no such difference in NK cells and neutrophils. INF-γ induced genes including CXCL9, OASL, IFI35, and IDO1 showed higher expression in responders (Welch's t-test $p = 0.004$, 0.005, 0.007, 0.01). **Conclusions:** Inflamed tumor microenvironment, evidenced by increased INF-γ irrespective of lymphocyte infiltration is associated with pathological response after a single dose of Pembrolizumab in HNSCC.

6060 Poster Session (Board #48), Sat, 1:15 PM-4:45 PM

Second primary thyroid cancer following index head and neck cancer. *First Author: Katherine M. Polednik, Saint Louis University School of Medicine, Saint Louis, MO*

Background: Thyroid cancer incidence has increased in the last three decades, and studies have shown that radiation treatment for index cancers may play a role in its development. We examined the rate of second primary thyroid cancer (SPTC) following index head and neck cancer (HNC) and determined whether radiation treatment among HNC survivors increased risk of developing SPTC. **Methods:** Patients with index HNC diagnosed from 1975-2014 in the Surveillance, Epidemiology, and End Results 9 database were included. We calculated incidence rate for SPTC per 100,000 person-years. A multivariable competing risk proportional hazards model tested risk of developing a SPTC following an index HNC. Covariates included age, county-level poverty percentage, year of diagnosis, anatomic site, stage, grade, surgery, radiation, chemotherapy, race, marital status, and sex. Two sensitivity analyses using proportional hazards models were also performed: (1) comparing patients who received both radiation and chemotherapy to those who did not receive both; and (2) restricting the main model to patients who received radiation. **Results:** There were 229 SPTC cases out of 127,563 HNC patients (0.2% SPTC). The rate of SPTCs was 26.1 per 100,000 person-years. In the main model, for every increasing year of age at diagnosis, patients were 3% less likely to develop an SPTC (adjusted hazard ratio [aHR] = 0.97, 95% confidence interval [CI]: 0.96, 0.98. Compared with non-Hispanic white patients, non-Hispanic Asian/Pacific Islander/Native American/Alaskan Native patients were 66% more likely to develop an SPTC (aHR = 1.66, 95% CI: 1.10, 2.50). Males were 27% less likely to develop an SPTC than females (aHR = 0.73, 95% CI: 0.55, 0.96). Radiation (aHR = 0.92, 95% CI: 0.68, 1.25), surgery (aHR = 0.79, 95% CI: 0.56, 1.11), and chemotherapy (aHR = 1.13, 95% CI: 0.76, 1.69) were not significantly associated with developing SPTC. The sensitivity models also did not find an association between treatment and risk of SPTC. **Conclusions:** Rate of developing SPTC following index HNC was very low, and previous exposure to radiation did not significantly increase risk in our study population. More studies are needed to understand the increasing incidence of thyroid cancer across the United States.

6061 Poster Session (Board #49), Sat, 1:15 PM-4:45 PM

Immune profiling of head and neck squamous cell carcinoma (HNSCC) by a multiplex immunofluorescence (mIF) panel using multispectral microscopy. *First Author: Janis De La Iglesia, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

Background: Treatments based on immune checkpoint inhibition have shown great promise in HNSCC. Comprehensive evaluation of lymphoid-inflamed tumor-immune microenvironment may contribute to the identification of a subgroup of patients that may have a favorable outcome using immunotherapy. **Methods:** HNSCCs were analyzed by a mIF panel (CD3, CD8, FOXP3, PD-1, PD-L1, pancytokeratin AE1/AE3, and DAPI) using multispectral microscopy and image analysis. Three regions of tumor core, tumor margin and adjacent stroma were chosen for measurement. The mIF results were correlated with clinical parameters. **Results:** Sixty-eight HNSCC were stained and numbers of positive cells from all 7 markers could be obtained. In the subset of 9 tumors with known p16 status (4 positive, 5 negative), numbers of PD-L1+ cells were marginally significantly higher in p16- tumor cores ($p < 0.1$) compared to p16+ tumor cores while numbers of CD3+ and CD8+ cells were higher in stroma of p16- tumors compared to p16+ tumors ($p < 0.01$ and $p = 0.02$, respectively). Regardless of p16 status, numbers of CD3+ and CD8+ cells in the tumor cores were marginally significantly higher in never smokers (N = 12) (both $p < 0.1$) and numbers of CD8+ cells within 25 micron from the tumor cells were again higher in never smokers ($p = 0.048$) compared to former (N = 14) and current smokers (N = 42). Patients with tumors harboring high numbers of CD8+ cells within 25 micron of the tumor cells showed a trend towards longer survival times ($p = 0.16$). **Conclusions:** This is the first study to examine the distribution of immune cells in tumor core, the invasive margin, and adjacent stroma and the proximity between immune and tumor cells. Our data suggest that p16- tumors may be more immunosuppressed by increased expression of PD-L1 while CD8+ cells are unable to infiltrate the tumor mostly residing in the stroma. In addition, never smokers may have more active immune response by having closer proximity of CD8+ cells to tumor cells compared to never and former smokers. Complete data from a total of 176 patients will be presented at the meeting.

6062 Poster Session (Board #50), Sat, 1:15 PM-4:45 PM

Number of nodal metastases associated with overall survival in HPV-negative head and neck cancer. *First Author: Doug Farquhar, University of North Carolina, Chapel Hill, NC*

Background: The 8th edition AJCC staging guidelines for HNSCC incorporated the number of positive nodal metastases into the pathologic staging criteria for HPV-positive oropharyngeal HNSCC. However, the number of positive nodes is not used for pathologic staging of HPV-negative HNSCC and may have prognostic significance. In this study, we evaluated whether the number of nodal metastases and other surgical pathology characteristics, including extracapsular extension (ECE), positive surgical margins (PSM), and perineural invasion (PNI), were associated with overall survival (OS) in HPV-negative HNSCC. **Methods:** Patients were identified from the Carolina Head and Neck Cancer Study (CHANCE). All HPV-negative patients without distance metastasis (M0) who received surgical treatment for their primary tumor were included. The number of positive nodes on surgical pathology was divided into 0, 1-4, and > 4 nodes. T and N stage were based on 8th edition AJCC guidelines. Hazard ratios (HR) were calculated by Cox proportional hazard models. **Results:** We identified 212 HPV-negative HNSCC patients who received primary surgery with neck dissections; (81 had no positive nodes, 90 had 1-3 positive nodes, and 41 had ≥4 nodes). Number of positive nodes, LVI, and ECE were all associated with 5-year OS in univariate models. In a multivariate model that controlled for T and N staging, the number of positive nodes remained significantly associated with OS (HR 2.8, 95% CI 1.8–4.3 for 1-4 nodes; HR 6.4 95% CI 3.6-11.1 for > 4 nodes). In this model, N-stage as defined by AJCC 8 was no longer significantly associated with survival (HR 1.2, 95% CI 0.5–2.6 for N1 vs. N0, HR 1.1 95% CI 0.5–2.4 for N2 vs. N0, HR 2.1 95% CI 0.8–5.7 for N3 vs N0). ECE, PSM and LVI were not independently predictive of OS in adjusted models. **Conclusions:** In this population of HPV-negative HNSCC patients, the number of positive nodes had a stronger association with 5-year OS than N staging based on nodal size and laterality found in AJCC 8. No other pathologic variables were associated with survival after adjusting T and N for stage. Further research is necessary to determine whether the number of positive nodes should replace other criteria in future prognostic staging systems.

6063 Poster Session (Board #51), Sat, 1:15 PM-4:45 PM

Using mobile and sensor technology to identify early dehydration risk in head and neck cancer patients undergoing radiation treatment: Impact on symptoms. *First Author: Susan K. Peterson, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Assessment and intervention with mobile and sensor technology may improve early detection and mitigation of treatment-related symptoms, impact quality of life (QOL), reduce complications, and lower health care costs. The CYCORE (CYberinfrastructure for COmparative effectiveness Research) system utilizes sensor and mobile technology to remotely assess daily weight, blood pressure (BP)/pulse, and patient-reported outcomes in head and neck cancer (HNC) patients undergoing radiation treatment (RT). Clinicians reviewed data daily to identify early risk of dehydration and support early intervention to improve symptom management. We compared longitudinal symptom data in patients randomized to use CYCORE during RT versus those randomized to usual care. **Methods:** Methods: HNC patients (n = 357) completed the 28-item MD Anderson Symptom Inventory (MDASI) at RT initiation (baseline), completion of RT (6-7 weeks post-baseline), and 6-8 weeks post-RT completion. Symptom severity and interference were rated on 0-10 scales; lower scores indicated better outcomes. Repeated measures ANOVA evaluated time point and group differences in MDASI scores. **Results:** Mean age was 60 years (range 25-86), 21% were female, 85% were White, and 54% completed college. Baseline MDASI mean scores were similar in patients randomized to CYCORE (n = 169) or usual care (n = 188). Mean scores on the severity of general and HNC-specific symptoms were lower in the CYCORE versus usual care group at completion of RT (2.92 vs. 3.4, p = .003; 4.21 vs 4.83, p = .009), and at 6-8 weeks post-RT completion (1.69 vs 1.96; p = .003; 1.78 vs. 2.11, p = .009). Mean scores on symptom interference in daily life were similar in both groups across time. **Conclusions:** HNC patients randomized to the CYCORE group during RT self-reported lower severity of general and HNC-specific symptoms compared to usual care. Sensor and mobile technology can enable monitoring of patients' symptoms and related outcomes during critical periods of outpatient cancer treatment, can provide timely information to facilitate rapid clinical decision making about care, and may ultimately result in better QOL and health outcomes. Clinical trial information: NCT02253238.

6064 Poster Session (Board #52), Sat, 1:15 PM-4:45 PM

Minimally-invasive dual testing for active HPV E6,E7 and PD-L1 expression in HNSCC. *First Author: Haitham Mirghani, Gustave Roussy Cancer Campus, Villejuif, France*

Background: Patients with Head and Neck Squamous Cell Carcinoma (HNSCC) have better prognosis when HPV associated or with a positive PD-L1 status. The often invasive nature of testing as well as the turnaround time for results are impactful on the doctor-patient relationship as available testing influences level of care. This assay was performed with minimally invasive swabs of lesions from HNSCC patients. Non-subjective and quantitative results for E6,E7 mRNA overexpression as well as PD-L1 expression in these tumors were obtained by a three color flow cytometry assay. **Methods:** Swabs from patients with oropharynx lesions at the Institut Gustave Roussy were fixed with a proprietary solution (IncellMAX, IncellDx) and sent for processing. Received samples were strained through a 35 uM filter, underwent ISH with E6, E7 mRNA probes (HPV OncoTect, IncellDx), stained with a PD-L1 Antibody (28-8), and stained with a cell cycle dye to verify cells. Stained samples were analyzed by flow cytometry. Institut Gustave Roussy provided FFPE lesion biopsy tissue collected from the same area of swab collection. Slides from FFPE lesion biopsy tissue were processed by Gustave Roussy with p16 IHC. Positive p16 results were confirmed by HPV gDNA ISH (Inform HPV III, Ventana). Slides were also processed by Bioreference Laboratories for PD-L1 expression by IHC (PD-L1 IHC 28-8 pharmDx, Agilent). **Results:** Oral pharynx swab samples from 40 unique patients with HNSCC were tested by flow cytometry for E6,E7 and PD-L1 overexpression. Results were compared to p16/ISH and PD-L1 IHC results from the tumor biopsy. Initial analysis of 30 samples show concordance of 73.3% between E6,E7 over expression by flow cytometry and p16 by IHC. [Additional data to be presented at the conference, currently pending PD-L1 IHC results]. **Conclusions:** Providing quantification of HPV E6, E7 mRNA and PD-L1 expression through a minimally invasive method presents a profound ability for clinicians to decide treatment options for patients. Ease of sampling coupled with the ability to both multiplex targets and scale-up the assay provides great possibility in treatment in disease.

6065 Poster Session (Board #53), Sat, 1:15 PM-4:45 PM

A double-blind, randomized pilot study of NS-21 in the prevention of radiation dermatitis for patients with head and neck cancer. *First Author: Chen-Hsi Hsieh, National Yang-Ming University, Taipei, Taiwan*

Background: The purpose of this single-institution pilot study was to evaluate the feasibility and safety of NS-21, a natural cortisone-free ingredient, on skin-related toxicity in patients with head and neck cancer (HNC) undergoing concurrent chemoradiation (CCRT) or radiotherapy (RT). **Methods:** Between July 2015 and November 2017, 29 HNC patients underwent RT or CCRT were double-blind, randomly allocated to application of either NS-21 (14 patients) or placebo (aloe vera gel, 15 patients) to the irradiated fields in neck three times per day from the first day of RT to the 2 weeks after RT is completed or to the development of severe skin toxicity. The skin moisture and dermatitis in the left and right irradiated-area of neck were recorded separately. The area in the level I-II-III-Va was named as upper neck and the area in the level IV was named as lower neck. The RT dose to the low- and intermediate-risk area was 46 Gy and 60 Gy, respectively. The maximum grade of radiation used the Common Terminology Criteria for Adverse Events (CTCAE) version 4.0. The relative humidity of skin was monitored by digital hygrometer. **Results:** The number of neck fields received radiation dose larger than 46 Gy ($Neck_{> 46Gy}$) was 80 and 82 in the study and placebo group, respectively. The occurrence of acute grade 3 or higher dermatitis in $Neck_{> 46Gy}$ was significantly lower in the NS-21 group than in the placebo group (5.0% vs. 20.3%; p = 0.024). The median time of grade 3 or higher dermatitis occurred was 6 and 7 weeks for the control and NS-21 group, respectively ($p < 0.001$). From beginning of RT to 2 weeks after the completion of RT, $Neck_{> 46Gy}$ ($p < 0.001$) and applying NS-21 (p = 0.014) were independent factors for the incidence of grade 3 dermatitis. There was a trend of skin moisture protection by using NS-21 in HNC patients under RT or CCRT (p = 0.052). Moreover, $Neck_{> 46Gy}$ ($p < 0.001$) and dermatitis grading (p = 0.006) were independent factors associated with the skin moisture. **Conclusions:** For HNC patients, applying NS-21 from the first day of RT or CCRT and through the treatment course that can decrease the incidence of acute grade 3 or higher dermatitis in the neck effectively and protect the skin moisture in the neck potentially. Clinical trial information: FEMH 104048F.

6066 Poster Session (Board #54), Sat, 1:15 PM-4:45 PM

Safety and effectiveness of transoral surgery for superficial head and neck cancer: The National Registration Survey of superficial head and neck cancer in Japan. *First Author: Chikatoshi Katada, Kitasato University, Kanagawa, Japan*

Background: The national registration survey of transoral surgery (TOS) for superficial head and neck cancer (SHNC) was performed to retrospectively examine safety and effectiveness. **Methods:** From April 2001 through July 2012, a total of 599 patients with SHNC (954 lesions) who underwent TOS as initial treatment were enrolled in 27 hospitals in Japan. Of these patients, we studied 899 lesions (665 initially treated lesions and 234 metachronous multiple cancers) in 568 patients who were given a central pathological diagnosis of initially treated squamous-cell carcinoma. The study variables were clinicopathological findings, the incidences of adverse events, and treatment outcomes. **Results:** The median age was 66 years, and 534 (94%) of the patients were men. A total of 202 lesions (22.4%) were located in the oropharynx, 660 (73.3%) in the hypopharynx, 23 (2.6%) in the larynx, 12 (1.3%) in the oral cavity, 2 (0.2%) in other sites. The surgical procedures were endoscopic mucosal resection in 374 lesions (41.6%), endoscopic submucosal dissection in 359 (39.9%), endoscopic laryngopharyngeal surgery in 48 (5.3%), transoral videolaryngoscopic surgery in 40 (4.4%), direct mucosectomy in 28 (3.1%), laser microlaryngeal surgery in 20 (2.2%), and others in 28 (3.1%). The median clinical tumor diameter was 12 mm. The histopathological findings of the 869 lesions treated by TOS were carcinoma in situ in 536 lesions (61.7%) and subepithelial invasive cancer in 333 lesions (38.3%). The median treatment time of 777 sessions of TOS was 49 minutes. Adverse events occurred in 89 patients (11.5%). Life-threatening complications occurred in 10 patients (1.3%), but there was no treatment-related death. Tracheotomy was performed in 72 patients (9.3%). Local recurrence was found in 53 lesions (5.9%), nodal recurrence in 26 patients (4.6%), and distant recurrence in 3 patients (0.5%). The median follow-up period was 46.1 months. At 3 years, the overall survival rate, the relapse-free survival rate and the cause-specific survival rate were 88.1%, 84.4% and 99.6%, respectively. **Conclusions:** TOS for SHNC is a safe and effective, minimally invasive treatment option. Clinical trial information: UMIN000008276.

6067 **Poster Session (Board #55), Sat, 1:15 PM-4:45 PM**

Neck dissection rate in node positive human papillomavirus associated oropharyngeal carcinoma following chemoradiotherapy. *First Author: Sandro Porceddu, Princess Alexandra Hospital, University of Queensland, Brisbane, Brisbane, Australia*

Background: With results of chemo-radiotherapy de-escalation trials for Human Papillomavirus (HPV)-associated oropharyngeal carcinoma (OPC) pending, any reduction in toxicity may be offset by the increased need for post-therapy neck dissection (PT-ND) for suspected residual nodal disease. We report the rate of PT-ND and overall regional failure rate following standard radiotherapy (RT) with or without chemotherapy (chemo)RT in node positive HPV-associated OPC. Secondary objectives include estimated 5-year regional failure free survival (FFS), loco-regional FFS, distant metastatic FFS and overall survival (OS). **Methods:** Patients treated between Jan 2005-Jan 2016 on a pre-defined (chemo)RT protocol and 12-week restaging PET/CT (treatment package) with a minimum of 18 months follow up (FU) were analysed. Patients receiving concurrent chemo were prescribed high-dose cisplatin and 70Gy/7 weeks to gross disease. Those ineligible for cisplatin received weekly cetuximab. PT-ND was performed if residual nodal disease was suspected on the restaging scan with complete response at the primary site and no evidence of distant disease. **Results:** 343 patients were eligible. Median follow up was 60 months, with 302 (88%) alive at the close-out date. Median age was 59 (range, 21-89) yrs. The predominant AJCC/UICC 7th Edition (Ed) T- & N-stage were T2 (37.3%) & N2b (44.9%), respectively. The 8th Ed group staging were; Stage I-49%, Stage II-28% & Stage III–23%. Median RT dose was 70Gy (range, 66-70Gy) and 336 (95.6%) received systemic therapy. At the completion of the treatment package 4.6% (16pts) underwent a ND. 10 pts (62.5%) were pathologically positive. The overall regional failure rate was 6.4%. The estimated 5-year regional FFS was 93% (95% CI: 90.2-95.9), loco-regional FFS 90.6% (95% CI: 87.3-94.0) and distant metastatic FFS 86.9% (95% CI: 83.1-90.8). 5-year OS by stage were; I–93.4% (95% CI: 89.5-97.5), II–82.9% (95% CI: 75.3-91.3) & III–75.9% (95% CI: 66-87.3). **Conclusions:** Following the treatment package the ND rate was low and regional failure uncommon. These findings serve as a benchmark to assess the benefit of de-escalation trials, which may be offset by an increased need for PT-ND.

6068 **Poster Session (Board #56), Sat, 1:15 PM-4:45 PM**

A randomised, double-blind, placebo-controlled phase IIa trial of AMG319 given orally as neoadjuvant therapy in patients with human papillomavirus (HPV) positive and negative head and neck squamous cell carcinoma (HNSCC). *First Author: Christian H.H Ottensmeier, Cancer Research UK, Southampton, United Kingdom*

Background: AMG319 is a PI3Kδ inhibitor. Preclinically, target inhibition abrogates Treg mediated immunosuppression, augmenting CD8$^+$ T-cell anti-tumour activity. This study aims to quantify the immunological effects of AMG319 on the tumour microenvironment in HNSCC patients (pts). **Methods:** The trial is a neoadjuvant window study of 54 pts, randomised 2:1 to AMG319/placebo for 20-29 days. Eligible pts have operable HNSCC, ECOG 0/1, adequate organ function and no active autoimmune disease. Primary endpoints are changes in tumour-infiltrating immune cell density, safety and toxicity. Changes in circulating immune markers, pAKT and change in tumour volume (pre-dosing vs immediately pre-surgery) are also assessed. Steady state plasma concentrations of AMG319 are determined at days 8, 15 and 22. Humoral and cellular immune responses to a tetanus vaccine are employed to confirm non-tumour immunocompetence. **Results:** Blinded clinical and laboratory data have been reviewed for 22 pts who received 400mg/day of AMG319/placebo. Ten pts experienced grade 2/3 treatment related adverse events (AEs): rash, diarrhoea/colitis, vomiting, fever, flu-like symptoms (days 7-11). AEs resolved with withdrawal of IMP and supportive treatment but led to early discontinuation in 9 pts; 8 pts received less than 80% of the intended dose. pAkt levels on both day 1 and 15 show inhibition of PI3K (51.6-88.9%) 4h post dosing in a proportion of pts. A $\geq$ 2-fold increase was seen in anti-tetanus antibody response in 5/10 pts analysed. One patient experiencing immune-like toxicity with a T1 oral cavity squamous cell carcinoma achieved a complete pathological response. **Conclusions:** The percentage inhibition demonstrated in the pAkt assay and observed in HNSCC is similar in magnitude to that seen previously with AMG319 in patients with advanced B cell malignancies, thereby supporting target inhibition. Cutaneous and GI toxicities are consistent with Treg depletion suggesting that efficacy and toxicity may be mechanistically interrelated. The trial is ongoing to further explore AMG319 solid tumour dosing regimens. Clinical trial information: NCT02540928.

6069 **Poster Session (Board #57), Sat, 1:15 PM-4:45 PM**

Preliminary toxicity data from the combination of pembrolizumab and definitive-dose radiotherapy for locally advanced head and neck cancer with contraindication to cisplatin therapy. *First Author: Jared Weiss, University of North Carolina Hospitals, Chapel Hill, NC*

Background: Bolus cisplatin in combination with radiation therapy is a standard of care for the treatment of locally advanced SCCHN, but contraindications such as hearing loss, tinnitus, inadequate renal function or neuropathy are common. Pembrolizumab is a PD1 inhibitor with FDA approval for the treatment of platinum-refractory recurrent SCCHN. **Methods:** This is a phase II study (NCT02609503) for patients with locally advanced SCCHN who are not optimal candidates for the standard therapy of cisplatin and radiation. The primary endpoint is PFS. Patients are treated with 3 cycles of pembrolizumab concurrent with radiation followed by 3 adjuvant cycles. Planned accrual is 29 subjects and 18 patients have been accrued. Because of rapid advance in studies combining PD1-axis agents with radiotherapy, we report early toxicity data on the first 12 patients who have completed six cycles of pembrolizumab and at least 30 days of followup from last pembrolizumab dose. **Results:** All patients completed 70 Gy radiation. 11 patients completed 6 cycles of pembrolizumab and 1 patient completed 5 (discontinued due to PD, not toxicity). The most common primary reason for cisplatin ineligibility was abnormal hearing (4) followed by tinnitus (3), nephropathy (2), neuropathy (2) and diabetes with poor control (1). The most common toxicities were mucositis and lymphopenia. Pneumonitis and autoimmune toxicity were absent. All toxicities that occurred more than once and listed as possible, probable or definitely related to pembrolizumab and radiation are listed in the table. PEG tubes were placed in 3 patients. **Conclusions:** Early data suggest low toxicity and high feasibility of pembrolizumab combined with radiotherapy. Clinical trial information: NCT02609503.

	Grade 1	Grade 2	Grade 3	Grade 4

Impact of patient symptoms and caregiver tasks on psychological distress in caregivers for head and neck cancer (HNC). *First Author: Emily Castellanos, Vanderbilt University Medical Center, Nashville, TN*

Background: Caregiver support for HNC patients affects clinical outcomes including survival. Psychological distress in caregivers may impair the quality of support they provide. The impact of patient symptom burden and caregiver tasks on caregiver psychological distress is unknown. **Methods:** Patient symptom burden was assessed with the Vanderbilt Head and Neck Symptom Survey 2.0 (VHNSS 2.0; 10 domains, 3 single items). Caregiver task burden was assessed with the Caregiver Task Inventory (CTI; 11 domains), and quantified as task number and task difficulty/distress. Psychological distress was measured with the Profile of Mood States short form (POMS-SF). Two-step clustering analysis was used to independently generate clusters of caregiver distress, caregiver task burden, and patient symptom burden. Chi-Square and logistic regressions were used to test for associations of the resultant clusters of task burden and patient symptoms with caregiver distress. **Results:** 89 HNC patient-caregiver dyads were included. Patients were mostly male (77%) and Caucasian (88%). Median time since diagnosis was 3.7 months (IQR 2–7); 90% received combined modality therapy. Caregivers were mostly Caucasian (92%), female (85%) and spouses (80%). We found two caregiver clusters of psychological distress (40% mod-high, 60% low), and two clusters of caregiver task scores (40% mod-high, 60% low). Similarly, two clusters of patient symptom burden were found: 51% mod-high, 49% low. Caregivers with mod-high task scores were more likely than low to report mod-high levels of psychological distress (71% vs. 24%, $p < 0.001$). Patients with mod-high symptom burden were more likely than low to have caregivers with mod-high psychological distress (55% vs. 23%, $p = 0.005$). No effect modification of patient symptom burden on the association between caregiver task and caregiver psychological distress was seen ($p > 0.05$). **Conclusions:** Psychological distress in HNC caregivers is associated more strongly with caregiver task scores than patient symptoms. Further work to define the caregiver and task characteristics that lead to psychological distress should inform future interventions to support caregivers and patients.

6071 Poster Session (Board #59), Sat, 1:15 PM-4:45 PM

A phase I study of the PI3K inhibitor buparlisib (B) with concurrent chemoradiotherapy (CRT) in patients with high risk locally advanced squamous cell cancer of the head and neck (LASCCHN). *First Author: Jochen H. Lorch, Dana-Farber Cancer Institute, Boston, MA*

Background: Prognosis in smokers with LASCCHN remains poor. Activating mutations of PI3K are linked to poor outcome and PI3K activation in response to RT is implicated in resistance to CRT. **Methods:** In this phase I study, the oral pan-PI3K inhibitor B combined with CRT was tested in pts with stage III/IV LASCCHN and ≥10 pack-year history of tobacco use treated with curative intent. Pts received B during a 2-week run-in phase and during CRT consisting of 70Gy/35fx of radiotherapy plus weekly cisplatin. **Results:** Twenty-three pts (19 m, 4 f) were enrolled. Four had stage III, 19 (83%) had stage IV disease. 18 were former smokers, 5 smoked currently. Primary tumor locations: Oral cavity (6, 26%), oropharynx (11, 48%), larynx (3, 13%), other 3 (13%). HPV was pos in 14 cases. Among 7 pts enrolled on dose level 1 (DL1) (B 40mg daily, CDDP 30mg/m^2/IMRT), 1 pt experienced gr 4 rash. Among 6 patients on DL2 (B 40mg daily, CDDP 35 mg/m^2/IMRT), DLTs were observed in 4 cases (gr 3 neutropenia, LFT abn, mucositis, rash). Ten additional pts were enrolled at the RP2D (DL1). Additional gr 3 AEs included anorexia, anemia, dysphagia and confusion. One pt experienced grade 4 hyperamylasemia. With a median follow-up of 12 months (range 3-24), 2 pts (2/9%) had recurrence, one of whom died .Five pts had a response to buparlisib alone during the run-in phase assessed clinically or radiographically. To date, targeted NexGen sequencing was available in 8 pts. 4/5 cases with response to B alone had sequencing results and demonstrated mutations in FANCD2/EP300; FANCA/FGFR3; FANCI/FLT1 and PIC3CA/EP300. The patient who died had PIC3CA/STL11 mutations. **Conclusions:** B was tolerable in combination with CRT and appears to have promising activity. Genetic analysis is ongoing and may be helpful to identify patients suitable for this approach. Clinical trial information: NCT02113878.

6072 Poster Session (Board #60), Sat, 1:15 PM-4:45 PM

The prognostic impact of level I lymph node involvement in oropharyngeal squamous cell carcinoma. *First Author: Roy Xiao, Cleveland Clinic Lerner College of Medicine, Cleveland Heights, OH*

Background: Current staging for oropharyngeal squamous cell carcinoma (OPSCC) may not capture the implications of regional lymph node involvement (LNI). We investigated the impact of level I LNI on survival for patients with OPSCC. **Methods:** We used the National Cancer Database for a cohort study of patients with OPSCC who underwent surgical resection from 2010-2014. The primary outcome was level I LNI, modeled by multivariable logistic regression. Overall survival (OS) was modeled by Cox proportional hazards regression. **Results:** Among 7,231 patients with OPSCC, 1,061 (14.7%) had level I LNI. Most patients had pT1 (3,412, 47.2%) or pT2 (2,860, 39.6%) tumors with pN2 (5,482, 75.8%) lymph node stage by AJCC 7th Edition. Independent predictors of level I LNI included higher pT stage (pT3 v. pT1, OR 1.82, 95% CI 1.44-2.31; pT4 v. pT1, OR 2.92, 95% CI 2.28-3.75) and higher number of positive regional lymph nodes (OR 1.06, 95% CI 1.05-1.08). Among included patients, 5,543 had known survival status. Level I LNI was a significant predictor of inferior OS (HR 1.83, 95% CI 1.56-2.15) after adjusting for covariates. Subset analysis by pT and pN stage revealed level I LNI to be a consistent predictor of OS for pN2 patients regardless of pT stage (Table 1). For patients with confirmed HPV status, level I LNI significantly predicted OS among HPV(-) patients (N = 888, HR 1.99, 95% CI 1.43-2.74) but not among HPV(+) patients (N = 2,339, HR 1.38, 95% CI 0.89-2.05). Level I LNI remained a significant predictor of OS within additional analyses subset by age, Charlson/Deyo Comorbidity Score, number of positive regional lymph nodes, and adjuvant treatments. **Conclusions:** Level I lymph node involvement in OPSCC is a significant and independent predictor of mortality. Patients with HPV(-) OPSCC and level I LNI may warrant intensified therapies.

Adjusted hazard ratio of mortality for level I nodal involvement subset by pT/pN. Stage:

	pN1			pN2		
	N	HR (95% CI)	*p*-value	N	HR (95% CI)	*p*-value
pT1	685	0.94 (0.46-1.95)	0.877	1,906	1.80 (1.22-2.66)	0.003*
pT2	512	1.76 (0.97-3.19)	0.064	1,678	1.91 (1.42-2.57)	<0.001*
pT3	109	3.64 (1.31-9.84)	0.014*	338	1.92 (1.19-3.03)	0.008*
pT4	76	1.72 (0.58-4.74)	0.315	239	2.03 (1.34-3.03)	<0.001*

*Statistically significant, $p<0.05$

6073 Poster Session (Board #61), Sat, 1:15 PM-4:45 PM

Cisplatin (CIS) versus cetuximab (CET) with definitive concurrent radiotherapy (RT) for head and neck squamous cell carcinoma (HNSCC): An analysis of veteran's health data. *First Author: Joshua Bauml, University of Pennsylvania, Philadelphia, PA*

Background: The addition of CIS or CET to RT improves outcomes compared to RT alone in the non-operative management of HNSCC, but limited data exist on the comparative effectiveness and safety of these approaches. We compared outcomes of pts treated with RT plus CIS or CET using population-based Veterans Health Administration (VHA) data. **Methods:** We identified stage III-IVb HNSCC patients (pts) treated non-surgically with RT and CIS or CET from 2002 to 2014 in the VHA. Pts were analyzed by the drug used in their first cycle (CIS or CET; intent-to-treat). Variables including primary cancer site, age, stage, smoking/alcohol use, and Charlson Comorbidity Index were used to generate propensity scores (PS) for the use of CET. We compared overall survival (OS) by treatment group using Cox regression models, matching for PS. We determined the risk of toxicities using PS-matched logistic regression. **Results:** A total of 3,986 pts were included in the analysis with a median follow-up of 3 years (yrs): 81% received CIS (19.8% low dose - 30-50 mg/m^2). CIS pts were younger ($p < 0.001$) and had fewer comorbidities ($p < 0.001$). In an unadjusted analysis, CET was associated with inferior OS ($p < 0.001$). This remained significant after matching for PS (HR 1.66, 95% CI 1.48-1.86, $p < 0.001$), corresponding to a median OS of 1.8 vs 4.2 yrs. CET was associated with inferior survival across all primary subsites. CET was associated with inferior survival vs low dose CIS, after PS matching (See Table). Matching for PS, CET was associated with a lower rate of neutropenia, renal failure and hearing loss than CIS (all $p < 0.001$). **Conclusions:** CET yields inferior OS compared to CIS with RT for non-operative management of Stage III-IVb HNSCC. Based on this registry study, CIS should remain the preferred partner for RT in this setting.

	Median OS (yrs)				
	CET	CIS	HR	95% CI	p value
Unadjusted [n = 3,986]	1.5	3.8	1.78	1.63-1.95	< 0.001
PS matched [n = 2,114]	1.8	4.2	1.66	1.48-1.86	< 0.001
Oral Cavity (n = 135)	0.8	1.0	1.62	1.07-2.44	0.02
Oropharynx (n = 1,485)	1.0	4.6	1.63	1.42-1.88	< 0.001
Larynx/Hypopharynx (n = 477)	1.4	3.2	1.87	1.49-2.34	< 0.001
Low dose CIS, PS matched [n = 902]	1.6	3.9	1.53	1.30-1.80	< 0.001

6074 Poster Session (Board #62), Sat, 1:15 PM-4:45 PM

A phase I dose-finding study of metformin in combination with concurrent cisplatin and radiation in patients with locally advanced head and neck squamous cell carcinoma. *First Author: Shuchi Gulati, University of Cincinnati Medical Center, Cincinnati, OH*

Background: Up to 60% of HNSCC present as locally advanced disease (LAHNSCC). Although prognosis has improved significantly, 3 year PFS and OS remain at 62%, and 73% respectively (RTOG 0522) despite definitive cisplatin (Cis) based chemo-radiation (CRT), underscoring the need for improved regimens. Metformin (MET) is hypothesized to suppress tumor cell growth by mTOR pathway inhibition, which mediates the phosphoinositide 3-kinase/Akt signaling pathway (frequently deregulated in HNSCC). Retrospective studies suggest that MET improves survival in HNSCC patients (pts). Therefore, we conducted a phase I open-label single site dose escalation study combining MET with CRT in LAHNSCC (NCT02325401). **Methods:** Previously untreated LAHNSCC (Stage III/IV) pts were enrolled to receive escalating doses of MET with a 7-14 day lead-in prior to CRT based on modified toxicity probability interval design. Starting dose of MET was 2000mg daily in addition to Cis (100mg/m2 days 1, 22 and 43) and standard radiation (70Gy) (Table 1). Adverse events were categorized per CTCAE v4.03. **Results:** 20 pts were enrolled, (2 replaced due to withdrawal of consent during lead-in period). Most common grade ≥ 2 toxicities were nausea (25%), vomiting (25%), diarrhea (20%), and AKI (15%). Dose limiting toxicity (DLT) included Grade 3 diarrhea (cohort 3) and AKI (cohort 2). MTD was established at 2550mg daily in combination with CRT. Median age was 55 (46-65); majority pts were male (95%), Caucasian (95%), tobacco users (70%), and HPV positive (70%). After a median follow up of 18 months (range 1-26), 1-year PFS, and OS remain at 94%. 1 death was reported (sudden cardiac, unrelated, occurred > 8 weeks after stopping MET). Pharmacokinetic data showed that Cis did not affect MET steady state. **Conclusions:** For the first time, MET is shown to be safe and tolerable in combination with CRT with an impressive impact on survival in LAHNSCC pts. This warrants further investigation in a phase II trial, with the established MTD of 2550 mg as the recommended dose. Clinical trial information: NCT02325401.

Dose-escalation schedule.

Dose Level	Dose Met Daily (divided doses)
Level -1	1500mg
Level 1	2000mg
Level 2	2550mg
Level 3	3000mg
Expansion	MTD

6075 **Poster Session (Board #63), Sat, 1:15 PM-4:45 PM**

Suboptimal regimens in sequential treatment (ST) with ICT (induction chemotherapy) followed by CCRT (concomitant chemotherapy) in "real life" patients with locally advanced pharyngo-laryngeal squamous-cell carcinoma (LAPLSCC) and prognosis. *First Author: Carmen Orte, Hospital de Barbastro, Huesca, Spain*

Background: ST is a treatment modality widely used in LAFLSCC. Although ICT with TPF (docetaxel-Cisplatin-5FU) and CCRT with 3- weekly Cisplatin have been proved as the most active regimens, unfit patients (p) often cannot receive them. There are few data about efficacy of modified ST regimens in unselected population. **Methods:** From 1998 to 2013, data from LAFLSCC patients treated in our institution with ST were retrospectively reviewed. Patient and treatment-related prognostic factors (PFs) were collected. Both uni and multivariate proportional hazards were used to determine associations with overall survival (OS) and DFS (disease-free survival). Local Ethical Committee approval was obtained. **Results:** 337 consecutive patients were treated with ST with ICT and CCRT. Median age: 57 years. Male:92%. Stage: 135 p III (40.1%), 202p IV (59.9%). Median follow-up: 38.9 m (0- 222 m). Median OS: 48,3m (95%CI 36-60). Median DFS: 105,3 m (95%CI 90-120). Analyzed tumor-related PFs: location, stage, differentiation. Patient-related PFs: age, blood cells ratios (NLR, dNLR, LMR), ACE-27 comorbidity index, Hemoglobin, albumin. Treatment-related PFs: ICT type , CCTR type, ICT response. In Multivariate analysis (MA) several PFs independently correlated with OS and DFS (Table 1). Use of TPF as ICT was independently linked to better OS and DFS. Use of 3-weekly Cisplatin as CCRT was associated with better OS. **Conclusions:** In unselected LALFSCC patients treated with ST, selection of proved efficacious therapies affects outcome, independently of other tumor and patient-related PFs. Suboptimal regimens work worse. In unfit patients other alternatives should be considered.

Outcome measure	Independent Prognostic factors (MA)	p-value	HR(95%CI)
OS	Stage (IV vs III)	0.007	1,70(1,15-2,49)
	Post-ICT Hemoglobin (< 10vs > 10 gr/dL)	0.001	2,83(1,55-5,14)
	ICT response (Non CR vs CR)	0.009	1,71(1,14-2,56)
	ICT(Non TPF vs other)	0.027	1,58 (1,05-2,38)
	CCRT (Non CDDP vs CDDP)	0.006	1,63 (1,15-2,32)
	LMR (< 3.1 vs > 3.1)	0.013	1,71(1,11-2,61)
DFS	ICT (non TPF vs TPF)	0.035	1,80(1,04-3,13)

6076 **Poster Session (Board #64), Sat, 1:15 PM-4:45 PM**

Avelumab-cetuximab-radiotherapy (RT) versus standards of care (SoC) in locally advanced squamous cell carcinoma of the head and neck (SCCHN): Safety phase of the randomized trial GORTEC 2017-01 (REACH). *First Author: Yungan Tao, Institut Gustave Roussy, Villejuif, France*

Background: Based on the hypothesis of a synergistic effect of the anti-PDL1 avelumab when combined with cetuximab (cetux) and RT, this new combination is tested in a large scale randomized trial against two well established SoC in LA SCCHN. **Methods:** This randomized multicenter phase III trial comprises cohorts of pts deemed fit (Cohort 1) to receive high dose cisplatin (CDDP 100 mg/m^2, Q3W) or unfit (Cohort 2) to receive CDDP. The SoC is IMRT (69.96 Gy, 33 fractions) combined with CDDP in cohort 1 and with cetux in Cohort 2 (400 mg/m^2 Day-7 and 250 mg/m^2 weekly). In both cohorts, experimental (exp) arms are IMRT concomitant with cetux (same as in SoC) and avelumab (10 mg/kg Day-7 and every 2 weeks) followed by avelumab 10 mg/kg bi-monthly for 12 months. The primary objective is to test whether exp arm is superior to SoC for progression-free survival in each cohort, with 400 and 268 pts to be randomized to Cohort 1 and 2 respectively. Monitoring of grade $\geq$ 4 acute adverse events in both exp arms was planned with null and alternative hypotheses of 15% and 35%. Overall 1-sided alpha error of 0.10, Lan-DeMets alpha spending function, 95% power. This safety phase was approved by the study Data and Safety Monitoring Committee" (IDSMC) and planned to be run on the first 82 pts in 3 steps, after 8 weeks follow-up of 14, 27 and 41 pts randomized in exp arms. Here we report the 1st step (stopping rule > = 7/14 gd > = 4 AE). **Results:** Between 09 and 12 2017, 29 pts Stage III/IV SCCHN were randomized including 14 in the exp arms. The 1st step safety analysis was presented to the IDSMC early in 2018. All pts received the entire RT as planned. Six out of the 14 pts in exp arms did not receive the entire systemic regimen: 3 did not receive the last dose of cetux, 2 received 5 doses of cetux and 3 of avelumab, one received 3 cetux and 2 avelumab. Three pts (21.4%) developed a grade 4 AE (1 dermitis, 1 lymphopenia, 1 mucositis, CTCAE v4). **Conclusions:** The safety stopping rule was not crossed and an approval to continue the trial was given by the IDSMC. Updated and completed results of the run in safety phase will be presented at the meeting. Clinical trial information: NCT02999087.

6077 **Poster Session (Board #65), Sat, 1:15 PM-4:45 PM**

Long-term outcomes for re-irradiation of recurrent head-and-neck cancers: Report of acute and long-term toxicity. *First Author: Nima Aghdam, Georgetown University Medical Center, Washington, DC*

Background: Long-term toxicity is a concern in patients undergoing head and neck re-irradiation. Durable local control is achieved in majority of patients in combination with chemotherapy and surgery. Here, we report the incidence and predictors of severe toxicity. **Methods:** From 2002 to 2016, 133 lesions in 123 patients received SBRT to the oropharynx (n = 21), hypopharynx (n = 8), nasopharynx (n = 9), paranasal sinus (n = 7), neck (n = 39), and other sites (n = 49). 92 lesions in 88 patients were treated definitively, and 41 lesions were treated with palliative intent. 36% underwent complete macroscopic resection before SBRT. Seventy-eight patients received chemosensitization. The median initial radiation dose was 70 Gy, and the median re-irradiation SBRT dose was 30 Gy (21-42.5 Gy) in 2-5 fractions. Median planning volume was 75 cm^3 (6-645 cm^3). Locoregional control (LRC) and overall survival (OS) were calculated using the Kaplan Meier method. χ^2 test was utilized for differences in rates of acute and late toxicity. Severe toxicity was defined based on the RTOG Common Toxicity Criteria ($\geq$grade 3). Logistic regression model was constructed to identify independent predictors of toxicity. **Results:** Median follow-up for surviving patients was 24.2 months. For definitively treated patients, 2-year OS and LRC rates were 42% and 36%, respectively. Durable local control was achieved in 56% of all patients. Of the patients treated definitively, 7.7% (n = 7) and 11% (n = 11) experienced severe acute and late toxicity, respectively. Patients who were treated in the neck and oropharynx experienced higher rates of severe late toxicity compared to other sites (19% vs 2%, p = 0.026). Additionally, there was a trend for higher acute severe toxicity in patients who received chemotherapy (11.4% vs. 0 %, p = 0.053). No patient experienced severe acute or late toxicity when re-treated with $\leq$ 30 Gy. Logistic regression model identified higher initial and re-irradiation dose as predictors of late severe toxicity. **Conclusions:** SBRT is an effective treatment for patients with locally recurrent or second malignancy in previously irradiated sites with acceptable toxicity.

6078 **Poster Session (Board #66), Sat, 1:15 PM-4:45 PM**

Regional lymph node metastases oncogenic mutations compared to primary tumors in HPV+ oropharynx patients. *First Author: John F. Deeken, Inova Schar Cancer Institute, Falls Church, VA*

Background: Residual disease after concurrent chemoradiation in locally advanced Head and Neck cancer is typically contained in involved lymph nodes (LNs), with primary tumors (PTs) showing complete response to treatment. This resistant phenotype in LNs is not well characterized. Clonal genomic evolution in node metastases may explain this phenotype. **Methods:** PTs and matched LNs from consecutive patients who underwent trans-oral robotic surgery with modified neck dissections as primary therapy were tested using NextGen sequencing using the Oncomine Comprehensive Assay run on the Ion Torrent S5 system. This platform detects genetic mutations in 143 known cancer related genes. Tumors from patients treated with primary surgery were used given the need for sufficient tumor content to run the assay. Results were interpreted using the Ion Reporter Software. **Results:** A total of 21 patients had sufficient tumor content in FFPE samples that passed QC testing. Eight (38%) matched sets of PTs and LNs displayed the same mutation profile. LNs from four patients (19%) showed loss of mutations detected in primary tumors. Nine patients (43%) showed gain of mutations in neck LNs compared to PTs. Genes showing gain of mutation in LNs included: TP53 (4), PIK3CA (3), FBXW7 (3), VHL (1), PTEN (1), JAK3 (1), and MAPK1 (1). **Conclusions:** Gain of mutations in regional LNs was detected in almost half of all HPV-positive oropharynx patients. Gain of mutations in genes such as TP53 and PIK3CA may define a resistant genotype when such patients are treated with primary chemoradiation.

6079 Poster Session (Board #67), Sat, 1:15 PM-4:45 PM

Post-treatment evaluation of head and neck cancer patients in the era of advanced imaging and value-based care. *First Author: Thomas Hirsch, Medical College of Wisconsin, Milwaukee, WI*

Background: Current guidelines recommend imaging (CT and/or PET) to evaluate treatment response and detect residual disease after nonsurgical management of head and neck cancers squamous cell cancers (HNSCC). To objectively evaluate the utility of these diagnostic tests, we reviewed our institutional cohort to better understand the value of these interventions compared to routine history and physical examination (PE). **Methods:** After IRB approval, we retrospectively reviewed an institutional cohort of 160 HNC patients who underwent definitive radiation +/- chemotherapy from 2003 - 2014. All patients had post-treatment history, PE, and imaging data, including a 4-month PET scan. The sensitivity, specificity, negative-predictive and positive-predictive values were calculated, along with Kaplan-Meier survival analyses for each symptom, PE, and imaging finding. **Results:** PE and symptoms had higher specificity than imaging but had lower sensitivity (see table). While imaging had good sensitivity and NPV, excess false positives led to poor specificity and PPV. When PE and symptoms were evaluated together, performance was similar to CT and PET. On KM analysis, all PE/symptom factors and PET response correlated with outcome, while baseline CT did not. There were no early interventions resulting from baseline CT scans. **Conclusions:** In an era of value-based care, a renewed emphasis on patient symptoms and PE findings may allow for improved resource utilization and cost of care. These are strong predictors of residual disease in the immediate post-treatment setting, suggesting a need to reevaluate current imaging paradigms, particularly the utility of post-treatment CT scans.

6080 Poster Session (Board #68), Sat, 1:15 PM-4:45 PM

Prevention of surgical site infection after oral cancer surgery by topical tetracycline: Results of a multicenter randomized control trial. *First Author: Madoka Funahara, Kyushu Dental University School of Oral Health Sciences, Faculty of Dentistry, Kitakyushu, Japan*

Background: In a pilot study, we showed that topical administration of a tetracycline could decrease oral bacteria levels for 6 hours in patients who underwent oral cancer surgery combined with tracheotomy and flap reconstruction. This multicenter, randomized control trial aimed to investigate the effectiveness of topical application of tetracycline ointment for prevention of surgical site infection (SSI) associated with major oral cancer surgery. **Methods:** One hundred and seventeen patients who underwent oral cancer resection combined with neck dissection, flap reconstruction, and tracheotomy were divided randomly into an intervention group (n = 56) and a control group (n = 61). The intervention consisted of topical administration of tetracycline ointment on the dorsum of the tongue every 6 hours for 48 hours postoperatively. Factors relating to the occurrence of SSI in both groups were subjected to logistic regression analysis. **Results:** SSI occurred in 11 patients (19.6%) in the intervention group and 22 patients (36.1%) in the control group. Multivariate analysis showed that a longer operating time and not receiving topical tetracycline were independent risk factors for development of SSI. **Conclusions:** Administration of topical tetracycline for 48 hours postoperatively is an effective way of preventing SSI after oral cancer surgery. Clinical trial information: 000018318.

6081 Poster Session (Board #69), Sat, 1:15 PM-4:45 PM

Second interim analysis of RIFTOS MKI, a global non-interventional study assessing the use of multikinase inhibitors (MKIs) in the treatment of patients with asymptomatic radioactive iodine-refractory differentiated thyroid cancer (RAI-R DTC). *First Author: Marcia S. Brose, Department of Otorhinolaryngology, Head and Neck Surgery and the Abramson Cancer Center of the University of Pennsylvania, Philadelphia, PA*

Background: Sorafenib and lenvatinib are oral MKIs approved for the treatment of RAI-R DTC; however, there is no consensus on when patients with asymptomatic RAI-R DTC should start treatment with a MKI. **Methods:** RIFTOS MKI is an ongoing, global, non-interventional study, enrolling patients with asymptomatic RAI-R DTC, designed to compare the time to symptomatic progression from study entry in the real-life setting between two cohorts. The classification into one of the two cohorts is based on the treating physician's decision to initiate a MKI at study entry (yes or no). Here, we report the results from a planned second interim analysis; no comparisons between cohorts were made. **Results:** Of 551 patients enrolled, and valid for analysis, 44% were male and the median age was 68 years; the median duration of observation was 9.0 months. Most patients had an ECOG performance status of 0 or 1 (95%) and distant metastases (87%) at study entry, and the most frequent histology was papillary (74%). The median time from initial diagnosis of DTC to study entry was 7 years, and RAI refractoriness was mainly due to a lack of RAI uptake (65%). The average dose per RAI treatment and median cumulative activity of RAI were 4.63 GBq and 8.51 GBq, respectively. A total of 28% of patients were treated with sorafenib at any time during the study. The median duration of sorafenib exposure was 6.7 months, and most patients (66%) received an initial dose of 800 mg/day. Of 113 patients included in the sorafenib safety analysis, 106 (94%) had $\geq$1 adverse event (AE), and 28 (25%) had $\geq$1 serious AE; hand–foot skin reaction (HFSR) was reported in 54 patients (48%), and grade $\geq$3 HSFR in 11 patients (10%). **Conclusions:** The RIFTOS MKI study is the largest non-interventional study in RAI-R DTC. Safety data from patients treated with sorafenib is consistent with the known safety profile of sorafenib. Of note, HFSR appears to be reported less frequently in real-life practice compared with phase 3 clinical studies. Clinical trial information: NCT02303444.

6082 Poster Session (Board #70), Sat, 1:15 PM-4:45 PM

An open-label, randomized phase III trial of gemcitabine and carboplatin (GC) followed by Epstein-Barr virus-specific autologous cytotoxic t lymphocytes (EBV-CTLs) versus GC as front-line therapy for patients (pts) with advanced nasopharyngeal carcinoma (NPC). *First Author: Han Chong Toh, Tessa Therapeutics Pte Ltd, Singapore, Singapore*

Background: Median overall survival (OS) and prognosis in patients with advanced EBV-positive NPC remain poor and treatment options are limited. In a small phase II trial (38 Asian pts), EBV-CTLs following chemotherapy (GC) as a first line setting for pts with metastatic and/or recurrent NPC has shown promising efficacy and acceptable toxicity: median OS and overall progression free survival (PFS) was 29.9 and 7.6 months respectively, with 2-year OS rate of 62.9% (Chia et al., Mol Ther., 2014). A Phase III trial has been initiated to evaluate the antitumor efficacy of GC-CTL versus GC in these pts (NCT02578641). **Methods:** This multicenter, randomized, open-label, two arm study is ongoing across 30 sites in Malaysia, Singapore, Taiwan, Thailand and USA. Eligible pts have a histologically confirmed metastatic or locally recurrent EBV-positive, non-keratinizing and/or undifferentiated NPC (not amenable to curative treatment with surgery and/or chemoradiation therapy), with measurable disease (RECIST v1.1) at screening, ECOG PS$\leq$2 and NCI CTCAE $<$ 2. Pts with CNS metastasis, autoimmune disease or prior immunotherapy are excluded. Prior chemotherapy or radiation with curative intent is allowed. 330 pts will be randomized 1:1 to receive either four cycles of GC followed by six cycles of EBV-CTLs (Arm A) or six cycles of GC alone (Arm B). Stratification factors include country and disease stage (metastatic versus locally recurrent). Analysis of the primary endpoint is based on the hazard ratio calculated using the Cox Proportional Hazard model. Secondary endpoints include PFS, overall response rate, clinical benefit rate and quality of life. Safety assessments will consist of monitoring and recording all adverse events (graded by NCI CTCAE v 4.0). **Results:** As of 31 Jan 2018, 226 of the planned 330 pts are enrolled. **Conclusions:** An Independent Data Monitoring Committee has reviewed the trial on 29 Aug 2017 and concluded that trial accrual continue as planned. Clinical trial information: NCT02578641.

6083 Poster Session (Board #71), Sat, 1:15 PM-4:45 PM

Integrative whole-genome analysis of salivary duct carcinoma. *First Author: Sehhoon Park, Seoul National University Hospital, Seoul, Korea South*

Background: Salivary duct carcinoma (SDC) is one of the most aggressive histological subtypes of salivary gland cancers. Conventional chemotherapy and radiation have shown only limited efficacy in metastatic SDC. Currently, clinically approved targeted-therapeutics are not available for treatment of this disease, mainly due to its rarity and limited understanding of the molecular mechanisms underlying its pathogenesis. Thus, we conducted multi-level genomic profiling of the SDC to delineate the genomic alterations prevalent in this disease. **Methods:** Whole-genome sequencing, whole exome-sequencing and transcriptome sequencing were performed on 10 discovery cohort of SDC samples. Genomic profiling was performed in additional 32 SDC samples to corroborate the findings obtained from the initial discovery cohort. **Results:** The cancer cohort is characterized by an average mutation burden of 85 somatic non-silent exonic mutations per tumor. The cohort displayed a mutational signature of BRCAness and APOBEC/AID. Several genes, including *TP53, RB1, SMAD4, HRAS, APC, PIK3CA* and *GNAQ* were recurrently mutated in SDC. A novel fusion gene, generated by genomic rearrangement, *MYB-NHSL1*, was identified. **Conclusions:** These findings represent an important layer in the systematic understanding of clinically meaningful genomic targets for precision medicine in SDC, a disease with a significant unmet clinical need.

6084 Poster Session (Board #72), Sat, 1:15 PM-4:45 PM

Novel approach for unresectable salivary duct carcinoma: Targeting HER2 and androgen receptor. *First Author: Daisuke Kawakita, Department of Otolaryngology Head and Neck Surgery, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan*

Background: Salivary duct carcinoma (SDC) is highly aggressive and rare cancer, often expressing androgen receptor (AR) and/or HER2. While chemotherapy has been failed to show significant efficacy on SDC, we have demonstrated efficacy and safety of AR- or HER2-targeted therapy in patients with unresectable locally advanced or recurrent/metastatic (LA/RM) SDC in a single-arm phase II trial. However, data regarding whether these targeted therapies prolong survival compared with conventional therapy is lacking. **Methods:** We conducted a multi-institutional retrospective cohort study of SDC patients in Japan. The survival impact of molecular-targeted therapy was compared with conventional therapy, including chemotherapy and/or cetuximab by multivariate proportional hazard models. **Results:** A total of 152 LA/RM patients were enrolled, of whom 65 received conventional therapy, 55 received HER2-targeted therapy, and 32 received AR-targeted therapy. Median follow-up time was 1.8 years (range: 0.1-9.5 years). The 2-year overall survival (OS) were 38.7% for conventional therapy, 69.3% for HER2-targeted therapy, and 57.9% for AR-targeted therapy. After adjustment by potential confounders, HER2-targeted therapy significantly improved OS compared with conventional therapy among HER2-positive patients (hazard ratio [HR]: 0.34; 95% confidence interval [CI], 0.16-0.71). AR-targeted therapy did not significantly improve OS compared with conventional therapy among AR-positive patients (HR: 0.63; 95% CI, 0.32-1.26). No other biomarker predicting efficacy of targeted therapies was found. **Conclusions:** Although this study was retrospective, this was the first study to demonstrate that novel therapy targeting HER2 prolonged OS compared with conventional therapy in patients with LA/RM SDC.

6085 Poster Session (Board #73), Sat, 1:15 PM-4:45 PM

A novel prognostic risk classification model for NUT midline carcinoma: a largest cohort analysis from the NMC registry. *First Author: Nicole Grace Chau, Dana-Farber Cancer Institute, Boston, MA*

Background: NUT midline carcinoma (NMC) is a rare subtype of squamous cancer defined by rearrangement of the *NUT* gene. Due to its rarity and under-diagnosis, there are no existing models to classify patients (pts) into risk groups based on baseline clinicopathologic factors. We aim to develop a prognostic risk classification model for NMC survival outcomes based on the largest cohort of NMC pts analyzed to date. **Methods:** Clinicopathologic variables and survival outcomes were extracted for N = 143 pts registered between 1990-2017 from the International NMC Registry. We performed survival tree regression to determine pt subgroups with statistically distinct risk factors and overall survival (OS) outcomes. Briefly, we performed Cox proportional-hazards regression for each potential factor. We dichotomized pts into two subgroups using the significant factor with the highest hazard ratio. We repeated this process within each subgroup until no further significant factors were found. **Results:** For N = 143 pts, median diagnosis age was 24 y (range = 18d-80y) and 48% were male. About half (54%) of tumors were without squamous cell differentiation; 54% had thoracic origin, 40% head/neck, and 6% other primary site. Most patients had the *BRD4-NUT* fusion (71%), followed by *BRD3-NUT* (13%), and *NSD3-NUT* (5%). At diagnosis, 78% had lymph node or organ metastases (mets). Median follow-up time was 2.9y (1d-19.1y). For N = 134 with survival data, median OS was 6.8m (95% CI = 5.8-9.7); 2-year OS was only 23% ($\pm$SE = $\pm$4%). Survival tree regression identified 3 distinct risk groups: (A) no mets [2-yr OS = 39.5$\pm$ 10%; N = 24]; (B) with mets, non-thoracic origin [2-yr OS = 38.7$\pm$10%; N = 27]; (C) with mets, thoracic origin [2-yr OS = 6$\pm$4%, N = 55]. **Conclusions:** This is the first risk classification model for NMC. Metastatic pts with thoracic primary tumors have markedly poorer prognosis compared to other subgroups.

6086 Poster Session (Board #74), Sat, 1:15 PM-4:45 PM

Phase II study on lenvatinib (LEN) in recurrent and/or metastatic (R/M) adenoid cystic carcinomas (ACC) of the salivary glands (SG) of the upper aereodigestive tract (NCT02860936). *First Author: Laura Locati, Head and Neck Cancer Medical Oncology Unit, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: Systemic chemotherapy and targeted therapies (TT) are almost ineffective in R/M ACC patients (pts). Sorafenib and axitinib showed some activity, possibly through their antiangiogenic effect. LEN is a stronger second-generation antiangiogenic inhibitor. Here we report the activity of LEN in R/M ACC pts. **Methods:** Pts with R/M disease, 1 previous line of chemotherapy and/or TT, received oral LEN 24 mg/day. Progression within 6 months at study entry was required. Primary endpoint was objective response rate (ORR) according to RECIST 1.1; secondary endpoints were progression free survival (PFS), overall survival (OS), toxicities (CTC 4.0) and assessment of quality of life (QoL) with EORTC QLQ C-30, EORTC QLQ-H&N35, EQ-5D. A 2-stage Simon design was applied, to test the null hypothesis of response $\leq$ 5% versus the alternative response $\geq$ 20%; 3 responses were required to reject the null hypothesis. **Results:** Twenty-eight pts were enrolled, F 16/M 12, median age 55 years (range: 22-73), 14 ACC of major and 14 of minor SGs, 96% metastatic. PS was 0 in 14 cases, 1 in 12 and 2 in 2 pts. Treatment related adverse events (AEs) were frequent (all grades 96%): asthenia 79%, hypertension 75%, stomatitis and weight loss 71%, TSH elevation 68%, were the most common. Grade $\geq$ 3 occurred in 50% of pts (asthenia 25%, hypertension 18%). No G5 toxicities occurred neither bleeding. Nine SAEs were reported, 6 of them drug-related. Dose was reduced in 21 pts within 12 weeks from therapy start, only 4 pts maintained the full dose throughout treatment. Among 26 evaluable pts, partial responses were 3 (11.5%) (3/26). Target lesions reduction between 23% and 28% was observed in 4 out 20 pts with stable disease. At a median follow up of 21.9 months (95% CI, 13.8-27.8), 6 pts are still on LEN and 12 died due to progression. Median PFS and DoR were 9 (95%CI 5.5-14.2) and 3.1 (1.8-21.7+) months, respectively. Median OS was 26.1 months (95% CI, 11.1-NR). QoL analysis is ongoing. **Conclusions:** Tumor size reduction was seen in 27% of pts suggesting activity of LEN in ACC. Toxicity was common but manageable. QoL has been studied for the first time. A randomized study is needed to confirm efficacy. Clinical trial information: NCT02860936.

6087 **Poster Session (Board #75), Sat, 1:15 PM-4:45 PM**

Combination of dabrafenib (DAB) and lapatinib (LAP) for the treatment of *BRAF*-mutant thyroid cancer. *First Author: Eric Jeffrey Sherman, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: mutations (BRAFm) are the most common mutations in thyroid cancer. BRAF inhibitors (DAB) are active in BRAFm melanoma, but there is less activity noted in BRAFm thyroid cancer. Preclinically, BRAF inhibitors inhibit BRAFm thyroid cancers only transiently due to activation of HER2/HER3, driven by a neuregulin-dependent autocrine loop. The addition of LAP, a HER2/HER3 kinase inhibitor, sensitizes the cell to growth suppression by BRAF inhibitors (Cancer Discov 5(3):520, 2013). This study evaluates the safety and efficacy of the combination of DAB and LAP. **Methods:** Eligibility included thyroid cancers with the presence of a BRAFV600E mutation. Any prior treatment was allowed. All patients received DAB 150 mg bid starting 2 weeks prior to LAP. Doses of daily lapatinib were escalated in a standard 3+3 design at (1) 750 mg; (2) 1250 mg; (3) 1500 mg. Patients removed before the start of LAP were not included in the analysis. An additional 6 patients were added at the MTD. Responses were defined using RECIST 1.1. **Results:** 21 evaluable patients were enrolled on the phase I portion of the study. Gender – 14/21 (67%) male; median age – 63 years; histology – differentiated thyroid cancer (DTC) 19 (90%), anaplastic thyroid cancer (ATC) 2 (10%); brain metastases – 5 (24%); prior BRAF inhibitor – 5 (24%); prior BRAF or tyrosine kinase inhibitor – 13 (62%). There was one DLT - Grade 5 event unlikely related to drugs in a patient with ATC. Grade 4 toxicities – 0. Grade 3 toxicities – lymphocytes (1); uveitis (1). Median progression-free survival (PFS) and overall response rate (RR) of the subsets in the DTC only group are listed in the table. Clinical trial information: NCT01947023. **Conclusions:** The combination of DAB 150 mg bid and LAP 1500 mg daily was safe and well-tolerated. Despite the number of subjects with prior treatment (including with BRAF inhibitors) and brain metastases, excellent activity was found with this combination in DTC. Further investigation with this regimen is warranted.

	#	RR	PFS (months)
DTC	19	58%	18
Dose Level 1 (LAP 750 mg)	5	60%	11
Dose Level 2 (LAP 1250 mg)	2	50%	16
Dose Level 3 (LAP 1500 mg)	12	58%	18
No prior BRAF inhibitor	14	64%	20
No brain metastases	14	57%	20
No prior BRAF inhibitor or brain metastases	11	64%	29

6088 **Poster Session (Board #76), Sat, 1:15 PM-4:45 PM**

A phase II trial of cabozantinib (CABO) for the treatment of radioiodine (RAI)-refractory differentiated thyroid carcinoma (DTC) in the first-line setting. *First Author: Marcia S. Brose, Department of Otorhinolaryngology, Head and Neck Surgery and the Abramson Cancer Center of the University of Pennsylvania, Philadelphia, PA*

Background: CABO is a multi-tyrosine kinase inhibitor targeting VEGF receptor kinase, RET, MET and AXL. We previously participated in a Phase I study which suggested activity in the RAI-refractory DTC patients that had had one or more prior therapies. To further study the activity of CABO in differentiated thyroid cancer, we conducted a single-arm open-label phase II study of CABO in patients with metastatic, RAI-refractory DTC in the first-line setting (clinicaltirals.gov: NCT02041260). **Methods:** Thirty-five patients with metastatic, RAI-refractory, unresectable or locally-advanced DTC were administered CABO 60 mg orally QD. Responses were monitored by CT scan every 2 months. The primary outcome was response rate (RR) and secondary outcomes included progression-free survival (PFS), time to progression (TTP), duration of response and clinical benefit rate and safety. **Results:** Our study completed accrual in August 2017. As of Feb 2018, the median time on study is 35 wks (range 3-197). Median age is 65 yrs (range 45 to 84); 17 pts (49%) are male. Of the 35 total patients, 22 (63%) have papillary, 3 (9%) have Hürthle cell and 10 (29%) patients have poorly differentiated histology. Partial response (PR) was achieved in 19 (54%) patients with a median duration of response of 40 wks (range 10 to 198+). Fifteen (43%) had stable disease (SD) with a median duration of 25 wks (range 8 to 143+), and 9 (26%) maintained their SD $>$ 6 mos for a clinical benefit rate (CR+PR+SD $>$ 6mos) of 80% (n = 28). Median PFS has not been reached and updated PFS data will be presented. Among the six patients who progressed, the median TTP was 35 weeks. Sixteen patients remain on study as of February 2018. CABO was well tolerated with dose interruptions and dose adjustments as needed; the most common treatment-related adverse events included hyperglycemia, diarrhea, fatigue/malaise, weight loss. **Conclusions:** This is the first study to document CABO anti-tumor activity in patients with RAI-refractory DTC in the first-line setting. The 54% RR is comparable to currently approved agents and warrants further investigation in this patient population. Clinical trial information: NCT02041260.

6089 **Poster Session (Board #77), Sat, 1:15 PM-4:45 PM**

Comprehensive genomic profiling of anaplastic thyroid carcinoma. *First Author: Daniel W. Bowles, University of Colorado, Aurora, CO*

Background: Anaplastic thyroid carcinoma (ATC) is a rare malignancy with a poor prognosis. We queried whether comprehensive genomic profiling (CGP) could uncover biomarkers that could enable targeted and immunotherapies. **Methods:** CGP was performed on 180 FFPE ATC samples using hybridization-captured, adaptor ligation based libraries to a mean coverage depth of $>$ 500X for up to 315 cancer-related genes. The results were analyzed for all classes of genomic alterations (GA) including short variant (SV) base substitutions and insertions and deletions; select rearrangements; and copy number changes. 408 consecutively sequenced papillary thyroid carcinomas (PTC) were included as a comparison group. Total mutational burden (TMB) was determined on 1.1 megabases of sequenced DNA. MSI status was determined by a proprietary algorithm. **Results:** There were 88 female (49%) and 92 (51%) male ATC patients with a median age of 64 years (range 25-86 yrs). All ATC cases were submitted as *de novo* ATC. ATC had significantly higher mean frequency of genomic alterations (GA) per sample and higher frequency of *TP53* mutations (Table). In contrast, PTC had significantly higher frequencies of *RET* and *BRAF* SV mutations and gene rearrangements in *BRAF*, *RET*, *ALK* and *NTRK*. TMB levels were similarly low in both groups and no cases featured a MSI-High status. Examples of ATC with responses to targeted therapies will be presented. **Conclusions:** ATC differs significantly in genomic alterations from classic PTC. Advanced stage PTC and ATC are frequently driven by *BRAF* GA or oncogenic rearrangements, suggesting ATC might result from dedifferentiation of *BRAF* mutated PTC. TMB appears to be low for both ATC and PTC.

	PTC	ATC	Significance
No. Patients	408	180	
Median age (years)	59	64	
Gender (F/M)	215/193	88/92	
GA/tumor	2.75	4.34	
Significant genes altered	*BRAF* *TERT* *TP53* *RET*	*TP53* *TERT* *BRAF* *NRAS* *PIK3CA* *NF1* *NF2* *PTEN*	
***TP53* GA Frequency**	11%	66%	P $<$ 0.0001
***RET* GA Frequency**	9%	2%	P = 0.002
***hTERT* Frequency**	58%	61%	NS
***BRAF* GA Frequency**	73%	39%	P $<$ 0.0001
***BRAF, RET, ALK*, or *NTRK* rearrangements**	13%	3%	P $<$ 0.0001
Total Mutational Burden ≥10 mut/Mb	2%	3%	NS
Opportunity for Targeted Therapies	High (BRAF, oncogenic fusions)	Moderate (BRAF, *NF1*, *NF2*, oncogenic fusions)	

TPS6090 **Poster Session (Board #78a), Sat, 1:15 PM-4:45 PM**

A phase 3, randomized, open-label study of epacadostat plus pembrolizumab, pembrolizumab monotherapy, and the EXTREME regimen as first-line treatment for recurrent/metastatic head and neck squamous cell carcinoma (R/M SCCHN): ECHO-304/KEYNOTE-669. *First Author: Ezra E.W. Cohen, University of California, San Diego, La Jolla, CA*

Background: Although the EXTREME regimen is a Category 1 evidence-supported combination recommended by NCCN guidelines as first-line (1L) treatment for patients with R/M SCCHN, it is associated with limited survival benefit and burdensome toxicities. There remains a high unmet need for more effective and well tolerated treatment strategies. Both the programmed cell death 1 (PD-1) receptor and indoleamine 2,3-dioxygenase 1 (IDO1) enzyme have been identified as key mechanisms that suppress T-cell–mediated antitumor immunity and induce tumor escape. Pembrolizumab (P) is a potent, highly selective humanized monoclonal antibody that directly blocks the interaction of PD-1 and its ligands. Epacadostat (E) is a potent, highly selective oral inhibitor of IDO1. Preliminary phase 1/2 data from the ECHO-202/KEYNOTE-037 study showed encouraging efficacy results and a tolerable safety profile with E + P in SCCHN. This randomized, open-label, phase 3 global study (NCT03358472) evaluates the efficacy and safety of E + P, P, and EXTREME as 1L treatment in patients with R/M SCCHN. **Methods:** Key eligibility criteria: histologically or cytologically confirmed R/M SCCHN considered incurable by local therapies, ECOG PS $\leq$1, no prior systemic therapy for R/M disease, and no prior IDO1 inhibitors or immune checkpoint therapies. Approximately 625 patients will be randomized 2:1:2 to E 100 mg BID + P 200 mg Q3W, P 200 mg Q3W, or EXTREME (cetuximab 400 mg/m^2 Cycle 1 Day 1, then 250 mg/m^2 QW + cisplatin 100 mg/m^2 or carboplatin AUC 5 Q3W + 5-FU 1000 mg/m^2/day continuously over Days 1–4 Q3W). Stratification includes ECOG PS, p16 status, and prior definitive systemic treatment for locally advanced disease. Patients receive $\leq$35 cycles of E + P or P, or $\leq$6 cycles of EXTREME followed by cetuximab maintenance; and are treated until disease progression, intolerable toxicity, or investigator/patient decision to withdraw. Primary endpoints are OS and PFS (per RECIST v1.1 assessed by central radiologist review). Secondary endpoints include ORR, safety and tolerability, and patient-reported outcomes. Clinical trial information: NCT03358472.

TPS6091 **Poster Session (Board #78b), Sat, 1:15 PM-4:45 PM**

A phase 2, multicenter, open-label study to evaluate the efficacy and safety of CDX-3379 in combination with cetuximab in patients with advanced head and neck squamous cell carcinoma (HNSCC). *First Author: Julie E. Bauman, Department of Medicine, Division of Hematology/Oncology, University of Arizona Cancer Center, Tucson, AZ*

Background: ErbB3 (HER3) and its ligand, neuregulin-1 (NRG1), are widely expressed in HNSCC and associated with tumor progression. ErbB3 may provide a key mechanism of resistance to therapies targeting EGFR and HER2. HPV− tumors, typified by poorer prognosis, have shown favorable response to ErbB3-targeted therapy. CDX-3379, an anti-ErbB3 monoclonal antibody with a half-life-extending Fc region YTE mutation, binds a unique epitope, locks ErbB3 in an inactive form, and blocks all ErbB3-dependent downstream signaling. CDX-3379 enhances antitumor activity of targeted therapies in preclinical models (Falchook ASCO 2016). In a phase (ph) 1 trial, CDX-3379 was well-tolerated alone and in combination with targeted agents. A patient (pt) with cetuximab-refractory HNSCC experienced a durable complete response to CDX-3379 + cetuximab, while 2 pts with BRAF-mutant non-small cell lung cancer, one dabrafenib-resistant, experienced partial responses to CDX-3379 + vemurafenib (Falchook ASCO 2016). A newly-initiated trial evaluates CDX-3379 + cetuximab in pts with HPV− cetuximab-resistant advanced HNSCC. **Methods:** A ph 2, multicenter, open-label clinical trial (NCT03254927) is enrolling ≤30 pts with advanced refractory HNSCC. Eligibility requires: screening biopsy; HPV−; RECIST 1.1 measurable disease; cetuximab resistance (progression within 6 months); prior PD-1-targeted check-point inhibition (if a candidate); no active brain metastases; and no nasal, paranasal sinus, or nasopharyngeal WHO Type III carcinoma. Pts receive CDX-3379 (initial dose 12 mg/kg IV q 21 days) + cetuximab (loading dose 400 mg/m^2; 250 mg/m^2 IV weekly) until progression/toxicity. Tumor assessments occur at 6-week intervals. Endpoints include objective response rate (ORR; primary), progression-free and overall survival, safety, pharmacokinetics, immunogenicity, and biomarkers (NRG, EGFR ligands). It is hypothesized that CDX-3379 + cetuximab will achieve ORR of 20%, with 80% power and a null hypothesis of ORR ≤5% and $\alpha = 0.05$ based on a Simon's 2-stage design. Three US sites are actively recruiting pts, with additional sites planned. Clinical trial information: NCT03254927.

TPS6092 **Poster Session (Board #79a), Sat, 1:15 PM-4:45 PM**

ECHO-310: A phase 3, randomized trial of epacadostat + nivolumab + chemo vs EXTREME as first-line treatment of recurrent/metastatic SCCHN. *First Author: Ezra E.W. Cohen, University of California, San Diego, La Jolla, CA*

Background: Novel combination treatments targeting broad immunosuppression in the tumor microenvironment (TME) may improve patient (pt) survival. Nivolumab (N) is a PD-1 inhibitor that was shown to significantly prolong overall survival (OS) in pts with platinum-refractory r/m SCCHN. Epacadostat (E) is a potent, highly selective oral inhibitor of indoleamine 2,3-dioxygenase 1 (IDO1), a tryptophan-catabolizing enzyme that contributes to immunosuppression in the TME. Preliminary phase 2 findings from the ECHO-204 study suggest encouraging efficacy with E + N in pts with r/m SCCHN. The ECHO-310 study (NCT03342352) compares E + N + chemo vs the EXTREME regimen as first-line treatment for r/m SCCHN. **Methods:** Eligible pts are ≥18 years old with treatment-naive r/m SCCHN (oral cavity, oropharynx, hypopharynx, and larynx), ECOG PS ≤1, and no prior IDO inhibitors or immune checkpoint therapies. Approximately 550 pts will be randomized (2:2:1) into 3 arms: Arm A receives blinded E 100 mg BID + N 360 mg Q3W + 6 cycles of chemo (cisplatin 100 mg/m^2 in Cycle 1, then 75 mg/m^2 Q3W in Cycles 2–6 or carboplatin AUC 5 Q3W + 5-FU 1000 mg/m^2 on Days 1–4 of each cycle); Arm B (EXTREME) receives cisplatin 100 mg/m^2 Q3W or carboplatin AUC 5 Q3W + 5-FU 1000 mg/m^2 on Days 1–4 of each cycle + cetuximab 400 mg/m^2 on Cycle 1 Day 1, then 250 mg/m^2 QW (starting Cycle 1 Day 8); and Arm C receives E-matched placebo BID + N 360 mg Q3W + 6 cycles of chemo (same as Arm A). Randomization will be stratified by PD-L1 status (expressing [≥1%] vs nonexpressing [< 1%]/nonevaluable), HPV status (oropharyngeal p16 positive vs oropharyngeal p16 negative/nonoropharyngeal SCC), and investigator's choice of cisplatin vs carboplatin. E and placebo treatment continue for up to 2 years or until permanent discontinuation of N, disease progression, unacceptable adverse event (AE), or consent withdrawal. Primary endpoints: OS and PFS in Arms A and B. Secondary endpoints: ORR and duration of response (DOR) in Arms A and B; ORR, PFS, and DOR in Arm C; and quality of life in Arms A and B. Tumor assessments (RECIST v1.1) are performed Q6W for 48 weeks and Q12W thereafter. AEs, graded per CTCAE v4.0, are evaluated for at least 100 days after end of treatment. Clinical trial information: NCT03342352.

TPS6093 **Poster Session (Board #79b), Sat, 1:15 PM-4:45 PM**

A phase 1b/2a, multi-center, open-label study to evaluate the safety and efficacy of combination treatment with MEDI0457 (INO-3112) and durvalumab (MEDI4736) in patients with recurrent/metastatic human papilloma virus–associated head and neck squamous cell cancer. *First Author: Charu Aggarwal, Hospital of the University of Pennsylvania, Medical Oncology, Philadelphia, PA*

Background: Anti–PD-1 immunotherapy has significantly changed outcomes for patients (pts) with recurrent/metastatic (RM) head and neck squamous cell cancer (HNSCC). However, only ≈20% of pts respond, so more effective therapies are needed. MEDI0457 (INO-3112), a plasmid DNA vaccine, comprises 3 plasmids expressing HPV-16 and HPV-18 E6 and E7 proteins along with IL-12. A pilot study in pts with locally advanced HPV-associated HNSCC found MEDI0457 to be safe and well tolerated; it was associated with induction of HPV-16/18 E6/E7–specific humoral and cellular immune responses and showed synergistic activity with anti–PD-1 therapy in immune correlative studies.[1] Durvalumab (MEDI4736) is a human IgG1 mAb that blocks programmed death-ligand 1 (PD-L1) binding to PD-1, stimulating anti-tumor immune response. 60-70% of HPV+ HNSCC can be PD-L1 positive.[2,3] We hypothesize that MEDI0457 administered with durvalumab may enhance anti-tumor effects against HPV-associated HNSCC and improve outcomes for pts with RM disease. **Methods:** This phase 1b/2a, open-label, multi-center study is evaluating MEDI0457 plus durvalumab in pts with confirmed HPV-16 or HPV-18–associated RM HNSCC after treatment with ≥1 platinum-based chemotherapy or platinum-ineligible pts in whom an approved treatment failed. Key exclusion criteria are nasopharyngeal cancer and prior immunotherapy. As this is the first study of MEDI0457 combined with durvalumab, a safety analysis run-in phase will assess the first 3-12 pts with a limit of 4 vaccine doses; this will be followed by the planned recommended dosing schedule in ≈50 pts until disease progression or unacceptable toxicity. Primary objectives are safety and objective response rate. Secondary objectives are disease control rate at 16 weeks, overall survival, progression-free survival, and pharmacokinetics and immunogenicity of durvalumab. Recruitment is ongoing (NCT03162224). [1] Aggarwal, *et al.* SITC 2017 [P125]. 2 Badoual, *et al. Cancer Res* 2013 [128]. 3 Lyford-Pike, *et al. Cancer Res* 2013 [1733]. Clinical trial information: NCT03162224.

TPS6094 **Poster Session (Board #80a), Sat, 1:15 PM-4:45 PM**

Pembrolizumab plus chemoradiation vs chemoradiation alone for locally advanced head and neck squamous cell carcinoma: The phase 3 KEYNOTE-412 study. *First Author: Jean-Pascal H. Machiels, Cliniques Universitaires Saint-Luc, Brussels, Belgium*

Background: Preclinical data in murine cancer models show improved tumor growth control and survival when radiation therapy (RT) is combined with a PD-1 inhibitor. Pembrolizumab is effective for treatment of recurrent/metastatic head and neck squamous cell carcinoma (HNSCC), and initial results from a phase 1b study suggest that pembrolizumab plus chemoradiation therapy (CRT) is tolerable in patients with locally advanced (LA) HNSCC. KEYNOTE-412 (NCT03040999) is a phase 3, randomized, placebo-controlled, double-blind trial to determine efficacy and safety of pembrolizumab given with CRT and as maintenance therapy vs placebo plus CRT in LA-HNSCC. **Methods:** Patients will be randomly assigned (1:1) to receive pembrolizumab 200 mg every 3 weeks plus cisplatin-based CRT or placebo plus cisplatin-based CRT. Treatment will be stratified by RT regimen (accelerated RT [56-70 Gy, 6 fractions/week for 6 weeks] or standard RT [56-70 Gy, 5 fractions/week for 7 weeks]), tumor site/p16 status (oropharynx p16 positive vs p16 negative or larynx/hypopharynx/oral cavity), and disease stage (III vs IV). Priming dose of pembrolizumab or placebo will be given 1 week before CRT, followed by 2 doses during CRT, and an additional 14 doses after CRT, for a total of 17 pembrolizumab or placebo infusions. Eligibility criteria include age ≥18 years; newly diagnosed, treatment-naive, oropharyngeal p16–positive (any T4 or N3), oropharyngeal p16–negative (any T3-T4 or N2a-N3), or larynx/hypopharynx/oral cavity (any T3-T4 or N2a-N3) SCC; evaluable tumor burden (RECIST v1.1); and ECOG performance status 0-1. Treatment will be discontinued at the time of centrally confirmed disease progression, unacceptable toxicity, or patient/physician decision to withdraw. Patients will be evaluated to determine the necessity of neck dissection 12 weeks after completion of CRT. The primary end point is event-free survival. Secondary end points are overall survival, safety, and patient-reported outcomes. Relationship between biomarkers and clinical activity will be included as an exploratory end point. Recruitment is ongoing in 21 countries and will continue until ~780 patients are enrolled. Clinical trial information: NCT03040999.

TPS6095 **Poster Session (Board #80b), Sat, 1:15 PM-4:45 PM**

EORTC 1559-HNCG: A pilot study of personalized biomarker-based treatment strategy or immunotherapy in patients with recurrent/metastatic (R/M) squamous cell carcinoma of the head and neck (SCCHN)—"UPSTREAM". *First Author: Rachel Galot, Cliniques Universitaires Saint-Luc, Brussels, Belgium*

Background: The treatment of R/M SCCHN includes platinum-based chemotherapy, cetuximab, and anti-PD-1 compounds. Some genetic alterations have been identified, making SCCHN attractive for molecular targeted therapies. However, when these agents are given to unselected SCCHN patients (pts), only limited activity is observed. EORTC 1559 is a biomarker-driven umbrella trial for R/M SCCHN that investigates the activity of immunotherapy or targeted agents in tumors harboring pre-defined biomarker(s). **Methods:** Pts with R/M SCCHN progressing after platinum-based chemotherapy are enrolled. Inclusion criteria are: ECOG 0-1 and measurable disease by RECISTv1.1. Previous treatment with anti-PD(L)1 is allowed. Before inclusion, a fresh tumor biopsy is taken and analyzed in a certified central laboratory (OncoDNA, Belgium). We designed a custom theranostic test that includes IHC, NGS and gene fusions. Based on a pre-defined algorithm, pts are allocated to different treatment cohorts: afatinib (one cohort for p16- cases with either EGFR or HER2 mutation/amplification or PTEN H-score $>$ 150 and another cohort for p16- cetuximab naïve pts), palbociclib (p16- and cyclin D1 amplification), niraparib (one cohort for p16+ oropharyngeal cancer and another cohort for p16- platinum sensitive disease) and entrectinib (NTRK1/NTRK3 or ROS1 fusions). Pts not eligible for the biomarker-driven cohorts are included in 1 of the immunotherapy cohorts (monalizumab monotherapy or monalizumab + durvalumab). Each cohort is designed as a phase II trial with its own statistical hypothesis. The 1^0 endpoint is either PFS or ORR depending on the investigated drug, cohort sizes range from 32 to 76 pts. The study is designed to allow the addition of new treatment cohorts based on new biomarker hypotheses. We are currently working on adding FGFR inhibitors cohorts. The EORTC HN1559 Upstream trial is the 1st international umbrella trial with a personalized treatment strategy or immunotherapy for pts with SCCHN. The study is open since November 2017 in Belgium and France with 12 first patients enrolled. We plan to open Italy, UK and Germany. Clinical trial information: NCT03088059.

TPS6096 **Poster Session (Board #81a), Sat, 1:15 PM-4:45 PM**

A phase 2, multicenter study to evaluate the efficacy and safety of autologous tumor infiltrating lymphocytes (LN-145) for the treatment of patients with recurrent and/or metastatic squamous cell carcinoma of the head and neck (HNSCC). *First Author: Rom S. Leidner, Earle A. Chiles Research Institute at Robert W. Franz Cancer Center, Providence Cancer Institute, Portland, OR*

Background: Adoptive cell therapy (ACT) with tumor-infiltrating lymphocytes (TIL) has demonstrated efficacy in the treatment of immunogenic tumors with high mutation loads, such as melanoma. Despite the heterogeneity of HNSCC tumors, most tumors are either virally-associated or carry high mutation loads that increase the potential antigens targeted by TIL ACT. Since outcomes for patients with recurrent and/or metastatic HNSCC remain poor despite existing approved therapies, a clear rationale exists for the potential application of ACT with TIL in patients with HNSCC. **Methods:** Clinical trial C-145-03 (NCT03083873) is a prospective phase 2 multicenter, open-label study evaluating the efficacy of a single autologous TIL infusion (LN-145) followed by IL-2 after a non-myeloablative lymphodepletion (NMA-LD) regimen in patients with recurrent and/or metastatic HNSCC. Patients undergo a surgical resection of a tumor lesion from which TIL are extracted and expanded at a central GMP manufacturing facility that prepares a cryo-preserved TIL (LN-145) product ready for shipment and infusion. One week prior to LN-145 infusion, patients undergo NMA-LD consisting of cyclophosphamide (60 mg/kg) daily x 2 days followed by fludarabine (25 mg/m^2) daily x 5 days. LN-145 is infused 24 hours after NMA-LD followed by up to 6 doses of IL-2 (600,000 IU/kg) every 8-12 hours. The primary efficacy endpoint is the objective response rate per RECIST v1.1. Secondary endpoints include an assessment of safety & other efficacy parameters such as progression free and overall survival. Patients must have been treated with at least one systemic therapy for recurrent and/or metastatic HNSCC and, in addition to the tumor resected for TIL manufacture, must have an additional measurable lesion for assessment of response. Additional eligibility criteria include amongst others: adequate bone marrow, liver, pulmonary, cardiac, and renal function; and ECOG performance status of 0 or 1. Clinical trial information: NCT03083873.

TPS6097 **Poster Session (Board #81b), Sat, 1:15 PM-4:45 PM**

PATHOS: A phase II/III trial of risk-stratified, reduced intensity adjuvant treatment in patients undergoing transoral surgery for human papillomavirus (HPV)-positive oropharyngeal cancer. *First Author: Mererid Evans, Velindre NHS Trust, Cardiff, United Kingdom*

Background: Incidence of Oropharyngeal squamous cell carcinoma (OPSCC) is rapidly increasing as a result of Human Papillomavirus (HPV), genotype 16 infection. Existing treatments for HPV+ OPSCC have high survival rates but often result in significant long-term toxicities, particularly affecting swallowing function, impacting on quality of life (QoL). PATHOS is a UK phase II-III randomized, multi-centre study. Patients undergo Transoral Surgery (Transoral Laser Microsurgery or Transoral Robotic Surgery) prior to post-operative stratification, according to pathological risk factors. Aim: To determine whether reducing intensity of adjuvant treatment; by lowering radiotherapy (RT) dose or, in patients with positive margins and/or Extracapsular Spread (ECS), omitting concurrent chemotherapy, will result in better long-term swallowing function whilst maintaining high Overall Survival rates. **Methods:** Patients are eligible if requiring primary resection and neck dissection, fit for surgery/treatment, histologically confirmed OPSCC (TNM T1-T3, N0-N2b), and $\geq$ 18 years. Following informed consent, patients are confirmed as HPV+. Baseline swallowing panel (including QoL) is carried out prior to surgery and during follow-up. Post-op group allocation: Clinical trial information: NCT02215265. PATHOS has recruited 152 patients across 18 UK sites to date, clearly demonstrating feasibility of recruitment. PATHOS will proceed to an international Phase III in collaboration with the European Organization for Research and Treatment of Cancer (EORTC) subject to funding being awarded. *Funded by Cancer Research UK (A17161). Coordinated by the Centre for Trials Research, Cardiff University.*

A	no pathological risk factors	No adjuvant treatment
B	close (1-5mm) primary tumour margins (-ve marginal biopsies), T3 tumours, N2, perineural invasion, vascular invasion	Post op: Randomised 1:1 B1: RT 60Gy in 30# over 6 wks (Control) B2: RT 50Gy in 25# over 5 wks (Test)
C	positive ($<$ 1mm) margins (-ve marginal biopsies), ECS	Post-op: Randomised 1:1 C1: RT 60Gy in 30# over 6 wks with concurrent Cisplatin chemotherapy (CT) (Control) C2: RT 60Gy in 30# over 6 wks without CT (Test)

TPS6098 **Poster Session (Board #82a), Sat, 1:15 PM-4:45 PM**

BEST OF: A phase III study assessing the best of radiotherapy (Intensity Modulated RadioTherapy, IMRT) compared to the best of surgery (Trans-Oral Surgery, TOS) in patients with T1-T2, N0 oropharyngeal squamous cell carcinoma (OPSCC). *First Author: Christian Simon, CHUV - Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland*

Background: The incidence of OPSCC has increased dramatically in the last 15 years. The standard treatment for early stage disease is either surgery or radiotherapy, both with comparable high tumor control rates but with different side effect profiles and technical constraints. Treatment choice is generally based on expert or center experience. It is still unclear whether they differ in terms of functional outcome. To clarify this, we proposed a randomised trial with the primary objective to assess and compare the patient-reported swallowing function over the first year after randomisation to either IMRT or TOS among patients with early stage OPSCC. Clinician and patient-reported outcomes will be used to assess treatment. **Methods:** This is a phase III randomised trial (NCT02984410) that will primarily assess the MD Anderson Dysphagia Inventory (MDADI) score reported by the patients at months 4.5, 6, 9, and 12 after randomisation. MDADI is composed of 19 questions on emotional, functional, and physical aspects, all related to swallowing, wherein scores range between 20 (poorest function) and 100 (best function). BEST OF is powered to detect a clinically significant difference in MDADI score at each of these time points: 4.5, 6, 9, and 12 months with a planned sample size of 170 patients. Key secondary endpoints include treatment response at 6 months after randomization, oncologic outcomes at year 1 and 5, toxicities based on CTCAE, quality of life (QOL) based on QLQ-C30 and HN43 and out-of-pocket costs. QOL domains will be ranked based on patient's priorities. Eligible cases are resectable T1 or T2, N0, M0 OPSCC assessed by a multidisciplinary team. The EORTC quality assurance program (QA) for surgery and pathology (SURCARE) and radiotherapy (RTQA) was implemented in the study. This integrated QA will be the model for future EORTC Head and Neck Cancer trials. BEST OF was opened for recruitment since December 2017 in Belgium and Switzerland and will soon open in France, UK, Germany, Poland, Italy and Portugal through a collaboration with EORTC HNCG and ROG, SAKK, NCRI, GORTEC, and IAG-KHT. Clinical trial information: NCT02984410.

TPS6099 Poster Session (Board #82b), Sat, 1:15 PM-4:45 PM

Hope for salivary gland cancer (SGC): EORTC HNCG/UKCRN 1206 randomized phase II study to evaluate the efficacy and safety of chemotherapy (CT) vs androgen deprivation therapy (ADT) inpatients with recurrent and/or metastatic androgen receptor (AR) expressing SGC (NCT01969578). *First Author: Laura Locati, Head and Neck Cancer Medical Oncology Unit, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: SGCs are rare and heterogeneous tumors (< 1% of all malignancies in Europe). Among more than 20 histotypes, only salivary duct carcinoma (SDC) and adenocarcinoma NOS express AR. These variants are aggressive and associated with poor prognosis. Surgery is the main curative treatment but upon relapse, patients are left with very few options. This study (NCT01969578) aims to evaluate the efficacy and safety of ADT (experimental arm) vs chemotherapy (standard arm) in patients with recurrent and/or metastatic, AR overexpressing SDC and adenocarcinoma, NOS by demonstrating a 15% improvement in Progression Free Survival (PFS) rate at 6 months in favor of ADT. **Methods:** Trial design: In this multicenter, randomized, phase II intergroup study a total of 76 treatment patients (Cohort A) are planned to be randomized to receive ADT or platinum-based chemotherapy. Patients previously treated with chemotherapy will be enrolled in a separate Cohort B to receive ADT. Patients from Cohort A randomized to chemotherapy can also enter in Cohort B at disease progression. The primary endpoint is PFS for Cohort A and best overall response for Cohort B. AR overexpression is mandatory at study entry. Mechanisms of AR activation and resistance will be studied. This study is led by EORTC Head and Neck Cancer Group with UNICANCER/REFCOR, International Rare Cancer Initiative UK Salivary Gland Cancer Group and RARECARENet. It will run in 35 sites in 10 countries: Austria, Belgium, France, Germany, Greece, Hungary, Italy, Portugal, The Netherlands, and United Kingdom. Sites from the EURACAN European Reference Network are participating. On 9 th February 2018, 54 patients are registered; 27 have been enrolled, of which 17 have been randomized in Cohort A. Identification of AR as a treatment target in SGC can be practice changing. Clinical trial information: NCT01969578.

6500 Oral Abstract Session, Fri, 2:45 PM-5:45 PM

Randomized trial comparing a web-mediated follow-up via patient-reported outcomes (PRO) vs. routine surveillance in lung cancer patients: Final results. *First Author: Fabrice Denis, Institut Inter-regional de Cancérologie Jean Bernard, Le Mans, France*

Background: In a previous interim analysis, we found a 7-month median overall survival (OS) benefit (p = 0.002) associated with web-based monitoring to detect recurrence in lung cancer patients after initial treatment, vs. scheduled imaging. We hypothesized that benefit was due to earlier detection of symptoms and relapses, prompting earlier treatment and supportive care. Final results with 2-year follow-up is presented. **Methods:** Advanced-stage lung cancer patients without evidence of disease progression after initial treatment were randomly assigned to compare a web-mediated follow-up (experimental arm) based on weekly self-scoring of 13 common patient symptoms with a routine follow-up (control arm) with 3-6 months repeated CT-scans. In the experimental arm, an alert email was sent to the oncologist when self-scored symptoms matched predefined criteria. The IRB protocol-specified primary outcome was OS. After a pre-planned interim analysis in which OS improvement was observed, the IDMC suggested a cessation of further recruitment in 1-2016 and recommended to offer eligible patients in the control arm to cross over to the intervention. **Results:** From 6-2014 to 1-2016, 121 patients were included in the intent-to-test survival (ITT) analysis. Ten out of 34 living patients in the control arm were eligible to cross over following the interim analysis. With 2 years of follow-up and 70 deaths observed, the median OS was 23.0 months in the experimental arm and 14.8 months without adjustment for crossover in the control arm (HR 0.62, 95% CI 0.39 to 0.995, p= 0.048). Censoring crossover resulted in a hazard ratio of 0.53 (95% CI 0.33 to 0.85, p = 0.009) with consistent results also observed based on a rank-preserving structural failure time model (psi = -0.55, 95% CI -1.09 to -0.03). **Conclusions:** With a longer follow-up and although eligible patients from the control arm crossed over to receive intervention after the preplanned interim analysis, the OS remained significantly larger with the web-mediated follow-up based on PRO than with routine disease follow-up by CT scans alone. This is the first study to show the benefits of PROs during surveillance in cancer patients. Clinical trial information: NCT02361099.

6501 Oral Abstract Session, Fri, 2:45 PM-5:45 PM

Patient-reported outcomes, emoji, and activity measured on the Apple Watch in cancer patients. *First Author: Carrie A. Thompson, Division of Hematology, Mayo Clinic, Rochester, MN*

Background: Patient-reported outcomes (PROs) are important measures in patients with cancer, but may be burdensome to collect. We aimed to measure PROs via mobile technology, using novel emoji PRO scales and associations between PROs and wearable data. **Methods:** Adult patients (pts) with diagnosis ($<$ 5 years) of lymphoma, myeloma, brain, pancreatic, breast, and ovarian cancer, life expectancy of $>$ 6 months, and ownership of an iPhone $\geq$5.0 were recruited and provided with an Apple Watch. Pts completed baseline and weekly PROs for 12 weeks: PROMIS physical function, fatigue, sleep, social/role function short forms; single-item linear analog self-assessment (LASA) of quality of life (QOL), fatigue, and physical function. Pts were randomized into 3 groups for mode of survey response: paper, iPhone, and Watch. Watch and iPhone groups completed an emoji mood scale and an emoji ordinal scale for physical, emotional, and overall QOL. Activity levels were analyzed using the square root of the average daily values to minimize the effects of outliers. Associations between PROs and activity levels were assessed using Spearman correlations for univariate analyses, stepwise linear regression models for multivariate associations, and mixed models for longitudinal associations. **Results:** From 2/2017-8/2017, 296 pts were recruited. Pts wore the watch for an average of 9.8 hours/day and did 4590 mean steps/day (SD 3724). Weekly survey response rates ranged from 60% (Watch group) to 77% (iPhone group). Logging more steps/day was associated with less fatigue and sleep disturbance, better global physical QOL, physical function, and social function, while more minutes of exercise/day was associated with better global mental QOL and sleep. Spearman correlations showed very strong associations between the emoji ordinal scale and LASAs: -0.80 for fatigue, 0.70 for physical well-being, 0.68 for emotional well-being, and 0.75 for overall QOL (all p $<$ 0.001). The baseline emoji mood scale was strongly related to all baseline PROMIS PROs (all p $<$ 0.001). **Conclusions:** Collecting PROs in cancer patients via mobile technology is feasible. Apple Watch activity data is significantly associated with PROs, and emoji scales are a promising tool.

6502 Oral Abstract Session, Fri, 2:45 PM-5:45 PM

The effect of a lay health worker-led symptom assessment intervention for patients on patient-reported outcomes, healthcare use, and total costs. *First Author: Manali I. Patel, Division of Oncology; Clinical Excellence Research Center; Stanford University School of Medicine, Stanford, CA*

Background: Rising cancer costs demand models that safely lower expenditures and improve patients' experiences and outcomes. In response, we developed a risk-stratified proactive symptom assessment intervention which consisted of a lay health worker, supervised by a nurse practitioner, who telephonically assessed symptoms weekly for high-risk patients and monthly for low-risk patients. We implemented the intervention in an oncology group with collaboration from a health plan to test the effect on patient-reported outcomes, healthcare use and cost. **Methods:** We enrolled all newly diagnosed health plan beneficiaries with Stage 3 and 4 cancer from 11/2014 through 9/2015. We evaluated patient-reported satisfaction, emotional and mental health with validated assessments at enrollment and 5-months post-enrollment. We compared healthcare use and costs to all patients with Stage 3 and 4 cancer diagnosed from 11/1/2013-10/31/2014 (control). We assessed differences in demographic and clinical factors using chi-square and t-tests. To evaluate differences in healthcare use and costs we used generalized linear models adjusted for age, stage, co-morbidity, cancer diagnosis, and length of follow-up. **Results:** There were 186 patients in the intervention and 102 in the control. In both arms, median age was 78 years, 55% were female, and gastrointestinal malignancies were the highest proportion of diagnoses. There were statistically significant improvements in mental and emotional health (p $<$ 0.05) and satisfaction with care (p $<$ 0.05) at 5-months follow-up compared with baseline. Patients in the intervention had significantly lower mean number of inpatient admissions per quarter (0.72 vs. 1.02, p = 0.03); mean number of emergency department visits per quarter (0.61 vs. 0.92, p = 0.04), and lower median total healthcare costs ($22344 vs $28414, p = 0.03) as compared to the control. **Conclusions:** A lay health worker-led symptom assessment intervention significantly improved patient satisfaction and reduced healthcare use and costs and may represent one solution to improve care for patients.

6503 Oral Abstract Session, Fri, 2:45 PM-5:45 PM

Frequency of post-treatment surveillance and survival in localized prostate cancer: AFT-30 a national study. *First Author: Ronald C. Chen, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: The optimal frequency of post-treatment PSA surveillance is undefined, and different existing guidelines based on expert opinions recommend frequencies ranging from 1x/year to 4x/year. Whether more frequent surveillance improves survival is unknown. **Methods:** Using the backbone of the National Cancer Data Base (NCDB), medical records of 10,477 randomly sampled patients diagnosed with localized prostate cancer from 2005-2010 were abstracted from 1007 sites throughout the US to provide additional data for this study. 53% of the cohort received primary radiotherapy; 47% received radical prostatectomy. Primary exposure is number of post-treatment PSA tests in the first 2 years, and primary outcome is overall survival. **Results:** There were 4,088 low-risk, 3,241 intermediate, and 3,148 high-risk patients. Median age at diagnosis was 64 years, and median follow-up was 8 years. At last follow-up, 17% (low-risk), 33% (intermediate), and 50% (high-risk) patients had died. Median numbers (IQR) of PSA tests in the first 2 post-treatment years were: 4 (2-5)(low-risk), 4 (2-5) (intermediate), and 4 (2-5)(high-risk). Cox multivariable models showed no significant association between frequency of PSA surveillance and overall survival in any risk group (Table). **Conclusions:** More frequent PSA surveillance after definitive treatment for localized prostate cancer is not associated with improved survival. This is the first large-scale study to provide data to inform guidelines and patient/physician decisions. Based on these results, surveillance guidelines recommending PSA tests every 3-6 months likely represent overutilization of care.

Cox multivariable analysis for overall survival.

	Low risk HR (p-value)	Intermediate risk HR (p-value)	High risk HR (p-value)
PSA frequency (REF: lowest third)			
Middle third	1.15 (0.50)	1.11 (0.49)	1.04 (0.73)
Highest third	1.14 (0.55)	1.13 (0.43)	1.01 (0.94)

Model adjusted for age, race, treatment, comorbidity score, facility type, census track education and income.

6504 Oral Abstract Session, Fri, 2:45 PM-5:45 PM

Lung cancer screening rates: Data from the lung cancer screening registry. *First Author: Danh Pham, James Graham Brown Cancer Center, University of Louisville, Louisville, KY*

Background: Lung cancer is the leading cause of cancer related mortality in the United States. Since 2013, the United States Preventive Services Task Force (USPSTF) recommended annual screening for lung cancer with low-dose computed tomography (LDCT) for those aged 55-80 years for those who have smoked at least 30 pack years who currently smoke or have quit within the past 15 years. Current literature has provided only estimates of lung cancer screening since implementation. Our study aims to present the number of screening LDCTs being performed across the United States. **Methods:** Using data from the Lung Cancer Screening Registry (LCSR) provided by the American College of Radiology (ACR) in 2016, we collected the total number of LDCT from all 1,796 accredited radiographic screening sites. We used the 2015 National Health Interview Survey (NHIS) to estimate screening eligible smokers per USPSTF criteria and compared them with the 2016 LCSR reported screens. Analyses excluded respondents with missing data and history of lung cancer. **Results:** In 2016, 1.9% of 7.6 million eligible smokers were screened. These rates varied by region from 1.0% in the West to 3.5% in the Northeast (Table). The majority of eligible smokers were populated in the South and had the most accredited screening sites, but were still amongst the lowest in screening rate. Approximately 85% of the screened current smokers were offered smoking cessation. **Conclusions:** Annual LDCT screening remains inadequate following USPSTF recommendations despite the time since implementation and potential to prevent thousands of lung cancer deaths each year. It remains unclear why the lung cancer screening rate is dramatically lower than other cancer screening modalities such as mammography and colonoscopy. Further initiatives are needed including awareness programs and mandating lung cancer screening as a national quality measure.

LDCT screens performed in 2016 compared to eligible smokers per USPSTF criteria.

U.S. Census Region	No. of Accredited Centers	Estimated Eligible Smokers	LDCT Screens	Rate (%)
Northeast	404	1,152,141	40,105	3.5
Midwest	497	2,020,045	38,931	1.9
South	663	3,072,095	47,966	1.6
West	232	1,368,694	14,080	1.0
Total	**1796**	**7,612,975**	**141,260**	**1.9**

6505 Oral Abstract Session, Fri, 2:45 PM-5:45 PM

Integrating tobacco treatment into cancer care: A first snapshot of RCT findings. *First Author: Elyse R. Park, Massachusetts General Hospital, Boston, MA*

Background: Despite ASCO recommendations that tobacco use be assessed and managed, most cancer patients who smoke do not receive tobacco treatment. Evidence-based tobacco treatment has not yet been integrated into routine oncology care, and the optimal tobacco treatment strategy in this context is unknown. **Methods:** We conducted a two-arm, two-site RCT to compare sustained counseling plus medication (Intervention Group; IG) to standard tobacco counseling (comparison group; CG) to assist newly diagnosed cancer patients to quit smoking. Both treatment groups received 4 weekly telephone-delivered motivational counseling sessions. The IG additionally received 4 biweekly plus 3 monthly counseling sessions (total 11) and 12-weeks of free FDA-approved cessation medication (nicotine replacement therapy (NRT; patch/lozenge), varenicline, or bupropion). Eligibility criteria included a recent cancer diagnosis (breast, GI/GU, gyn, head & neck, lymphoma, lung, melanoma), cigarette use in the past 30 days, and English/Spanish speaking. The primary outcome was 6-month biochemically verified abstinence. **Results:** 303 (70% of confirmed eligibles) patients were enrolled and randomized to a treatment group. Participants were 56% female; 82% white non-Hispanic and 10% black; mean age = 58.3 (sd = 9.7); 40% had a non-smoking related tumor. 86% completed the 6-month surveys. 80% of IG patients used a smoking cessation medication, among which 83% selected NRT. Using intention-to-treat, 6-month quit rates were 33% in the IG group vs. 19% in the CG group ($p < .02$). Using intention-to-treat, 57% of IG patients were adherent to sustained counseling (≥7 sessions), which was associated with increased 6-month quit rates ($p < .0001$). Cost per patient was $1,273 (IG) vs. $838 (CG). **Conclusions:** Among newly-diagnosed cancer patients, a treatment program of sustained telephone-delivered counseling and free medication produced a higher 6-month quit rate vs. a briefer counseling program. The cost-per-quit compared favorably to other cessation interventions. Findings provide strong support for the benefit of sustained tobacco treatment and a model for effective implementation of tobacco treatment into oncology care settings nationwide. Clinical trial information: NCT01871506.

6506 Oral Abstract Session, Fri, 2:45 PM-5:45 PM

Uptake of genetic testing and outcomes in a randomized study of remote genetic services as compared to usual care in community practices without genetic providers. *First Author: Angela R. Bradbury, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA*

Background: Providing remote genetic services by phone or videoconference for patients at community practices without access to genetic providers could increase access to genetic testing. How uptake of testing compares to usual care options for genetic testing has not been reported. **Methods:** To date, 106 patients at 6 community practices were randomized to remote genetic counseling (35 phone; 31 videoconferencing) and 40 to usual care (recruitment to end 3/2018). Primary outcomes were uptake of genetic counseling and testing at 6 months. Secondary outcomes include knowledge, state and general anxiety, depression, and cancer-specific distress in phone versus videoconferencing arms. We used Fisher's exact tests, T-tests, and logistic regressions for analyses. **Results:** 92% of participants are female, 17% are non-white, 33% are college graduates and 65% have a history of cancer. 86% had multigene panel testing. At 6 months, 79% (52/66) of participants in the remote services arms had pre-test genetic counseling as compared to 5% (2/40) in the usual care arm ($p < 0.001$). 56% (37/66) in the remote services arm completed genetic testing and 4 genetic carriers were identified (*ATM, MUTYH* and 2 with *BRCA2*) as compared to 12.5% (5/40) and 0 carriers in the usual care arm ($p < 0.001$ for genetic testing uptake). Highest income levels ($p < 0.05$), older age ($p = 0.07$) and being married ($p = 0.06$) were associated with uptake of testing. In secondary analyses comparing the videoconference and phone arms, we have found greater knowledge gains (phone: +7.4, SD 10.5 v. VC: 17.8, SD 16.5, $p < 0.01$) and reductions in depression (phone +0.1, SD 2.3 v. VC: -1.1, SD 2.0, $p = 0.07$) from baseline to post-disclosure with videoconferencing as compared to phone. **Conclusions:** These data suggest that offering remote genetic services by phone or real-time videoconference may increase the uptake of testing and identification of genetic carriers in community practices without access to genetic services. Continued evaluation of the relative benefits of videoconferencing over telephone counseling in patients at community practices is critical to understanding how to optimize patient outcomes. Clinical trial information: NCT02517554.

6507 Oral Abstract Session, Fri, 2:45 PM-5:45 PM

PRECISE: A clinical-grade automated molecular eligibility screening and just-in-time (JIT) physician decision support solution for molecularly-selected oncology trials. *First Author: Jessica Tao, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Clinical informatic systems that aid in identifying and matching actionable molecular alterations to the appropriate targeted therapies are critical for ensuring both the delivery of optimal routine care and the successful implementation of precision oncology research programs. We developed DARWIN PRECISE (PRECision Insight Support Engine), a clinical-grade informatics solution that identifies and dynamically tracks patients based on molecular and clinical data. PRECISE also provides JIT notifications to study teams and treating oncologists, facilitating patients' seamless matching and enrollment to molecularly-selected trials. **Methods:** Under an IRB-approved study, we prospectively followed all patients identified by PRECISE and subsequently enrolled to molecularly-selected clinical trials at MSKCC between 16-April-2014 and 31-January-2017. Demographic, clinical, and molecular data were abstracted from the institutional data warehouse. Characteristics of therapeutic accruals facilitated by PRECISE were measured using descriptive statistics. **Results:** Patients treated by 150 unique oncologists and all accruals to 42 therapeutic trials that used PRECISE were included in the analysis. During the study period, a total of 742 patient-accruals occurred across the 42 trials. Of these, PRECISE prospectively identified 327 (44%) of accrued patients. Patients identified and subsequently enrolled by PRECISE harbored a wide variety (n = 32) of molecular alterations; with SNVs, CNAs, or fusions in *ERBB2* (23.5%), *PIK3CA* (18.2%), *BRAF* (9.3%), and *FGFR1/2/3* (6%) occurring most frequently. The median time from initial identification by PRECISE to trial consent was 82 days (IQR: 35-166), and the median time from tumor sequencing to consent was 161 days (IQR: 64-350). **Conclusions:** PRECISE facilitated the identification and enrollment of 44% (n = 327) of all patients accrued to molecularly-matched studies using this informatic platform. Automated JIT decision-support tools like PRECISE represent a novel and effective method for enhancing patient accrual to molecularly-selected therapies.

6508 Oral Abstract Session, Fri, 2:45 PM-5:45 PM

A cloud-based virtual tumor board to facilitate treatment recommendations for patients with advanced cancers. *First Author: Subha Madhavan, Innovation Center for Biomedical Informatics, Georgetown University Medical Center, Washington, DC*

Background: A deficiency in current approaches in Precision Oncology is the sole focus on gene mutations while overlooking the patient context, including medical and treatment history, as well as other multi-omic data, such as proteomics, germline, and phosphoprotein assays. Optimally every patient facing a molecular treatment decision will benefit from an expert tumor board, but it is impossible to convene this for every patient. **Methods:** We developed a cloud-based, asynchronous virtual tumor board (VTB) that integrates multi-modal patient data to formulate, discuss, and rank treatments. The VTB utilizes 8 linked databases, a treatment scoring model based on the AMP/ASCO variant interpretation guidelines and an AI-based treatment recommender. Molecular and clinical data including past medical history, molecular and pathology reports were aggregated from 1342 cases from $>$ 300 community and academic hospitals. A preliminary list of therapy options and trials were prepared by the VTB which integrates variant annotations, biomarker implications, trial eligibility criteria, outcomes, and literature. Medical and scientific experts reviewed each case, discussed through an asynchronous chat room, modified, and ranked treatment options delivered as a report to the treating oncologist. **Results:** Automation through VTB, increased the volume of cases reviewed per month by twofold. The VTB also led to a larger set of options compared to a lab report alone. Across 642 patients, the VTB enabled genomic-based therapy options in 503 (78.6%) patients. Additionally, proteomic data strengthened on-label treatment recommendations in 229 (36%), and off-label treatment recommendations in 80 (12%) patients. Importantly, by considering patients' previous treatment histories, the VTB omitted treatment options in 64% of patients to which patients had developed resistance. **Conclusions:** The VTB provides a scalable platform for integration and asynchronous team communication for facilitating case review with no geographical and time/attendance restrictions. We anticipate that further development of such decision support tools will be important for widespread adoption of cancer precision medicine.

Clinical trajectory modeling to predict hospitalization or death after palliative chemotherapy. *First Author: Kenneth L. Kehl, Dana-Farber Cancer Institute, Boston, MA*

Background: Hospitalization or death within 30 days of palliative-intent chemotherapy for metastatic cancer represent undesirable outcomes. An automated framework for predicting the risk of hospitalization or death within 30 days of chemotherapy could inform clinical decision-making, research, and quality improvement efforts. **Methods:** We piloted a machine learning framework for time-dependent clinical trajectory modeling using administrative data and applied it to prediction of hospitalization or death within 30 days of palliative cytotoxic chemotherapy. Patients with stage IV non-small cell lung cancer (NSCLC) diagnosed 2008-2013 were identified in SEER-Medicare. Inpatient, outpatient, durable medical equipment, prescription, home health, and hospice claims were extracted. The sequence of claims for the 60 days, or "clinical trajectory," prior to each date of chemotherapy was embedded into a feature space based on context similarity, and the sequence was fed into a stacked ensemble model to predict hospitalization or death within 30 days of each chemotherapy date. These administration dates were divided into 80% training and 20% validation sets. Discrimination was measured with the c-statistic (AUC). No manual feature engineering was performed. **Results:** 43,250 dates of chemotherapy administration were identified for 6,067 patients with stage IV NSCLC. 8,057 chemotherapy dates (19%) were followed by hospitalization (N = 7,629) and/or death (N = 1,688) within 30 days. In the validation set, our framework predicted the composite of hospitalization or death with an AUC of 0.83. Among 42,823 chemotherapy dates that were not followed by death without hospitalization within 30 days, our framework predicted hospitalization with an AUC of 0.84. **Conclusions:** Clinical trajectory modeling predicts hospitalization or death within 30 days of palliative-intent cytotoxic chemotherapy for stage IV NSCLC with good discrimination. These results could inform clinical decision-making and targeted cancer care delivery interventions.

End of life spending among cancer patients in an ACO vs. non-ACO. *First Author: Miranda Lam, Harvard T.H. Chan School of Public Health, Boston, MA*

Background: Nearly 25% of the annual Medicare budget is devoted to care of beneficiaries who die in a given year. Therefore, there has been increased policy and provider focus on understanding the care provided to patients at the end of life. Of the many initiatives aimed at improving the value of healthcare services in the United States, Accountable Care Organizations (ACOs) are receiving substantial policy attention. Early evidence shows modest reductions in total healthcare costs for Medicare beneficiaries. However, we are unaware of any data looking specifically at the impact of ACOs on spending for cancer patients at the end of life. **Methods:** We analyzed a 20% sample of Medicare beneficiaries age 66 years or older. We followed CMS guidelines to attribute patients to an ACO or non-ACO practice. Using ICD-9 codes, we identified patients with cancer. We matched ACO and non-ACO practices within the same HRR and narrowed to patients who died in 2013 or 2014. We calculated mean annual standardized total costs in the 180 days prior to death and stratified by inpatient, outpatient, physician, skilled nursing facility, home health, hospice, radiation oncology, and chemotherapy spending. Spending was adjusted for patient characteristics and by chronic conditions. **Results:** 36% of patients were in an ACO. ACO and non-ACO patients were similar in terms of patient characteristics (age, race, sex, dual eligibility, comorbidities). ACO beneficiaries had modest but significantly higher total annual standardized costs compared to beneficiaries not in an ACO ($47,629 vs. $45,582; p = 0.02). The ACO and non-ACO patients had similar spending by categories: inpatient ($23,908 vs. $22,843; p = 0.06), outpatient ($4,939 vs. $4,403; p = 0.09), physician services ($13,412 vs. $12,975; p = 0.26), SNF ($2,164 vs. $1,952; p = 0.18), HHA ($2,009 vs. $2,027; p = 0.82), hospice ($683 vs. $793; p = 0.07), radiation oncology ($449 vs. $422; p = 0.62), and chemotherapy ($1,927 vs. $1,813; p = 0.57). **Conclusions:** Spending in the last 6 months of life among cancer patients treated in an ACO was slightly higher compared to those not treated in an ACO. This study suggests that ACOs have not had a meaningful impact in reducing costs at the end of life for cancer patients.

Are National Comprehensive Cancer Network (NCCN) Evidence Blocks (EB) Affordability Ratings (AR) representative of real-world costs? An evaluation of advanced non small cell lung cancer (aNSCLC). *First Author: Scott David Ramsey, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: The NCCN EB are designed to provide AR on the overall cost of drug treatments (tx), including medication, administration, supportive care, side effect management and hospitalization. This study characterized the relationship between real-world costs of aNSCLC tx and NCCN AR. **Methods:** We used the Truven MarketScan claims database to identify patients (pts) treated with aNSCLC tx evaluated by the NCCN EB from 2006-2011. We estimated mean per patient per month (PPPM) cost (including inpatient, outpatient, and pharmacy costs) for each regimen, adjusted for patient characteristics using generalized linear models with log-link gamma. Tx regimens were grouped into their respective NCCN EB AR. Weighted linear regression was used to examine the correlation between adjusted mean PPPM costs per regimen and NCCN AR. **Results:** The study identified 15,574 pts (mean age: 65 [SD = 11], 53% male). The mean PPPM cost per regimen ranged from $12,188 to $66,996 (mean $22,782, median $16,412). EGFR and ALK tx and generic chemotherapy had different AR despite having similar mean PPPM costs (EGFR/ALK: $13,665-$27,782, AR 2; chemo: $16,175-$28,195, AR 3-4). The mean PPPM costs per regimen by AR had low correlation (R^2= -0.34) and was not statistically significant (p = 0.13). Pairwise comparisons show a significant difference in mean PPPM costs between AR 1 and other groups; there were no significant differences in mean PPPM costs among AR 2, 3, and 4. **Conclusions:** Real-world costs are often inconsistent with the NCCN AR. Given the intended use of NCCN EB to inform tx decisions and value discussions between providers and pts, our results suggest that the NCCN AR need to be further refined and validated.

NCCN AR	Mean PPPM (95% CI)	Difference vs. AR = 2	Difference vs. AR = 3	Difference vs. AR = 4
AR 1: Very Expensive (n = 860)	$40,084 ($31,123, $49,044)	-$19,230*	-$15,226*	-$19,734*
AR 2: Expensive (n = 2177)	$20,854 ($17,755, $23,953)	–	$4,003	-$505
AR 3: Moderately expensive (n = 3155)	$24,857 ($21,349, $28,365)	–	–	-$4,508
AR 4: Inexpensive (n = 9307)	$20,349 ($18,517, $22,182)	–	–	–
AR 5: Very inexpensive (n = 0)	–	–	–	–

Cost-effectiveness of multi-gene panel sequencing (MGPS) for advanced non-small cell lung cancer (aNSCLC) patients. *First Author: Lotte Maria Gertruda Steuten, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: MGPS, compared to single-marker genetic testing (SMGT), has the potential to identify more patients who could benefit from targeted therapies, but the impact on outcomes and total costs of care is uncertain. Our goal was to estimate the cost-effectiveness of MGPS vs SMGT in aNSCLC. **Methods:** aNSCLC patients (stage IIIB or metastatic) diagnosed between 2011-2016 were identified from the Flatiron Health database, representing curated electronic health record-derived clinical information from > 250 oncology practices nationwide. After stratifying patients in MGPS or SMGT cohorts, we analyzed the percentage of patients that receive targeted treatment; survival; and total costs of care. SMGT included *EGFR* and *ALK* testing; MGPS also allowed detection of *BRAF, RET, ROS1, HER2* and *MET* mutations. Cost data sources were the CMS Fee Schedule and 2017 ASP drug cost. We estimated the incremental cost-effectiveness ratio (ICER) and performed sensitivity analyses from a US payer perspective over a lifetime horizon, using a decision model. **Results:** We identified 5688 aNSCLC patients receiving MGPS (n = 875) or SMGT (n = 4813), of which 22% tested positive for *EGFR* (18.5% MGPS, 17.3SMGT) or *ALK* (3.59% MGPS, 3.78% SMGT). Among MGPS tested patients, an additional 8% were found to have *BRAF, RET, ROS1, HER2* or *MET* mutations. Of MGPS tested patients, 21% received targeted treatments vs 19% with SMGT. Model-projected survival was 1.14 life years (LYs) in SMGT vs 1.20 LYs in MGPS. Lifetime total costs were $8,814 higher per patient for MGPS. The ICER of MGPS vs SMGT was $148,478 per LY gained. If all patients with actionable mutations would receive targeted treatment in MGPS-guided care vs the proportion currently receiving targeted treatments under SMGT, the ICER would be $110K/LY gained. Sensitivity analyses shows widely varying ICERs ($139/LY to $661,625/LY). **Conclusions:** Based on data from a nationwide oncology patient database, MGPS has moderate cost-effectiveness compared to SMGT in aNSCLC patients. Efforts to increase the proportion of patients who receive targeted therapies would improve the cost-effectiveness of MGPS, assuming incremental costs and outcomes of targeted treatments remain unchanged.

6514 Poster Discussion Session; Displayed in Poster Session (Board #340), Sat, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Sat, 4:45 PM-6:00 PM

Cost-effectiveness analysis of abiraterone acetate (AA) versus docetaxel (D) for the management of metastatic hormone naïve prostate cancer (mHNPC). *First Author: Chethan Ramamurthy, Fox Chase Cancer Center, Philadelphia, PA*

Background: Therapies previously reserved for castration resistant prostate cancer (CRPC) have demonstrated improved progression-free (PFS) and overall survival (OS) in mHNPC. Four randomized trials have provided level 1 evidence for using either D or AA in addition to androgen deprivation therapy (ADT) for mHNPC, but the cost-effectiveness of these options has not been compared. **Methods:** A Markov cohort model was developed to project cost-effectiveness of each treatment until disease progression. Survival curves for progression/death were abstracted and digitized from the CHAARTED and LATITUDE studies. Clinically or financially significant adverse events (AEs) were modeled (neutropenia, neutropenic fever, and severe fatigue); utility values were obtained from the literature. Drug costs were obtained from a range of sources (Average Wholesale Price; VA costs). Effectiveness was measured in PFS quality adjusted life years (PFS QALYs) and cost-effectiveness was calculated using incremental cost-effectiveness ratios (ICER). **Results:** Adding D or AA to ADT improved PFS QALYs by 0.26 and 0.54, and increased cost by $12,185 and $208,684, respectively. Resulting ICERs were $46,519/QALY (D vs ADT) and $705,323/QALY (AA vs D). Results were highly sensitive to AA price, although even under lowest prices, the ICER was $404,451/QALY (AA vs DC) (Table 1). AA cost must be reduced by 76% for it to fall below a willingness-to-pay threshold of $150,000/QALY. **Conclusions:** Addition of AA modestly increases PFS QALYs compared with D, but substantially increases costs. While therapy subsequent to progression will impact the overall cost-effectiveness of the respective frontline options, the relative durations of treatment for CRPC are shorter. Thus, cost-effectiveness of mHNPC therapy is an important consideration given that OS is similar between studies for D and AA.

Effect of varying medication costs on ICERs.

	Cost ($)	ICER (AA vs D) ($)	ICER (D vs ADT) ($)
Base case		705,323	46,519
Abiraterone (cost/30d supply)	9358*		
LB	5,550	404,450	46,519
UB	11,275	856,743	46,519
Docetaxel (cost/mg)	10*		
LB	1.6	726,302	24,206
UB	12	700,210	51,958

*Base case; LB = lower bound, UB = upper bound

Potential life-years lost: The impact of the cancer drug regulatory process in Canada. *First Author: Joanna Gotfrit, Ottawa Hospital, Ottawa, ON, Canada*

Background: Canada has an established publicly-funded healthcare system but a complex drug approval and funding process. After proof of efficacy (POE; key publication/presentation), before becoming publicly accessible each drug undergoes a Health Canada approval process, a health technology assessment (HTA), a pricing negotiation and finally individual provincial funding agreements. We quantified potential life-years lost due to delays in this process. **Methods:** We analyzed drugs for advanced lung, breast and colorectal cancer that underwent the HTA process between 2011-2017. Life-years lost were calculated by: (documented PFS/OS improvement) x (number of eligible patients) x (time from POE to first public funding). For conservative calculation, we assumed all eligible patients in Canada had access at the time of first public funding, while in reality provinces fund at different time-points. **Results:** We analyzed 21 drugs. Of these, 15 have been funded publicly. See Table 1 for time delays and life-years lost for select publicly funded drugs. The time from POE to first public funding ranged from 1.2-7.5 years (median 2.1 years). Total progression-free life-years lost from POE to first public funding were 36,854 (lung 9,015; breast 4,134; colorectal 23,706 years). Total overall life-years lost from POE to first public funding were 48,366 (lung 32,388; breast 5,823; colorectal 10,155 years). **Conclusions:** The number of potential life-years lost during the drug regulatory and funding process in Canada is substantial. Recognizing that inter-provincial differences exist and that eligible patients may not all receive a given drug, if even a fraction does so, the impact of delays remains substantive. Other countries with similar systems likely experience similar delays. Collaborative national initiatives are required to address this major barrier to treatment access.

Tumour Site	Drug Name	Indication	Time from efficacy to first public funding (years)	Progression-free life-years lost	Overall life-years lost
Lung	Pembrolizumab	1st line, expressing PD-L1 > 50%	1.2	2240	8229
Breast	Pertuzumab	Her2/neu(+), in combination with a taxane/trastuzumab	1.9	1001	2494
Colorectal	Cetuximab	1st line, KRAS wild type	6.4	4352	10154

Trends of new cancer drug approvals from the perspective of a publicly funded healthcare system: Analyses of the pan-Canadian Oncology Drug Review (pCODR) recommendations. *First Author: Saroj Niraula, CancerCare Manitoba and Univ of Manitoba, Winnipeg, MB, Canada*

Background: United States Food and Drug Administration (FDA) primarily takes into account the therapeutic index before approval of a new cancer drug whereas in countries with public funding of healthcare cost-effectiveness, utility, and adoption feasibility are also considered rigorously. **Methods:** Data from the pan-Canadian Oncology Drug Review (pCODR) – a national drug review system that makes evidence-based funding recommendations to Canada's provinces and territories - were collected. Analyses based on rationale of the pCODR recommendations and any conditions thereof, pCODR timelines compared to FDA approvals, published results of the pivotal clinical trials used to support the pCODR recommendations, cost/Quality Adjusted Life Years (QALY), and Incremental Cost Effectiveness Ratio (ICER)/QALY of the new drugs compared to controls were performed using established methods. **Results:** From inception to January 31, 2018, 60 new cancer drugs for 91 indications were reviewed by pCODR. There was a median of 15 months' time lag between FDA approval and final pCODR recommendation. Eighteen of the 91 pCODR reviews (approved previously by FDA for public use) received negative recommendation on the grounds of inadequate clinical benefits. Of the 73 that received positive pCODR recommendation, 90% were approved conditional on improvement in cost-effectiveness to an acceptable level. Surrogate outcomes were used as the primary basis for approval in 83% of the reviews, of which 4 drugs subsequently led to a compromise in overall survival compared to respective controls by a median of 1.5 months. Median ICER/QALY of new drugs, compared to the controls was $186,403 (range 7.2k to 4 millions). **Conclusions:** Close to a quarter of cancer drugs approved for public use by FDA do not meet Canadian standards for efficacy, and some may have detrimental effect on survival. A vast majority of the pCODR approved drugs are cost-ineffective at presented price. With finite resources to share among multiple societal priorities like education and preventative health, incremental cost of new cancer drugs is unsustainable even in the wealthiest of nations.

6517 Poster Discussion Session; Displayed in Poster Session (Board #343), Sat, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Sat, 4:45 PM-6:00 PM

FDA acceptance of surrogate endpoints in later lines of therapy. *First Author: Emerson Yu-sheng Chen, Oregon Health and Sciences University, Portland, OR*

Background: U.S. Food and Drug Administration (FDA) utilizes surrogate endpoints in order to speed drugs to market. Surrogates reduce development time, though they do so to a larger extent in the front line rather than in later line settings. **Methods:** We examined all adult cancer drugs approved by the FDA from 01/2006 to 12/2017. Data regarding the approval type (regular or accelerated), cancer type, treatment indication, and basis for approval were extracted from the FDA website and any relevant publications. Basis for approval was categorized into response rate (RR), progression-free or relapse-free survival (PFS/RFS), and overall survival or quality-of-life (OS/QoF) endpoints. Drugs for mainly pediatric cancers and cancers limited to genetic syndromes were not included in this study. Statistical analysis was performed using SAS 9.4 version. **Results:** 182 drug indications among 108 cancer drugs were identified. 67 (36.8%) drug indications were approved for first-line setting, 75 (41.2%) for second-line setting, 24 (13.2%) for third-or-later-line setting, and 16 (8.8%) for adjuvant or maintenance settings. 49 (26.9%) were approved based on OS/QoF endpoints. 133 (73.1%) were approved based on surrogate endpoints: 69 (37.9%) being RR and 64 (35.2%) being PFS/RFS. Accelerated instead of regular approval was more likely to be sought in subsequent lines of therapy (19.4% in first-line, 30.7% in second-line, 62.5% in third line, $p < 0.01$). Surrogate endpoints had a trend toward being used in subsequent lines of therapy (68.7% in first-line, 70.7% in second-line, and 87.5% in third-line approvals, $p = 0.18$). However, RR specifically was used more frequently in subsequent lines of therapy compared to PFS/RFS or OS/QoF (22.4% in first-line, 45.3% in second-line, and 79.2% in third-line approvals, $p < 0.01$). **Conclusions:** Surrogate endpoints are increasingly used in oncology trials with the intention of speeding drugs to market. They are used most often in later lines of therapy, when definite endpoints like OS or QoF can be expeditiously evaluated, and the 'acceleration' of approval is actually limited. Accelerated approval based on surrogate endpoints is thus granted preferentially in later lines of therapy, when the impact is likely modest.

6518 Poster Discussion Session; Displayed in Poster Session (Board #344), Sat, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Sat, 4:45 PM-6:00 PM

Internet- and mobile-based lifestyle intervention for prostate cancer patients on androgen deprivation therapy: Prospective, multicenter, randomized trial. *First Author: Yong Hyun Park, Department of Urology, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of (South)*

Background: Androgen deprivation therapy (ADT) has several adverse effects including loss of libido, osteoporosis, and metabolic complications. We aimed to examine whether the Smart After-Care service (internet- and mobile-based lifestyle intervention) has an effect on clinical outcomes in patients with prostate cancer (PCa) on ADT. **Methods:** Two hundred patients with PCa on ADT were randomly assigned to the Smart After-Care or control group. The Smart After-Care group received a mobile application and wearable device, providing general health information, nutritional and medication care and exercise program (aerobic exercise at least 90 or 150 minutes every week for 12 weeks depending on patients' aerobic fitness and strengthening exercise at least 2 times a week for 12 weeks) while the control group was imparted brief education for the exercise program. Primary endpoint was an increase in patients' physical function as assessed using 2 minutes' walk test. Secondary endpoints included improvement in muscle strength (30 seconds chair stand test, grip strength test), short physical performance battery, body composition, and health-related quality of life (EORTC-QLQ-C30, and PR 25). **Results:** In the aspect of physical performance, both groups showed significant improvement in 2 minutes' walk test and 30 seconds chair stand test after 12 weeks of intervention, whereas a repeat measures ANOVA showed a significant improvement in 2 minutes' walk test ($P = 0.042$) over time in the Smart After-Care group as compared to the control group. The Smart After-Care group had additional improvement in right hand grip strength ($P = 0.038$) and reduction in body fat percentage ($P = 0.022$) compared to the controls. Also, the Smart After-Care group showed significant improvement in social functioning ($P = 0.016$) as well as in appetite loss ($P = 0.048$). Both groups showed significant improvement in urinary symptom, whereas the Smart After-Care group showed significant improvement in sexual functioning ($P = 0.032$). **Conclusions:** The Smart After-Care service is an effective method in PCa patients on ADT in improving exercise capacity and general health related quality of life. Clinical trial information: NCT03264209.

Objective metrics of patient activity: Use of wearable trackers and patient reported outcomes in predicting unexpected healthcare events in cancer patients undergoing highly emetogenic chemotherapy. *First Author: Alexander S. Martin, University of Southern California, Los Angeles, CA*

Background: Functional status and predictors that identify those cancer patients at risk for unplanned hospitalization can have broad implications for the health care system and clinical trials. We evaluated the feasibility of monitoring physical activity (PA) using wearable activity trackers in cancer patients on highly emetogenic chemo as well as potential correlations between PA and unplanned healthcare events (UHE) and ECOG scores. **Methods:** This study was conducted as a multi-institutional single arm observational clinical trial of 65 patients with solid tumors undergoing highly emetogenic chemo based on Hesketh classification. We measured PA by analyzing daytime hourly metabolic equivalents (1 MET = resting metabolic rate) from 10 AM - 7 PM over 60 days via Microsoft band 2. Patient reported outcome data was collected using smartphone apps. UHE were collected by review of medical records over the 60 days of band wear plus 90 days of clinical follow up. **Results:** Data was successfully captured from 41 of the 65 activity trackers. Patients were compliant with wearing the activity trackers for $>$ 7 of 9 total hrs on 67.7% of study days. Only 9 out of 41 patients exhibited $>$ 60 hours of non-sedentary activity, defined as $>$ 1.5 METs, over the 60-day band wear period. Mean step counts/day were similar between higher and lower PA groups at 2564 steps/d and 2261 steps/d respectively. 9 patients with $>$ 60 hrs of 1.5 METs had significantly fewer UHE compared to the 32 patients with $<$ 60 hrs of 1.5 METs ($p = 0.02$). The physician reported ECOG scores had no correlation with PA or UHE. **Conclusions:** In solid tumor patients undergoing highly emetogenic chemo regimens, activity trackers are feasible and identify those patients with a profile of lower activity that predicts UHE. Incorporation of activity trackers has the potential to identify patients who are at need for interventions to prevent hospitalization and may also predict the subset of patients enrolled in clinical trials who are more likely to record serious adverse events.

Opioid use in long term cancer survivors. *First Author: Lisa Catherine Barbera, Odette Cancer Centre, Sunnybrook Health Sciences Centre, Toronto, ON, Canada*

Background: Our research team previously found that the rate of opioid use in cancer patients surviving at least 5 years beyond diagnosis was 1.2 times higher compared with age-sex matched controls without cancer. The purpose of this study was to evaluate the factors associated with opioid use after 5 years of survival from cancer diagnosis. **Methods:** We conducted a retrospective cohort study using linked provincial administrative data. Patients were aged 24-70 and economically disadvantaged, making them eligible for government funded pharmacare. The index date was defined as the 5 year anniversary from the diagnosis date. Patients were accrued continuously between April 1, 2010 and March 31, 2015 on their index date. Those with any evidence of recurrence (resuming anti-cancer therapy, palliative care) were excluded. Patients were observed until death, relapse or end of data accrual. The main outcome was opioid prescription rate after index date. The main exposures were opioid use prior to diagnosis date, opioid use between diagnosis date and index date (none, continuous, at diagnosis only, other), certain cancer surgeries (e.g. thoracotomy) and chemotherapy agents known to cause neuropathy. A negative binomial regression model was used to estimate the relative rates of opioid use after index date. **Results:** Our cohort included 7,431 individuals. The factors most strongly associated with a higher rate of opioid use after index date was continuous opioid use between diagnosis and index date. The RR was 63.4 (95% CI 39.4-102.1) for those with no pre-diagnosis opioid use and 76.6 (95% CI 40.7-144.0) for those with pre-diagnosis opioid use. The only group with no increased risk used opioids only at diagnosis and had no prior use. Surgery was not significant. Chemotherapy was not significant with the exception of those who used opioids initially. A history of depression, comorbidity and more than 2 years of diabetes were also associated with higher risk. **Conclusions:** Cancer patients who use opioids continuously after diagnosis are at increased risk of continued use after 5 years of survival. Further work is needed to understand the reasons for ongoing use after diagnosis. Increased attention is needed to ensure safe prescribing for this group to minimize issues with dependence.

6521 Poster Session (Board #347), Sat, 1:15 PM-4:45 PM

Implementation of breast cancer pathway for genetic counseling and testing in multi-state health system. *First Author: Stephanie L. Graff, Sarah Cannon Cancer Institutes HCA Midwest Health, Overland Park, KS*

Background: Genetic counseling and/or testing (GC/T) are important aspects of breast cancer care. The National Comprehensive Cancer Network has guidelines for GC/T but reports demonstrate variable compliance. Across the Sarah Cannon Cancer Network (SCCN), pathways were developed and implemented by physician leadership teams to select patients (pts) who meet criteria for GC/T. Participating physicians receive pathways training. Adherence metrics are tracked in real time. This study evaluates compliance with GC/T for pts treated on and off pathway in the SCCN. **Methods:** Data was collected from seven SCCN markets in six states to create 3 data sets. 1. Pre-pathway: treated prior to implementation of pathways. 2. Off pathway: treated off pathway by physicians not yet trained on pathways after pathways implementation. 3. On pathway: treated by at least one physician trained on pathways. Pathway criteria for GC/T include: age $<$ 50 years, male breast cancer, $\geq$ 2 affected relatives, ovarian cancer (family or self), triple negative biology $<$ 60 years of age, 2 primary breast cancers, Ashkenazi Jewish ancestry. All pts were navigated by nurse navigators who entered the data into iNavigate, SCCN's proprietary software. Data represents all breast cancer pts in iNavigate between December 2012 and November 2017. Pathways were implemented March 2016. Chi-squared tests were performed without continuity correction, using Bonferroni correction methods to account for multiple comparisons **Results:** Summarized in Table 1. **Conclusions:** Following implementation of pathways guiding genetic counseling and/or testing (GC/T), patient referral improved by 61.3% (95% CI: 56.1%, 66.4%; $p < 0.0001$). For pts not managed on pathway, GC/T improved by 15.7% (95% CI: 10.9%, 20.6%; $p < 0.0001$), possibly due to increased navigator or system awareness. These findings support pathways as one way to ensure best practice and guidelines based care across a large, multi-state health system.

	Total Patients	Eligible GC/T	GC/T Offered
Pre-Pathway	4321	1151	245 (21.3%; 95% CI: 19.0%, 23.7%)
Off Pathway	2711	889	329 (37.0%; 95% CI: 33.9%, 40.2%)
On Pathway	1277	453	374 (82.6%; 95% CI: 78.8%, 85.8%)

6522 Poster Session (Board #348), Sat, 1:15 PM-4:45 PM

Trends and disparities in place of death for cancer patients in the United States, 1999-2015. *First Author: Fumiko Ladd Chino, Duke University Radiation Oncology, Durham, NC*

Background: Dying in a preferred place is an essential component of high quality cancer care. Comprehensive national trends and disparities in place of death are unknown as prior research is limited in scope and to patients $\geq$65. **Methods:** CDC WONDER contains death certificate data for all US counties and is maintained by the National Center for Health Statistics. Place of death was obtained for all cancer deaths from 1999- 2015, as well as year of death, age, sex, race, ethnicity, marital status, and education. Place of death was dichotomized to death at home or hospice facility vs other location. Using data from the most recent year (2015), univariate (UVA) and multivariate (MVA) logistic regression were used to test for disparities in place of death associated with sociodemographic variables. **Results:** In the study period, 9,646,498 cancer deaths occurred, with 45.5% dying at home or hospice facility. 30.3% of deaths occurred in patients $<$ 65. From 1999-2015, inpatient deaths decreased from 36.6% to 24.6%, while home deaths (38.4 to 42.6%) and hospice facility deaths (0 to 14.0%) increased (all $p < 0.001$). On UVA, older age, female sex, white race, Hispanic ethnicity, marriage, higher education, and pancreatic or colorectal cancer were associated with death at home or in a hospice facility. On MVA, all assessed factors were associated ($p < 0.05$) except education and ethnicity. In particular, being married (OR 2.04, 95% CI 1.98-2.10) and having pancreatic cancer (OR 1.36, 95% CI 1.33-1.40) were associated with death at home or hospice, while being black (OR 0.74, 95% 0.73-0.76) or Asian (OR 0.65, 95% CI 0.62-0.68) and having breast cancer (OR 0.90, 95% CI 0.88-0.92) had decreased odds of dying at home or hospice. Despite improvements over time, in 2015 black patients remained 42% more likely to die in hospital (32.8% black vs 23.1% white) and 21% less likely to die at home (34.6% black vs 43.7% white) (both $p < 0.001$). **Conclusions:** Inpatient cancer deaths decreased by one third with commensurate rise in home and hospice facility deaths over the study period. Multiple sociodemographic factors were associated with place of death; targeted efforts to increase utilization of palliative care and hospice services may decrease these disparities.

6523 Poster Session (Board #349), Sat, 1:15 PM-4:45 PM

Methodologic challenges of defining oncology provider networks from administrative claims data. *First Author: Karyn Beth Stitzenberg, Univ of North Carolina, Chapel Hill, NC*

Background: Provider characteristics measured from administrative claims data are increasingly used to study health care organization/delivery and to measure quality of care. Most studies use claims from a single large payer to calculate provider statistics and examine networks. This study compares and contrasts findings generated from claims of different but overlapping payer populations. **Methods:** Outpatient claims data from 2003-13 Medicare and a large private payer were used to construct colorectal cancer provider networks where edges between providers correspond to the number of shared patients. Payer-specific network and provider statistics were compared. Network metrics on the private network were compared to distributions of subsampled Medicare networks to identify statistical differences controlling for patient numbers. The study was IRB approved. **Results:** 1735 surgeons and medical oncologists were identified from Medicare and 1321 from private claims with 1163 appearing in both. Across networks, there were 33164 pairs of providers connected by at least one patient. 4835 (14.6%) pairs appeared only in the private network, while 18218 (54.9%) appeared only in Medicare. Average volume for surgeons and medical oncologists was similar between networks (R^2 = .85), but 24.5% of providers' volume rank differed by at least one quintile group between payers. Likewise, average clustering coefficients were similar in magnitude across payers (.51 vs .53), but many providers had vastly different values in the two networks. Most of the same clusters/communities of providers were detected in both networks. However, there were two cases in which the combined network detected distinct communities of providers that Medicare alone missed. **Conclusions:** Provider networks constructed from Medicare claims alone differ from networks constructed from other large payers. Researchers should be cautious extrapolating findings from networks constructed from a single payer to other contexts. For example, this study brings into question whether Medicare data alone can be used to accurately quantify patient volume of any individual provider.

6524 Poster Session (Board #350), Sat, 1:15 PM-4:45 PM

Trends related to program participation, implementation, best practices, challenges and resource requests among oncology care model (OCM) participants. *First Author: Daniel Gutkin, Amgen, Thousand Oaks, CA*

Background: The OCM is an alternative payment model (APM), developed by the Center for Medicare & Medicaid Innovation (CMMI) to improve the quality of oncology care. The Patient Outcomes & Policy Regional Executive (POPRE) team was tasked with engaging OCM participants to understand their unique challenges and develop appropriate resources to address their concerns. We examined trends related to participation, implementation, best practices, and resource requests among OCM participants. **Methods:** Between May and October 2017, the POPRE team conducted interviews at 57 OCM sites, including 30 community, 24 academic, and 3 payer-based accounts. Participants answered questions pertaining to their OCM processes, challenges and needs. **Results:** The top OCM provider challenges identified were data extraction/analysis, electronic medical record (EMR) integration, and cost of care estimates. Common data extraction/analysis difficulties included labor intensive data collection, entry, and abstraction. EMR integration gaps centered on risk adjustment factors, tumor staging, triage processes, supportive care/pain care plans, among others. Patient & provider education materials, tech/IT tools, and EMR integration tools were the three most common requests from OCM providers. Care coordination solutions, including utilization of pathways, innovative software tools for symptom monitoring, and triage/virtual consults, were among the top OCM Best Practices shared. EMR integration solutions included the adoption of well-known pathways, care and survivorship plans, and symptom screening/risk stratification tools. **Conclusions:** The majority of participants interviewed experienced difficulties with OCM requirements. Most of those challenges were related to data extraction/analysis and EMR integration issues; however many practices utilized those gaps to innovate, adapt, and request appropriate resources to address these concerns. Resolving common data and solving EMR integration challenges may help improve other critical OCM practice transformations, thus enhancing patient care, providers' engagement and overall program's viability.

6525 Poster Session (Board #351), Sat, 1:15 PM-4:45 PM

Value-based healthcare delivery models in oncology: A systematic review. *First Author: Emeline Aviki, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: With the rising cost of health care in the US has come increasing emphasis on optimizing value. Value-based healthcare delivery models are designed to maximize outcomes and minimize costs through changes in care delivery. Little is known about the impact of value-based interventions in cancer care. We performed a systematic review to describe the landscape of value-based interventions in cancer. **Methods:** This review included peer-reviewed and non peer-reviewed articles describing value-based interventions in cancer care. We identified articles through structured searches of PubMed/MEDLINE, EMBASE, CINAHL, and Cochrane Central Register of Controlled Clinical Trials since passage of the Affordable Care Act. We used the Effective Public Health Practice Project Quality Assessment Tool to evaluate the quality of studies reporting results. **Results:** Twenty-three articles describing 22 unique value-based interventions in cancer met inclusion criteria. Of the 23 articles, 12 were published in the peer-reviewed literature, and 13 reported outcomes and were assessed for quality. All were of moderate (n = 6, 46%) or weak (n = 7, 54%) quality. The 22 value-based interventions included 6 (27%) bundled payments, 4 (18%) accountable care organizations (ACOs), 9 (41%) patient-centered medical homes, and 3 (14%) other interventions. Most interventions were conducted in community settings (n = 16 of 21, 76%) and performed through commercial insurance contracts (n = 13 of 15, 87%), including all bundled payments and all cancer-specific ACOs. Of the 12 interventions with outcomes reported, the majority (n = 7, 58%) improved value, 4 had no impact on value, and 1 reduced value, though this effect was no longer significant after 2-3 years. **Conclusions:** This systematic review of value-based healthcare delivery models in cancer care found that reports of outcomes are often lacking and are of variable quality when available. Despite promising early signs, the efficacy of these interventions in cancer remains unclear. Moving forward, rigorous evaluations and increased outcome reporting will enable continued innovation to achieve the highest value of care for cancer patients.

6526 Poster Session (Board #352), Sat, 1:15 PM-4:45 PM

Treatment patterns among patients diagnosed with stage IV cancers who died within one month of diagnosis. *First Author: Helmneh M. Sineshaw, American Cancer Society, Atlanta, GA*

Background: Little is known about the factors associated with treatment in patients diagnosed with metastatic cancers and who die soon after diagnosis. We examined patterns of treatment in patients diagnosed with metastatic lung, colorectal, breast, and pancreatic cancer who died within one month of diagnosis. **Methods:** Using the National Cancer Data Base, we identified de novo stage IV lung, colorectal, breast, and pancreatic cancer patients ages $\geq$18 years and diagnosed between 2004-2014 who died within one month of diagnosis. We used descriptive analyses to calculate percentages and multivariable logistic regression analyses to generate adjusted odds ratios for receipt of specific types of treatment. **Results:** Among 97,884 patients, 66% had lung, 18% pancreatic, 12% colorectal, and 3.7% breast cancer. Surgery was least common in pancreatic (0.4%) and most common in colorectal (28.8%) cancer. Rates of chemotherapy ranged from 5.8% in colorectal to 11.3% in lung and breast cancer. Rates of radiation ranged from 1.2% in pancreatic to 18.7% in lung cancer. Endocrine therapy was initiated for 23.7% of patients with hormone receptor-positive breast cancer. Over the study period, surgery for colorectal and breast cancer, chemotherapy and radiation treatment for lung cancer, and chemotherapy for breast and pancreatic cancer progressively declined (P trend < 0.01). Age, insurance, and facility type were strongly associated with receipt of treatment across most cancer types. Uninsured patients had 43% lower odds of receiving surgery for colorectal cancer, 34% lower odds of initiating chemotherapy for lung cancer, and 47% lower odds of initiating chemotherapy for breast cancer compared with their privately insured counterparts. Compared with patients with lung cancer treated at NCI-designated cancer centers, those treated at community cancer centers had 48% lower odds of initiating radiation. **Conclusions:** Treatment of patients diagnosed with imminently fatal metastatic cancer (death within one month of diagnosis) varied markedly by cancer type and patient/facility characteristics. More research is needed to identify patients with imminently fatal metastatic cancer who would benefit from early treatment.

6527 Poster Session (Board #353), Sat, 1:15 PM-4:45 PM

Results from a pilot of an innovative 4R Cancer Care Delivery Model: Impact on patient self-management. *First Author: Julia Rachel Trosman, Center for Business Models in Healthcare, Chicago, IL*

Background: Under the "NCI ASCO Teams" Project, we proposed a 4R Model of teamwork and patient self-management (pSM) (Trosman JOP '16). 4R is Right Info / Care / Patient / Time. It enables patient (pt) and care team to manage interdependent care along the care continuum with an innovative multimodality personalized 4R Care Project Plan. We piloted 4R at 3 centers (academic, community, safety net) and assessed its impact on pSM. **Methods:** 4R Plans were administered to breast cancer pts stage 0-III Sep '16 – Aug '17 (4R cohort). We surveyed the 4R cohort and a comparable historical cohort of pts who received care pre-4R, Jun '15 – May '16 (control). We used simple frequencies and Fisher's exact test in analyses. **Results:** Survey response rates: 68%, 185/271 (4R cohort); 47%, 241/410 (control). 75% of 4R respondents reported 4R Plans very useful / useful in overall understanding and organizing their care; 68% found 4R's novel "project" component, very useful / useful in managing timing & sequencing of interdependent care. Care complexity impacted 4R usefulness: 67% of pts who received $>$ 6 care services found 4R very useful / useful vs. 47% of pts who received $<$ = 6 services, p = .01. Pts with lower care complexity suggested how to make 4R more useful to them, eg focus on endocrine therapy. Table compares pSM metrics in the 4R and control cohort. Care complexity was a significant factor of feeling overwhelmed for pts in the control cohort (51% of pts receiving $>$ 6 care services felt overwhelmed vs. 31% of pts receiving $<$ = 6 services, p = .02), but not a significant factor for pts in the 4R cohort (30% vs. 28%, p = .9). **Conclusions:** The 4R model significantly improved pt self-management in early breast cancer and reduced the impact of care complexity on pts, but provider factors of pSM need improvement. A 4R pilot at additional 12 cancer centers across the U.S. is in progress.

Aspect of pSM	%, 4R cohort, N = 185	%, Historical control cohort, N = 241	P value
Know stage of your cancer	93	80	.0001
Care plan clear / very clear	84	67	.0001
Able to manage own care well / very well	78	69	.05
During care, seldom / never overwhelmed, not in control of your care	71	58	.008
Care coordination by providers to support the patient	72%	69%	.5
Having a "go to" clinician to support the patient	76%	78%	.7

6528 Poster Session (Board #354), Sat, 1:15 PM-4:45 PM

Defining survivorship and surveillance with evidence. *First Author: Robert Dood, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Survivorship involves a multidisciplinary approach to surveillance and management of comorbidities and secondary cancers, however timing is based on arbitrary 5 year cutoffs. Here, we used a novel method analyzing annualized mortality rates to systematically define these cut-offs for transitions of care. **Methods:** The SEER database was queried for survival data on patients aged 18-100 years with any incident diagnosis of any cancer, grouped by ICD-O-3 tumor type. Excess mortality hazard, calculated as an annualized mortality risk above the baseline population was plotted over time. The time this hazard took to stabilize defined a high-risk period. The % morality elevation above age/sex-matched controls in the latter low-risk stable period was reported as the mortality gap. **Results:** Over 2.3 million patients with 68 different primary tumor types were evaluated. High risk surveillance periods ranged from 1 month to 21 years. High risk period durations ranged from under 1 year (breast, prostate, lip, ocular, and parathyroid cancers) up to 19 years (unspecified gastrointestinal cancers). Cluster analysis produced 6 groups. Subanalyses of selected tumor types revealed that stratifying on stage and histologic type can change the risk cluster and guidance for care. **Conclusions:** These findings indicate that a standardized 5 year surveillance period is both inadequate for some cancers while excessive for others. High risk cancers require the most resources with the longest high-risk period, highest persistent baseline mortality risk, and longest period of primary cancer mortality, all arguing for longer follow-up with an oncologist.

Medians by cluster (5-95 %ile).

Cluster	High-risk period, yrs	Mortality gap, %	Cancer types
1	2.5 (0.0-5.0)	1.4% (0.3-2.4)	Prostate, Breast, Cervix, Skin, Uterine corpus, Thyroid
2	7.5 (5.0-12.6)	2.9% (1.4-4.8)	Hematologic, Ovary, Gum/mouth, Tongue, Oropharynx
3	5.0 (4.0-8.0)	2.4% (0.9-4.5)	Colon, Bladder, Lymph node, Kidney, Rectum, Larynx
4	6.5 (5.3-10.8)	3.4% (2.0-8.5)	Hypopharynx, Pharynx, Ill-defined, Uterine NOS
5	9.0 (6.4-16.9)	2.4% (1.1-6.0)	Lung/bronchus, stomach, Brain/CNS, Esophagus
6	12.0 (9.3-12.9)	3.0% (1.1-4.2)	Intrahepatic bile ducts, Pleura, Pancreas

6529 Poster Session (Board #355), Sat, 1:15 PM-4:45 PM

Use of next-generation sequencing tests to guide cancer treatment: Results from a survey of U.S. oncologists. *First Author: Andrew N. Freedman, NCI, Rockville, MD*

Background: The proliferation of next-generation sequencing (NGS) tests provides an opportunity to advance oncology care. However, there are limited data about when and how NGS tests are used and the extent to which test results inform clinical care. **Methods:** Between February and May 2017, a survey developed by the National Cancer Institute and American Cancer Society was mailed to a nationally-representative sample of oncologists; 1281 responded, reflecting a 38% participation rate. Oncologists reported their use of NGS tests over the past year, including their use in different clinical scenarios. We restricted our analysis to the 1123 respondents who treated patients with solid tumors. Weighted percentages were used to describe NGS test use and its association with oncologists' demographic and practice characteristics. **Results:** Overall, 63% of oncologists reported using NGS tests to guide treatment decisions. Among these oncologists, 36% used them "often" to guide treatment decisions for patients with advanced refractory disease, 29% to determine eligibility for clinical trials and 19% to decide whether to use FDA-approved drugs off-label. For 28% of oncologists, NGS test results informed treatment recommendations "often," 53% reported "sometimes," and 19% of oncologists reported that results "never" or "rarely" informed treatment recommendations. Oncologists $<$ 50 years of age, practicing in an urban or suburban setting, treating patients at an academic center, holding a faculty appointment or receiving genomics training were more likely to use NGS tests. Over 50% of all oncologists reported that one or more patients presented with NGS test results from a commercially-available company they had not ordered. **Conclusions:** Most U.S. oncologists use NGS tests for their patients with solid tumors to inform treatment options for those with advanced cancer, and to identify clinical trials and/or approved drugs for off-label use. Among oncologist using NGS tests, over 80% reported that results informed their treatment recommendations either sometimes or often. Research is needed to more clearly establish the clinical utility of NGS tests and to inform clinical guidelines for their use in practice.

6530 Poster Session (Board #356), Sat, 1:15 PM-4:45 PM

Patient predictive factors for clinical trial participation. *First Author: Adrianne Rose Mallen, University of South Florida/Moffitt Cancer Center Gynecologic Oncology Fellowshi, Tampa, FL*

Background: Clinical trials (CT) in cancer research are considered the gold standard in evaluating efficacy of a new treatment and quite, literally, save lives. On average, only 3% of adult patients with cancer enroll in CT. Our primary aim was to assess patient predictive factors for CT participation. Our secondary aim was to assess overall survival for patients enrolled in CT versus no CT (NCT). Methods: A 14-year retrospective chart review was conducted for analysis of sociodemographic, clinicopathologic and treatment characteristics of 558 advanced stage epithelial ovarian cancer patients who were treated at a single-institution NCI-CCC at some point in their treatment course. **Results:** A total of 399/558 patients (71.5%) did not participate (NCT) versus 160/558 (28.5%) who did at some point in their treatment course (CT). Overall, 238/558 (43%) had CT discussion with their provider. The majority, 126/160 (78.75%) participated in CT at time of recurrence, 20/160 (12.5%) at time of adjuvant chemotherapy only and 14/160 (8.75%) for both adjuvant therapy and recurrence. Patients were well-matched in terms of disease characteristics. Younger age (58.04 in CT vs 63.07 in NCT, $p < 0.0001$), type of insurance ($p < 0.0001$), receipt of neoadjuvant chemo ($p = 0.014$), receipt of intraperitoneal chemo ($p = 0.00024$) and gynecologic oncologist as adjuvant chemo provider ($p = 0.005$) were also statistically significant patient factors associated with greater CT participation. Race ($p = 0.02$), educational level ($p = 0.095$), religion ($p = 0.39$), marital status ($p = 0.66$), distanced traveled for care ($p = 0.99$), debulking status ($p = 0.72$) and platinum sensitivity ($p = 0.13$) were not statistically significant patient factors. After adjusting for clinical factors associated with OS, women who participation in a clinical trial had significantly better OS (HR = 0.698, 95% CI (.544, 0.896), $p = 0.005$). **Conclusions:** Encouragement for clinical trials appears to be warranted. Improved survival was significant for CT patients and is further justification for offering the gold standard of treatment at our NCI-CCC. Understanding of patient predictive factors warrants further exploration so we can overcome barriers to patient enrollment in CT.

6531 Poster Session (Board #357), Sat, 1:15 PM-4:45 PM

Factors associated with follow-up physician visits among women with early stage breast cancer. *First Author: Farah Quyyumi, Columbia University Medical Center, New York, NY*

Background: In patients with early stage breast cancer (BC), follow-up guidelines vary widely among national organizations. ASCO recommends clinical examination every 3-6 months for 3 years, every 6-12 months for the next 2 years, and then annually. We sought to evaluate patterns and predictors of provider follow-up care within the first five years following diagnosis. **Methods:** Using the Surveillance, Epidemiology, and End Results (SEER)-Medicare linked dataset, we evaluated patients diagnosed with stage I-II BC who underwent lumpectomy from 2002-2007 with follow-up to 2012. Patients who died in the 5 years following diagnosis were excluded. We defined discontinuation of follow-up care as $>$ 12 months without a visit claim from either a surgeon, medical oncologist (MO) or radiation oncologist (RO). We performed a multivariate logistic regression analysis to determine factors associated with discontinuation. Patients were censored if a new cancer was diagnosed. **Results:** A total of 30,053 BC patients were included in the analysis. In addition to the surgeon, 85.8% saw a MO, 71.9% saw a RO, and 65.8% saw all 3 providers in the first year. The mean number of total visit claims for years 2-5 were 4.2, 3.1, 2.5 and 2.1, respectively. During the 5 years, 6,302 (21.0%) patients discontinued follow-up visits. Discontinuation increased with increasing age. Women with a higher stage cancer were less likely to discontinue follow-up (OR 0.78, 95% CI 0.73-0.83). Patients with a low grade tumor were more likely to discontinue follow-up compared to those with a high grade cancer (OR 1.09, 95% CI 1.02-1.18). For every year of diagnosis, patients were 3% less likely to discontinue seeing all three physicians. Hormone status, race, SES and marital status were not associated with discontinuation of follow-up visits. **Conclusions:** Clinical practice guidelines for surveillance of BC after diagnosis are based on expert opinion and have an unclear effect on outcomes. Coordination of follow-up care between oncology specialists may reduce discontinuation rates and increase clinical efficiency. More research is needed to determine the optimal follow-up for maintaining adherence to therapy, reducing over-testing and decreasing cost.

6532 Poster Session (Board #358), Sat, 1:15 PM-4:45 PM

Early discharge after induction chemotherapy for acute myeloid leukemia: Safety outcomes and hospital readmissions. *First Author: Nikita V. Baclig, University of Washington, Seattle, WA*

Background: Adults with acute myeloid leukemia (AML) typically remain hospitalized after induction chemotherapy for the duration of pancytopenia. Several studies have suggested that outpatient management following completion of chemotherapy is safe and associated with lower resource utilization. This has become standard practice at our institution if logistics allow. Here, we examine outcomes of adults $\geq$18 years of age with newly-diagnosed AML (acute promyelocytic leukemia excluded) or high-grade myeloid neoplasms (i.e. $\geq$10% blasts) who received AML-like induction chemotherapy with a regimen as or more intense than 7+3 between 8/2014 and 7/2017 and who were discharged early (ED) or remained hospitalized based on individual provider assessment. **Methods:** Patients were identified via institutional electronic medical records. Clinical information was collected through manual patient record review from the day after chemotherapy until count recovery (absolute neutrophil count $\geq 0.5\times10^9$/L and self-sustained platelet count $\geq 20\times10^9$/L), receipt of further chemotherapy, transfer to a different institution, or completion of 45 days on study. Patients were considered ED if discharge occurred within 3 calendar days of study start and control if not. **Results:** 260 patients (median: 61 [range 20-90] years) underwent induction chemotherapy, 168 of whom (64.6%) were ED. Age and gender distribution were similar between ED and control patients. Mean time on study was similar between ED and controls (25.6 vs. 25.2 days; $p = 0.73$). There was no difference in death rate (5.6% vs. 4.3%; $p = 0.59$), rate of febrile neutropenia (69.6% vs. 67.4%; $p = 0.71$), or proportion of patients requiring ICU-level care (8.9% vs. 15.2%, $p = 0.12$) between groups during the study period. In the ED group, 71.4% were readmitted with 0.95 readmissions on average per patient. Mean length of time between discharge and readmission among ED patients was 7.2 days. Overall, ED patients spent fewer days in the hospital than control patients (7.1 vs. 16.0; $p < 0.0001$). **Conclusions:** ED appears safe outside a clinical trial setting. Despite high readmission rates among ED patients, total hospital stay was shorter than for controls.

6533 Poster Session (Board #359), Sat, 1:15 PM-4:45 PM

Financial toxicity in patients with colorectal cancer and neuroendocrine tumors. *First Author: Leonidas Apostolidis, Department of Medical Oncology, National Center for Tumor Diseases, Heidelberg University Hospital, Heidelberg, Germany*

Background: Financial toxicity of cancer has so far been discussed primarily in the US health care system and has been shown to be associated with higher morbidity and mortality. In Germany with its third-party paid health care system the socio-economic impact of cancer is poorly understood. This study aims to provide data on financial consequences of a colorectal cancer (CRC) or neuroendocrine tumor (NET) diagnosis on patients' economic situation and psychosocial outcomes. **Methods:** This prospective study recruited 247 patients (n = 125 CRC / n = 122 NET) from November 2016 to March 2017 at the National Center for Tumor Diseases, Heidelberg University Hospital. They completed a survey on income, cancer-related out-of-pocket costs, distress (DT) and quality of life (EORTC-LQ). **Results:** Overall, 80.6 % (n = 199) stated to have higher out-of-pocket costs, and 37.2 % (n = 92) reported income loss as a sequel to their disease. While monthly out-of-pocket costs did not exceed 200 € in 76.9 % of affected patients, 44.6 % of those with income losses report losing more than 800 € per month. A multiple regression analysis showed effects of economic deteriorations on patient's quality of life and distress depending on the type of health insurance: high financial loss relative to income was significantly associated with a lower estimation of patient's quality of life (p = 0.0009) and more distress (p = 0.0037). Patients with private health insurance indicate better quality of life (p = 0.0134) and less distress (p = 0.0005) compared to those with statutory health insurance. **Conclusions:** Distress and reduced quality of life due to financial problems intensify the burden that already results from a cancer diagnosis. As many patients have to face financial loss and most are insured under the statutory health insurance scheme, there is a need for targeted support measures at the individual and system level in Germany.

6534 Poster Session (Board #360), Sat, 1:15 PM-4:45 PM

Burdensome end-of-life (EOL) transitions among frail older adults with advanced cancer. *First Author: Daniel E Lage, Massachusetts General Hospital, Boston, MA*

Background: Older adults with advanced cancer residing in nursing homes (NHs) are a vulnerable population that has not been well studied in terms of clinical needs and health care utilization. We sought to describe the clinical characteristics of these patients and examine their burdensome care transitions at the EOL. **Methods:** We conducted a retrospective analysis of deceased older adults (> 65 yrs) with advanced solid tumors (defined using Medicare claims, per prior literature) who resided in U.S. NHs and enrolled in Medicare fee-for-service (2008-2009). Medicare claims data were linked with geriatric assessments as part of the Minimum Data Set. Clinical characteristics, including comorbidities, pain scores, activities of daily living (ADLs) and cognition, were measured within 90 days of death. Using Medicare claims and per prior studies on end of life health care utilization, we defined a burdensome transition as two or more hospitalizations or an intensive care unit (ICU) admission in the last 90 days of life. **Results:** We included 34,670 patients with advanced solid tumors. Many residents had comorbid congestive heart failure (CHF) (29.3%), chronic obstructive pulmonary disease (COPD) (34.1%), and diabetes (35.0%). Over half (53.8%) had moderate or severe cognitive impairment; 66.5% were dependent in all ADLs, and 21.1% experienced daily pain. Only 55.4% of patients used hospice. 36.0% of patients experienced a burdensome transition at the EOL, and burdensome transitions were more common for patients who did not receive hospice (45.3% vs. 28.6%, $p < 0.01$). In adjusted analyses, the following characteristics were associated with a higher risk of a burdensome transition at the EOL: female sex (OR 1.2, $P < 0.001$), CHF (OR 1.56, $P < 0.001$), COPD (OR 1.3, $P < 0.001$), diabetes (OR 1.3, $P < 0.001$), full dependence in ADLs (OR 1.9, $P < 0.001$), and receipt of chemotherapy in the last 90 days of life (OR 1.7, $P < 0.001$). **Conclusions:** Although NH residents with advanced cancer have substantial comorbidities, cognitive deficits, and functional impairments, over a third experienced a burdensome care transition at the EOL. Interventions are critically needed to reduce burdensome transitions at EOL in this vulnerable population.

6535 Poster Session (Board #361), Sat, 1:15 PM-4:45 PM

Patient-reported satisfaction with multidisciplinary (MD) v serial care (SC) for lung cancer. *First Author: Kenneth Daniel Ward, Division of Social and Behavioral Sciences, School of Public Health, University of Memphis, Memphis, TN*

Background: Coordinated MD lung cancer care, with all key specialists concurrently providing input to develop a consensus care plan with patients and their caregivers, is much-advocated over the usual SC model but lacks rigorous evaluation. **Methods:** Prospective comparative effectiveness trial enrolled newly-diagnosed lung cancer patients receiving MD or SC within the same US healthcare system. At baseline, 3 and 6 months, patients completed several satisfaction measures from the Consumer Assessment of Healthcare Providers and Systems, and the National Health Interview Survey 'Perceived Financial Burden of Care' instrument. All Group (MD v SC), time (baseline, 3, 6 months), and group by time interactions were analyzed in mixed linear models. Associations were adjusted for insurance, race, clinical stage, and ECOG performance status. **Results:** The 456 patients (159 MD, 297 SC) were similar in sex and health insurance. The MD cohort was slightly older (69 vs. 66) and had more racial minorities (37% vs. 29%). Statistically significant group by time interactions, indicating greater improvement over time for MD, were observed for satisfaction with treatment plan (p = .0036) and quality of care received from the whole care team (p = .0377). However, perceived financial burden of care increased slightly over time for MD but decreased slightly for SC (p = .0352). Collapsed across time, MD patients were more likely to perceive their cancer care to be better than that received by other patients (p = .0025). Collapsed across treatment group, depression increased significantly from baseline to 3 months (p = .0118), and improvements over time occurred for satisfaction with length of time to diagnosis, length of time to complete treatment, and communication from physicians, nurses, and about disease-specific information. **Conclusions:** Compared with SC, MD patients perceived their care to be better than that received by other lung cancer patients, and had greater improvements over the course of treatment in satisfaction with their treatment plan and care team. These positive patient-reported outcomes occurred despite slightly greater perceived financial burden of care. Clinical trial information: NCT02123797.

6536 Poster Session (Board #362), Sat, 1:15 PM-4:45 PM

Outcomes of embedded palliative care outpatients consults on timing of palliative care access, symptoms, and end-of-life quality indicators among advanced non-small cell lung cancer patients. *First Author: Sriram Yennu, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: There are no studies comparing the outcomes of embedded consults (EPC) as compared to independent outpatient palliative care consults (PC).Our aim was to determine the timing of palliative care access, symptoms and EOL outcomes of advanced non-small cell lung cancer patients referred to EPC as compared to those referred to PC. **Methods:** We retrospectively reviewed a random sample of EPC (Aug, 2012 - Jun, 2013) and PC consults (Jan, 2009 –Jul, 2012) at MD Anderson Cancer Center. Baseline features, symptoms (ESAS), EOL quality outcomes (intensive care unit deaths, admissions, emergency center visits , and hospitalizations and length of stay in the last 30 days before death; cancer treatments 14 days before death; hospice discussions and referrals; do not resuscitate order at first follow-up; advanced care planning (ACP) discussions, and completion of advanced directives), time from referral to first consult, ACP date to death, and overall survival from consult to death were retrieved. **Results:** 340 were evaluable (EPC = 147). At baseline, mean ECOG (2.2 vs 1.9, $p < .001$), and median pain (6 vs 5, p = .038) were higher in EPC. Time from referral to first consult was shorter (median 0 vs 7 days, $p < .001$) and dyspnea was better in EPC at follow-up (-1 vs 0, p = .039). A higher proportion in EPC (77% vs 58%, $p < .001$) had ACP discussions and these occurred earlier (median 4 vs 1 month before death, $p < .001$). No other significant differences in symptoms or EOL outcomes were found. **Conclusions:** EPC consults at referral had earlier access and worse pain and performance status. EPC was not associated with significant improvement in symptoms or EOL outcomes except for better dyspnea control, and more frequent as well as earlier ACP discussions. Further research is needed.

6537 Poster Session (Board #363), Sat, 1:15 PM-4:45 PM

Diffusion of innovation in oncology: A case study of immuno-oncology (IO) adoption for advanced non-small lung cancer (aNSCLC) patients across practices in the US. *First Author: Caroline Savage Bennette, Flatiron Health, New York, NY*

Background: IO agents are being adopted rapidly into clinical care; however, variation in speed and breadth of adoption across oncology practices remains unknown. Our objective was to evaluate adoption patterns in the treatment of aNSCLC and identify practice characteristics associated with adoption trajectories. **Methods:** 43,697 patients diagnosed with aNSCLC from Jan'11-Dec'17 were obtained from the Flatiron Health electronic health record-derived database, a national sample of academic and community practices. We estimated the proportion treated each month with IO (nivolumab, pembrolizumab or atezolizumab) versus other therapies from time of first IO approval (Mar'15) through Dec'17 in 123 practices that treated aNSCLC patients during this time. We used k-means clustering to identify patterns of IO adoption. Multivariable logistic regression models were used to adjust for differences in case-mix and evaluate association of practice size, location, and Quality Oncology Practice Initiative (QOPI) certification program with IO adoption. **Results:** We identified 4 distinct groups of practices based on trajectories that differed in speed and extent of IO adoption (Table). 17% of practices adopted IO rapidly and extensively; 28% were slower and more limited in their adoption; 24% initially had limited IO use, but adoption accelerated rapidly after 18 months; 32% initially adopted rapidly, but slowed markedly after 1 year. In multivariable analyses, we found no significant association between a practice's size, location, or QOPI certification and IO adoption trajectory. **Conclusions:** There is significant variability in adoption of IO therapy by oncology practices. Further research is needed to characterize drivers of this variation at the physician level and its impact on patient outcomes. Understanding variability in the diffusion of new innovations could guide development of targeted educational interventions to optimize use of new effective therapies.

	Rapid & extensive adopters, N = 21	Slower & limited adopters, N = 34	Later adopters, N = 29	Decelerating adopters, N = 39
% IO use in Dec'15	19.8	10.0	10.0	20.8
% IO use in Dec'17	50.7	30.8	48.0	36.6

6538 Poster Session (Board #364), Sat, 1:15 PM-4:45 PM

A multidisciplinary toxicity team for cancer immunotherapy-related adverse events. *First Author: Jarushka Naidoo, Johns Hopkins Kimmel Comprehensive Cancer Center and Bloomberg-Kimmel Institute for Cancer Immunotherapy, Baltimore, MD*

Background: Immune checkpoint inhibitors (ICI) cause immune-related adverse events (irAEs). The spectrum of irAEs requiring referral to non-oncology specialists has not been well described. We established an immune-related toxicity (IR-Tox) team of oncology (n = 8) and medical subspecialists (n = 20), to support multidisciplinary irAE diagnosis and management. **Methods:** Patients (pts) treated with ICIs were electronically referred to the IR-Tox team between 01/2017-03/2018. IR-Tox team met monthly to discuss complex irAEs, and identify areas of clinical need. Pt demographics, treatment, and irAE details were collected. Pt features and irAE associations were analyzed using Chi-square tests. **Results:** The IR-Tox Team received 92 referrals for 80 pts (outpt: 61%, inpt: 39%). Median age was 65 years (range: 21-91), 55% were male, and 14% had prior autoimmune disease. Pts most commonly had non-small cell lung cancer (35%), melanoma (19%), or gynecologic malignancies (10%). Pts received ICI monotherapy (56%) or combination immunotherapy (44%), as standard-of-care (46%) or on clinical trials (54%). Referrals related to diagnosis (32%), management (11%), or both (51%) were received from faculty (68%), fellows (12%), and nurses (20%). Referrals were for suspected irAE (90%), pre-ICI assessment in known autoimmune disease (9%), or ICI re-challenge (1%). Sixty-three irAEs were confirmed (CTCAE grade 1 = 19%; 2 = 43%; 3+ = 38%), and 26 patients developed $>$ 1 irAE (2 irAEs = 19, 3 irAEs = 7). IrAEs included pneumonitis (22%), arthritis (17%), dermatitis (13%), colitis/diarrhea (13%), idiopathic thrombocytopenia purpura (5%) hepatitis (5%) and thyroid dysfunction (5%). A new irAE of bony inflammation was identified (n = 2). Grade 3+ irAEs (p = 0.04) and colitis/diarrhea (p = 0.01) were more likely with combination immunotherapy. Medical specialty input was obtained in 85% of pts, and 35% required an invasive procedure for irAE diagnosis or management. **Conclusions:** Creation of an IR-Tox Team facilitated identification and management of complex irAEs. This new model provides a valuable forum to identify educational/service needs, manage multi-system irAEs, identify new irAEs, stratify irAE risk, and establish research collaborations.

6539 Poster Session (Board #365), Sat, 1:15 PM-4:45 PM

Reportable actionability versus pragmatic actionability: Implementing precision medicine at three large health systems. *First Author: Michael A. Thompson, Aurora Health Care, Delafield, WI*

Background: Precision medicine (PM) molecular panel (MP) testing report actionable findings with associated targeted therapies (including immunotherapies). However, these actionable findings "reported actionability" by molecular testing companies are often not realized as "pragmatic actionability" in the real world setting. We explored the concordance among PM MP therapy recommendations and subsequent drug treatment orders by clinicians at Aurora Health Care (AHC), Henry Ford Health System (HFHS), and Hoag Memorial Hospital Presbyterian (HMHP). **Methods:** Structured clinical, genomic report data, and treatment orders were obtained from the Syapse database. At AHC, HFHS, and HMHP, we identified 996 MP reports from 748 patients who received testing between 2014 and 2018. **Results:** 713 MP reports had "reported actionable" (positive) treatment recommendations and a subsequent treatment order across all 3 health systems. 24.4% (174/713) of MP reports were followed by a treatment order that matched to at least one reported actionable treatment. The translation from a MP-reported actionable finding to a prescribed treatment order was 28.1% (105/374) at AHC, 20.9% (9/43) at HFHS, and 20.3% (60/296) at HMHP, which has borderline statistical significance (p = 0.0563). Of the 713 MP reports analyzed, there was an average of 7.8 therapy recommendations per MP report. There were no significant rate differences in actionability of individual drug recommendations between the two molecular testing vendors examined. We did not examine the actionability of MP report recommendations for investigational agents. **Conclusions:** Of all 996 MP reports in the initial sample, only 17.5% resulted in a treatment order which matched a MP report recommendation. The translation of reported actionability to pragmatic actionability was consistent across all 3 health systems. This may reflect different definitions of "actionable" between molecular testing companies and clinicians as well as patient performance status changes over time, insurance coverage for off-label use, or referral to a clinical trial. Further research is warranted to understand the issues involved.

6540 Poster Session (Board #366), Sat, 1:15 PM-4:45 PM

Patient comorbid conditions and cancer clinical trial participation. *First Author: Joseph M. Unger, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: The American Society of Clinical Oncology (ASCO) recently recommended modernizing criteria related to comorbid conditions routinely used to exclude patients from clinical trials. We investigated how baseline comorbid conditions influence clinical-trial decision making and trial participation. We also modeled how reducing major trial comorbidity exclusion criteria might impact participation, to provide a benchmark for evaluation of the ASCO recommendations. **Methods:** Data were from a large national web-based survey of 5,499 cancer patients in the cancer treatment-decision-making process. Self-reported data on 18 comorbid conditions were collected. We examined how individual and combinations of comorbidities – using the "best" subset method – influenced patterns of trial discussions, offers, and participation. We also simulated how trial participation rates would change if individual and combinations of comorbidity exclusion criteria were removed. Logistic regression was used. Multivariable regression included adjustment for important demographic and socioeconomic variables. **Results:** Most patients (66%) had $\geq$1 baseline comorbidities. The most common comorbid condition was hypertension (35%). Hypertension, prior cancer, and hearing loss were most strongly and uniformly associated with outcomes; each increase in the number of these conditions (0 vs. 1 vs. $\geq$2) was associated with a decreased risk of trial discussions (11% lower, p = .02), trial offers (18% lower, p = .004), and trial participation (22% lower, p = .006). The removal of all comorbidity restrictions would generate an 18% relative increase in trial participation, or (if the overall participation rate is 5%) a 1% absolute increase. **Conclusions:** The presence of baseline comorbid conditions adversely impacts trial discussions, trial offers, and trial participation itself. Although the modernization of trial eligibility criteria will benefit many patients, this effort alone is unlikely to substantially increase trial participation rates overall.

6541 Poster Session (Board #367), Sat, 1:15 PM-4:45 PM

Cancer pain in the emergency department: A multicenter study of the Comprehensive Oncologic Emergencies Research Network. *First Author: Christopher John Coyne, University of California San Diego, San Diego, CA*

Background: Despite initiatives to improve cancer analgesia, patients with cancer frequently present to the emergency department (ED) with pain related issues. To our knowledge, no previous studies have investigated how the presence and severity of pain in cancer patients presenting to the ED may relate to morbidity and mortality. This study aims to investigate these associations. **Methods:** We conducted a multicenter prospective cohort study of patients with active cancer presenting to 18 EDs within the Comprehensive Oncologic Emergencies Research Network (CONCERN) between December 1st, 2016 and June 1st, 2017. We recorded initial, final and highest ED pain scores and used logistic regression to estimate their association with the following outcomes: 30-day mortality, 30-day ED revisits, and 30-day hospital readmissions. Pain was recoded into none (0), mild (1-3), moderate (4-6) and high (7-10). We also recorded demographics and ECOG scores. **Results:** We enrolled 1075 patients. The cohort was 52% female with a median age of 64. Approximately 70% of patients had pain, while only 48% of patients received an analgesic. 62% reported having home pain medications. The median highest pain score was 5, while the initial and final were 4 and 1, respectively. Of the patients who presented with pain, 64.8% reported improvement prior to discharge, 28.7% reported no change and 6.5% worsened. A high initial pain score was associated with increased 30-day mortality (OR 2.3, 95%CI 1.11-4.87). An ECOG score of 2 was associated with increased 30-day ED revisits (OR 1.7, 95%CI 1.14-2.5) and readmissions (OR 2.2, 95%CI 1.47-3.27). **Conclusions:** Pain remains a significant issue for cancer patients presenting to the ED, and was present in nearly 3/4 of our cohort. While not all patients received pain medications, we did note a low median final pain score. Severe pain on presentation appeared to be associated with increased mortality. This knowledge may aid physicians when determining ED disposition for those patients with high initial pain scores. An ECOG score of 2 appears to be associated with increased ED revisits and readmission, which may reflect a population in need of more aggressive outpatient symptom management.

6542 Poster Session (Board #368), Sat, 1:15 PM-4:45 PM

Practice transformation: Early impact of OCM on hospital admissions. *First Author: Molly Mendenhall, Oncology Hematology Care, Cincinnati, OH*

Background: The purpose of the Oncology Care Model is to improve quality and reduce cost through practice transformation. A foundational tenant is to reduce avoidable ER visits and hospitalizations. In anticipation of being an OCM participant, we instituted a multidimensional campaign designed to meet these objectives. **Methods:** Prior Actions: Established phone triage unit. After-hours and weekend call. Instituted weekend urgent care. Year One: Improved education provided by nurse navigators and APPs prior to start of treatment (OCM Treatment Planning visit). Implemented triage pathways: 38 symptom and 27 follow-up pathways (modified COME HOME, Barbara McAneny, M.D.). Proactive symptoms follow-up calls to help circumvent emergent admissions. Increased APP staffing to provide blocked time slots for same day patient visits w/o schedule disruptions. Initiated "Call Us Early – Call Us First" campaign. Incorporated verbal and/or written instructions at all patient touch points, emphasizing patient's responsibility to call before going to the emergency room. **Results:** Based on data from the Chronic Condition Warehouse, as provided by CMS, we were successful at reducing the acute care admissions rate by 16 percent. OCM patient survey scores improved. Readmissions (4.9 vs 5.6/100 pts), ER utilization (17 vs 18.6/100 pts), and Observation Stays (2.7 vs 3.6/100 pts) remained below Risk Adjusted National averages. **Conclusions:** By implementing a cost efficient, reproducible, and scalable campaign targeting ER avoidance and hospitalizations, we were able to decrease hospital admissions. Reported Medicare savings amounted to nearly $798,000 in inpatient cost per quarter over 1,600 patients.

	Baseline Jan '16 – Mar '16	Year One Jul '16 – Jun '17	Year One Benchmark (Risk Cohort)
Patients per Quarter	1,722	1,600	-
Mean Patient Risk Score	2.999	3.000	> 2.724
Admissions per 100 Patients, per Quarter	27.0	22.6	25.9
Cost per Admission Event	11,122	11,106	-
Inpatient Cost per Patient, per Quarter	3,003	2,505	-

6543 Poster Session (Board #369), Sat, 1:15 PM-4:45 PM

Cancer survival in the context of growing hospital participation in Medicare ACOs. *First Author: Stephen Matthew Schleicher, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Accountable Care Organizations (ACOs) represent one of the main policy-level interventions to improve healthcare quality. We investigated the trend of 1) hospital participation in ACOs over time and 2) cancer survival rates at participating hospitals. **Methods:** We searched public reporting websites of all Pioneer and Medicare Shared Savings Program (MSSP) ACOs. We matched ACO participant lists with the Dartmouth Hospital Atlas to identify participating hospitals. Five year mortality rates of patients with cancer were captured in 100% Medicare fee-for-service claims data from 2011 assessed at the hospital level, as previously described.[1] We calculated unadjusted cancer mortality rates for newly joining ACOs over time, and pooled estimates of survival comparing ACO to non-ACO control hospitals across hospital referral regions. **Results:** We identified 1,059 hospitals that participated in Medicare ACOs that joined through 2017. There was a trend towards increased hospital participation in ACOs, defined as the percentage of ACOs that included hospitals, over time (26.5% in 2012-2014 vs. 57.7% in 2015-2017). The five year overall survival rate for patients with cancer treated at new ACO hospitals was fairly stable over time (53.1% in 2012-2014 vs. 54.4% in 2015-2017). Similarly, there was no significant change in the odds of cancer survival for ACO vs. non-ACO hospitals over time. **Conclusions:** Despite growth in hospital participation within Medicare ACOs over time, the quality of cancer care at hospitals joining MSSP has remained stable.

	2012[2]	2013	2014	2015	2016	2017
New Medicare ACOs	146	106	119	89	100	99
Percent of ACOs including hospitals	22%	28%	28%	69%	59%	45%
Survival rate in new ACO hospitals	52.8%	53.3%	53.5%	54.4%	54.8%	53.9%
Odds ratio (95% confidence interval) for survival (ACO vs. non-ACO)	1.00 (0.98, 1.02)	0.97 (0.92, 1.02)	0.98 (0.94, 1.03)	1.01 (0.97, 1.05)	1.01 (0.98, 1.05)	1.01 (0.97, 1.05)

[1]Pfister DG, et al. JAMA Oncol, 2015; [2]Includes the 32 initial Pioneer ACOs.

6544 Poster Session (Board #370), Sat, 1:15 PM-4:45 PM

24-hour cancer clinic: An approach to same-day care. *First Author: Jonathan Thomas Kapke, Medical College of Wisconsin, Wauwatosa, WI*

Background: Managing healthcare delivery and optimizing the cost of care for cancer patients is a difficult task for healthcare systems. Cancer patients are at risk for complications of their disease and adverse effects of treatment that often require urgent medical care. The inability to access oncology specific care 24-hours a day can lead to increased use of the Emergency Department (ED), which is often associated with unnecessary diagnostic testing, high rates of hospital admission, low patient satisfaction and excessive cost. On 11/1/16, Froedtert & the Medical College of Wisconsin opened the 24-hour Cancer Clinic (24hCC). The 24hCC is staffed by oncology trained providers and offers around the clock access to patients for a variety of urgent care needs. In this study, we evaluated resource utilization, admission rates, patient satisfaction and cost for patients seen in the 24hCC compared to the ED. **Methods:** We analyzed de-identified data for patients seen in the 24hCC and the ED between 1/1/17 and 1/24/18 as part of a quality improvement project. Utilization was defined as the quantity of imaging, ECG and lab studies ordered. Cost was measured based on hospital charges. Patient satisfaction surveys were reviewed. **Results:** Prior to the 24hCC, oncology patients seeking urgent, same-day care were often directed to the ED. There were an average of 250 ED visits per month with an admission rate of 55%. During the time period analyzed, 897 patient visits were completed in the 24hCC and 1621 in the ED. There was 56%, 32% and 11% less imaging, ECG and lab utilization respectively for patients seen and discharged from the 24hCC compared to the ED. The admission rate from the 24hCC was 18% compared to 42% from the ED. The mean overall rating of care for the 24hCC was 97.5%, with a 89.7% top box score (9 or 10 on 1-10 scale). When comparing diagnostic charges in the 24hCC to the ED during the first six months of data collection, the median charge was $1554 less for discharged patients and $2269 less for admitted patients. **Conclusion:** Our data demonstrates that a 24-hour oncology specific clinic can provide same-day care that is associated with decreased utilization, less hospital admission, improved patient satisfaction and lower cost for selected non-emergent cancer patients.

ECHO palliative care in Africa (ECHO-PACA): Improving access to quality palliative care. *First Author: Sriram Yennu, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: There is limited access to quality Palliative Care (PC) for advanced cancer patients being treated in Sub Saharan Africa due to limited PC knowledge among health care providers in the region. The goal of this innovative project was to improve access by offering cost-effective training to these providers using Project ECHO (Extension for Community Healthcare Outcomes), an established telementoring and support program.Our aim was to evaluate feasibility, attitudes, knowledge, and efficacy of participants of ECHO-PACA to deliver PC. **Methods:** An interdisciplinary team at the UT MD Anderson Cancer Center, guided by PC providers in Sub Saharan Africa, developed a standardized curriculum based on PC needs in the region. Participants were then recruited and monthly telementoring sessions consisting of case presentations, discussions, and didactic lectures began in July 2016. Program participants included 14 clinics and teaching hospitals from Ghana, Kenya, Nigeria, South Africa, and Zambia, with sessions offering participants the ability to interact and learn new skills in PC. Participants were surveyed at the beginning, mid-point and end of the 16 month program to evaluate changes in self-perceived efficacy in pain assessment and management, Identification of signs/symptoms of imminent death, Identifying and addressing challenging communication issues related to end of life. **Results:** Median participation per session was 30. Median duration of monthly meetings was 90 minutes. 33 of 40 initial participants (83%) completed the survey. There was significant improvement in appropriate use of non-opioid analgesics for persistent pain ($p = .03$), titrating opioids to optimize pain control ($p = .03$), Identification of signs/symptoms of imminent death ($p = .05$), and Identifying and addressing challenging communication issues related to end of life ($p = .02$). **Conclusions:** ECHO-PACA was a feasible, cost effective, pragmatic approach to disseminate PC knowledge without the need for travel, which has the potential to increase access to quality PC through enhancing the skills of providers in resource challenged areas of Sub Saharan Africa. Further studies are needed to evaluate ECHO-PACA impact on patient outcomes.

6546 Poster Session (Board #372), Sat, 1:15 PM-4:45 PM

Do accountable care organizations impact prostate cancer screening? *First Author: Quoc-Dien Trinh, Brigham and Women's Hospital/ Harvard Medical School, Boston, MA*

Background: Accountable care organizations (ACO) are an alternative payment model designed to incentivize efficient, high value care. In this model, groups of providers are reimbursed together, with incentives for high-value, coordinated care. Prostate cancer screening is a service with large variations in use and questionable value—especially in men over 70. We analyzed trends in PSA screening and biopsies of American men depending on whether their providers joined ACOs. **Methods:** We relied on Medicare claims data to identify men whose primary care providers joined ACOs between 2010 and 2014. We examined whether trends in PSA and biopsy rates were different in men with ACO-affiliated providers versus those with non-ACO affiliated providers. Inverse-probability weighting and difference-in-differences analyses were utilized to compare utilization of both screening tests. Analyses were stratified by age groups: 1) 66-69 and 2) $\geq$70. **Results:** For men whose providers joined ACOs between 2010 and 2014, the prevalence of PSA screening for men aged 66-69 declined from 62.4% to 55.9%. Non-ACO affiliated providers also had a similar decline in rates of PSA screening of 62.4% to 55.9%. Trends in biopsy rates were similar in both groups: 4.7% to 5.3% in ACOs and 4.6% to 5.3% in non-ACOs. The difference-in-differences analyses showed that the change in use of PSA from 2010 to 2014 was not significantly different at ACOs and non-ACOs ($p = 0.3$). The trend in biopsies was not significantly different in ACOs and non-ACOs ($p = 0.7$). Similar non-significant differences were observed in men aged $\geq$70 years old (Table 1). **Conclusions:** Overall, trends in PSA screening and biopsies from 2010 to 2014 were similar at both ACO and non-ACO affiliated providers, regardless of patient age. This suggests that the implementation of ACOs did not impact on the use of PSA screening or biopsy, including in older age ranges where PSA screening is considered lower value.

Biopsy and PSA screening prevalence in 2010 and 2014 with difference in difference analysis comparing ACO and non-ACO patients.

	ACO		Non-ACO		Difference in Difference
	2010	2014	2010	2014	p value
Ages 66-69					
PSA	62.4	55.9	60.5	54.4	0.3
Biopsy	4.7	5.3	4.4	5.2	0.7
Ages 70+					
PSA	54.3	46.0	54.2	46.4	0.2
Biopsy	4.3	4.8	4.1	4.6	0.5

6547 Poster Session (Board #373), Sat, 1:15 PM-4:45 PM

Implementation of individualized care plans in high risk oncology patients: A team based model to decrease unnecessary utilization. *First Author: Girish Chandra Kunapareddy, Cleveland Clinic Foundation, Cleveland, OH*

Background: Due to complexity of disease and treatments, oncology patients (pts) have among the highest hospitalization rate. In our cancer institute, just 6% of all discharged pts accounted for $>$ 40% of all unplanned readmissions (UR), and continue to be of highest risk of future admissions, ICU stay, ED visits, overuse of chemotherapy and underutilization of hospice resources. We hypothesized that developing individualized care plans (ICP) will better provide the complex care necessitated by this group **Methods:** An Interdisciplinary Care Team (ICT) was created consisting of palliative medicine and oncology physicians/social workers/care coordinators/nurse managers. Twice monthly, pts with the highest utilization over a 60-day period with at least two UR were identified. ICPs were created using the team-based approach with parallel input from primary outpatient providers. Communication plans were created to ED and outpatient teams **Results:** A total of 71 pts, 356 hospitalizations, and 260 ED visits were evaluated over a 6-month period, with an avg number of hospitalizations of 0.82 per pt month (ppm). After creation ICT, this decreased to 0.23 ppm. Average ED visits, UR, avg length of stay per admission also decreased (see Table 1). Nearly all solid tumor pts had metastatic disease at ICT review, while pts with hematological malignancies were early in their treatment course receiving myelosuppressive therapy. These results were compared to a historical cohort prior to ICT with the same inclusion criteria, which maintained to show a high relative impact **Conclusions:** Creation of individualized care plans for high-utilizing cancer patients decreased number of hospitalizations, ED visits, unplanned readmissions, and length of stay in all disease groups, but ST patients seemed to have a greater impact than in HM patients

Effect of ICP.

	All Patients N = 71	Solid Tumor N = 40	Malignant Hematology N = 31
Hospitalizations			
Before ICP	0.82	0.79	0.89
After ICP	0.36	0.27	0.49
30-day Readmissions			
Before ICP	0.49	0.48	0.51
After ICP	0.13	0.05	0.29
ED Visits			
Before ICP	0.60	0.61	0.57
After ICP	0.24	0.18	0.42
Average LOS per Admission			
Before ICP	7.17	6.24	8.48
After ICP	4.06	2.55	6.17

6548 Poster Session (Board #374), Sat, 1:15 PM-4:45 PM

Risk stratification and predictive value of the HOSPITAL score for oncology patient readmissions. *First Author: Anu Radha Neerukonda, University of Chicago Medical Center, Chicago, IL*

Background: Hospital readmissions are costly, frequent and harmful. Prediction models such as the HOSPITAL scoring system are reasonably accurate and efficient in predicting the readmission risk after hospital discharge in a general medicine population. However, their utility remains unknown for cancer patients. HOSPITAL is the acronym for 7 variables included in the score: Hemoglobin before discharge (positive if $<$ 12 g/dl), discharge from an Oncology service, Sodium level before discharge (positive if $<$ 135 mmol/L), Procedure performed during hospitalization, Index admission Type, number of Admissions in the previous 12 months, and Length of stay (positive if $\geq$ 5 days). **Methods:** We retrospectively calculated HOSPITAL scores at the time of discharge for all oncology discharges at the University of Chicago Medical Center between November 2016 and November 2017 (N=2957). We used SQL, our internal data warehouse and electronic medical records database for data collection. The HOSPITAL score was calculated for each discharge, with each categorized into 1 of 3 risk groups based on number of points: low risk (0-4), intermediate risk (5-6), and high risk ($\geq$7). **Results:** Table 1 reflects number of patients in each readmission risk category. Based on the HOSPITAL point scoring allotment described, 88% of oncology admissions were identified as intermediate or high risk, with very few patients in low risk category. This is in stark contrast to 38% of all general medicine patients who were identified as intermediate or high risk in the original publication externally validating the HOSPITAL score. **Conclusions:** Findings from this study indicate that HOSPITAL score may not be effective in differentiating readmission risk within an oncology specific patient population, and that other variables such as performance status need to be incorporated. Further research needs to be done for developing and validating specific readmission risk prediction models in the oncology population.

Readmission rate by hospital risk group.

Readmission Risk Group	Number of medical oncology discharges	Percentage of all medical oncology discharges	Readmission Rate
Low	352	11.9%	17%
Intermediate	1058	35.8%	15%
High	1547	52.3%	18%

6549 Poster Session (Board #375), Sat, 1:15 PM-4:45 PM

Clinician perspectives on electronic health records, communication, and patient safety across diverse medical oncology practices. *First Author: Minal R Patel, University of Michigan, Ann Arbor, MI*

Background: We know little about clinicians' documentation and communication challenges and how these might affect the safety of ambulatory oncology care. The present study investigated variation in electronic health record (EHR) capability and satisfaction, clinician communication, and clinicians' actions that enable a safety culture. **Methods:** We distributed paper questionnaires to nurses and prescribers (physicians, nurse practitioners, and physician assistants) in 28 practices that participate in a statewide quality improvement collaborative. Previously-validated measures included the Safety Organizing Scale (SOS) that reflects actions consistent with a safety culture, satisfaction with clinic technology, and satisfaction with communication with other clinicians. We constructed an index to reflect EHR capability (1 = all paper to 5 = all electronic). Linear regression models (with robust standard errors to account for clustering) were used to examine the relationship between covariates of interest and the SOS, adjusting for practice size and ownership. **Results:** The survey response rate was 68%. The mean (SD) of the SOS was 5.3(1.1), with a practice-level range of 4.9-5.4 (based on 7-point scale where higher scores reflect increased safety actions). Higher satisfaction with technology and clinician communication was significantly associated with increased SOS scores, while increased EHR capability was associated with lower SOS scores. Prescribers reported lower SOS scores than nurses (see table). **Conclusions:** Practices vary in their performance of patient safety actions. Supporting clinicians to integrate increased technology is a promising target for interventions. The inverse relationship between EHR capability and safety suggests that technology distracts clinicians from attending to patient safety. Improvement strategies may benefit from tailoring by clinician type to account for observed differences.

Variable	β(SE)	95% CI
Technology satisfaction	0.67(0.1)***	0.5,0.8
Clinician communication satisfaction	0.29(0.1)***	0.1,0.4
EHR capability index	-0.14(0.03)***	-0.2,-0.1

Impact of a cognitive computing clinical trial matching system in an ambulatory oncology practice. *First Author: Tufia C. Haddad, Mayo Clinic, Rochester, MN*

Background: Only 3-5% of cancer patients participate in clinical trials even though up to 20% are eligible. Cognitive computing has promising potential to assist trial enrollment efficiency and accuracy by performing background analytics. The Watson for Clinical Trial Matching (CTM) cognitive system utilizes natural language processing to derive patient and tumor attributes from unstructured text in the electronic health record that can be matched to complex eligibility criteria in trial protocols. Screening patients for trials was performed on an ad hoc basis with traditional methods prior to implementation of the CTM system in the Mayo Clinic breast oncology practice. **Methods:** The Watson CTM system was trained by Mayo subject matter experts and implemented in July 2016. Systemic therapy trials enrolling breast cancer patients were included in the system. Clinical research coordinators validated Watson-derived clinical trial matches on the day prior to patient clinic visits. They gave the oncology providers a list of matched trials for each patient to facilitate treatment decision making at point of care. Enrollment and timing metrics were tracked and compared with manual screening methods. **Results:** Watson CTM facilitated screening of all breast cancer patients for systemic therapy trials with matches validated by coordinators in 40% of patients. Over the 18 month (mo) period following implementation, 6.3 patients/mo were enrolled to breast cancer systemic therapy trials compared with 3.5 patients/mo in the period prior. The average monthly enrollment increased by 80%. This was further increased to 8.1 patients/mo when including accruals to breast cancer cohorts of phase I trials within the experimental therapeutics program. Time to match patients to trials with the CTM system was faster than manual methods but variable depending on the role of the screener and the depth of the matching. **Conclusions:** Implementation of the Watson for CTM system with a screening coordinator team was associated with an increase in breast cancer clinical trial enrollment. The system enabled high volume screening in an efficient manner and promoted awareness of clinical trial opportunities within the breast oncology practice.

6551 Poster Session (Board #377), Sat, 1:15 PM-4:45 PM

Statistical significance of bevacizumab trials when considering the portfolio of all studies. *First Author: Derrick L Tao, Oregon Health & Science University School of Medicine, Portland, OR*

Background: Although clinical trials of novel medications have historically been interpreted individually, there is increasing recognition that trials should be considered as part of a broader clinical trials agenda or portfolio. If a single drug is tested in many tumor types, the interpretation of any single trial result must account for the number of times that agent is trialed. We attempted to better understand the effect of the trials portfolio for bevacizumab, an antibody approved in many tumor types. We conducted a systematic review of cancer trials of bevacizumab efficacy when added to a chemotherapy backbone in solid tumors and adjusted results for the number of reported trials. **Methods:** We queried MEDLINE for "solid tumor", "bevacizumab" and "meta-analysis" on 2/2/2018, extracting all included randomized controlled trials, their reported improvement in median progression free survival (PFS), overall survival (OS), and accompanying p values. We investigated 1. What percent of individual studies met traditional nominal statistical significance for PFS and OS and 2. What percent retained this significance after adjusting for multiplicity using the Bonferroni correction, a commonly used method. **Results:** Our search identified 3 meta-analyses, including 48 randomized trials, 47 reported PFS and OS data. Of the 48 trials, 8 (17%) were phase II and 40 (83%) were phase III. Most common tumor types among the 48 trials included colorectal (14; 29%) and breast (9; 19%). A statistically significant PFS benefit (using a $p < .05$ cutoff) was reported in 30 of 47 trials (64%). After adjusting the p-value for multiplicity using the Bonferroni correction ($P < .00106$), 21 trials reported statistically significant improvements (45%). A statistically significant OS benefit (using $P < .05$) was reported in 7 of 47 (15%) trials. After adjusting p-value for multiplicity using the Bonferroni correction ($P < .00106$), 1 trial (2%) reported statistically significant improvement. **Conclusions:** The number of statistically significant studies of bevacizumab is reduced when corrected for multiplicity, suggesting that the current analytic plans may overestimate clinical benefit and could benefit from portfolio-based analysis.

6552 Poster Session (Board #378), Sat, 1:15 PM-4:45 PM

Analysis of use of a molecular reporting and treatment decision support tool in more than 1300 cancer cases. *First Author: Gabriel Alejandro Bien-Willner, Molecular Health Inc., The Woodlands, TX*

Background: Comprehensive characterization of the cancer genome has elucidated the molecular determinants driving response and resistance to targeted therapies. Current NGS-based personalized medicine requires a lot of manual work (e.g., publication and database review) to find relevant biomarker information necessary to create an impactful diagnostic report. Molecular Health Guide (MH Guide) allows for rapid and efficient variant interpretation and treatment support using referenced curated data including evaluation of various quality parameters. **Methods:** We constructed an integrated database of biologic and clinical data called Dataome, upon which we have developed a medical device (MH Guide) for medical reporting, wherein content can be used for clinical treatment decision support (registered medical device in Europe). We assess the clinical information provided by MH Guide in a cohort of patients including the number of recommended and contraindicated drugs and available clinical trials. **Results:** 1352 cancer patients with various solid tumor types (n = 107) were analyzed with MH Guide (2014-2017). The system identified 14,000, 4,800 and 2,300 tumor-type specific biomarkers associated with effective therapies, adverse events and ineffective therapies, respectively. These were based on clinical (10,300) as well as pre-clinical (11,400) data. Putative effective therapies were linked to $>$ 4,700 clinical trials. **Conclusions:** Comprehensive characterization of the cancer genome has elucidated pathways that drive cancer, mechanisms of therapy resistance, and provided important insights for the development of new therapies. To benefit from this in routine medical practice, we need tools and technologies that efficiently assist with interpretation of clinico-molecular patient data against the rapidly growing biomedical knowledge. MH Guide can assist clinicians in making informed decisions about the benefits of therapies in an evidence driven manner. Based on its performance, German health insurance companies have agreed to support the clinical use of MH Guide in a study aimed to reduce non-responders and adverse events; thus, lowering the overall cost of care and improve quality of life.

6553 Poster Session (Board #379), Sat, 1:15 PM-4:45 PM

Association of baseline body mass index (BMI) with overall survival (OS) in patients (pts) with metastatic non-small cell lung cancer (mNSCLC) treated with nivolumab (N) and pembrolizumab (P). *First Author: Jizu Zhi, U.S. Food and Drug Administration, Silver Spring, MD*

Background: Poor performance status (PS) is associated with worse clinical outcomes for pts with mNSCLC. However, in the real-world PS is not routinely captured in electronic health records (EHRs). Pts with poor PS may also have cachexia and low BMI. As such, underweight BMI may be a proxy for deteriorated real-world PS when PS score is missing. We have shown that female gender and positive EGFR/ALK mutation status predict longer OS, but not age or other factors. We explore the association of baseline BMI with OS in real world mNSCLC pts treated with N or P. **Methods:** We conducted a retrospective analysis of mNSCLC pts treated with N or P using de-identified real-world data (RWD) from the Flatiron Health network. Index date was start of first single agent N or P. Baseline BMI (kg/m2) was calculated from the most recent weight and height recorded within 30 days prior to index date and categorized as: Underweight (< 18.5), Normal (18.5 – 24.99), Overweight (25 – 29.99), and Obese (30+). Association of baseline BMI with OS was assessed using multivariate Cox proportional hazards model adjusted for gender, age, and EGFR/ALK status prior to N or P start. Eligible pts had valid values for all parameters. **Results:** 703 pts met inclusion criteria (Table). For OS, gender was significant overall, EGFR/ALK mutation was significant overall and for women. **Conclusions:** We observed BMI-based differences in OS for real world mNSCLC pts treated with N or P. Underweight BMI is associated with shorter OS and obese BMI is associated with longer OS. In pts with cancer, declining BMI and PS may signal biologic processes indicative of progressive disease that negatively affect OS. Since PS data is commonly missing in EHRs, our results suggest that BMI can potentially be used as a proxy for poor PS in RWD studies. Investigating the impact of changes in BMI on OS and correlation of BMI with PS would further verify this assumption.

		All		Male		Female	
BMI	**N (%)**	**aHR**	**p**	**aHR**	**p**	**aHR**	**p**

6554 Poster Session (Board #380), Sat, 1:15 PM-4:45 PM

Trial prospector update: A point of care automated clinical trials matching application. *First Author: David Lawrence Bajor, University Hospitals Seidman Cancer Center and Case Western Reserve University, Cleveland, OH*

Background: Advances in oncological care and patient outcomes are commonly based on clinical trials, however only 3-7% of cancer patients participate. One major barrier to patient enrollment is the physician effort needed to identify clinical trials for which their patients are eligible. As clinical trial eligibility becomes more complex with cohorts defined by specific lines of therapy or genetic data this barrier grows. Health information technology presents an opportunity to develop automated systems capable of matching patients to appropriate clinical trials in real time without impeding clinical workflow. **Methods:** Trial Prospector (TP) is a web-based, point-of-care, automated clinical trials matching application. (Sahoo SS, et al. Trial Prospector: matching patients with cancer research studies using an automated and scalable approach. *Cancer Informatics* 13:157-66, 2014. Corresponding author. PMID: 25506198) In order to enhance its utility, we systematically reviewed eligibility criteria in all lung cancer trials on clinicaltrials.gov, and integrated five new criteria into TP, including the capability to match based on next-generation sequencing data. We then deployed TP in lung cancer clinics, surveyed users for usability, independently verified the accuracy of TP, and measured clinical trial accrual. **Results:** A total of 380 patient visits (282 unique), were included; 10.3% of patients were subsequently accrued to a clinical trial. Among a sample of 25 TP reports, the accuracy of TP, defined as the percentage of correctly matched trials, was 98%. Clinician surveys (n = 38) revealed that 82% found the information provided by TP to be accurate, 71% reported that TP saved them time in identifying potential clinical trials, and 87% would recommend utilizing TP for eligibility screening. **Conclusions:** TP is an adaptable software platform that accurately matches patients to clinical trials in a point-of-care setting. Further testing is warranted to determine the optimal settings for deployment and the impact on physician effort and trial accrual.

6555 Poster Session (Board #381), Sat, 1:15 PM-4:45 PM

Artificial intelligence methods to predict chemotherapy-induced neutropenia in breast cancer patients. *First Author: Peter Abdul DeWan, Precision Health Ai, New York, NY*

Background: While chemotherapy improves outcomes in breast cancer patients, it also increases the risk of neutropenia. There is a need for improved risk prediction models of chemotherapy-induced neutropenia. This study developed an artificial intelligence (AI) model to predict neutropenia risk within six months of chemotherapy and compared it to traditional logistic regression models. **Methods:** We obtained a cohort of 10,288 breast cancer patients from the ASCO CancerLinQ Discovery™ dataset, who were treated with doxorubicin and cyclophosphamide (AC) followed by paclitaxel (T) with or without pre-chemotherapy WBC growth factor prophylaxis. We created a hierarchy of predictors, then trained and evaluated a neural network algorithm. **Results:** Using only the relevant predictors for this more specific study, we demonstrate an average 27% increase across the scenarios in AUC ROC ($p < 0.001$) compared to existing studies (Lyman, 2011). We improve prediction by an average of 45%, achieving 0.56 positive predictive value (PPV) and 0.92 negative predictive value (NPV) prior to chemotherapy. **Conclusions:** These results demonstrate that this larger dataset combined with an AI algorithm enabled substantial improvement in prediction of chemotherapy-induced neutropenia. In the clinical setting, this would improve decisions, and enable early intervention for patients that would benefit most from prophylaxis, thus reducing neutropenic fever and infections requiring hospitalization.

Factors impacting progression-free survival (PFS) as a predictor of overall survival (OS). *First Author: David J. Stewart, The Ottawa Hospital, Ottawa, ON, Canada*

Background: Unlike OS hazard ratios (HRs), PFS HRs are unaffected by crossover or post-progression survival, but PFS HRs are poor predictors of OS HRs. We hypothesized that absolute PFS gain (ΔPFS) might predict absolute OS gain (ΔOS). **Methods:** We assessed 279 randomized solid tumor drug comparisons with ≥200 incurable patients from J Clin Oncol or New Engl J Med, 2007 to June, 2017. We used nonlinear regression analysis of PFS & OS curves to calculate half-lives ($t_{1/2}$s: time to death or progression in $\frac{1}{2}$ the remaining patients) and to assess if PFS curves fit 2-phase vs only 1-phase decay models. ΔPFS ≥ 1.5 months (m) is a better predictor of ΔOS ≥ 2m if $t_{1/2}$s are used than if medians are used (Stewart, Proc AACR, 2018 #1644). We used $t_{1/2}$s from the 149 studies with ΔPFS $p < 0.05$ to calculate positive and negative predictive value (PPV & NPV) of ΔPFS ≥ 1.5 m as a predictor of ΔOS ≥ 2 m in selected subgroups. PPV = (no. studies with ΔPFS ≥ 1.5 m & ΔOS ≥ 2 m)/ (no. studies with ΔPFS ≥ 1.5 m & any ΔOS). NPV = (no. studies with ΔPFS < 1.5 m & ΔOS < 2 m)/ (no. studies with ΔPFS < 1.5 m & any ΔOS). **Results:** See table. 4 of 14 ICI trials (29%) and 6 of 265 trials with other drugs (2%) had ΔOS that was both ≥ 2 m & significant ($p < 0.05$) despite insignificant ΔPFS ($p > 0.05$). **Conclusions:** With low CO, ΔPFS that is both significant & greater than 1.5 m predicts ΔOS greater than 2 m. with high PPV and NPV across tumor types other than prostate cancer and across drugs other than ICIs. ICIs (most of which had PFS curve 2-phase decay) generally had high ΔOS despite low ΔPFS.

The influence of socioeconomic status, tumor characteristics and patterns of breast cancer care on breast cancer specific survival among elderly women. *First Author: Amanda L. Kong, The Medical College of Wisconsin, Milwaukee, WI*

Background: The purpose of this study was to examine the relationship between patient demographic and socioeconomic status (SES), tumor characteristics, initial and follow-up breast cancer care, and 3-year breast cancer mortality among a population-based cohort of elderly women with incident breast cancer. **Methods:** We identified women with newly diagnosed breast cancer in 2006-2009 from the Surveillance and Epidemiology End Result study linked with Medicare claims (SEER-Medicare). A Classification and Regression Tree (CART) model was applied to 15 individual indicators of neo-adjuvant and adjuvant breast cancer treatment, tumor characteristics, and patient demographic and SES variables to identify patterns (i.e. combinations of variables) with the greatest discriminant value in predicting 3-year mortality by cause of death (outcome = breast cancer vs. other causes vs. alive) . **Results:** Nineteen unique patterns were identified as best discriminating 3-year mortality by cause of death. Breast cancer mortality probabilities associated with these patterns ranged from 2.6% to 39.7%. CART identified the number of positive nodes as the best single discriminator between high and lower breast cancer mortality, followed by the use radiation therapy and tumor stage. Patient's SES was a discriminant factor in four of the ten patterns associated with high ($>$ 15%) breast cancer mortality while non-use of adjuvant hormonal therapy was a discriminant factor in six of the ten high breast cancer mortality patterns. Receipt of treatment within 50 days from diagnosis was associated with two of the lowest probabilities of breast cancer mortality (3.1% and 7.7%). **Conclusions:** Greater adoption of certain patterns of care could improve breast cancer survival of elderly women with incident disease overall, and reduce SES disparities therein.

Feasibility of a self-funded model to provide breast cancer services to uninsured women in New York City. *First Author: Janice Zaballero, Breast Treatment Task Force, New York, NY*

Background: Despite access-expanding mandates in the ACA, approximately 30% of New York State residents remain uninsured. Most safety net programs provide services only to patients who qualify for Medicaid, leaving a large percentage of women without access to affordable breast cancer screening and diagnostics. In response, we developed Breast Treatment Task Force (BTTF) to provide these services to uninsured patients earning $23,760 - $47,520 annually (200%-400% FPL). **Methods:** We surveyed imaging centers located in New York City to determine unused imaging capacity. BTTF then negotiated reduced rates for breast imaging services at these sites. We developed referral networks composed of community organizations including Planned Parenthood. We raised nearly $400,000 through philanthropy to fund operations. We collected demographics for all patients, and patient satisfaction was assessed through surveys administered after receiving services. **Results:** We identified 24 imaging centers with unused capacity totaling 20,000 screening exams and diagnostic procedures. In 2017, BTTF facilitated care for 646 patients in the form of 409 screening exams and 832 diagnostic procedures. Average wait time from abnormal mammogram to diagnostic procedure was less than six days. The median age of BTTF patients was 40, and the majority were from minority backgrounds (34% Asian, 32% Hispanic, and 19% African-American). Median annual income per patient was approximately $30,000, and 61% of patients were employed. Attendance rates for diagnostic services and patient satisfaction rates were each 99% (versus industry averages of 60% and 67%, respectively). Nine patients were newly diagnosed with cancer. Since 2007, BTTF has delivered $16 million in medical services with an annual budget of under $400,000. **Conclusions:** BTTF constructed two networks: 1) network of private imaging centers willing to donate a significant portion of unused capacity and 2) network of large community referral partners to identify low-income patients. This model offers an example of how to successfully provide important breast cancer screening and diagnostic services to non-Medicaid-eligible women who cannot afford health insurance.

Cigarette price, smoking behaviors, and lung cancer mortality in Indiana. *First Author: Ryan Nguyen, Indiana University School of Medicine, Indianapolis, IN*

Background: Increasing tobacco costs have been proven to be one of the most effective interventions of decreasing tobacco use. The relationship between tobacco cost and lung cancer mortality has not been as well established. We investigated the relationship of cigarette price with smoking prevalence, cigarette consumption, and lung cancer incidence and mortality in Indiana and nationally. **Methods:** We obtained average cigarette pack prices, cigarette pack sales, smoking prevalence, and lung cancer incidence and mortality rates in Indiana and nationally from 1995-2015. Average cigarette pack prices were inflation adjusted to 2015 then assessed for Pearson correlation coefficient (r) with cigarette pack sales, smoking prevalence, and lung cancer incidence and mortality. Cigarette price was also correlated with smoking prevalence among state-level characteristics that included gender, age, ethnicity, education, and income. **Results:** From 1995 to 2015, average cigarette pack price in Indiana rose from $2.29 to $5.41. Increasing cigarette price in Indiana was associated with decreasing cigarette consumption (r= -0.91, $p < 0.001$) and decreasing overall smoking prevalence (r= -0.72, $p < 0.001$). However, those in the lowest income level had higher smoking prevalence associated with rising cigarette price (r= 0.67, p = 0.001). Increasing cigarette price correlated with decreasing lung cancer mortality both in Indiana (r= -0.79, $p < 0.001$) and nationally (r= 0.96, $p < 0.001$). **Conclusions:** Increasing tobacco taxes and subsequent increasing cigarette prices were associated with decreased smoking prevalence, cigarette consumption, and lung cancer mortality in Indiana. Lower socioeconomic populations in Indiana may not be as price-responsive as similar populations nationally. Policies aimed at increasing tobacco prices should prioritize diverting revenues towards health programs and tobacco-cessation initiatives for lower-income individuals.

6560 Poster Session (Board #386), Sat, 1:15 PM-4:45 PM

Impact of high-deductible insurance on breast cancer care among lower-income women. *First Author: James Frank Wharam, Department of Population Medicine, Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, MA*

Background: High-deductible health plans (HDHP) are increasingly common but delay important breast cancer diagnostic tests and treatment. We hypothesized that such delays would be especially pronounced among lower-income HDHP members. **Methods:** We used 2004-2012 data from a large US health insurer and a pre-post controlled survival design. We included 152,155 lower-income HDHP group members age 25-64 without evidence of breast cancer. These women were continuously enrolled for 1 year in a low-deductible ($\leq$\$500) plan followed by up to 4 years in a HDHP ($\geq$\$1000) after an employer-mandated switch. The comparison group included 1,316,548 contemporaneous, coarsened exact-matched lower-income women whose employers offered only low-deductible plans. Measures were times to first diagnostic breast imaging, breast biopsy, incident early-stage breast cancer diagnosis, and breast cancer chemotherapy. Outcomes were analyzed using Cox survival models adjusted for baseline patient characteristics. We also analyzed measures among 120,755 high-income HDHP members and their 1,095,592 high-income matched controls. **Results:** After the index date, lower-income HDHP members experienced delays in receipt of breast cancer diagnostic imaging (adjusted hazard ratio, aHR: 0.93 [0.92,0.95]), biopsy (0.89 [0.86,0.93]), early-stage breast cancer diagnosis (0.89 [0.80,0.98]), and chemotherapy initiation (0.80 [0.71,0.90]) compared with controls. Corresponding hazard ratios among high-income HDHP members (0.96 [0.95,0.98], 0.93 [0.89,0.97], 0.77 [0.69,0.85], and 0.76 [0.68,0.86], respectively) were similar to those of lower-income HDHP members and confidence intervals overlapped. Findings were also similar when analyzing an even lower income HDHP subgroup. **Conclusions:** Both lower-income and high-income women who were switched to HDHPs experienced delays in diagnostic breast imaging, breast biopsy, early-stage breast cancer diagnosis, and chemotherapy initiation. Further research should determine if such delays cause adverse health outcomes. Oncologists, primary care physicians, and population health managers should consider HDHPs a risk factor for delayed breast cancer services.

6561 Poster Session (Board #387), Sat, 1:15 PM-4:45 PM

Increasing access to NGS tests for women and racial minorities to lift barriers to molecular driven clinical trial enrollment. *First Author: Jared Cotta, University of Miami; Sylvester Comprehensive Cancer Center, Miami, FL*

Background: Molecular-driven oncology clinical trials are a rapidly growing category of clinical research. These trials are focused on generating evidence for the relationship between molecular markers and targeted therapies, often requiring patients to have Next-Generation Sequencing (NGS) results before being considered for qualification. This requirement adds another barrier to clinical trial enrollment for populations that already face healthcare disparities. **Methods:** Defining Platforms for Individualized Cancer Treatment (DePICT) is an IRB approved observational trial designed to monitor outcomes of Broward County, FL residents with late-stage refractory cancer who undergo NGS. Rather than requiring NGS results, DePICT subsidized NGS testing to ensure access to all patients. Enrollment demographics were analyzed to see if these conditions improve gender and minority representation. **Results:** DePICT has recruited 176 patients. 70% of the total cohort is female, compared to 39% female in the institute's accrual of Broward residents. Table 1 shows the base line demographic data for DePICT in comparison to the institutional recruitment. DePICT produced a 26% relative increase in minority recruitment.102 DePICT patients had at least one 12 week follow up (65% women; 13% Black, 25% Hispanic). The follow-up determined which patients pursued an MTB recommended targeted treatment or clinical trial. 12 patients continued on to interventional trials; 50% were women, 50% identified as minorities. An additional 10 patients continued on to targeted therapies; 64% were women and 64% identified as a minority. **Conclusions:** By providing access to NGS testing DePICT accrued underrepresented patients who face healthcare disparities. Targeting underrepresented populations for NGS may improve the enrollment of women and racial minorities to oncology clinical trials. Healthcare providers may encourage testing through education or subsidy programs. Employing these methods to reduce disparities will improve generalizability of clinical research.

	Black	Non-Hispanic White	Hispanic	Minority recruitment
DePICT	15%	57%	23%	38%
SCCC	11%	62%	19%	30%

6562 Poster Session (Board #388), Sat, 1:15 PM-4:45 PM

Financial toxicity associated with conflict-induced cross-border travel for cancer care: Experience of Iraqi patients in Lebanon. *First Author: Deborah Mukherji, The American University of Beirut Medical Center, Beirut, Lebanon*

Background: Conflict-induced cross-border travel for cancer care is commonly observed in the Middle East region. There has been very little research conducted on the impact this has on patients or on how cancer centers can adapt their services to meet the needs of this population. This study examines the experience of Iraqi patients with cancer seeking care in Lebanon at the American University of Beirut Medical Center (AUBMC). The aim of this study was to understand the social and financial context of conflict-related cross-border travel for cancer diagnosis and treatment. **Methods:** After IRB approval, 60 Iraqi patients and caregivers were recruited and interviewed. For background epidemiological data regarding the population of patients seeking cancer care at AUBMC, the diagnoses of adult patients with Iraqi nationality were reviewed from January 2013 to December 2016. **Results:** For the retrospective sample, the total number of patients was 1284 with 40% presenting with advanced solid tumors. The prospective data emphasized the difficulties around access to the necessary financial resources for cancer treatment abroad as well as patterns of mobility. Fifty four respondents (90%) reported high levels of financial distress. Patients relied upon the sale of possessions (48%), homes (30%) and vast networks to raise funds for treatment. Thematic analysis revealed several key drivers for undergoing cross-border treatment, including (1) the conflict-driven exodus of Iraqi oncology specialists; (2) destruction of hospitals or road blockages; (3) referrals by Iraqi doctors to Lebanese hospitals (4) geographical proximity of Lebanon and (5) lack of diagnostic equipment, radiotherapy machines, and reliable provision of chemotherapy in Iraqi hospitals. **Conclusions:** As a phenomenon distinct from medical tourism, conflict-related deficiencies in healthcare at home force patients with limited financial resources to undergo treatments in neighboring countries. We highlight the importance of shared decision-making and taking the unique socioeconomic status of this population of patients into account when planning treatment.

6563 Poster Session (Board #389), Sat, 1:15 PM-4:45 PM

Assessing the impact of early Medicaid expansion on insurance, stage at diagnosis, and survival among young adults ineligible for dependent coverage. *First Author: Justin Barnes, Saint Louis University, St. Louis, MO*

Background: Cancer outcomes in young adults have lagged behind other age groups, which may be related to lower rates of insurance. While some data suggest the Affordable Care Act (ACA) may improve outcomes in young adult cancer patients eligible for dependent coverage through the ACA Dependent Coverage Provision, the impact of the ACA on cancer outcomes among young adults ineligible for dependent coverage has not been well-studied. Our objective is to assess changes in insurance rates, stage at diagnosis, and survival that are associated with early (2010-2011) Medicaid expansion. **Methods:** Using the Surveillance, Epidemiology, and End Results (SEER) 18 database, we identify young adults aged 27-34 years diagnosed with a first primary malignancy between 2007-2014. We utilize a quasi-experimental design, comparing expansion-related changes in insurance rates, stage at diagnosis, and survival in the intervention group (cases from states that expanded Medicaid early) to the control group (cases from other, non-expanding states) using difference-in-differences analyses applied to linear probability and Cox proportional hazards regression models. **Results:** A total of 47,750 cases were included in the analyses. Relative to young adults in states that did not expand Medicaid early, young adults in early expansion states had increases in Medicaid insurance (1.51 Percentage Points [PP], 95% CI = 0.15 to 2.87, p = 0.030), decreases in uninsurance (-1.99 PP, 95% CI = -3.03 to -0.95, $p < 0.001$), increases in early stage diagnoses (2.72 PP, 95% CI = 1.09 to 4.34, p = 0.001), decreases in late stage diagnoses (-1.34 PP, 95% CI = -2.53 to -0.16, p = 0.027), but no change in cancer-specific survival (HR: 0.95, 95% CI = 0.85 to 1.07, p = 0.41). **Conclusions:** For young adults ineligible for dependent coverage, early Medicaid expansion is associated with increases in Medicaid insurance rates and early stage diagnoses as well as decreases in the uninsured rate and late stage diagnoses, though evidence for a further downstream effect on survival is lacking.

6564 Poster Session (Board #390), Sat, 1:15 PM-4:45 PM

Superior survival in adolescents and young adults (AYA) with acute lymphoblastic leukemia (ALL) treated in pediatric vs. adult centers is only partially attributable to inadequate adoption of pediatric protocols: A population-based IMPACT Cohort study. *First Author: Sumit Gupta, Hospital for Sick Children, Toronto, ON, Canada*

Background: Retrospective studies have shown that AYA with ALL have superior survival when treated in pediatric vs. adult centers (locus of care; LOC). Clinical studies showing superior survival using pediatric treatment protocols have led to their adoption by some adult centers. Whether this has narrowed LOC disparities in real world settings is unknown. **Methods:** The IMPACT Cohort is an Ontario population-based cohort that has captured demographic, disease and treatment (treatment protocol, chemotherapy doses) data for all 15-21 year olds diagnosed with ALL between 1992-2011. Cancer outcomes were determined by both chart abstraction and linkage to provincial administrative health care databases. We examined predictors of outcome, including disease biology, treatment exposures, LOC, and time period (1992-98 vs.1999-2005 vs. 2006-11). **Results:** Of 271 patients, 152 (56%) received therapy at an adult center. 5-year event-free survival (EFS $\pm$ standard error) among AYA treated at a pediatric vs adult center was 72%$\pm$4% vs. 56%$\pm$4% (p = 0.03); 5-year overall survival (OS) was 82%$\pm$4% vs. 64%$\pm$4% ($p < 0.001$). No significant interaction was noted between pediatric vs. adult LOC and time period. Neither induction deaths nor dose reductions varied by LOC. In the latest time period, 39/59 (66%) AYA treated at an adult center received a pediatric protocol, as compared to 4/40 (10%) in the middle period. Late period AYA treated at adult centers with pediatric protocols experienced superior outcomes compared to those of contemporaneous AYA treated on an adult protocols, but inferior to those of AYA treated at pediatric centers (EFS 72%$\pm$5% vs. 60%$\pm$9% vs. 82%$\pm$3%; p = 0.02; OS 77%$\pm$7% vs. 65%$\pm$11% vs. 91%$\pm$4%; p = 0.004). **Conclusions:** Survival disparities between AYA treated in pediatric vs. ALL centers have persisted over time, partially attributable to inadequate adoption of pediatric protocols by adult centers. Although use of pediatric protocols has improved survival, residual survival disparities remain and do not seem to be due to excessive toxicity or dose reductions.

6565 Poster Session (Board #391), Sat, 1:15 PM-4:45 PM

Changes in access to care and financial hardship associated with Affordable Care Act (ACA) implementation for cancer survivors aged 19-64 years. *First Author: Amy J. Davidoff, Yale School of Public Health, New Haven, CT*

Background: In 2014, as part of the ACA implementation, Medicaid eligibility was expanded in over half of states and insurance marketplaces were created in all states, with premium subsidies for selected individuals. Our prior research indicated a 38% reduction in the uninsured rate for cancer survivors by 2015. Here we examine subsequent changes in access and financial hardship. **Methods:** We pooled data for cancer survivors aged 19-64 years from the 2012, 2013 & 2015 National Health Interview Survey (N = 2996). We examined perceived access barriers (unmet need, medication cost-related non-adherence (CRN)), ability to pay medical bills, worry about future bills, and food insecurity. Linear probability regressions examined changes between the 2012-2013 and 2015 periods. Models controlled for eligibility for both Medicaid and premium subsidies to purchase insurance, constructed using family structure, income and employment, and linked data on state-specific Medicaid expansion policies. Models also controlled for demographics and comorbidities. **Results:** Prior to ACA implementation, 18% of cancer survivors delayed healthcare due to cost, 13% had unmet need for medical care, 18% reported CRN, 31% reported being highly worried about paying future medical bills and 23% reported food insecurity. Post-ACA there were adjusted decreases of 4.5 percentage points (PPT) in delayed care, 4.8 PPT in any unmet need, 7.4 PPT decline in worry about future bills, all at $p < .01$. No reductions were observed in unmet drug need, medication CRN, or food insecurity. In 2015, 13% still reported delayed healthcare, 14% reported CRN, and 25% worried about ability to pay future medical bills. **Conclusions:** After the ACA implementation, cancer survivors experienced significant reductions in access burden and financial worry. Despite improvements, cancer survivors still experience healthcare access limits, and worry about future financial health. ACA coverage changes, participation, access and health outcomes for cancer survivors need ongoing monitoring, particularly given repeal of the individual mandate.

6566 Poster Session (Board #392), Sat, 1:15 PM-4:45 PM

Addressing financial concerns of cancer clinical trial participants: Longitudinal outcomes of an equity intervention. *First Author: Ryan David Nipp, Massachusetts General Hospital, Boston, MA*

Background: Cancer patients' (pts) financial concerns (FCs) represent a barrier to clinical trial (CT) participation and interventions targeting pts' FCs are needed. We sought to assess the impact of an equity intervention on CT pts' FCs. **Methods:** We developed an equity intervention to reimburse non-clinical expenses related to CTs (e.g. travel, lodging) for low income pts. From 7/2015-7/2017, we surveyed intervention and control pts matched by age, sex, cancer type, specific CT and CT phase. We longitudinally assessed pts' FCs (cost concerns for CT-related travel and lodging), cost-coping strategies (e.g. altering medical care or lifestyle due to costs) and financial wellbeing (FWB; COST measure, scores range 0-44, higher scores = better FWB) at baseline, day 45 and day 90. We used longitudinal models to assess intervention effects over time. **Results:** We enrolled 260 pts (157 intervention, 103 controls); median age = 59.2 (range: 23.8-83.3); 66% female; 72% on phase I CTs. Intervention pts had lower incomes than controls (under $60k: 52% vs 24%, $P < .001$). At baseline, intervention pts were more likely than controls to report FCs for CT-related travel (41% vs 7%, $P < .001$) and lodging (33% vs 2%, $P < .001$). Intervention pts were more likely to report travel to appointments as their most significant FC (23% vs 7%, P = .001). Intervention pts were also more likely to report forgoing needed care (14% vs 1%, P = .001) and using savings to pay for care (84% vs 43%, $P < .001$). At baseline, intervention pts had worse FWB than controls (COST score: 15.3 vs 23.9, $P < .001$). Over time, intervention pts experienced greater improvements in their FCs about CT-related travel (-10% vs +1%, P = .02) and lodging (-4% vs +4%, P = .03) compared with controls. Intervention pts also reported travel to appointments as their most significant FC less often (+2% vs +11%, P = .08) and had improvements in their COST scores (+1.1 vs -0.3, P = .20), although these differences were not significant. **Conclusions:** This equity intervention improved CT pts' FCs over time. Our findings highlight the substantial FCs of cancer CT pts, and underscore the need for interventions to address these concerns to improve access to CT participation for all pts with cancer.

6567 Poster Session (Board #393), Sat, 1:15 PM-4:45 PM

Impact of hospital safety-net burden on oncology patterns of care and outcomes. *First Author: Reith Sarkar, University of California, San Diego School of Medicine, La Jolla, CA*

Background: Safety-net hospitals serve a vital role in treating underserved populations. These hospitals often receive less funding, which could lead to different patterns of care for patients treated at these facilities. The purpose of this study was to determine the patterns of care and oncologic outcomes among a large cohort of cancer patients treated at safety-net hospitals. **Methods:** We identified 3,398,962 patients within the National Cancer Database with 10 common cancers including breast, prostate, lung, head and neck, colon, rectal, pancreas, cervix, bladder, and uterus diagnosed between 2004 and 2015. Safety-net burden was defined from the percentage of uninsured or Medicaid patients seen at each facility, and hospitals were then categorized as low (LBH), medium (MBH), or high burden (HBH) hospitals. We evaluated the impact of safety-net burden on patterns of care, as well as other outcomes including surgical margin status, and overall survival using multivariable linear, logistic, and Cox regression models. **Results:** Cancer patients seen at HBHs were more likely to be young, female, black, Hispanic, and reside in a low-income zip-code. HBHs were more likely to be academic, smaller institutions, and located in the South. After controlling for patient and tumor-related factors HBHs had differing patterns of treatment, and overall were less likely to operate (odds ratio [OR] 0.83; 95% confidence interval [CI] 0.82-0.84; $p < 0.0001$) and were more likely to provide radiation (OR 1.09; 95% CI 1.08-1.1; $p < 0.0001$) than LBHs. With respect to surgery, HBHs had higher rates of positive surgical margins (OR 1.08; 95% CI 1.06-1.1; $p < 0.0001$) than LBHs. HBHs had higher all-cause mortality when compared to LBHs (hazard ratio 1.09; 95% CI 1.08-1.10; $p < 0.0001$). **Conclusions:** Oncologic care at safety-net hospitals is associated with different patterns of care, as well as adverse clinical outcomes. Future research should focus on determining the etiology of this disparity, and work to devise strategies to improve outcomes among patients treated at safety-net hospitals.

6568 Poster Session (Board #394), Sat, 1:15 PM-4:45 PM

Overall survival based on oncologist density in the United States: Do we need to redefine underserved areas for oncologic care? *First Author: Kathan Mehta, University of Pittsburgh Medical Center, Pittsburgh, PA*

Background: ASCO has predicted shortage of 2,550 to 4,080 oncologists by 2020, disproportionately higher in underserved areas. The Conrad-30 program was established for international medical graduates, trained on J1 visas, to work in medically underserved areas (MUAs) and health professional shortage areas (HPSAs) to correct this disparity. Thirty spots per year are available for each state and primary care providers (PCP) are given priority. The designation of an area as MUA or HPSA is based on shortage of PCPs but not specialists. **Methods:** We evaluated the impact of oncologist density (OD) defined as number of oncologists per 100,000 (100K) population on overall survival and concordance with MUA or HPSA designation of areas by quartiles of OD. We studied the distribution of oncologists on visa in areas by quartiles of OD by merging SEER data with AMA physician's master file using Federal Information Processing Standards (FIPS) code of the area. **Results:** We identified 68,791 adult patients with newly diagnosed hematologic malignancies or metastatic solid cancers (excluding CNS cancers and patients with CNS mets) in 612 FIPS code areas captured by SEER in 2011. After controlling for confounders, compared to patients in areas with lowest quartile of OD (< 2.9 oncologists per 100K population), patients in areas with 2nd, 3rd and 4th quartile (2.9-6.5, 6.5-8.4, > 8.4 oncologists per 100K population respectively) of OD had better overall survival (HR 0.96, p = 0.001; HR 0.93, $p < 0.001$; HR 0.9, $p < 0.001$ respectively). There was no difference in proportion of MUA or HPSA designated areas among the four quartiles (79.6%, 71.9%, 64.5%, and 76.5% from 1st to 4th quartile, p = 0.1). There was no difference in proportion of oncologists working on visa among the 4 quartiles of OD (7.2%, 4.9%, 6.4%, and 6.4% from 1st to 4th quartile, p = 0.5). **Conclusions:** Patients in areas with higher OD have better overall survival. MUA or HPSA designation is not concordant with OD in different FIPS code areas. The Conrad-30 program is not promoting placement of oncologists on visa in areas with low OD. The Conrad-30 program should be amended to create designated spots for oncologists in each state proportionate to underserved population.

6569 Poster Session (Board #395), Sat, 1:15 PM-4:45 PM

Geographic distribution and survival outcomes for rural cancer patients treated in clinical trials. *First Author: Joseph M. Unger, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: Studies show that cancer patients from rural areas have worse cancer outcomes than their urban counterparts. But studies relying on cancer population data are unable to account for differences in access to care. In contrast, clinical trial patients receive protocol-directed care by design, so large clinical trial databases are ideal for examining the impact of residency on outcomes. **Methods:** We compared the geographic distribution and survival outcomes for rural versus urban cancer clinical trial patients. We examined 36,995 patients from all 50 states enrolled in 44 phase III or II-III SWOG treatment trials from 1986-2012, comprising 17 different cancer-specific analysis cohorts. We examined overall survival (OS), progression-free survival (PFS), and cancer-specific survival (CSS) for patients by rural/urban status to determine if residency – based on Rural-Urban Continuum Codes (RUCCs) – was associated with outcome. We used multivariate Cox regression to estimate the association of residency and survival outcomes, controlling for major disease-specific prognostic factors and demographic variables and stratifying by study. Different definitions of rurality were examined. The distribution of rural vs. urban patients by geographic region was described. **Results:** Overall, 19% of patients were from rural locations, the same as the rate of rural individuals in the U.S. Rural patients were older ($\geq$65 years, 31% vs. 27%, $p < .01$) and less likely to be African American (5% vs. 12%, $p < .01$), but were similar with respect to sex (40% each) and were well represented within major geographic regions. Clinical prognostic factors were very similar. In multivariable regression, rural patients with adjuvant-stage ER-/PR- breast cancer had worse OS (HR = 1.27, p = .008) and CSS (HR = 1.26, p = .02). No other statistically significant differences were found. Results were consistent regardless of the definition of rurality. **Conclusions:** Rural and urban patients with uniform access to cancer care through participation in a trial had similar outcomes. This finding suggests that improving access to uniform treatment strategies for cancer patients may help resolve the rural/urban disparity in cancer outcomes.

6570 Poster Session (Board #396), Sat, 1:15 PM-4:45 PM

Investigating hospice utilization for oncology patients using a claims database. *First Author: Margaret C. Horvath, UnitedHealthcare, Waltham, MA*

Background: Cancer is the second leading cause of death in the United States and also one of the most expensive diseases to treat. End of life care is often low in quality despite the availability of palliative care, advanced care planning, and hospice. Research studying Medicare beneficiaries has found most patients receive hospice, but with short length of stays (LOS). Limited studies exist on hospice use among non-elderly (18-64 year old) cancer patients with commercial insurance. **Methods:** Retrospective review of claims databases of Optum (Eden Prairie, MN) affiliated insurers identified patients, aged 18-64, who died of cancer between September 1, 2011 and August 31, 2016. Mortality information was sourced from the Social Security Administration Death Master File. Patients were identified as receiving 6 months of continuous insurance enrollment (CE) and 12 months CE prior to death date. Patients were described by cancer diagnosis and hospice LOS at the end of life. This project was considered exempt by the IRB at the University of Minnesota. **Results:** Among 15,330 cancer patients who died during this study period, we identified 3,730 patients aged 18-64 at time of death with 6 months of CE and a subset of 3,263 patients with 12 months CE. Our study included 99.5% of the target population. In the 6 month CE cohort, 2,263 (60.67%) patients received hospice with a median hospice LOS of 13 days, and 38.93% of patients received hospice received $\leq$7 days. We observed variation in hospice use by cancer type ranging from 49.11% (prostate cancer) to 66.84% (pancreatic cancer) $p < 0.001$. Median LOS ranged from 8 days (liver cancer) to 16 days (colorectal cancer). Similar results were found for the 12 month CE cohort. **Conclusions:** In our database, a majority of the non-elderly oncology patients received some hospice. We observed that over a third of the patients that received hospice had short LOS ($\leq$7 days), representing an opportunity for quality improvement. More studies are needed to improve the quality of EOL care for non-Medicare oncology patients in the U.S.

Hospital utilization and disposition among patients with malignant bowel obstruction: A population-based comparison of surgical to medical management. *First Author: Sarah Bateni, University of California Davis Medical Center, Sacramento, CA*

Background: Malignant bowel obstruction (MBO) is often a terminal event in end-stage cancer patients. The decision to intervene surgically is complex, given the risk of harm in patients with a limited lifespan and the limited population-based research investigating clinically relevant outcomes with surgical versus medical MBO treatment. Therefore, we sought to compare hospital utilization and disposition among MBO patients treated with surgical versus medical management. **Methods:** We performed a retrospective analysis of hospitalized patients with MBO from 2006-2010 at all California licensed hospitals from the Office of Statewide Health Planning and Development dataset. Hospital-free days (HFD) at 30, 90, and 180 days were calculated accounting for all hospitalizations, emergency department visits, and skilled nursing facility lengths of stay. Adjusted-regression and competing risks models were used to compare HFDs, disposition, complications, in-hospital death, and survival for surgically versus medically treated MBO patients using inverse probability to treatment weighting with propensity scores. **Results:** We identified 4,576 MBO patients treated medically (74.8%) or surgically (25.2%). Surgical patients had higher rates of complications (44.0% vs. 21.3%) and in-hospital death (9.4% vs. 3.8%) with lower rates of disposition to home (75.4% vs. 88.6%) compared to medical patients ($p < 0.0001$ all). Surgical patients had fewer 30- and 90-day HFDs compared to medical patients ($p < 0.05$). However, at 180-days, there were no differences in HFDs between treatment groups. Additionally, there were no differences in overall survival for surgical and medical patients (median 6.5 vs. 6.4 months, $p > 0.05$). **Conclusions:** In this population-based analysis, medically managed MBO patients fared better with respect to less hospital utilization at 30 and 90 days, fewer in-hospital deaths, and more frequent returns to home. These data underscore the impact of surgical management on MBO patients at the end-of-life.

6572 Poster Session (Board #398), Sat, 1:15 PM-4:45 PM

Effect of blinding on completion rate of patient-reported outcome measures in FDA cancer trial submissions, 2007-2017. *First Author: Jessica Roydhouse, US Food and Drug Administration, Silver Spring, MD*

Background: Patient-reported outcomes (PROs) are commonly included in clinical trial data submitted for FDA review. Open-label designs are frequent in cancer trials. Between-arm differences in PRO missingness have the potential to affect results. We aimed to compare PRO completion rates between study arms pre- and on-treatment in randomized open-label and double-blind cancer trials. **Methods:** Descriptive analysis of RCTs supporting cancer indications submitted to FDA for regulatory review. We identified trials for malignant disease from 2007 – 2017 using internal FDA databases. Applicant study reports were reviewed to assess PRO use and reporting of completion rates. Completion rates were collected per PRO and compared between arms. Results were summarized at the trial and instrument level using descriptive statistics. **Results:** Ninety-six of 169 trials (57%) associated with malignant hematology and oncology indications from 2007 – 2017 contained PROs. Fifty-one of the 96 trials (53%) were randomized, controlled trials with useable information on PRO completion. Median completion rates at six months were close to 90%. At six months, 16% of PROs in the double-blind trials had between-arm completion differences of $>=$ 10%, and the median between-arm completion difference was 12%. Furthermore, 8% of PROs had a $>=$ 10% higher completion rate in the control arm of these double-blind trials. However, for open-label trials at 6 months, 20% of PROs had between-arm differences of $>=$ 10%, with a median between-arm completion difference of 25%. For these, completion was better in the experimental arm. **Conclusions:** PRO completion rates were generally high for those studies that reported them, even for open-label trials. However, between-arm differences in completion rates favoring the experimental arm were larger and more frequent in open-label trials. Imbalances in PRO completion rates between arms affect PRO interpretation. Procedures must be put in place to reduce missingness, and accurate reporting of completion rates upon trial conclusion is critical.

6573 Poster Session (Board #399), Sat, 1:15 PM-4:45 PM

Prevalence of quality of life(QoL) outcomes and association with survival in cancer clinical trials. *First Author: Bishal Gyawali, Program on Regulation, Therapeutics and Law, Division of Pharmacoepidemiology and Pharmacoeconomics, Brigham and Women's Hospital, Boston, MA*

Background: QoL outcomes provide essential information for patients and physicians in oncology care, but these data are not always reported in pivotal trials of new therapies. We investigated the prevalence of quality of life outcomes in modern cancer drug trials and the relation, if any, between quality of life and surrogate endpoints. **Methods:** Retrospective cohort study of all phase III clinical trials of drugs for advanced or metastatic solid tumors published between 2010 and 2015. We investigated the inclusion and reporting of QoL endpoints in clinical trials of cancer drugs and the association between positive progression-free survival (PFS) and QoL outcomes. **Results:** Of the 352 Phase 3 trials included, 147 (42%) reported QoL outcomes. There were 162 (46%) that did not include a QoL endpoint and 43 (12%) that did not report pre-specified QoL endpoints, cumulatively enrolling a total of 125 962 patients. Factors significantly associated with lower rates of inclusion of QoL endpoints were cancer type (head and neck and other solid malignancies), primary endpoints of response rates or non-PFS surrogate endpoints, and smaller studies. Among the 147 trials that reported QoL outcomes, 99 (67%) reported no effect, 38 (26%) reported a positive effect, and 10 (7%) reported a negative effect of treatment on patients' global QoL. The correlation between PFS and positive QoL was low (r = 0.34; area under the curve [AUC]: 0.72). **Conclusions:** Despite the palliative intent of treatments in the advanced/metastatic setting, the availability of QoL data remains poor, primarily due to non-inclusion of QoL endpoints in large cancer clinical trials. Greater inclusion of pre-specified QoL measures and improved reporting of QoL outcomes are needed.

6574 Poster Session (Board #400), Sat, 1:15 PM-4:45 PM

Validity of using cancer registry data for comparative effectiveness research. *First Author: Zachary David Guss, University of California, San Diego School of Medicine, La Jolla, CA*

Background: Researchers often use cancer registry data to compare survival for different treatment options in clinical situations where higher level evidence does not exist. However, the retrospective non-randomized approach using cancer registry data for comparative effectiveness research raises important questions about study validity. The purpose of this project was to determine whether retrospective research with cancer registry data produces results concordant with randomized controlled trials (RCTs). **Methods:** Landmark RCTs involving surgery, systemic therapy or radiation were identified for nine common tumor sites including gastrointestinal, breast, lung, prostate, lymphoma, urinary, gynecologic, head and neck, and central nervous system. We identified experimental and control arms for each trial and recreated these arms using patients from the National Cancer Database (NCDB), matching eligibility criteria from the trial whenever possible. We used multivariable Cox regressions to determine hazard ratios for overall survival for each trial. The multivariable analyses controlled for potential confounders including clinical and tumor variables. We compared hazard ratios from the NCDB analyses with hazard ratios from randomized controlled trials. **Results:** Eighty-six RCTs were identified and included in this analysis. Overall survival hazard ratios for forty RCTs (45%) were found to be outside the 95% confidence interval reported for the RCTs. Fifty-one (59%) of the RCTs found no significant difference in overall survival between treatment arms, and among these trials 37 (73%) had significant findings showing superiority of one arm within NCDB. Thirty-five (41%) of the RCTs found a significant difference in overall survival between treatment arms, and among these trials 12 (34%) found no significant difference in survival within NCDB. The discordant results between RCTs and NCDB did not differ by disease site or treatment modality. **Conclusions:** Comparative effectiveness analyses using NCDB frequently produce results discordant from existing RCTs. These results suggest that comparative effectiveness research emanating from cancer registry should be interpreted with caution.

6576 Poster Session (Board #401), Sat, 1:15 PM-4:45 PM

Predicting acute care use following initiation of systemic therapy for solid tumors. *First Author: Robert C Grant, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Emergency department (ED) visits and hospitalizations are undesirable and costly. We developed and validated the PROACCT (Prediction Of Acute Care use during Cancer Treatment) score to predict at least one acute care visit during the first 30 days (AC30) after initiating systemic therapy for cancer. **Methods:** Using administrative data, we identified patients in Ontario with the 18 most common non-hematological cancers who initiated non-hormonal systemic treatment regimens between July 1, 2014 and June 30, 2015, randomly split into development and validation cohorts. We created a score to predict AC30 using multivariate logistic regression and backward covariate selection in the development cohort. Combinations of tumor sites and regimens were grouped into quintiles based on AC30. The score was assessed in the validation cohort. **Results:** AC30 occurred in 21% (3561/17144) of patients. Eleven factors predicted AC30 in the development cohort and formed the score: tumor site and regimen (2^{nd} quintile: 2; 3^{rd}-4^{th}: 3; 5^{th}: 4), Aggregated Diagnosis Group comorbidity index (6-10: 1; 11+: 2), recent/concurrent radiation (1), female sex (1), recent ED visit (1), rural residence (1), local health integration network (0, 1 or 2), and Edmonton Symptom Assessment Scale anxiety (4+: 1), lack of appetite (4+: 1), nausea (4+: 1), and tiredness (4+: 1). Among the 196 tumor-regimen combinations, tumors with poor prognoses, such as pancreatic and lung, and platinum- and taxane-containing regimens, carried the highest risk for AC30. The score had c-statistics of 0.66 and 0.65 in the derivation and validation cohorts, respectively (both $P < 0.001$) (Table). **Conclusions:** PROACCT identifies factors that predict AC30 in patients with solid tumors starting systemic treatment and could be incorporated into electronic health records to select patients for preventative interventions.

AC30 by PROACCT score.

6577 Poster Session (Board #402), Sat, 1:15 PM-4:45 PM

Racial, age, and sex disparities in chronic lymphocytic leukemia (CLL) patients treated with novel therapies. *First Author: Meghan Thompson, Hospital of the University of Pennsylvania, Philadelphia, PA*

Background: Differences in outcomes have been reported in CLL pts receiving chemo±immunotherapy with non-Caucasians and males having inferior outcomes. Less is known if such disparities exist for pts receiving targeted therapies. We investigated how demographics impact outcomes of CLL pts treated with targeted agents. **Methods:** We analyzed 3 multicenter, retrospective cohort studies of CLL pts treated with ibrutinib (ibr) (front-line (F/L) or relapsed/refractory (R/R) disease) or venetoclax (ven) (R/R disease). Baseline demographics, responses (ORR), discontinuations (DC), progression-free survival (PFS), and overall survival (OS) were stratified by age ($<$ 65 vs $\geq$65 yr), sex (male (M) vs female (F)) and race (Caucasian vs other). Cox regression was used for comparisons. **Results:** 1068 pts were included: F/L ibr (n = 391), R/R ibr (n = 536), R/R ven (n = 141). F/L ibr pts were 38% F, 59% age $\geq$65 and 8% non-Caucasian. R/R ibr pts were 37% age $\geq$65 (sex / race data unavailable). R/R ven pts were 34% F, 63% age $\geq$65 and 13% non-Caucasian. Del17p was similar within all cohorts. AEs were the most common discontinuation (DC) reason in all ibr groups, while CLL progression was most common in ven pts. A higher proportion of M discontinued ven vs F (34% vs 17%). Table 1 includes ORR, PFS, OS and DC stratified by age, sex and race. **Conclusions:** In the largest series of pts treated with novel agents, we did not find differences in outcomes when stratified by age, sex and race. These data suggest ibr and ven may in part overcome traditional disparities.

Real-world data (RWD) on tumor response (rwTR) in advanced non-small cell lung cancer (aNSCLC) patients receiving cancer immunotherapy and targeted therapies. *First Author: Michael Lu, Genentech, Inc., San Francisco, CA*

Background: Overall response rate (ORR) based on Response Evaluation Criteria in Solid Tumors (RECIST) is an established early efficacy endpoint used in clinical trials. Comparison of real world tumor response (rwTR) and ORR can provide important insights for health professionals, regulators, and researchers. **Methods:** We retrospectively analyzed electronic health records (EHRs) of patients with metastatic or recurrent NSCLC treated with epidermal growth factor receptor (EGFR)-targeted therapy (afatinib or erlotinib) and a programmed cell death 1 (PD-1) inhibitor (nivolumab), as well as a subset of *BRAF* mutation (*BRAF*mut)–positive patients in the Flatiron (FIH) EHR and FIH-Foundation Medicine (FMI) Clinico-Genomics database (CGDB) from 2011 to 2017. Structured and unstructured data elements from FIH EHRs were processed via technology-enabled abstraction. RwTR was based on abstraction of clinician's assessment of radiographic evidence. **Results:** All patients with rwTR (CGDB, n=595; *BRAF*mut, n=30) were evaluated. Observed rwTR rates for the relevant patient populations are described in the Table. **Conclusions:** This analysis demonstrates the potential of leveraging routinely captured EHRs to provide RWD on treatment effectiveness in patients with NSCLC. These results show that rwTR for targeted and immunotherapies appear to correlate well with RECIST ORR rates in pivotal clinical studies matched by EGFR mutation status, treatment, and line of treatment. Future work includes expanding similar rwTR evaluation to more treatment contexts.

6579 Poster Session (Board #404), Sat, 1:15 PM-4:45 PM

State breast density inform mandate laws and utilization of adjunctive screening tests and cancer detection following screening mammography. *First Author: Cary Philip Gross, Yale School of Medicine, New Haven, CT*

Background: In response to concerns about the limited sensitivity of mammography among women with dense breasts, 32 states have enacted laws to inform patients about these limitations and recommend adjunctive screening tests such as breast ultrasound. Inform mandate laws represent a novel approach to ensure awareness of technologies that have not yet been proven to affect health outcomes. We evaluated the effect of inform mandate laws on utilization of adjunctive screening, biopsy and diagnosis of incident breast cancer. **Methods:** Using blinded administrative claims data from anonymous insurers conducting business in the United States, we included women age 40-59 who underwent screening mammography in 2015. We classified beneficiaries according to receipt of screening mammography in a state with an inform mandate law. Receipt of screening or diagnostic ultrasound, breast biopsy, and incident breast cancer within nine months of screening mammogram was identified from claims. Logistic regression was used to evaluate the association between inform mandate laws and receipt of screening ultrasound, diagnostic ultrasound, biopsy, and cancer detection, while adjusting for age and type of health plan. Robust variance estimates accounted for clustering by state. **Results:** Our sample included 1,595,864 women who received a screening mammogram in 2015. Of these women, 58.2% were living in a state with an inform mandate law in place at the time of index mammogram. The adjunctive screening ultrasound rate was 3.1% among women in inform mandate states vs 1.4% in non-mandate states. After adjustment, residence in an inform mandate state was associated with significantly higher odds of adjunctive screening ultrasound (OR 2.22, 95% CI 1.14-4.34). In contrast, inform mandate status was not associated with receipt of diagnostic ultrasound, breast biopsy, or cancer detection. **Conclusions:** Women residing in states with breast density inform mandate laws are more likely to receive screening breast ultrasound. However, there was no significant relationship between inform mandate laws and utilization of other adjunctive tests or the likelihood of cancer detection.

6580 Poster Session (Board #405), Sat, 1:15 PM-4:45 PM

Toward understanding toxicity over time (ToxT) in myeloma cooperative group trials: Feasibility of a novel longitudinal adverse event analysis in ECOG-ACRIN E1A06. *First Author: Susanna J. Jacobus, Dana-Farber Cancer Institute, Boston, MA*

Background: Given the many chronically administered agents now used in cancer therapy, there is pressing need to elucidate safety and tolerability of therapy over time. Conventional methods of evaluating adverse events (AEs) focus on the incidence of high grade toxicity. The Toxicity over Time (ToxT) analytic approach captures the AE time profile with graphs and tabular displays plus quantifies the impact accounting for AE onset, duration and patterns of severity. ToxT has been applied to Alliance trials (Thanarajasingam et al, *Lancet Oncol 2016).* The goal of this study was to demonstrate feasibility of application of the ToxT statistical package to an ECOG-ACRIN trial. E1A06 was of interest given results of similar efficacy between treatment arms but significant differences in toxicity and quality of life as well as overall suboptimal treatment adherence. **Methods:** Newly diagnosed, transplant ineligible multiple myeloma pts were randomized to MPT (melphalan, prednisone, thalidomide) or mPR (lower dose melphalan, P, lenalidomide). Pts received 12 cycles of induction (I) followed by T or R maintenance until progression. Grade (G) 3+ non-hematologic (NH) and G4+ hematologic (H) AE data were collected every cycle. Treatment-related AEs of high incidence during I were selected for initial evaluation. Analyses with ToxT incorporate Kaplan-Meier and repeated measures methods. **Results:** 306 pts were enrolled. G3+ NH toxicity rates over I were 36% mPR vs. 51% MPT. Median time to 1st occurrence for pts experiencing G3+ AEs was similar (48 days mPR vs. 54 days MPT) and associated with ECOG PS score and stage at baseline. Each arm had 14 cases of fatigue, occurring more gradually on MPT (37d vs. 55d). G4 leukopenia incidence rates were 4% mPR vs. 13% MPT, with median onset 19d vs. 31d, respectively. Infection incidence rates were higher and onset earlier on MPT (8%, 79d vs. 14%, 46d). **Conclusions:** The feasibility of applying ToxT to an ECOG MM dataset was demonstrated. Longitudinal AE analysis has the potential to guide patient education on AEs and timing of symptom control interventions, ultimately improving tolerability of chronically administered cancer therapies.

6581 Poster Session (Board #406), Sat, 1:15 PM-4:45 PM

Assessing the difference in efficacy and effectiveness of cancer systemic treatment (tx): A comparison of clinical trial (CT) overall survival (OS) and toxicity data with population-based, real world (RW) OS data. *First Author: Cameron Phillips, University of Toronto, Toronto, ON, Canada*

Background: Often, when counseling patients on therapy, we utilize CT survival and toxicity data to help inform decision-making. While it is commonly believed CT data, derived from highly selected patients (pts), overestimates OS and underestimates toxicity compared with unselected patients in the RW, less is known about how often this occurs and the magnitude of this difference. We aim to quantify systematically the magnitude of OS and toxicity differences between CTs and population-based RW involving contemporary cancer systemic txs. **Methods:** All pts receiving IV cancer drugs with palliative intent indications that were first funded in Jan 2008 – Mar 2017 under Cancer Care Ontario's New Drug Funding Program (NDFP) were identified. A literature search was performed to identify landmark CTs with established OS efficacy data (e.g. median OS, 1-year OS rate or Kaplan-Meier OS curves) for each drug indication. Serious adverse event (SAE) rates were collected. Drug indications were included if the public funding criteria matched the CTs' eligibility criteria. RW OS and hospitalization (H) rates during treatment were ascertained by linking NDFP data to other population-based databases with end of follow-up at May 31, 2017. **Results:** 32 indications from 21 drugs (9 chemotherapy, 10 targeted therapies, 2 immunotherapy) involving 8,344 CT pts and 29,424 RW pts were included. 29 indications (91%) showed worse OS in the RW when compared to CTs with a median median OS difference of 4.4 months (IQR: 3.2-10.0) and a median 1-year OS difference of 12% (IQR: 8%-21%). Drugs used in the last-line setting had worse OS difference at 1-year (22% vs. 11%). The median difference between RW H and CT SAEs was 12% (IQR: 6%-21%). **Conclusions:** In most cases, substantially worse OS and greater toxicity were observed in the RW compared to CTs. This study has established a catalogue of population-based OS and H for pts receiving contemporary cancer systemic txs, and provides more relevant information for health-care providers when counseling pts on survival expectations prior to the initiation of systemic txs in the real world.

6582 Poster Session (Board #407), Sat, 1:15 PM-4:45 PM

Enrollment in high-deductible health plans and access to care, out-of-pocket spending, and hospital emergency department use among cancer survivors. *First Author: Zhiyuan Zheng, American Cancer Society, Atlanta, GA*

Background: Little is known about the associations between enrollment in high-deductible health plans (HDHP) and access to care, spending, and health care utilization among working age cancer survivors. **Methods:** The 2010 to 2015 National Health Interview Survey was used to identify privately insured working age (18-64 years) cancer survivors (HDHP n = 1170; low-deductible health plan [LDHP] n = 2084) and those without a cancer history (HDHP n = 23,548; LDHP n = 50,251). We used multivariable logistic regression to examine associations between HDHP status, cancer history and three measures: reduced access to care for financial reasons, high out-of-pocket (OOP) spending, and hospital emergency department (ED) use. Predictive margins were generated to compare cancer survivors to those without a cancer history, stratified by HDHP status. Odds ratios (OR) were generated to compare HDHP to LDHP cancer survivors as well as the impact of health saving accounts (HSA) among HDHP enrollees. Analyses were also stratified by family income level (low, middle, or high). **Results:** Among low income HDHP enrollees, cancer survivors were more likely to report reduced access to care (24.8% vs 17.8%), high OOP spending (47.8% vs 34.5%), and ED use (30.1% vs 16.2%) than those without a cancer history (all $p < .05$). Compared to LDHP cancer survivors, HDHP cancer survivors were more likely to report reduced access to care (low income: OR = 2.18; high income: OR = 2.15), high OOP spending (low income: OR = 4.75; middle income: OR = 2.35; high income: OR = 2.05), and ED use (middle income: OR = 1.58, all $p < .05$). Among HDHP enrollees, HSA was associated with lower rates of reduced access to care (OR = .85) and ED use (OR = .88) and higher rate of high OOP spending (OR = 1.34, all $p < .05$), compared to HDHP enrollees without HSA. **Conclusions:** HDHP increases the risks of reduced access to care, high OOP spending, and ED use for cancer survivors, and the patterns vary by family income level. Future studies based on longitudinal data to investigate causal relationship is warranted, especially among low income working age cancer survivors enrolled in HDHPs.

6583 Poster Session (Board #408), Sat, 1:15 PM-4:45 PM

Work status after treatment for breast cancer: A controlled, prospective, longitudinal study of an ethnically diverse cohort. *First Author: Victoria Susana Blinder, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Cancer-associated job loss is associated with financial strain, debt, and bankruptcy. The identification of workers at highest risk is critical to the development of interventions. **Methods:** We surveyed employed women aged 18-64 with stage I-III breast cancer who spoke Chinese, English, Korean, or Spanish. Baseline surveys were during adjuvant tx; follow-up surveys were 4 months post-tx. Our primary outcome was post-tx work status (working full- or part-time vs. any other work status). We used healthy peers to control for disparities in non-cancer unemployment and multivariable analyses to identify predictors of work status in pts. **Results:** Our sample (n = 440) was 23% black, 18% Chinese, 8% Korean, 30% Latina, and 21% non-Latina white (NLW). 31% had household income < 200% of the Federal Poverty Level (FPL), 26% were under-/uninsured, 33% worked in service/manufacturing, 84% had chemotx. Overall, 72% were working post-tx. The proportion of working pts vs. controls was 0.78 for blacks, 0.71 for Chinese, 0.73 for Korean, 0.77 for Latinas, and 0.96 for NLW. Among pts, independent predictors of *not* working were older age, Chinese ethnicity, low income, service/manufacturing job, lack of employer accommodations, and stage III cancer (Table 1). **Conclusions:** Breast cancer exerts a disparate negative impact on employment in minority women, which persists after controlling for disparities in background unemployment. Chinese pts were observed to have triple the odds of job loss (vs. whites). Interventions are needed to promote job retention in minority and low-income women, particularly those who lack work accommodations or are in high-risk jobs.

Odds of not working 4 months post-treatment.

Trends in chronic opioid therapy among cancer survivors. *First Author: Talya Salz, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Cancer survivors may be at increased risk of opioid use disorders, due to opioid exposure during therapy, prevalent pain after therapy, and heightened risk of addiction among those with tobacco- and alcohol-related cancers. We hypothesized that chronic opioid therapy (COT) receipt among survivors would exceed receipt among people without cancer. **Methods:** Adults ≥65 years in SEER-Medicare data diagnosed with lung (N = 16,192), colorectal (15,429), or breast (23,474) cancer between 2008 and 2013 were followed through 2014 or death. Survivors were matched 1:1 at diagnosis (index date) on age, sex, and race with cancer-free controls. We defined COT receipt as the presence of claims for ≥90 consecutive days of opioid prescriptions. We described proportion of survivors and controls receiving COT each calendar year. For each year after index date, we used logistic regression to compare COT receipt between survivors and controls. **Results:** Among controls, there was a secular trend of increased COT receipt from 3% in 2008 to 6% in 2013. Similarly, for survivors in the first follow-up year, COT receipt increased from 5% in 2008 to 10% in 2013. For each follow-up year, COT receipt among lung and colorectal survivors (but not breast cancer survivors) exceeded that of controls. However, the odds ratios comparing COT receipt between survivors and controls diminished over time since the index date (Table). **Conclusions:** A secular trend of increased COT receipt over calendar years was seen in survivors and controls, but the increase was blunted among survivors. Proportion of COT receipt among survivors approached that of controls as survivors lived longer after diagnosis. Although the opioid epidemic appears to include survivors, the common use of opioids during therapy does not appear to lead to later increased rates of opioid use beyond that of the general population. Differences between cancer populations merit further investigation.
Odds ratios for COT receipt (reference = controls)

Follow-up years after index date	1	2	3	4	5	6
Lung	3.03*	2.84*	2.01*	1.78*	1.88*	2.80*
Colorectal	1.39*	1.35*	1.23*	1.22*	1.13	1.13

Prediction of venous thromboembolism (VTE) in multiple myeloma (MM): Myeloma clot score (MCS). *First Author: Kristen Marie Sanfilippo, Barnes and Jewish Hospital/Washington University, St Louis, MO*

Background: Guidelines support pharmacologic thromboprophylaxis in MM patients identified as "high-risk" for VTE. Tools for VTE risk assessment in MM are contradictory and have not been validated. Such risk stratification would allow for use of thromboprophylaxis in MM patients at high-risk of VTE while avoiding anticoagulant exposure in patients at low risk. We aimed to develop and validate a risk prediction model for VTE in MM. **Methods:** We identified patients starting chemotherapy for MM within the Veterans Administration between 9/1999 and 12/2013. Using a split-sample method, we randomly created derivation (2/3) and validation cohorts (1/3). Variables associated with an increased risk of VTE within 6-months of chemotherapy start (univariate $p \leq 0.05$) and those with a $p \leq 0.10$ and an effect consistent with prior literature were offered into a backward stepwise model. Variables were removed until remaining variables predicted VTE ($p < 0.05$ OR $p \leq 0.30$ **plus** consistency with prior literature). A Myeloma Clot Score (MCS) was developed based on the parameter estimates. **Results:** The derivation cohort included 3036 patients of who 371 developed VTE within 6-months of starting chemotherapy. The MCS (Table 1) had a c-statistic of 0.68 in the derivation cohort and similar in the validation cohort. Incidence of VTE over the 6-month study period by score is in Table 1. In the validation cohort, the Hosmer-Lemeshow test was nonsignificant, showing adequate calibration. **Conclusions:** We developed and validated a risk model for predicting VTE in patients with MM starting chemotherapy. This MCS could be used to select patients who are likely to benefit from thromboprophylaxis.

Multivariate model and incidence of VTE by MCS score.

				Incidence of VTE by MCS Score		
Multivariate Risk Model Covariate	Hazard Ratio	*p* value	MCS Points	Score Range	Derivation Cohort	Validation Cohort
VTE before MM	2.77	<0.001	4	≤1	3.7%	4.4%
Low-Dose Dexamethasone	2.12	<0.001	3	2-5	10.9%	11.2%

A novel approach to mine the Veterans Administration Informatics and Computing Infrastructure (VINCI) allows one to assess the efficacy of cancer therapies: Abiraterone and enzalutamide in Veterans with metastatic prostate cancer (PC). *First Author: Harshraj Leuva, James J Peters VAMC, Bronx, NY, US*

Background: Novel efficacy endpoints are needed that correlate with overall survival [OS] and can describe real world outcomes. **Methods:** We mined national VA data (VINCI) using a novel set of equations validated in $>$ 10,000 patients that estimate simultaneously occurring exponential rates of tumor growth [*g*] and regression [*d*] using data gathered while a patient receives cancer treatment. We have previously established that *g* is highly correlated with OS and can esti mate doubling time (dt). Importantly, since the equations include time as a variable, this approach is ideal for real world analyses where re-assessments depend on the practitioner and are highly variable. To validate *g* in a real-world cohort, we collected cases of PC, demographics, treatments and outcomes from VINCI and compared parameters by receipt of chemotherapies for PC. **Results:** 5,890 Veterans were treated with abiraterone [ABI], enzalutamide [ENZA] or both. Median age was 75 years including 2,596 Veterans $>$ 80 years, and 23% identified as African American [AA]. PSA values beyond the initial measurement were available in 88% of patients with little clinical difference between those with and those without serial PSA values. *g* and *d* could be estimated in 83-85%f Veterans with p-values for fits $<$ 0.1 in all and $<$ 0.001 in the majority. *g* values for Veterans receiving either ABI [$0.0038d^{-1}$; dt 182d] or ENZA [$0.0040d^{-1}$; dt 173d] in first line were indistinguishable (p = 0,27), suggesting comparable efficacy. Consistent with the clinical bias, in second line, ENZA [$0.0071d^{-1}$; dt 98d] appears superior to ABI [$0.0091d^{-1}$; dt 76d] ($p < 0.01$). However, preliminary analyses find *g* on 1st line ABI remains constant in the majority and ABI continuation may be beneficial. Importantly *g* was independent of age, treatment location, and race, demonstrating comparable benefit in AA and non-AA Veterans. **Conclusions:** This is the largest real world assessment of ABI and ENZA efficacy in PC with a high percentage of AAs. The results underscore the value of determining *g* as an excellent measure of efficacy and argue for its use in outcomes research.

6587 Poster Session (Board #412), Sat, 1:15 PM-4:45 PM

Cancer patient-reported knowledge and preferences for liquid biopsies and blood biomarkers at a comprehensive cancer centre. *First Author: Min Joon Lee, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Novel blood-based biomarkers, including cell-free DNA and plasma signatures, are becoming a reality in precision oncology. Yet, little is known about cancer patients' perspectives on blood biomarkers in clinical practice. **Methods:** A 54-item self-administered questionnaire and four interviewer-administered trade-off scenarios were administered to cancer patients across all sites at Princess Margaret Cancer Centre. **Results:** Of 632 eligible patients, 66% (n = 417) completed the survey; 54% female; median age 61 (range 18-101) years. Patients had a median accuracy score of 18% (range 0-81%) on their knowledge of the role of biomarkers on their own cancer. Disease site was significantly associated with knowledge (P = 0.029); patients with breast, genitourinary, and thoracic cancers performed better than patients of other sites. Females (P = 0.012) and those with higher education (P = 0.019) and income (P = 0.0016) also scored better. Scores were not associated with the stage at diagnosis, time since diagnosis, age or ethnicity. Using chart review, 91% had been evaluated in at least one setting with either tissue, blood, or clinical biomarkers; however, only 20% of them were aware of this. In the scenario-based preference testing, if given a choice, 90% (n = 372) preferred a liquid (blood) over a tissue biopsy; however, these patients only accepted a median waiting period of one additional week (IQR: 0-3 weeks) and a 5% decrease (IQR 0-10%) in sensitivity of identifying the right treatment before switching their preference to the tissue biopsy. The majority (n = 216; 58%) were not interested in switching even with no potential complications from tissue biopsy. People with higher education were more likely to switch based on the level of risk ($P < 0.001$). **Conclusions:** Although patients had limited understanding of their cancer-specific blood-based biomarkers, 90% preferred blood over tissue biomarkers, but with little tolerance to waiting longer for results or decreased test sensitivity. Developing blood biomarkers and performing liquid biopsies are therefore desirable to patients, but only if they had similar or improved test characteristics over their tissue counterparts.

6588 Poster Session (Board #413), Sat, 1:15 PM-4:45 PM

Safety and tolerability of cancer drugs studied in phase 3 randomized controlled trials (RCTs) over the last decade. *First Author: Domen Ribnikar, Institute of Oncology, Ljubljana, Slovenia*

Background: Data suggest that newly approved cancer drugs have worse safety and tolerability profiles than older drugs used as control groups in trials. However, less is known about the toxicity profile of cancer drugs studied in unselected phase 3 clinical trials including those not resulting in regulatory approval. **Methods:** We searched clinicaltrials.gov to identify phase 3 RCTs evaluating experimental drugs in patients with metastatic breast, colorectal, lung and prostate cancer. We included all RCTs completed between 1 January 2005 and 31 October 2016. Odds ratios (OR) and 95% CI were computed for the following safety and tolerability end points: toxic death, treatment discontinuation without progression and commonly reported grade 3-4 adverse events (AEs). Data were then pooled in a meta-analysis using RevMan 5.3 software. **Results:** The analysis included 143 RCTs comprising 88,603 patients. 75% of the trials evaluated targeted therapies (including endocrine and immunotherapy). Compared to control groups, experimental drugs were associated with higher odds of toxic death (OR, 1.14; 95% CI, 1.03-1.27), treatment discontinuation without progression (OR, 1.64; 95% CI, 1.56-1.71) and grade 3-4 AEs (see Table). **Conclusions:** New cancer drugs studied in phase 3 RCTs are associated with worse safety and tolerability profiles compared to standard therapies when reported by investigators and have increased treatment-related mortality. Cancer patients considering enrollment on phase 3 trials should be aware of these risks.

Toxicity	OR	95% CI	p	% of trials with significantly higher odds in the experimental arm	% of trials with significantly lower odds in the experimental arm
Toxic death	1.14	1.03-1.27	0.02	5	0
Treatment discontinuation	1.64	1.56-1.71	< 0.001	46	7
Anemia	1.15	0.96-1.38	0.13	14	11
Neutropenia	1.09	0.86-1.39	0.47	28	25

Classifying lung cancer stage from health care claims with a clinical algorithm or a machine-learning approach. *First Author: Gabriel A. Brooks, Dana-Farber Cancer Institute, Boston, MA*

Background: Cancer stage is a critical determinant of cancer outcomes, however stage is not available in claims-based data sources used for evaluating real-world outcomes. We compare two new methods for classifying lung cancer stage from claims data. **Methods:** We used the linked Surveillance, Epidemiology, and End Results (SEER)-Medicare data to identify patients with lung cancer diagnosis in 2011-'12 who received chemotherapy within 6 months of diagnosis. We developed two approaches for using claims records to classify stage group (AJCC stage 1-3 vs. stage 4), using SEER stage as the gold standard. The first method was a clinical algorithm that assigned stage group based on treatment received (inclusive of surgery, radiation, and chemotherapy). The second method employed an ensemble of machine learning algorithms and analyzed an expanded set of claims-derived variables that considered treatments received, inpatient and outpatient visits, diagnosis codes, and demographic variables. We then used the Least Absolute Shrinkage and Selection Operator to select parsimonious variable sets of $\leq$ 10, 15, 20, 30, 40, and 50 variables. Classification methods were evaluated and compared on the basis of sensitivity, specificity, and accuracy, in reference to the stage 1-3 group. **Results:** The study sample included 14,743 patients with a mean age of 72.1 years. 54.6% were male. The best performing machine-learning classifier was the random forests algorithm. Sensitivity, specificity, and accuracy for the clinical algorithm were 53% (95% CI = 52-54%), 89% (88-90%), and 71% (71-72%), vs. 91% (90-92%), 89% (88-90%), and 90% (90-91%) for the random forests with 15 variables. Key variables for the random forest algorithm included secondary malignancy codes, treatments received (including type of surgery, number of radiation fractions, and specific chemotherapies), presence of COPD, and geographic region. **Conclusions:** Compared with a clinically derived algorithm, a machine-learning classifier demonstrated substantially improved sensitivity and accuracy. Improved accuracy of claims-based stage classification can support clinically relevant, real-world analyses of cancer care quality and outcomes.

6590 Poster Session (Board #415), Sat, 1:15 PM-4:45 PM

Development of a dashboard for end-of-life care at an academic hospital. *First Author: Kerin B. Adelson, Yale University, New Haven, CT*

Background: Accurate, reproducible, transparent and continuous healthcare utilization measures derived from structured EHR data may facilitate higher value cancer care at the end of life in both community and academic settings. Prior manually abstracted data from Smilow Cancer Hospital at Yale-New Haven showed high rates of chemotherapy and hospital utilization within 30 days of death. However, these data were not actionable due to the challenges with manual collection, physician attribution and date of death. **Methods:** The Yale Smilow Cancer Hospital and Flatiron Health used a commercially-available obituary source to supplement EHR data for a cohort of patients who received care at Smilow and died in 2016 - 2017. We developed an algorithm to attribute each patient to the correct oncologist based on visit frequency. We then used structured EHR data to measure rates of utilization for the following measures within 30 days of death: inpatient admission, ICU, chemotherapy and immunotherapy. Automated reports with internal benchmarks were generated to summarize resource utilization by individual physician, disease team, and practice site with patient level detail. Prior to wide scale launch across our enterprise, we provided oncologists in our community based practices feedback on use of chemotherapy in the last 30 days of life. **Results:** We found high rates of utilization at the end of life at both academic and community sites, and were able to identify outliers at the site of care, disease team and physician level. In the group that received quarterly feedback on chemotherapy in the last 30 days of life we saw a 23% improvement (see table). **Conclusions:** Performance dashboards with patient-level granularity identify performance outliers and opportunities for care improvement interventions. The reusable date of death, physician attribution and dashboard infrastructure allows measurement over time and rapid development of new measures. Efforts are underway to apply patient risk stratification to interpretation of practice variation, in addition to benchmarking against a national patient sample.

Chemotherapy in final 30 days.

Timeframe	Measure Score	N
2017 Q1	30.3% (22.3, 39.5)	109
2017 Q2	24.6% (18.2, 32.5)	138
2017 Q3	23.3% (16.2, 32.3)	103

6591 Poster Session (Board #416), Sat, 1:15 PM-4:45 PM

Adherence to oral anticancer medications after implementation of an ambulatory adherence program at a large urban academic hospital. *First Author: Marjorie Adams Curry, Georgia Cancer Center for Excellence at Grady Health System, Atlanta, GA*

Background: Oral anticancer medications (OAMs) offer convenient administration, reducing the burden of cancer treatment, but create new challenges including adherence to treatment and toxicity management. Using the Quality Oncology Practice Initiative, we identified a baseline 30% OAM adherence in the cancer center at Grady Health System, the largest public hospital in Atlanta, Georgia. To improve patient adherence, we conducted a quality improvement initiative in our ambulatory hematology and medical oncology clinics. **Methods:** The aim of this initiative was to increase OAM patient adherence by 30 percentage points. Through cause and effect analysis, significant barriers to adherence were identified including a lack of reminders and increased toxicities. This led to the development of two strategies: low cost adherence aids and a pharmacist-led OAM adherence program. Patients initiating new OAM regimens were consulted by a pharmacist for education and assistance with drug procurement. Patient education consisted of one-on-one education, drug information handouts, a treatment calendar, and a pillbox filled by the pharmacist. Patients were scheduled for mid-cycle adherence and toxicity assessments with the pharmacist. The adherence endpoint was satisfied if the patient had the drug available $\geq$80% to $<$ 120% of the days evaluated for four treatment cycles. To define the impact of this QI initiative, we collected prescription refill data prior to and after the intervention using prescription fill data and specialty pharmacy records. **Results:** Data was collected from 50 patients prior and 52 patients after implementation of the QI initiative. Five hundred and ninety-one interventions were documented including drug acquisition support, pillbox preparation, treatment calendar creation, supportive care adjustments and toxicity management. The program increased adherence from 30% to 85% in 2 years. Furthermore, the variability in adherence among patients was reduced (CI -3.24 – 156.7 *vs.* 52 – 140). **Conclusions:** A pharmacist-led adherence program combined with low cost adherence aids exceeded the goal for the adherence initiative at Grady Health System.

6592 Poster Session (Board #417), Sat, 1:15 PM-4:45 PM

The impact of the ASCO Choosing Wisely campaign for breast and prostate cancer on physician behavior. *First Author: Danielle Lee Rodin, Harvard T.H. Chan School of Public Health, Boston, MA*

Background: In April 2012, ASCO published its Choosing Wisely (CW) list of low-value services not supported by clinical evidence. The effectiveness of this campaign in changing physician behavior in oncology remains unknown. **Methods:** Retrospective analysis of breast and prostate cancer patients diagnosed from 2010-2013 and contained in the Surveillance, Epidemiology, and End Results (SEER)-Medicare linked database. Quarterly rates of imaging tests (positron emission tomography, computed tomography, bone scans) for staging in low-risk prostate cancer (T1-2a, Gleason $<$ 7, PSA $<$ 10 ng/mL) and for staging and post-treatment surveillance in early-stage breast cancer (AJCC I and II, N0, no neoadjuvant chemotherapy) was determined. Change in the proportion of patients receiving low-value tests before and after publication of the CW recommendations was evaluated using interrupted time series analysis. Tests were attributed to the specialty of the referring provider associated with the claim. **Results:** The cohorts consisted of 14,596 prostate, 43,591 breast staging, and 32,548 breast surveillance patients. Use of staging tests for prostate cancer was declining pre-CW (-0.52% per quarter) and experienced a small, but significant increase in the rate of decline post-CW to -0.79% per quarter, P = 0.0013; average utilization was 26.5% of patients pre-CW and 20.7% post. Use of surveillance imaging for breast cancer was stable pre-CW at 25.2%; it decreased post-publication by -0.61 percentage points per quarter (P $<$ 0.001) to 21.3% post. No significant change in use of breast cancer staging was observed (-0.05% per quarter, P = 0.37), with an average rate of 10%. Low-value test orders by specialty presented in Table 1. **Conclusions:** Following CW, there was a modest change in some physician behaviors toward recommendations. Further multidisciplinary efforts coupled with incentives may be needed to educate providers on judicious use of imaging.

Distribution of low-value tests by specialty.

	Surgeons	Radiation Oncologists	Medical Oncologists	Primary Care Providers	Other/ Unknown
Prostate staging	63.9%	4.3%	1.6%	16.9%	13.2%
Breast staging	44.7%	0.6%	17.8%	24.6%	12.4%
Breast surveillance	8.3%	5.0%	25.0%	40.6%	21.1%

6593 Poster Session (Board #418), Sat, 1:15 PM-4:45 PM

Use of hypofractionated radiotherapy for early stage breast cancer after implementation of evidence-based clinical guidelines. *First Author: Santosh Gautam, HealthCore, Inc., Wilmington, DE*

Background: Evidence-based guidelines have endorsed use of hypofractionated whole breast irradiation (WBI), a shorter course regimen delivered over 3-4 weeks instead of conventional WBI over 5-6 weeks, for certain early stage breast cancer patients. In 2016, health insurer Anthem updated its clinical guidelines making hypofractionated WBI the standard for eligible members in its fully-insured plans. This change did not apply to self-insured groups allowing these members to serve as an internal control. The objective of the study was to evaluate the impact of this guideline change on adoption of hypofractionated WBI. **Methods:** We used Anthem claims data to identify women with incident breast cancer diagnosis followed by lumpectomy and subsequent WBI during 2015-2016. We further retained patients guideline-endorsed for hypofractionated WBI, i.e. those aged 50 or older, without prior chemotherapy or lymph node involvement. We defined hypofractionated WBI as 11-24 fractions (3-5 weeks of WBI) and conventional WBI as 25-40 (5-8 weeks of WBI). We compared pre-and post-intervention (year 2015 vs 2016) hypofractionated WBI rates between members in fully insured plans (intervention group) and members in other plans (comparison group) using a regression-adjusted difference-in-difference (DID) analysis controlling for age and comorbid conditions. **Results:** Compared to patients in comparison group (N = 2,333), those in intervention group (N = 728) were older (mean age 63.1 vs 61.4; p $<$ .001) and had more comorbid conditions (mean Deyo-Charlson index 0.74 vs 0.60; p = 0.002). The rate of hypofractionated WBI increased from 53% in pre- to 68% post-intervention period for intervention group, an increase of 28%. In contrast, the rate changed from 58% to 63%, an increase of just 9%, in comparison group. The adjusted DID results suggested that change in guidelines increased the hypofractionated WBI adoption rate by 9% (p = 0.035). **Conclusions:** The changes in health plan guidelines resulted in higher rates of hypofractionated WBI adoption. Health plans could play an important role in accelerated adoption of evidence-based guidelines.

6594 Poster Session (Board #419), Sat, 1:15 PM-4:45 PM

***CYP2C19*-guided voriconazole prophylaxis in neutropenic AML patients.** *First Author: James Kevin Hicks, Moffitt Cancer Center, Tampa, FL*

Background: Acute myeloid leukemia (AML) patients who have prolonged neutropenia are at increased risk of morbidity and mortality due to invasive fungal infections. Voriconazole (VCZ), an effective antifungal prophylactic, is metabolized by the polymorphic CYP2C19 enzyme. Approximately 25% of individuals are genetically predicted to be CYP2C19 rapid metabolizers, thus at increased risk of breakthrough fungal infections due to low VCZ concentrations. We implemented a quality improvement pilot utilizing *CYP2C19* genotype to optimize prophylactic VCZ dosing. **Methods:** AML patients with prolonged neutropenia are eligible for *CYP2C19* genotyping (Luminex xTAG CYP2C19 Kit v3). Phenotypes are assigned per Clinical Pharmacogenetics Implementation Consortium guidelines. *CYP2C19*-guided recommendations for our quality improvement pilot are as follows: avoidance of VCZ in ultrarapid metabolizers, VCZ 300 mg twice daily (BID) for rapid metabolizers, and VCZ 200 mg BID for all other phenotypes. Therapeutic drug monitoring (TDM) is performed at the discretion of the medical team (goal trough concentration of 1-5.5 mcg/ml). **Results:** To date, 193 AML patients have undergone *CYP2C19* genotyping; 3 (1.6%) ultrarapid, 50 (25.9%) rapid, 78 (40.4%) normal, 55 (28.5%) intermediate, and 7 (3.6%) poor metabolizers were observed. 154 patients (79.8%) received VCZ for prophylaxis, 11 (5.7%) for treatment, and 28 (14.5%) did not receive VCZ. Of the 154 patients receiving prophylactic VCZ, 137 (89%) were dosed per *CYP2C19*-guided recommendations. Pre-intervention (VCZ 200 mg BID) and post-intervention (VCZ 300 mg BID) VCZ trough concentrations were compared. Only 36.4% (4/11) of CYP2C19 rapid metabolizers receiving VCZ 200 mg BID achieved the goal trough concentration, whereas 75% (21/28) of rapid metabolizers receiving VCZ 300 mg BID achieved the goal trough concentration. *CYP2C19*-guided VCZ dosing resulted in trough concentrations in the target range for 70.1% (47/67) of all patients. **Conclusions:** Implementation of *CYP2C19* genotyping to guide VCZ prophylactic dosing is feasible, with 70.1% of all patients having a VCZ goal trough concentration. Future analysis will determine if *CYP2C19*-guided VCZ dosing prevents breakthrough fungal infections.

6595 Poster Session (Board #420), Sat, 1:15 PM-4:45 PM

Does training oncologists to have goals of care discussions affect healthcare utilization among patients with advanced cancer? *First Author: Nina A. Bickell, Mount Sinai School of Medicine, New York, NY*

Background: Aggressive treatment near the end of life is a measure of poor quality care. Goals of Care (GoC) discussions may affect healthcare utilization among patients with advanced cancer. We coached oncologists to improve communication skills (CS) & report the effect of CS coaching on hospital, ER, hospice & ICU admission in the last month of life. **Methods:** We randomized solid tumor oncologists at 4 academic, community, municipal and rural hospitals to participate in a RCT of communication skills training & recruited their newly diagnosed advanced cancer patients with $<$ 2 year prognosis. Ten CSs were assessed via checklist review of audiotaped visits. Charts were abstracted, patients or their caregivers were surveyed at 6 months to assess utilization of: chemotherapy, ICU, hospitalizations, ER visits and hospice in the last 30d of life and over the 6 months enrolled in the study. A GoC discussion included discussion of prognosis, treatment preferences, and what's important to patients given their cancer diagnosis. We enrolled 22 of 25 eligible oncologists (88%). 263 patients were recruited & surveyed to assess whether a GoC discussion occurred. 250 (95%) had charts abstracted and were resurveyed at 6 months to assess utilization at other hospitals. **Results:** Patients' mean age was 63 yrs (20-89), 60% male, 53% white, 29% black & 19% Latino. 35 patients (13%) died within 6 months of baseline survey with no difference between patients of intervention (INT) or control (CNTL) oncologists. Compared to CNTLs, INT oncologists' skills improved with coaching (1.63 vs -0.09; p = .04). 43% INT and 46% CNTL patients reported a GoC discussion. The average rate of hospitalization/ pt = 0.32 (0-3) and ER visits = 0.44 (0-4) with no difference between INT & CNTL. Rates of aggressive treatment in the last 30d of life varied: chemotherapy = 21%; ICU stay = 7% with no difference between INT & CNTL patients. Hospice enrollment occurred 2 weeks prior to death; no difference in INT vs CNT (13.5d vs 14d). **Conclusions:** Despite improving oncologists' communication skills to conduct GoC discussions, there was no impact on rates of hospitalization, receipt of aggressive treatments or enrollment in hospice at the end of life. Clinical trial information: NCT02374255.

6596 Poster Session (Board #421), Sat, 1:15 PM-4:45 PM

Improving documentation of pain and constipation management within the cancer center of a large public healthcare network. *First Author: Giselle Dutcher, Department of Medicine, Emory University School of Medicine, Atlanta, GA*

Background: Cancer patients commonly suffer from pain and constipation, and a high number of patients have inadequate control of these symptoms. At the Cancer Center for Excellence at Grady Health System, a large public healthcare network in Atlanta, baseline QOPI measures for pain and constipation documentation were below benchmark levels. We conducted a quality improvement (QI) initiative to improve the management of pain and constipation. **Methods:** Given the low baseline rates of QOPI documentation for pain (58%) and constipation (60%) assessment, we aimed for a 20-percentage point increase in documentation of these measures. Cause and effect analysis identified causal factors. This led the team to develop a new note template that automatically integrates pain and constipation assessment data from the nursing note into the practitioner's documentation. We developed a new process in the electronic medical record (EPIC) to link appropriate orders with the pain and constipation plan. Mandatory use of the new note began in June 2017. We reviewed documentation pre- (12 months) and post- (4 months) intervention. **Results:** Integrating a nursing assessment into the note for the practitioner increased pain score documentation from 66% to 87% and pain management from 47.2% to 83.2%. Similarly, documentation of constipation assessment increased from 18.9% to 82.8% and constipation management increased from 11.78% to 75%. This QI intervention improved pain control by the 3rd visit from 47% to 57%. This strategy also reduced emergency department (ED) visits and hospitalizations from 21% to 9%. **Conclusions:** Using a standardized visit template and mandated assessment of constipation and pain lead to an increase greater than the 20% goal for documentation of these symptoms. This intervention resulted in improved pain and constipation control. This strategy suggests a reduction in ED visits.

6597 Poster Session (Board #422), Sat, 1:15 PM-4:45 PM

Does training oncologists to have goals of care discussions increase and improve the quality of GoC discussions with advanced cancer patients? *First Author: Nina A. Bickell, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Advanced cancer patients often have a poor understanding of the incurability of their cancers and this correlates to higher rates of aggressive treatment near end of life. Goals of Care (GoC) discussions may affect patients' decisions about aggressive treatment near end of life. We coached oncologists to improve communication skills and assessed its impact on prevalence and quality of GoC discussions. **Methods:** At an academic, community, municipal and rural hospital, we recruited & randomized solid tumor oncologists & their newly diagnosed advanced cancer patients with $<$ 2 year prognosis. Prior to and after completing 4 coaching sessions, a post-imaging visit was audiotaped and reviewed by VitalTalk trained specialists to assess oncologists' communication skills. Consented patients were surveyed after their 3 month post-imaging visit & GoC discussions defined as: cancer treatment preferences, what's important to you in life given your diagnosis and prognosis. **Results:** We enrolled 22/25 eligible oncologists (88%) & 265 patients. On average, doctors were 44 yrs old (32-66) & in practice 14.5yrs (5-40). There was no significant difference between intervention (INT) and control (CNTL) oncologists' prior communication skills training (58% v 56%; p = 0.80) & comfort having GoC discussions (58% v 56%; p = 0.80). On average, CNTL physicians had no change in the number of demonstrated skills (5.45 to 5.36/10); INT physicians increased from 6.6 to 8.3/10 skills (p = 0.04). Patients' mean age was 63 yrs (20-89), 60% male, 52% white, 30% black & 19% Latino. Overall, 61% of patients reported their treatment's goal was to cure their cancer; 40% reported cure to be likely. 49% had a complete GoC discussion (48% INT v 51%; p = 0.61). 65% of patients reported their oncologist talked about their GoC, "the very best" they could imagine (63% INT v 68% CNTL; p = 0.39). 51% did not report a GoC discussion with no difference between INT (52%) & CNTL (49%) patients (p = 0.61). **Conclusions:** Using a coaching model to teach oncologists' communication skills improved skills to carry out a GoC discussion but did not increase rates of GoC discussions among advanced cancer patients with $<$ 2 year life expectancy. Clinical trial information: NCT02374255.

6598 Poster Session (Board #423), Sat, 1:15 PM-4:45 PM

Use of QT interval prolonging drugs (QT drugs) and electrocardiogram (ECG) monitoring in patients (pts) receiving first-line anti-cancer systemic therapy (tx): A population-based analysis. *First Author: Rossanna C. Pezo, Sunnybrook Health Sciences Centre, Odette Cancer Centre, Toronto, ON, Canada*

Background: QT interval prolongation, measured on ECG, is a known toxicity of many drugs used in oncology and can lead to serious arrhythmias. To our knowledge, there are no published studies investigating ECG use in pts on standard systemic tx involving QT drugs. **Methods:** All cancer pts ≥ 66 years diagnosed in 2005-2011 in the Ontario Cancer Registry were linked to population-based administrative databases to ascertain pt demographics, comorbidities, systemic tx and ECG use. The Ontario Drug Benefit Program database was used to identify prescription QT drug use (as per CredibleMeds.org classification). Univariable and multivariable analyses were used to examine factors associated with ECG use within 30 days of systemic tx initiation. **Results:** A total of 59,484 pts (median age 74; 48% women) were included. Common cancers were breast (23%), prostate (22%), lung (10%) and colon (9%). Prior diagnoses included hypertension (56%), diabetes (24%), coronary artery disease (CAD; 24%), and heart failure (HF; 9%). Among pts on at least 1 QT drug (n = 48,236; 81%), the majority (n = 41,727; 87%) received a prescription within 30 days of systemic tx initiation, commonly for anti-emetics (n = 18,232; 44%). Overall, only 27% pts on QT drugs had an ECG within 30 days of systemic tx initiation; ECG use was low even among pts with CAD (35%), HF (42%), pts on ≥3 concurrent QT drugs (37%) and pts on anti-emetic (30%) and *anti-cancer* (21%) QT drugs. On multivariable analysis, adjusting for age, sex, comorbidities, rural setting and cancer type, ECG use was associated with recent cancer diagnosis (2011 versus 2005; OR = 1.37, 95% CI 1.26-1.49), Charlson score ≥1 (OR = 1.22; 95% CI 1.15-1.29) and multiple QT drugs (OR = 1.15 per each additional QT drug, 95% CI 1.12-1.17). Use of anti-emetic (OR = 0.93; 95% CI 0.88-0.99) and *anti-cancer* QT drugs (OR = 0.74, 95%CI 0.70-0.79) were paradoxically associated with fewer ECG use. **Conclusions:** Our study highlights common use of QT drugs and under-use of ECG in cancer pts at risk of arrhythmia. Since ECG is an inexpensive, non-invasive and widely available test, it should be used routinely for monitoring the QT interval in such pts.

6599 Poster Session (Board #424), Sat, 1:15 PM-4:45 PM

Implementation of dietary education within a multidisciplinary team approach to improve treatment accuracy and efficiency in prostate cancer external beam radiation therapy. *First Author: Taylor L Evans, James J. Peters VAMC, Bronx, NY*

Background: Prostate cancer is the most common cancer in the Veterans Health Administration. Radiation is an important treatment option for prostate cancer patients. Imaging is done before each daily radiation treatment to ensure the radiation beam is aimed accurately. Imaging can be inaccurate due to excess gas or stool in the rectum, which alters the treatment field and leads to delays in the daily treatment schedule, increased radiation exposure due to re-imaging, repetitive staff treatment delivery interventions, and an unsatisfactory veteran experience. **Methods:** A quality improvement project utilizing A3.9 Box Process Improvement Methodology (problem solving template) was undertaken to address identified gastrointestinal concerns hindering daily treatment. A dietitian integrated services into the radiation oncology clinic by providing dietary education and counseling to avoid gas-producing foods and manage bowel regularity for prostate cancer patients. Daily images were reviewed for accuracy. For 3 months prior to intervention, we examined daily treatment images and documented any interruption in treatment delivery from gas or stool in the rectum as a nutrition-related defect. Initial data analysis revealed that 62 of 195 (31.79%) daily treatment deliveries experienced nutrition-related defects. **Results:** As a result of changing the radiation therapy process to include dietary education to patients, we experienced a 53% reduction rate in nutrition-related defects (from 31.79% to 14.87%). Calculated cost avoidance showed an annual savings of approximately $19,300 with implementation of a multidisciplinary approach. A total of 120 daily treatment visits and 90 patient treatment hours can be saved annually with this approach. **Conclusions:** This project improved overall clinic function by implementing a multidisciplinary approach to prostate cancer radiation oncology care, increased patient's satisfaction, reduced excess radiation exposure, and improved department efficiency.

6600 Poster Session (Board #425), Sat, 1:15 PM-4:45 PM

Prevalence of HIV, hepatitis B virus (HBV), and hepatitis C virus (HCV) among newly diagnosed cancer patients treated in academic and community oncology practices: SWOG S1204. *First Author: Scott David Ramsey, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: Universal screening of newly diagnosed cancer patients for HIV, HBV and HCV viruses is not routine in oncology practice. Amid concerns about viral reactivation and adverse outcomes during antineoplastic therapy, experts disagree about whether testing should be routinely performed. In this study we estimated the prevalence of HIV, HBV, and HCV infection among persons with newly diagnosed cancer. **Methods:** This multicenter, prospective cohort study included 9 academic and 9 community SWOG oncology institutions. Eligible patients included those with any malignancy presenting to clinic within 120 days after cancer diagnosis. Patients either provided documentation of known viral status or were tested for HIV, HBV or HCV upon enrollment. **Results:** In total, 3,092 patients were registered. The median age of the cohort was 61 years old, most were female (60%), 18% were black, 18% were Hispanic and 3% were Asian. Screened patients had similar clinical and demographic characteristics to those registered. Infection rates adjusted for cancer type were 9.7% for HBV, 2.8% for HCV and 1.4% for HIV. At clinic presentation, observed viral status was previously diagnosed for 17% of HBV patients, 69% of HCV patients and 94% of HIV patients. Cancers that had the highest prevalence per infection (HBV, HCV) included liver (22%, 18%), lung cancer (13%, 5%), head and neck cancer (13%, 5%) and non-colorectal GI cancers (15%, 1%). HBV risk was highest in those who had sexual contact with HIV+ person(s) or were infected with HIV or HCV. HCV risk was highest in those who injected drugs or were tested because they had on-the-job blood exposure, injection drug use or transfusion before 1992. **Conclusions:** The overall prevalence of HBV and HCV in this population of cancer patients is substantially higher than the general population (3.9% and 1.3%, respectively). Much of the HBV and HCV infection detected in this study was previously undiagnosed, suggesting that screening may be desirable. The low rate of previously unknown HIV infection suggests routine testing is unnecessary except in cancers highly associated with HIV. Funding: NIH/NCI CA189974, CA180888, CA180819

6601 Poster Session (Board #426), Sat, 1:15 PM-4:45 PM

Identifying and interpreting actionable molecular alterations from next-generation sequencing results in the community: A Sarah Cannon molecular cancer conference. *First Author: Holli Hutcheson Dilks, Sarah Cannon Research Institute, Nashville, TN*

Background: Next-generation sequencing (NGS) data can often be difficult to interpret and act upon for treating medical oncologists. Sarah Cannon developed a Molecular Cancer Conference (MCC) in May 2017 at a community clinic in Chattanooga, TN with the goal of helping medical oncologists identify and interpret molecular alterations from NGS results obtained in routine clinical practice. Herein, we report the workflow and effectiveness of the MCC in identifying actionable results and guidance in care. **Methods:** Molecular profiles from one community medical oncology office were reviewed by a MCC committee over a six month pilot period. The committee – made up of medical oncologists and research staff at the site, and a human geneticist, cancer cell biologist, and clinical pharmacologist linked in remotely from Sarah Cannon Research Institute in Nashville, TN via web-conference. The MCC met every 2 weeks to review all tissue- and blood-based NGS results from the interim. Mutations were analyzed using public databases and published literature; and patient diagnosis and clinical trial molecular inclusion/exclusion criteria were used to guide therapy and clinical trial recommendations, as well as approved therapies. **Results:** From 175 reports, 3608 molecular alterations were detected (avg. = 20.6 mut/pt; including VUSs) by commercially available NGS labs. Clinical trials were discussed for 148 patients (85%), and 26 patients (15%) were enrolled on clinical trials. Uncommon alterations were identified including a *FGFR2-VCL* fusion in cholangiocarcinoma, *ERBB2* amplifications in NSCLC, and two unique *ERBB2* VUSs in a HNSCC. Each of these mutations was treated with a targeted therapy as part of a clinical trial protocol. **Conclusions:** Sarah Cannon's MCC was established to review and analyze patient molecular profile reports for community-based medical oncologists. Utilization of the MCC resulted in patients being screened for and enrolled on clinical trials. These findings highlight the feasibility and impact of having an expert committee review complex results and provide scientific advice to help guide care for patients in the community.

6602 Poster Session (Board #427), Sat, 1:15 PM-4:45 PM

A nationwide analysis of palliative care service utilization in hospitalized metastatic cancer patients. *First Author: Kaushal Parikh, New York Medical College, Valhalla, NY*

Background: ASCO guidelines recommend palliative care consultation (PC) to patients with advanced cancer to improve quality of life and overall survival. However, limited data are available on contemporary trends in PC utilization in hospitalized metastatic cancer patients. **Methods:** We used the 2005-2014 Unites States National Inpatient Sample to identify all hospitalizations in adult patients with a primary or secondary discharge diagnosis of lung, prostate, breast, or colorectal cancers, with documented metastasis. Multivariable logistic regression models accounting for the complex survey design were used to analyze associations of PC with various cancer related complications, comorbidities, and patient and hospital demographics. **Results:** Of the 3,040,740 cases included in the study, 289,600 (9.5%) had PC. Median ages of patients with prostate, lung, colorectal, and breast cancers were 76, 67, 65, and 61 years, respectively. There was a 550% increase in PC utilization between 2005 and 2014 (2.7% to 17.5%; $P < 0.001$). While the utilization rate was highest with metastatic lung cancer (3% in 2005 to 20.2% in 2014; $P < 0.001$), increase in utilization was highest for colon cancer (577%; 2.2% in 2005 to 14.9% in 2014; $P < 0.001$). Overall, cancer related pain (adjusted Odds ratio (aOR) 2.35, 95% confidence interval (CI) 2.26-2.45; $P < 0.05$) and failure to thrive (aOR 2.19, 95% CI 2.09-2.29; $P < 0.05$) were strongly associated with PC referrals. Age $>$ 65 years (aOR 1.56, 95% CI 1.46-1.67; $P < 0.05$), respiratory failure (aOR 2.10,95% CI 2.03-2.16; $P < 0.05$), and sepsis (aOR 1.12, 95% CI 1.078-1.16; $P < 0.05$) were also independently associated with PC. PC was more likely to be utilized in teaching hospitals (aOR 1.25, 95% CI 1.16-1.34; $P < 0.05$), large-sized hospitals (aOR 1.25, 95% CI 1.13-1.37; $P < 0.05$), and west coast hospitals (aOR 1.31, 95% CI 1.17-1.47; $P < 0.05$). **Conclusions:** Despite a significant rise between 2005 and 2014, palliative care services are still underutilized for hospitalized advanced cancer patients in the United States. Cancer related pain and failure to thrive were strongly associated with PC utilization. Regional and hospital based variations exist in PC utilization in patients with metastatic tumors.

6603 Poster Session (Board #428), Sat, 1:15 PM-4:45 PM

TelePsychiatry for cancer patients undergoing active treatment. *First Author: Christian Otto, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Numerous studies have demonstrated the effectiveness of telepsychiatry in non-cancer related disease; however, there are limited reports of telepsychiatry for cancer patients under active treatment. The MSK Counseling Center initiated a telepsychiatry program for patients residing near MSK regional care sites with limited counseling services. **Methods:** Patients were identified who lived within the catchment area of two MSK regional sites in Westchester County and Suffolk County, NY. Patients were invited to participate who had previously been seen in-person who were scheduled for psychotherapy follow-up or medication management. Data on telepsychiatry visits performed by 5 psychiatrists was collected over a 2-year period beginning in January 2016. Telepsychiatry sessions took place between the patient at the MSK regional site and the psychiatrist at the Manhattan Counseling Center. Sessions were supported by Cisco Jabber Movi videoconferencing software and high definition videoconferencing equipment. Patients were asked to fill out a technology acceptability questionnaire post-visit. **Results:** Thirty-eight patients (14 males; 56.3 $\pm$ 10.8 years) with 19 cancer diagnoses, and 26 psychiatric diagnoses (1.8$\pm$ 0.9/patient) completed 159/187 telepsychiatry visits (cancellation rate 15.0%). Each patient had an average of 4.2$\pm$5.8 visits. Anxiety disorder-unspecified, adjustment disorder with mixed anxiety and depressed mood, and major depressive disorder were the three most common diagnoses. Fifty percent (N = 19) of patients completed the questionnaire. Most respondents (96.0%) highly agreed or agreed that telepsychiatry visits made it easier for them to obtain care, and that the quality of care was the same as in-person. The majority of patients who completed the questionnaire underscored the benefits of avoiding lengthy travel to Manhattan for appointments, the ease of scheduling, decreased appointment wait time, and the similarity to in-person visits. **Conclusions:** Telepsychiatry has high acceptability among cancer patients and offers a means of providing care to established patients who are stable, while decreasing the stress encountered from frequent travel, missed work, and associated caregiver requirements.

6604 Poster Session (Board #429), Sat, 1:15 PM-4:45 PM

Utilization of telemedicine at two high-volume cancer care organizations. *First Author: Rob Williams, Ontario Telemedicine Network, Toronto, ON, Canada*

Background: The Ontario Telemedicine Network (OTN) in Support of Cancer Care Ontario (CCO), and Memorial Sloan Kettering (MSK) are leveraging telemedicine and digital health care to improve patient/provider satisfaction, care coordination, and clinical outcomes, while decreasing costs. **Methods:** Data on patient telemedicine services and provider activity was reviewed, in addition to implementation challenges and lessons learned. New virtual services were outlined regarding their ability to enhance patient accessibility and clinical effectiveness. **Results:** OTN has enabled 268 CCO sites across the 14 Ontario Regional cancer centers which have generated 20,138 cancer telemedicine sessions in 2016/17. Prostate, lung, breast, and colorectal cancers had the highest telemedicine utilization. Telemedicine sessions were employed by 20% (N = 40) of provincial radiation oncologists, and 20% (N = 34) of medical oncologists. In 2015, telemedicine supported the delivery of oral and intravenous chemotherapy in 1,269 cases and facilitated 368 palliative care visits. Telemedicine saved patients: 6.4 million km of driving, 64K hours of travel time, and over $4.7 million in travel and accommodation costs. MSK sees 19K new actively treated patients annually, 76% access the patient portal to view appointment notifications, complete patient assessments, review lab results, retrieve learning materials, send and receive secure messages from providers, and review billing. Patient assessments include PRO-CTCAE daily symptom surveys, with symptom alerts, to track recovery in post-surgical patients. TeleGenetics at MSK has delivered 3416 virtual visits to patients and family members at four regional locations, telepsychiatry has supported 160 sessions to 3 regional sites; and an inpatient fall prevention program using video monitoring of a patient's movements has decreased falls 42% in GI and 34% in neurology cancer inpatients while decreasing patient attendant costs $393K. **Conclusions:** Utilization of telemedicine and digital care platforms among cancer patients and providers is steadily increasing due to convenience, significant cost savings, high satisfaction rates, increased care coordination, and improved clinical outcomes.

6605 Poster Session (Board #430), Sat, 1:15 PM-4:45 PM

The effect of supervised, individualized exercise on cost savings during cancer treatment. *First Author: Karen Y Wonders, Maple Tree Cancer Alliance, Dayton, OH*

Background: Research indicates that endurance exercise training is helpful in attenuating the deleterious effects of cancer treatments. However, nationally less than 5% of patients are ever referred to a cancer exercise program. Cost is a barrier to these programs, as they often are not reimbursable under most insurance plans. Therefore, the purpose of this investigation was to determine if exercise training during cancer treatment helped to minimize side effects and reduce health care costs. **Methods:** This was a retrospective, two-group study which ascertained the protective effect of an exercise-training program during cancer treatment. Medical records were reviewed to determine outcome data for length of hospital stays, hospital readmits, ER visits, treatment compliance, fatigue, and anxiety/depression related to oncology conditions. Patients were excluded if they had pre-existing conditions prior to treatment. Individuals in the exercise group (EX, n = 672) completed 12 weeks of prescribed, individualized exercise. Individuals in the sedentary group (SED, n = 728) did not participate in an exercise program during treatment. **Results:** Patients in the EX group had significantly lower reports of fatigue, pain, cardiac problems, depression, and anxiety than their SED group counterparts ($p < 0.05$). The EX group tolerated their treatment significantly better than the SED group ($p < 0.05$). Most notable, the EX group had a significantly lower number of ER visits, 30-day readmits, and length of stay ($p < 0.05$). **Conclusions:** These data point to a protective effect of individualized exercise that translated to improved patient outcomes and cost savings for the payer, provider, and patients, alike.

6606 Poster Session (Board #431), Sat, 1:15 PM-4:45 PM

A proportional comparison of cancer burden and patient advocacy organization (PAO) funding by histology demonstrates many underfunded histologies. *First Author: Suneel Deepak Kamath, Northwestern University Feinberg School of Medicine, Division of Hematology/Oncology, Chicago, IL*

Background: PAOs in oncology are vital in funding research for rare cancers, young investigators and innovative projects, but some histologies may be underfunded relative to their burden. This study examined the alignment of cancer burden by histology with PAO funding for each histology to raise awareness of areas of unmet need. **Methods:** The GuideStar database was used to find all cancer PAOs with > $5 million (M) in annual revenue (AR) using NTEE codes and 165 cancer-related search terms. Care delivery PAOs were excluded. PAOs were classified by the histology they support. AR was obtained from IRS Form 990s for each PAO. Total annual revenue (TAR) per histology was calculated by adding ARs for each PAO in that histology. Cancer burden based on annual incidence, deaths and person-years of life lost (PYLL) was obtained from SEER data. Comparison of TAR with incidence, deaths and PYLL of each histology was done using descriptive statistics. **Results:** 125 PAOs with TAR of $6.4 billion were included. 64 (51%) were histology agnostic. Cancers with the most PAOs were pediatric (14, 11%), breast (13, 10%), leukemia (4, 3%) and lung (4, 3%). There were no PAOs with AR > $5 M for esophageal, gastric, kidney or bladder cancers. Histology-agnostic PAOs had $5 billion (78%) of TAR. Cancers with largest TARs were breast ($460M, 7%), pediatric ($207M, 3%), leukemia ($201M, 3%) and lymphoma ($145M, 2%). The ratios of TAR by histology vs. incidence, deaths and PYLL are shown in Table 1. PAOs in pediatric cancer, breast cancer, leukemia and lymphoma had the highest ratios in all 3 metrics. Colon, liver and uterine cancer PAOs had the lowest ratios. **Conclusions:** Cancer PAOs generate substantial AR that complements government research funding. Cancer PAOs overall can be better funded, especially PAOs in GI, GU and gynecologic cancers to drive research and awareness.

	Breast	Colon	Uterine	Leukemia	Liver	Lymphoma	Lung	Melanoma	Ovary	Pancreas	Pediatric	Prostate
TAR (millions $)	460	18	5	201	6	145	92	14	23	58	207	76
TAR/Incidence ($)	1804	133	87	3241	115	1802	412	160	1012	1087	13,586	472
TAR/Deaths ($)	11,207	359	490	8219	185	6840	588	1433	1614	1354	115,901	2847

6607 Poster Session (Board #432), Sat, 1:15 PM-4:45 PM

Duration of physician-industry relationships and prescribing changes in oncology. *First Author: Aaron Philip Mitchell, The University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Physicians who accept payments from a pharmaceutical company are more likely to prescribe that company's cancer drug[s]. Whether long-term physician-industry relationships are more likely than intermittent relationships to result in practice changes is unknown. **Methods:** Open Payments data, containing industry-physician financial transactions, was linked to Medicare Part D prescription drug claims for 2013-2015. We identified physicians who treated each of 4 cancer types which had multiple orally-administered treatment options: renal cell (axitinib, everolimus, pazopanib, sorafenib, sunitinib), lung (erlotinib, afatinib), CML (dasatinib, nilotinib), and prostate (abiraterone, enzalutamide). We used modified Poisson regression to test if the number of years (either 1, 2, or 3) in which a physician received payments was associated with increased prescribing of the paying company's cancer drug in 2015. We also tested whether physicians at NCI-designated cancer centers were more likely to receive industry payments. **Results:** The physician cohort sizes were: RCC, 674; lung, 966; CML, 367; prostate, 1,483. Controlling for physician characteristics including practice size, prescribing volume, and total dollar amount received, physicians who received payments in all 3 years (vs. 1 year) were more likely to use the paying company's drug within RCC (RR:1.69, 95%CI 1.32-2.17) and lung cancer (RR: 1.42, 95%CI 1.15-1.77), but not CML (RR:1.13, 95%CI 0.94-1.35) or prostate cancer (RR: 0.93, 95%CI 0.85-1.01). Results were similar comparing physicians who received payments in 3 years vs. 2 years: RCC RR:1.53, 95%CI:1.21–1.94; lung RR: 1.12, 95%CI:0.93–1.35; CML RR:1.13, 95%CI 0.94–1.35; prostate RR: 0.93, 95%CI:0.85–1.01. Physicians at NCI institutions were less likely to have received any industry payments during the study period (RR:0.70, 95% CI:0.61-0.80). **Conclusions:** Longer-term industry relationships may be associated with greater changes in drug prescribing than time-limited ones. Conflict-of-interest policies and disclosures may be more informative if specifying duration of industry relationships. This study was limited by a short time range, and lack of payment records prior to 2013.

6608 Poster Session (Board #433), Sat, 1:15 PM-4:45 PM

What role does the patient perspective play in determining access to innovative therapies? *First Author: Clare Frances Jones, PRMA Consulting Ltd, Fleet, United Kingdom*

Background: The 21st Century Cures Act 2016 (21st CCA) requires the FDA to do more to incorporate patient perspectives into their decision-making on products, particularly patients' experience of disease and effects related to treatment. This experience may be captured using patient-reported outcome measures (PROMs). We sought to understand how patient-relevant outcomes beyond survival were considered in evaluations of oncology drugs by regulators, oncology societies, and payers (health technology assessment [HTA] agencies), and how this might change in future. **Methods:** We reviewed EMA summaries of product characteristics and FDA package inserts of products approved in 2017 plus documents from completed or ongoing assessments by national HTA agencies in England, France, and Germany for reference to PROMs, quality of life, or symptoms of disease. PubMed and Google were searched for published ASCO value framework or ESMO MCBS v1.1 scores. Clinicaltrials.gov was searched to identify PROMs included in Phase 2 or 3 industry-sponsored trials initiated between 2013-2017. **Results:** None of the 16 FDA labels included any mention of PROMs or patient-reported symptom measures (other than AEs). Of 13 products in Europe, 7 reported PROMs or symptom measures. Few HTAs have been completed; documentation for 7 products (NICE 4; TC 1; IQWiG 4; G-BA 2) referred to measures of interest. No systematic scoring of newly approved products using ASCO was identified; ESMO MCBS v1.1 scores are available within updated treatment guidelines. Of 70 industry-sponsored Phase 2 or 3 trials, 68 reported including a PROM, the most commonly used were EORTC-QLQ-C30 (24% of trials) and associated disease-specific modules. Other pan-tumor PROMs used in > 1 trial included EQ-5D (23%) and PROMIS (4%) or PRO-CTAE (4%) (and only since 2015). Results will be updated in May 2018 **Conclusions:** To date, the 21st CCA appears to have had no impact on FDA approvals. However, recent inclusion of PRO-CTCAE or PROMIS in trials may be related to 21st CCA. In Europe there is wider consideration of PROMs. The use of these instruments and other patient-relevant measures of benefit by stakeholders determining access to innovative therapies should be monitored and encouraged further.

6609 Poster Session (Board #434), Sat, 1:15 PM-4:45 PM

Cost-effectiveness analysis of brentuximab vedotin with chemotherapy in newly diagnosed stage III/IV Hodgkin lymphoma. *First Author: Scott F. Huntington, Yale University, New Haven, CT*

Background: In a recent randomized, open-label trial (ECHELON-1), brentuximab vedotin combined with doxorubicin, vinblastine, and dacarbazine (A+AVD) decreased the risk of progression in adults diagnosed with stage III/IV Hodgkin lymphoma (HL) compared to standard bleomycin-containing chemotherapy (ABVD). However, the cost-effectiveness of incorporating brentuximab vedotin into the first-line setting is unknown. **Methods:** We constructed a Markov decision-analytic model to measure the costs and clinical outcomes for A+AVD compared to ABVD as first-line therapy in a cohort of patients with stage III/IV HL. Progression-free survival and transition probabilities were estimated from ECHELON-1 by fitting parametric survival distributions. Centers for Medicare & Medicaid Drug Pricing Files from December 2017 were used for drug costs (106% of average sales price). Additional expenditures and clinical utilities were estimated from literature. Lifetime direct health care costs, quality-adjusted life-years (QALYs), and incremental cost-effectiveness ratios (ICERs) were calculated for A+AVD compared with ABVD from a societal perspective within the United States. Our model was also used to estimate price reductions of brentuximab vedotin that would achieve more favorable cost-effectiveness under indication-specific pricing. **Results:** A+AVD was associated with an improvement of 0.48 QALYs compared to treatment with standard ABVD. However, incorporating brentuximab vedotin into first-line therapy led to significantly higher lifetime costs ($334,863 versus $193,780), causing the ICER for A+AVD compared with ABVD to be $292,266/QALY. If indication-specific pricing was implemented, price reductions of brentuximab vedotin by 40% to 60% in the first-line setting would produce ICERs of $100,000 to $150,000/QALY. **Conclusions:** Substituting brentuximab vedotin for bleomycin during first-line therapy for stage III/IV HL is unlikely to be cost-effective under current drug pricing. Should indication-specific pricing be implemented, discounting brentuximab vedotin in the first-line setting by 40% to 60% could reduce ICERs to widely acceptable values.

6610 Poster Session (Board #435), Sat, 1:15 PM-4:45 PM

Cost-effectiveness of chimeric antigen receptor T-cell therapy in pediatric relapsed/refractory acute lymphoblastic leukemia. *First Author: Reith Sarkar, University of California, San Diego School of Medicine, La Jolla, CA*

Background: Chimeric antigen receptor T-cell (CAR-T) therapy is a new class of cancer therapy with promising results, but comes at a high upfront cost. We sought to evaluate the cost-effectiveness of CAR-T therapy among pediatric patients with relapsed/refractory (r/r) acute lymphoblastic leukemia (ALL). **Methods:** We built a microsimulation model for pediatric patients with r/r ALL who received either CAR-T therapy or standard of care chemotherapy. Outcomes modeled included costs, quality of life (health utility), treatment complications, and survival, all of which were estimated from published literature. Long-term survival beyond the time-frame of clinical trial data was estimated using Social Security actuarial life-tables adjusted with standardized mortality ratios. Cost-effectiveness was measured with the incremental cost-effectiveness ratio (ICER), with ICERs under $100,000 per quality-adjusted life year (QALY) considered cost-effective. One-way and probabilistic sensitivity analyses were used to assess overall stability of the model. **Results:** Compared to standard of care chemotherapy CAR-T increased the total cost of treatment by $378,600 and increased effectiveness by 6.72 QALYs, resulting in an ICER of $56,300 per QALY. The model was sensitive to assumptions about long-term CAR-T survival, the cost of CAR-T, and duration of IVIG required in CAR-T responders. The base model assumed a 79% one-year survival with CAR-T therapy, though if the one-year survival decreased to 61% then the ICER of CAR-T increased above $100,000 per QALY. If the cost of CAR-T infusion increased from $475,000 to $781,000, or if the duration of IVIG infusions extend beyond 12 years then the ICER of CAR-T therapy increased above $100,000 per QALY. In the probabilistic sensitivity analysis CAR-T was cost-effective in $>$ 99% of iterations at a willingness to pay of $100,000 per QALY. **Conclusions:** Despite its high cost, CAR-T therapy has an acceptable cost-effectiveness profile for pediatric r/r ALL. Additional follow-up of this cohort is required to establish long-term outcomes and further inform questions about the cost-effectiveness of CAR-T therapy.

6611 Poster Session (Board #436), Sat, 1:15 PM-4:45 PM

Trajectories of medical care cost by service type for recurrent and de novo advanced cancer patients. *First Author: Matthew P. Banegas, Kaiser Permanente Center for Health Research, Portland, OR*

Background: Understanding cost trajectories for advanced cancer patients may identify drivers of high cost transitions and inform cost reduction efforts. Total medical care costs were measured by service type in year prior to and following diagnosis of de novo or recurrent advanced breast (BC), colorectal (CRC), or lung cancer (LC). **Methods:** Data on patients with de novo or recurrent BC ($n_{stage\ IV}$= 352; $n_{recurrent}$= 765), CRC ($n_{stage\ IV}$ = 1072 and $n_{recurrent}$= 542) and LC ($n_{stage\ IV}$= 4042 and $n_{recurrent}$= 339) from 2000-2012 from three integrated health plans were used. Average monthly and total costs of ambulatory, inpatient, medication, and other services were estimated for (1) *pre-index*: 12 months preceding de novo or recurrent advanced cancer diagnosis (index); and (2) *post-index*: index month and following 11 months. Separate generalized linear repeated measures regression models estimated costs, controlling for demographic and clinical characteristics, for each cancer. Recurrent patients were stratified based on time from initial diagnosis to recurrence (<1 yr versus ≥ 1 yr). **Results:** Adjusted total medical care costs increased significantly from pre- to post-index for all services among de novo and recurrence ≥ 1 yr patients (Table). Among patients with a CRC and LC recurrence $<$ 1 yr, inpatient costs were significantly higher in pre- than post-index. **Conclusions:** Substantial variations in cost trajectories for advanced cancer patients were observed by cancer site and type of advanced disease. These estimates from a capitated system offer novel insight, as new payment models shift away from fee-for-service to bundled/episode-of-care payments.

		Stage IV		Recurrent < 1 yr		Recurrent ≥1 yr	
		Pre-Index	Post-Index	Pre-Index	Post-Index	Pre-Index	Post-Index
Cancer		Total Cost, in Thousands [2012$USD]					
Breast	Ambulatory	$1.6	$20.9	$16.5	$23.3	$8.1	$18.5
	Inpatient	$1.8	$19.0	$9.6	$13.4	$3.9	$15.2
	Medication	$1.5	$27.2	$12.2	$18.1	$6.6	$23.7
Colorectal	Ambulatory	$2.2	$16.5	$11.3	$15.5	$6.5	$13.9
	Inpatient	$2.1	$31.5	$34.4	$19.8	$7.2	$14.6
	Medication	$2.0	$16.8	$6.6	$19.9	$5.1	$17.1
Lung	Ambulatory	$3.5	$18.2	$18.2	$17.4	$9.2	$18.2
	Inpatient	$2.8	$19.0	$36.2	$17.3	$9.9	$14.0
	Medication	$4.1	$12.5	$5.5	$12.3	$6.4	$15.1

6612 Poster Session (Board #437), Sat, 1:15 PM-4:45 PM

The potential cost-effectiveness of first-line immunotherapy + chemotherapy for advanced non-squamous non-small cell lung cancer (NSCLC). *First Author: Joshua A. Roth, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: In May of 2017, the U.S. FDA granted accelerated approval for pembrolizumab + pemetrexed & carboplatin for previously untreated advanced non-squamous NSCLC—the only first-line indication for immunotherapy + chemotherapy ('IO+Chemo') in NSCLC. Preliminary value estimates are needed to inform decision making. Using data from the Phase II KEYNOTE-021 trial, we estimated the potential value of IO+Chemo from a U.S. payer perspective. **Methods:** We created a partitioned survival decision model to assess the cost-effectiveness of IO+Chemo vs. pemetrexed & carboplatin ('Chemo') in Stage IIIB/IV non-squamous NSCLC. One year overall (OS) and progression-free survival came from KEYNOTE-021 and were extrapolated with parametric curves. The base case used a Weibull curve for long-term OS (6% 5 year OS), and scenarios used Log-Logistic (21% 5 year OS) and Gompertz ($<$ 1% 5 year OS) curves to model more and less durable responses. First- and second-line therapy resource use and Grade 3/4 adverse event rates were derived from KEYNOTE-021. We applied 2017 Average Sales Price for drugs and 2017 CMS reimbursement for procedures. Utilities were derived from the literature. We estimated life years (LY), quality-adjusted life years (QALYs), and costs over a lifetime horizon. Outcomes were discounted at 3% per year. **Results:** In the base case, IO+Chemo and Chemo resulted in 2.23 and 1.43 LYs, 1.20 and 0.77 QALYs, and $328,640 and $147,418 cost, respectively. The IO+Chemo costs per LY and QALY gained were $227,149 and $422,313, respectively. The cost per QALY varied greatly in OS scenarios (See Table), showing the strong influence of durable responses on value. **Conclusions:** In the first cost-effectiveness analysis of frontline IO+chemo in advanced non-squamous NSCLC, we found that pembrolizumab-based therapy is unlikely to be cost-effective (ie $<$ $150,000 per QALY) regardless of long-term OS assumptions. Future studies should reassess IO+chemo value with Phase III KEYNOTE-189 data.

IO+Chemo: OS Curve Fit	IO+Chemo: QALYs Gained	IO+Chemo: Additional Cost	Cost Per QALY
Log Logistic	0.88	$189,830	$214,899
Weibull (Base Case)	0.43	$181,222	$422,313
Gompertz	0.09	$170,445	$1,891,845

6613 Poster Session (Board #438), Sat, 1:15 PM-4:45 PM

The financial impact of hypofractionated radiation for prostate cancer. *First Author: Assaf Moore, Tel Aviv University, Tel Aviv, Israel*

Background: Until recently, dose intensified radiotherapy with 1.8-2 Gy fractions was the standard radiation method for prostate cancer. Multiple studies have demonstrated similar efficacy and tolerability with moderate hypofractionation (2.5-3 Gy per fraction). In recent years there has been an increasing focus placed on understanding the cost and value of cancer care. The objective of this study was to assess the societal economic impact of treating localized prostate cancer in the United States (US) with moderate hypofractionation vs standard fractionation. **Methods:** We calculated the national annual target population of patients treated with definitive external beam radiotherapy using the Surveillance, Epidemiology, and End Results (SEER) database. Treatment costs for various fractionation schemes were based on billing codes and 2018 pricing by the Centers for Medicare and Medicaid Services (CMS). **Results:** We estimate that 28,500 patients with localized prostate cancer are treated with radiotherapy annually in the US. The cost of standard fractionation in 45 or 39 fractions is US$ 26,782 and 23,625 per patient, respectively. With moderate hypofractionation in 28 or 20 fractions, the cost is US$ 17,793 and 13,402 per patient, respectively. The use of moderate hypofractionation would lead to 24.7-50% annual savings of $US 166,147,848 – 381,128,820 in the United States. **Conclusions:** Moderate hypofractionation may have the potential to save approximately US$ 0.16-0.38 billion annually in the United States, likely without impacting survival or tolerability. Depending on insurance provider, this option may lead to lower personal financial toxicity. It would be reasonable for public and private payers to consider providing reimbursement only for moderate hypofractionation.

6614 Poster Session (Board #439), Sat, 1:15 PM-4:45 PM

A value framework analysis of the Canadian Cancer Trials Group. *First Author: Joseph Del Paggio, Department of Medicine, University of Toronto, Toronto, ON, Canada*

Background: To identify new therapies that offer substantial benefits to patients, investigators and research funding bodies may wish to consider value framework thresholds in the design of clinical trials. To our knowledge, existing value frameworks have not been applied to the research output of a cooperative cancer trials group. Herein, we apply the European Society for Medical Oncology Magnitude of Clinical Benefit Scale (ESMO-MCBS) to the published output of the Canadian Cancer Trials Group (CCTG). **Methods:** Statistical design, study characteristics, and results of all published phase III trials of the CCTG were abstracted. Studies that showed a statistical significance in favor of the experimental therapy were graded using ESMO-MCBS v1.1. To identify the proportion of all trials that were designed to detect a difference which would be considered meaningful, we also applied the ESMO-MCBS to the statistical power calculations. We defined "substantial benefit" as trials that met a grade of A, B, 5, or 4 for the ESMO-MCBS. **Results:** During 1979-2017, CCTG published 477 trials. 132 trials were phase III and formed the study cohort; 49% of these trials were statistically "positive". The most common disease sites were breast (18%), hematologic (17%), and lung (15%). Forty-six percent of trials were conducted in the palliative setting. Experimental therapies included cytotoxic (36%), molecular (20%), and hormonal (10%) agents. Median sample size was 490. In 40% of trials the primary endpoint was overall survival; a survival surrogate was used in 33% of trials. Among the 58 "positive" trials for which the ESMO-MCBS could be applied, 28 (48%) met thresholds for substantial benefit. The ESMO-MCBS could be applied to the power calculation for 79 trials; 70% of these trials were designed to detect an effect size that could meet ESMO-MCBS thresholds for substantial benefit. RCT authors were more likely to strongly endorse the experimental therapy among those trials meeting ESMO-MCBS thresholds (74% vs 40%, $p = 0.010$). **Conclusions:** The majority of CCTG phase III trials are designed to detect clinically meaningful differences in patient outcome. However, only one quarter of all trials ultimately yield results that meet ESMO-MCBS thresholds for substantial benefit.

6615 Poster Session (Board #440), Sat, 1:15 PM-4:45 PM

Network metanalysis and cost-effectiveness of abiraterone, docetaxel or placebo plus androgen deprivation therapy (ADT) for hormone-sensitive advanced prostate cancer. *First Author: Pedro Nazareth Aguiar, Faculdade de Medicina do ABC, Santo Andre, Brazil*

Background: Prostate cancer is the leading neoplasm among men worldwide. The objective of this study is to evaluate the cost-effectiveness of the addition of chemotherapy or abiraterone to ADT after a network meta-analysis and an indirect comparison between chemotherapy and abiraterone. **Methods:** We made a literature review and included studies that evaluated the addition of docetaxel or abiraterone to ADT versus ADT alone for patients with castration-sensitive metastatic prostate cancer. Studies' outcomes were modeled on a logarithmic scale using the Bayesian hierarchical model for indirect comparisons between interventions. Then, we developed an analytical model to determine the cost-effectiveness of the addition of docetaxel or abiraterone versus ADT alone. Direct and indirect costs were included in the model considering Brazilian costs. **Results:** Four clinical trials were included in the network meta-analysis. Evidence suggests that the addition of abiraterone to ADT is the best therapeutic option in terms of OS ($>$ 95% probability; HR 0,81; 95% CrI 0,66 – 1,00) and FFS ($>$ 99% probability; HR 0,50; 95% CrI 0,40 – 0,62) compared to ADT plus docetaxel. Abiraterone plus ADT had fewer cases of febrile neutropenia than docetaxel plus ADT (1% versus 15%). Compared to ADT alone, the addition of chemotherapy generated 0.492 QALY and the addition of abiraterone generated 0.999 QALY. Abiraterone led to a QALY gain of 0.506 compared to docetaxel. In Brazil, the incremental costs per QALY were $40,500, $100,251 and $173,145, respectively. At current costs, docetaxel plus ADT is more cost-effective than abiraterone plus ADT. The factors that had the greatest influence on cost-effectiveness were the overall survival and failure-free survival confidence intervals. Price discounts on abiraterone purchasing was the factor that led to the greatest impact on the incremental cost (ranging from $100,000 to $40,000). **Conclusions:** We conclude that the addition of chemotherapy to ADT is more cost-effective than the addition of abiraterone to ADT. However, discounts on abiraterone cost might improve cost-effectiveness.

6616 Poster Session (Board #441), Sat, 1:15 PM-4:45 PM

Utilization of imaging during staging and surveillance of localized colon cancer in a large insured population. *First Author: Urshila Durani, Mayo Clinic, Rochester, MN*

Background: It is unknown if staging and surveillance imaging in Stage I/II colon cancer are under- or over-utilized. On one hand, the Choosing Wisely campaign advocates against positron-emission tomography (PET) imaging and overzealous use of CT surveillance. Meanwhile, the NCCN recommends CT chest/abdomen/pelvis (CT C/A/P) at staging for Stage I/II colon cancer. For Stage II only, NCCN recommends surveillance CT C/A/P every 6-12 months for up to 5 years. Herein, we measure both underutilization and overutilization of staging and surveillance imaging in Stage I/II colon cancer. **Methods:** Insurance claims data from 2008-2016 were queried using OptumLabs (Cambridge, MA) for Stage I/II adult colon cancer patients who underwent surgery alone. Utilization of PET and CT C/A/P imaging was evaluated both during initial staging (N = 6,291) and surveillance for patients with at least 1 year of follow up (N = 5,466). Over-utilization was defined as (1) any usage of PET during staging or surveillance or (2) $>$ 2 CT A/P or PET scans per year during surveillance. **Results:** Overall, 31% of Stage I/II colon cancer patients did not receive a staging CT A/P and 95% did not receive a CT chest on diagnosis. However, rates of staging CT A/P increased from 62% (2008) to 75% (2016) and rates of CT chest rose from 2.3% (2008) to 7.1% (2016). Use of PET imaging also increased slightly from 5.2% (2008) to 6.5% (2016) despite guidelines recommending against its use. On surveillance, 30% of patients with at least 1 year of follow up received a CT A/P or PET within the first year of surveillance. This dropped to 18% in year 2, 9% in year 3, 6% in year 4, and 3% in year 5 of follow up. Of patients who had surveillance CT A/P or PET, the proportion receiving $>$ 2 scans within the first year (representing overutilization) declined from 32% (2008) to 10% (2016), $p = 0.01$. **Conclusions:** A large proportion of Stage I/II colon cancer patients do not receive appropriate staging CTs at diagnosis; however, the utilization of PET imaging at staging remains appropriately low. Furthermore, the vast majority of patients undergoing surveillance do not even receive 3 years of imaging follow-up. Among those who do receive surveillance imaging, overutilization has declined over time.

6617 Poster Session (Board #442), Sat, 1:15 PM-4:45 PM

Immunotherapy (IO) versus non-IO for oncology drugs: Comparing survival benefits (SB) using restricted *mean* survival time. *First Author: Amanda Putri Rahmadian, Sunnybrook Research Institute, Toronto, ON, Canada*

Background: Current measures of *absolute* SB (*median* survival time/rate at fixed times on Kaplan-Meier (KM) curves) and *relative* SB (hazard ratios) are limited in properly capturing SB for IO trials. Restricted *mean* survival time (RMST) captures entire area under KM curves, directly measuring SB. This study aimed to quantify the magnitude of SB in recent oncology drugs using RMST difference and RMST ratio (*absolute* and *relative* SB, respectively), and compare those of IO and non-IO. **Methods:** All Food and Drug Administration approved oncology drugs from 01/2011-11/2017 and randomized control trials (RCTs) used for approval were identified. RCTs with overall survival (OS) or progression-free survival (PFS) as primary endpoints and published KM curves were included. Curves were extracted using established methods (Guyot et al., 2012) with DigitizeIt. RMST differences, ratios, and confidence intervals (CI) were calculated and meta-analyzed using random-effects models to estimate overall absolute and relative SB of contemporary oncology drugs, and to compare those of IO and non-IO. Meta-regression was used to adjust for confounders (crossover, time horizon, year approved, trial phase, companion diagnostics, and approval type). **Results:** 94 RCTs with 51 639 patients were included (13 IO and 81 non-IO). Overall RMST differences (*absolute* SB) were 1.55 mos for OS (95% CI 1.32-1.77) and 2.99 mos for PFS (95% CI 2.65-3.33). Overall RMST ratios (*relative* SB) were 1.11 for OS (95% CI 1.09-1.13) and 1.42 for PFS (95% CI 1.36-1.48). IO PFS RMST difference was less than non-IO (1.56 mos vs. 3.23 mos, $p <$ 0.00001), while RMST ratios were similar (1.33 vs. 1.43, $p = 0.16$). Contrastingly, IO OS RMST difference was larger than non-IO by 0.6 mos (2.02 mos vs. 1.43 mos, $p = 0.02$). OS RMST ratios were slightly larger for IO than non-IO (1.18 vs. 1.09, $p = 0.0006$). Meta-regression showed the adjusted SB for OS was 0.83 mos greater for IO vs. non-IO, $p = 0.01$. **Conclusions:** Overall, absolute SB of recent oncology drugs are modest. Unlike popular belief, observed SB of IO drugs are not dramatically superior to non-IO drugs. RMST differences and ratios of oncology drugs in clinical trials should be routinely reported to fully measure SB.

6618 Poster Session (Board #443), Sat, 1:15 PM-4:45 PM

Trends of hospitalizations with invasive fungal infections in patients with acute leukemia and hematopoietic stem cell from 2005-2014 in the United States. *First Author: Sukriti Kamboj, Guthrie/ Robert Packer Hospital, Sayre, PA*

Background: Invasive fungal infections (IFI) are a cause of morbidity, mortality and increased health costs in patients with Acute Leukemia (AL) and hematopoietic stem cell transplant (HSCT). With this study, we aim to examine trends of IFI related hospitalizations in patients with AL and HSCT in the United States. **Methods:** We utilized Nationwide Inpatient Sample (NIS) data from 2005- 2014 and identified patients with AL (acute lymphoblastic leukemia and acute myelogenous leukemia) and HSCT hospitalization using ICD 9 CM codes. Patients with missing information on age, gender and mortality were excluded. Patients with age < 18 years were excluded as well. IFI (candidemia, aspergillosis, zygomycosis) were identified by using appropriate ICD 9 codes in secondary diagnosis field. P-values for trends were generated using Cochran Armitage test. **Results:** A total of 666,567 hospitalizations with HM were identified. Out of which 15,316 (2.31%) had IFIs. A majority were males (57.8%), Caucasian (58%) and belong to age group 50-64 (36.8%). Overall Incidence of fungemia was 2.3% and remained stable over 11 years (2.16% in 2005 to 2.2 % in 20114, relative increase = 7.25%, p trend-0.0064). Overall In-hospital mortality was 21.84% (unchanged over 11 years with a relative decrease of 8.1 % with p trend - 0.131. After stratifying for specific IFIs, in-hospital mortality for candidemia (35.0%), zygomycosis (26.51%) and aspergillosis (18.48%). None of which have changed over 11 years. In multivariate analysis, old age (age > = 65 years), female gender was associated with higher mortality and elective admissions were associated with lower mortality. **Conclusions:** Despite much advances in fungemia treatment and prophylaxis, incidence and outcomes of IFI have not changed over last decade. Future studies to identify limiting factors are needed to provide crucial information to prevent fungemia and improve outcomes.

6619 Poster Session (Board #444), Sat, 1:15 PM-4:45 PM

Gastrointestinal (GI) cancer (CA) drugs approved by the US Food and Drug Administration (FDA): Clinical value and cost considerations. *First Author: Di Maria Jiang, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: The mounting cost of CA drugs has presented significant financial toxicity to all stakeholders over recent years. We aimed to assess the clinical value and cost of GI CA drugs approved by the FDA. **Methods:** Approved GI CA drugs between 2006 and 2017 listed on fda.gov and their updated supporting data were identified. Clinical benefit was quantified by ASCO Value Framework v2 2016 (range < 180) and ESMO Magnitude of Clinical Benefit Scale (MCBS) v1.1 2017 (range 1-5). Higher scores indicate larger net benefit. Substantial benefit was defined as grade 4/5 by ESMO. For EGFR inhibitor outcomes, only patients with wild-type KRAS were assessed. Preliminary data presented on fda.gov were used if trial data is unpublished. Toxicity was omitted if unavailable. The Micromedex REDBOOK was used to estimate the total drug cost for each new agent, based on 2018 average wholesale prices for median treatment durations (or progression-free survival if unavailable). **Results:** Five monoclonal antibodies (Mab), 5 targeted therapies (TT), 1 recombinant fusion protein, 3 cytotoxic (CT) and 2 immunotherapy (IO) agents received approval for metastatic GI CA. Median ASCO scores/drug cost in USD per patient were 36/ $65,310 (Mab), 38/$153,402 (TT), 55/$30,329 (CT) and 21/$78,864 (IO). Selected scores and drug costs are presented (Table). Only cetuximab for refractory colorectal CA (CRC) met the ESMO benefit threshold. *pNET: pancreatic neuroendocrine tumor; HCC: hepatocellular carcinoma; PDAC: pancreatic ductal adenocarcinoma; MSI-H: microsatellite instability-high* **Conclusions:** Although beneficial, most FDA-approved GI CA drugs met neither the ESMO definition of substantial improvement in benefit nor have a high ASCO value score, and incur considerable costs.

CA	Treatment Line	Approved Drug	ASCO value score	ESMO MCBS	Total Drug cost (USD) per patient
CRC	≥3	Cetuximab	72	5	44,132
		Panitumumab	2	1	23,939
pNET	≥1	Everolimus	1	2	153,402
		Sunitinib	38	3	200,610
HCC	1	Sorafenib	46	2	110,050
	2	Regorafenib	35	3	56,252
PDAC	1	Abraxane	62	1	38,171
	2	Nal-irinotecan	55	2	26,182
MSI-H	≥2	Nivolumab	44	3	98,208
	≥3	Pembrolizumab	28	2	216,952

6620 Poster Session (Board #445), Sat, 1:15 PM-4:45 PM

Can oral chemotherapy parity laws reduce patients' out-of-pocket (OOP) costs? *First Author: Andrea Phillips Sitlinger, Duke University Medical Center, Durham, NC*

Background: Insurance plans vary coverage for infusional (IV) vs oral drugs, leading some to suggest that patients on oral drugs pay more OOP than those on IV drugs. 43 states have passed laws requiring insurers to cover oral drugs equivalently to IV drugs. Yet, there is little evidence that these "parity laws" are effective. Our aim was to estimate impact of parity laws on OOP expenses for oral vs IV drugs. **Methods:** We sought to determine how quickly patients on oral vs IV drugs reach their plan's annual OOP maximum (max) as a surrogate for OOP expense. We used 2017 data from Healthcare.gov public use files to generate cost-sharing profiles for all 3,092 unique Marketplace plans. Chronic lymphocytic leukemia (CLL) and metastatic prostate cancer (mPC) were chosen as two representative malignancies since both have accepted, first-line, IV and oral treatment options. We created guideline-concordant, first-line treatment regimens for simulated patients with CLL (oral ibrutinib vs IV bendamustine/ rituximab) or mPC (oral abiraterone vs IV docetaxel). Drug, professional, facility, imaging, and lab claims were simulated to calculate OOP costs. The mean number of days to reach the OOP maximum for each Marketplace plan and treatment regimen were recorded. We assessed variation according to insurance coverage levels ("metal tier": Catastrophic, Bronze, Silver, Gold, Platinum). **Results:** For CLL patients, 95% of plans reached OOP max in approximately one month of treatment for both oral and IV drugs (oral: mean 36 days; IV: mean 29 days). 99% of mPC patients reached their OOP max for oral treatment in a mean 15 days, but only 57% of plans reached OOP max for IV mPC treatment. Metal tier impacts time to reach OOP max (table). **Conclusions:** Parity laws do not lower patient costs when both IV and oral treatment options are expensive. In these cases, patients reach the OOP max rapidly. The small subset of patients most likely to benefit from parity laws are those on oral therapy for a disease where the comparable IV drug is inexpensive (eg, generic docetaxel for mPC).

	Days to Reach OOP Maximum			
	CLL		mPC	
Metal tier	IV	Oral	IV	Oral
Catastrophic	1	1	190	1
Bronze	2	8	211	1
Silver	28	36	327	29
Gold	29	36	327	29
Platinum	113	36	285	29

TPS6621 Poster Session (Board #446a), Sat, 1:15 PM-4:45 PM

A randomized, controlled trial to assess a multi-level intervention to improve adherence to oral cancer medications. *First Author: Rashmika Potdar, Einstein Medical Center Philadelphia, Newtown Square, PA*

Background: Cancer treatment with oral cancer medication is complex. Cancer patients require substantial skills to adhere to- and achieve the goals of therapy. Medication adherence among cancer patients is increasingly important, as treatment with oral medications is increasingly prevalent. The rates of adherence to oral therapy vary widely by population, cancer type, and level of education. To date, however, there is no clear evidence on the effect of improvements in health literacy on patients' adherence to oral cancer medications. We hypothesize that compared to usual care, the addition of a multilevel intervention will result in greater adherence to oral cancer medications. **Methods:** In a single-center, patients are randomized 1:1 to receive usual care, including clinical care plus education by a registered nurse (Arm 1), or the addition of a multilevel intervention (Arm 2). The multilevel intervention includes a brief web-based educational video on cancer and oral cancer drugs, periodic reinforcement of educational messages with videos, brief phone calls 24 hours and 2 weeks after each encounter, and offer of facilitative services, if needed. Health literacy is recorded at baseline, using REALM R. Adult cancer patients on any oral cancer medication are eligible to participate in the study. Exclusion criteria include ECOG ≥3, concurrent chemo-radiation, hormonal therapy, nonadherence (defined as history of missing 2 or more Oncology clinic appointments), pregnancy, residence in a nursing home, dementia, or lacking decisional capacity. The primary outcome of interest is medication adherence, indicated by the proportion of expected refills completed for oral cancer medications during the follow up period. Secondary outcomes include adherence to follow up visits, adherence to other prescribed medications, healthcare utilization, and other healthcare outcomes. With a one-sided alpha = 0.05, the target sample size of 110 patients, would yield 90% power to test the primary hypothesis. To date, we have randomized 19 participants, and enrollment proceeds as planned. Clinical trial information: NCT03245411.

TPS6622 Poster Session (Board #446b), Sat, 1:15 PM-4:45 PM

Ambulatory cancer care electronic symptom self-reporting (ACCESS) for surgical patients: A randomized controlled trial. *First Author: Cara Stabile, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: An increasing proportion of cancer surgeries are ambulatory ($\leq$ 1 day in hospital) procedures. Providing patients and their caregivers with ongoing, real-time support after discharge is imperative to delivering high-quality postoperative care in this new health care environment. Despite abundant evidence that patient self-reporting of symptoms improves quality of care, **Reference:** 1. Kotronoulas G, Kearney N, Maguire R, et al. What is the value of the routine use of patient-reported outcome measures toward improvement of patient outcomes, processes of care, and health service outcomes in cancer care? A systematic review of controlled trials. *Journal of Clinical Oncology.* 2014;32(14):1480-1501. the most effective way to monitor and manage such data remains unknown. **Methods:** This is a two-armed, prospective randomized controlled trial evaluating two approaches to the management of patient-reported data: (1) Team Monitoring—symptom monitoring by the clinical team, with nursing outreach if symptoms exceed normal limits; and (2) Enhanced Feedback—real-time feedback to patients about expected symptom severity, with patient-activated care as needed. It is hypothesized that Enhanced Feedback about expected symptom severity would be more effective than Team Monitoring in improving patient-centered outcomes and the patient/caregiver experience. Breast, prostate, gynecologic, and head and neck cancer patients undergoing ambulatory cancer surgery (n = 1,700) will complete an electronic survey about their symptoms for up to 30 days after surgery. Information provided to patients in the Enhanced Feedback group is procedure-specific and based on continuously updated survey data from previous patients. Qualitative interviews will also be performed. Accrual began in August 2017. Primary outcomes will evaluate unplanned emergency department visits within 30 days. Secondary outcomes will assess the patient/caregiver experience (i.e., patient engagement, patient anxiety, and caregiver burden). Findings will be relevant in designing future coordinated care models targeting improved health care quality and patient experience. Clinical trial information: NCT03178045.

7000 Oral Abstract Session, Sat, 3:00 PM-6:00 PM

Ivosidenib (IVO; AG-120) in mutant IDH1 relapsed/refractory acute myeloid leukemia (R/R AML): Results of a phase 1 study. *First Author: Daniel Aaron Pollyea, University of Colorado School of Medicine, Aurora, CO*

Background: IVO is an oral, targeted inhibitor of mutant isocitrate dehydrogenase 1 (mIDH1) that is being evaluated in a phase 1 dose escalation and expansion study of mIDH1 advanced hematologic malignancies (NCT02074839). Here we report updated efficacy and safety data from all patients with R/R AML receiving IVO 500 mg once daily (QD). **Methods:** The primary efficacy endpoint was the CR+CRh rate (complete remission [CR] according to modified IWG 2003 criteria plus CR with partial hematologic recovery [CRh]). CRh was defined as absolute neutrophil count $> 0.5 \times 10^9$/L *and* platelet count $> 50 \times 10^9$/L. The overall response rate (ORR) comprised CR, CR with incomplete hematologic or platelet recovery, partial response, and morphologic leukemia-free state. The data cutoff date for this analysis was Nov 10, 2017. **Results:** A total of 258 patients were treated with IVO. Among 179 R/R AML patients who received IVO 500 mg QD, 17 (9.5%) remained on treatment at data cutoff. In R/R AML patients, the CR+CRh rate was 31.8% (95% CI: 25.1%, 39.2%), including CR in 24.0% (95% CI: 18.0%, 31.0%). Median duration of CR+CRh was 8.2 months (95% CI: 5.6, 12.0), and median duration of CR was 10.1 months (95% CI: 6.5, 22.2). The ORR was 41.9% (95% CI: 34.6%, 49.5%). Treatment was well tolerated; the most common adverse events (AEs) of any grade, irrespective of causality and occurring in ≥25% of 179 R/R AML patients were diarrhea (33.5%), leukocytosis (31.3%), nausea (31.3%), febrile neutropenia (29.1%), fatigue (28.5%), and electrocardiogram QT prolonged (25.7%). The majority of these AEs were grades 1–2 and unrelated to treatment. IDH differentiation syndrome (IDH-DS) was reported in 19 of 179 (10.6%) patients, including grade ≥3 IDH-DS in 9 (5.0%); study drug was held owing to IDH-DS in 6 patients (3.4%), and no instances of IDH-DS led to dose reduction, permanent treatment discontinuation, or death. Updated mutation clearance results will be provided. **Conclusions:** In a high-risk, molecularly defined R/R AML patient population, IVO induced durable remissions and was well tolerated. Studies in previously untreated AML populations are ongoing. Clinical trial information: NCT02074839.

7001 Oral Abstract Session, Sat, 3:00 PM-6:00 PM

Association of early intervention in transfusion independent (TI) patients (Pts) with lower-risk myelodysplastic syndromes (MDS) treated with attenuated doses of hypomethylating agents (HMAs) with high response rates and long duration of response. *First Author: Mahesh Swaminathan, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: HMAs are the standard of care for most pts with higher risk MDS. However, the role of the therapy is not well defined in lower risk MDS. Data from our center has indicated that attenuated dose schedules of HMA are safe and active in pts with low risk MDS (Jabbour et al. Blood 2018) but the safety and activity of these therapies is not known in TI pts with low risk MDS. To study this, we performed an analysis of a cohort pts with TI low risk or int-1 risk MDS by IPSS. **Methods:** Eighty-seven pts with low-risk or int-1 risk MDS treated with HMAs from 2012 to 2017 were analyzed. Pts had been treated in prospective trials of attenuated HMA at a single institution. Therapy could consist of decitabine 20 mg/m2 IV QD x 3 days every 28 days or azacitidine 75 mg/m2 daily x 3 days every 28 days or azacitidine at the same dose and schedule for 5 days. All pts were TI at baseline. **Results:** The median age was 70 (25-85); 64 pts (74%) were males; 57 pts (66%) were int-1 risk and 30 (34%) were low risk by IPSS. By the MDACC Lower Risk Prognostic Model: 51 pts (59%) were intermediate risk, 23 (26%) high risk and 13 (15%) low-risk. Cytogenetics were good in 59 (68%), intermediate in 22 (25%) and poor in 6 pts (7%). The median time to treatment was 4.13 months and the median number of prior treatments was 0 (0-1). The median total courses of treatment was 14 (1-41). TET2, ASXL1 and RUNX1 mutations occurred in 30%, 9% and 8%, respectively. Of the 87 pts, 80 were evaluable. No deaths were observed during the first 8 weeks of therapy and no severe hematological toxicity. The overall response rate (ORR) was 74% [CR – 40 (50%), mCR with and without HI – 5 (6%), 3 (4%), respectively, HIP – 10 (13%) and HIN – 1 (1%)]. The median OS was not reached and the median event-free survival (EFS) was 35.4 months. Two pts (3%) had progressive disease; 19 (24%) had no response; 6 (8%) progressed to acute myeloid leukemia. Five pts (6%) became transfusion dependent at the time of response evaluation. **Conclusions:** Early intervention with attenuated doses of HMAs in TI pts with lower risk MDS is safe and active and could potentially alter the natural history of MDS.

7002 Oral Abstract Session, Sat, 3:00 PM-6:00 PM

Bosutinib vs imatinib for newly diagnosed chronic myeloid leukemia in the BFORE trial: 24-month follow-up. *First Author: Jorge E. Cortes, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Bosutinib is a dual Src/Abl tyrosine kinase inhibitor approved for the treatment of newly diagnosed chronic phase (CP) chronic myeloid leukemia (CML) and CML resistant/intolerant to prior therapy. Here we compare efficacy of first-line bosutinib and imatinib after ≥24 mo (median: 27 mo) of follow-up. **Methods:** In the ongoing, open-label, phase 3 BFORE trial (NCT02130557), 536 patients were randomized 1:1 to bosutinib (n = 268) or imatinib (n = 268 [3 untreated]). **Results:** Higher molecular and complete cytogenetic response (MR and CCyR) rates were observed for bosutinib vs imatinib at 12 mo; these differences continued after ≥24 mo (**Table**). The between-arm difference in major MR (MMR) rate was retained at 24 mo; however, differences in rates of deeper MRs (MR^4 and $MR^{4.5}$) were smaller. Times to MR and CCyR were shorter for bosutinib vs imatinib, consistent with 12-mo data. There were 6 transformations to accelerated/blast phase with bosutinib and 7 with imatinib. 71% vs 66% remained on bosutinib vs imatinib treatment. **Conclusions:** At 24 mo, a higher MMR rate was maintained with bosutinib vs imatinib. The results support the use of bosutinib as first-line therapy for CP CML. Clinical trial information: NCT02130557.

7003 Oral Abstract Session, Sat, 3:00 PM-6:00 PM

Long-term treatment-free remission (TFR) in patients (pts) with chronic myeloid leukemia in chronic phase (CML-CP) after stopping second-line (2L) nilotinib: ENESTop 144-wk results. *First Author: François-Xavier Mahon, Cancer Center of Bordeaux, Institut Bergonié, INSERM U1218, University of Bordeaux, Bordeaux, France*

Background: TFR is a new treatment goal in CML. In the ENESTop study (NCT01698905) in pts with CML-CP who sustained a deep molecular response with 2L nilotinib, 57.9% and 53.2% remained in TFR 48 wk (primary endpoint) and 96 wk after stopping treatment, respectively. We report an analysis of longer-term durability of TFR in ENESTop. **Methods:** Pts treated with ≥ 2 y of nilotinib following > 4 wk of imatinib (≥ 3 y total) and achieving $MR^{4.5}$ (*BCR-ABL1* ≤ 0.0032% on the International Scale [$BCR\text{-}ABL1^{IS}$] by quantitative real-time PCR) on nilotinib were eligible. Following a 1-y consolidation phase, pts with no confirmed loss of $MR^{4.5}$ could attempt TFR; nilotinib was restarted upon loss of major molecular response (MMR; $BCR\text{-}ABL1^{IS} \leq 0.1\%$) or confirmed loss of MR^4 ($BCR\text{-}ABL1^{IS} \leq 0.01\%$). The data cutoff for this analysis was Oct 18, 2017, when all pts had completed ≥ 144 wk of TFR, restarted nilotinib, or discontinued the study. **Results:** Of 126 pts entering TFR, 61 remained in TFR at data cutoff, 58 restarted nilotinib (loss of MMR, n = 34; confirmed loss of MR^4, n = 24), and 7 discontinued the study in this phase. The TFR rate at 144 wk was 48.4% (95% CI, 39.4%-57.5%). Of 67 pts in TFR at 96 wk, 6 were no longer in TFR at 144 wk due to confirmed loss of MR^4 (n = 3; at 108, 120, and 144 wk), death (n = 2), or study discontinuation (n = 1; pt/guardian decision). Of 34 pts restarting nilotinib due to loss of MMR, 33 (97.1%) and 31 (91.2%) regained MMR and $MR^{4.5}$, respectively; of 24 pts restarting due to confirmed loss of MR^4, 23 (95.8%) regained $MR^{4.5}$. Stable $MR^{4.5}$ for 48 wk was achieved by 42 of 54 pts who regained $MR^{4.5}$ (77.8%). No disease progression or deaths due to CML were reported; 144-wk treatment-free survival rate was 52.0% (95% CI, 42.9%-60.4%). Of 68 pts who remained in TFR for > 96 wk, 10.3%, 51.5%, 19.1%, and 11.8% experienced any-grade musculoskeletal pain–related adverse events in the consolidation phase and first, second, and third 48 wk of TFR, respectively. **Conclusions:** These results demonstrate the long-term durability of TFR following 2L nilotinib and show that most pts restarting nilotinib regained stable $MR^{4.5}$. Pts should be routinely monitored for late loss of response. Clinical trial information: NCT01698905.

7004 Oral Abstract Session, Sat, 3:00 PM-6:00 PM

Moxetumomab pasudotox in heavily pretreated patients with relapsed/refractory hairy cell leukemia: Results of a pivotal international study. *First Author: Robert J. Kreitman, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: A pivotal multicenter, single-arm study evaluated moxetumomab pasudotox, a first-in-class recombinant immunotoxin, in patients (pts) with relapsed/refractory hairy cell leukemia (HCL). **Methods:** Eligible pts (≥2 prior systemic therapies, including ≥1 purine nucleoside analog) received moxetumomab pasudotox 40 μg/kg intravenously on days 1, 3, and 5 of 28-d cycles, up to 6 cycles. Disease response and immunohistochemistry (IHC) minimal residual disease (MRD) status were determined by blinded independent central review. Primary end point was durable complete response (CR), defined as CR with hematologic remission (blood count normalization, HR) for > 180 d. **Results:** Eighty pts (63 male; median age 60 y) received moxetumomab pasudotox. Median number of prior systemic therapies was 3 (2–11); 39 pts (49%) had > 3 prior lines of therapy and 60 (75%) had prior rituximab. At 16.7 months median follow-up, objective response (OR) rate was 75% (60/80), HR rate 80% (64/80), CR rate 41% (33/80), and durable CR rate 30% (24/80). Of 33 pts achieving CR, 27 (82%) had IHC MRD negative status. Median time to HR was 1 mo. Median duration of OR and median PFS were not reached. Most frequent treatment-related adverse events (AEs) were nausea (28%), peripheral edema (26%), headache (21%), and pyrexia (20%); 8% had infections and 3% had neutropenia deemed treatment related. Three deaths occurred; none were treatment related. Treatment-related AEs leading to discontinuation were hemolytic uremic syndrome (HUS; 4 [5%]), capillary leak syndrome (CLS; 2 [3%]), and increased blood creatinine (2 [3%]). Seven pts (9%) had CLS (grade 2: n = 5; grade 4: n = 2), 7 (9%) had HUS (grade 2: n = 2; grade 3: n = 3; grade 4: n = 2), and 4 (5%) had both. CLS and HUS were manageable and reversible (no plasma exchange in HUS). Median immunoglobulin levels remained unchanged after treatment. Median CD4 cell counts were stable or improved after the first week of treatment. **Conclusions:** Moxetumomab pasudotox achieved a high rate of independently assessed durable CR, with the ability to eradicate MRD in heavily pretreated HCL patients, and showed a favorable safety profile without immuno/myelosuppression. Clinical trial information: 01829711.

7005 Oral Abstract Session, Sat, 3:00 PM-6:00 PM

Factors impacting disease-free survival in adult B cell B-ALL patients achieving MRD-negative CR after CD19 CAR-T cells. *First Author: Kevin Anthony Hay, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: Autologous T cells engineered to express a CD19-targeting 4-1BB-costimulated CAR (CAR-T cells) have produced high complete remission (CR) rates in adult B-ALL patients (pts; NCT 01865617), but factors associated with durable remission have not been determined. **Methods:** Pts who received CD19 CAR-T cells at or below the maximum tolerated dose with ≥ 6 months (mos) follow-up were included. Factors impacting disease-free survival (DFS) and overall survival (OS) were determined. **Results:** 56 pts (median age 40 yrs, range 20-76) with a median follow-up of 27.4 mos were studied. 50 (89%) achieved morphologic CR and 45 (80%) achieved CR without minimal residual disease (MRD- CR) by flow cytometry. Pts who achieved MRD- CR had better median OS compared to those with morphologic disease after CAR-T cells (16.8 vs 2.7 mos, p = .0301). In pts achieving MRD- CR, univariate analyses showed longer DFS with lower LDH (p = .0007), no extramedullary disease (p = .005), lower marrow blasts (p = .013), cyclophosphamide/fludarabine (Cy/Flu) lymphodepletion (p = .004), higher CAR-T cell dose (p = .033); and higher in vivo AUC d0-28 of CD4+ (p = .074) and CD8+ (p = .039) CAR-T cell counts. In a stepwise multivariable model, Cy/Flu lymphodepletion (HR 4.3, p = .001), low LDH (HR 1.4 for each 100 U/L increment, p = 0.003), and absence of extramedullary disease (HR 0.34, p = .001) before CAR-T cell infusion were associated with more durable DFS. In pts with normal LDH and no extramedullary disease who received Cy/Flu before CAR-T cells, the probabilities of 2 year OS and DFS were 62% and 62%, respectively. 18 pts underwent allogeneic HSCT after achieving MRD- CR (median 2.3 mos after infusion). Those with ≥5% marrow blasts before CAR-T cells who underwent HSCT had longer DFS and OS compared to those who did not receive HSCT (median EFS 20.0 vs 4.0 mos, p = .0006; OS 26.9 vs 6.7 mos, p = .035). In contrast, those with < 5% blasts before CAR-T cells may not benefit from HSCT after achieving MRD- CR (p = .14). **Conclusions:** More durable DFS after achieving MRD- CR was found in pts with low LDH, no extramedullary disease, and Cy/Flu before CAR-T cells. Those with morphologic disease before CAR-T cells who achieve MRD- CR may benefit from allogeneic HSCT. Clinical trial information: NCT 01865617.

7006 Oral Abstract Session, Sat, 3:00 PM-6:00 PM

Outcomes of patients (pts) treated with prior blinatumomab (Blin) in ZUMA-3: A study of KTE-C19, an anti-CD19 chimeric antigen receptor (CAR) t cell therapy, in adult pts with relapsed/refractory acute lymphoblastic leukemia (R/R ALL). *First Author: Bijal D. Shah, Moffitt Cancer Center, Tampa, FL*

Background: KTE-C19 showed promising efficacy (71% complete response [CR] or CR with incomplete hematologic recovery [CRi]) and manageable safety for pts with R/R ALL in Phase 1 of ZUMA-3 (Shah ASH 2017; NCT02614066). Blin, a CD19/CD3 bispecific T cell engager, is FDA-approved for R/R ALL. The impact of prior blin on KTE-C19 efficacy is unknown. Here, we report responses to KTE-C19 in pts who received prior blin. **Methods:** Eligible pts were aged ≥ 18 y with R/R ALL (Ph+ allowed), ≥ 5% bone marrow blasts (documented CD19+), and ECOG 0-1. Pts received 2, 1, or 0.5 × 10^6 CAR T cells/kg after low-dose conditioning chemotherapy. Pts who received the 2 × 10^6 dose could not have prior blin. Outcomes assessed included efficacy, safety, product characteristics, and levels of CAR T cells and cytokines in blood. **Results:** As of July 31, 2017, 29 pts were evaluable for safety, 24 for efficacy. Six, 14, and 9 safety-evaluable pts received 2, 1, and 0.5 × 10^6 CAR T cells/kg, respectively. Pts with (n = 11) vs without (n = 18) prior blin had worse performance status (ECOG 0: 27% vs 44%) and were more likely to be R/R to ≥ 2^{nd}-line therapy (55% vs 28%). With ≥ 8 wk of follow-up, 63% vs 75% of pts with vs without prior blin had CR or CRi, respectively. Overall, 88% (21/24) had minimal residual disease-negative remission (7/8 with vs 14/16 without prior blin). Of pts with vs without prior blin, 27% vs 28% had Grade ≥ 3 cytokine release syndrome and 36% vs 61% had Grade ≥ 3 neurologic events. KTE-C19 was manufactured successfully in both groups, with similar product characteristics (eg, CD4/CD8 ratio, % transduction). Pts with vs without prior blin had similar proportions of naïve (43% vs 36%) and effector memory (19% vs 20%) T cells. Postinfusion CAR T expansion was observed regardless of prior blin; peak CAR T cell levels occurred between Days 7 and 14 for both groups. **Conclusions:** While potentially confounded by multiple factors, these data demonstrate that prior blin did not preclude manufacturing of efficacious products. KTE-C19 continues to show promising efficacy and manageable safety in pts with R/R CD19+ ALL independent of prior blin. Clinical trial information: NCT02614066.

7007 Oral Abstract Session, Sat, 3:00 PM-6:00 PM

Tumor gene signature associated with neurotoxicity in R/R B-ALL patients treated with JCAR015, a CD19-directed CAR T cell product. *First Author: N. Eric Olson, Juno Therapeutics, Seattle, WA*

Background: CD19-directed chimeric antigen receptor modified T (CAR T) cells produce therapeutic responses in adult R/R B-ALL. However, CAR T therapy is also associated with serious toxicities including cytokine release syndrome (CRS) and neurotoxicity (NT). NT mechanisms are emerging and thus far efforts have focused on patient factors and CAR T product attributes and performance post infusion. **Methods:** RNA-Seq analyses was performed on pre-apheresis bone marrow samples obtained from 31 JCAR015 treated patients (ROCKET trial; NCT02535364). **Results:** Gene expression analysis identified a gene set that is differentially expressed between severe (grades 4-5, n = 7) NT patients and low (grades 0-1, n = 10) NT patients. The NT associated genes clustered B-ALL samples in public datasets (TARGET and GSE79533) by molecular subtype, with genes highly expressed in low NT ROCKET patients also being highly expressed in Ph+ and Ph-like subtypes. Genes highly expressed in severe NT ROCKET patients were highly expressed in non Ph-like subtypes in the public datasets. Machine learning applied to all ROCKET patients classified 16 patients as having Ph-like gene expression and 15 patients having non Ph-like expression. No grade 4+ NT events occurred in Ph-like patients, and grades 3+ (p = 0.03) and 4+ NT (p = 0.0002) were significantly more frequent in the non Ph-like patients. Looking at 3 other B-ALL CD19 CAR T studies (FHCRC2639, NCT01865617; MSK 09-114, NCT01044069 and PLAT-02, NCT02028455), no grade 4+ NT events were observed in any Ph+ patients, suggesting that this finding may not be limited to the ROCKET trial. Pre CAR T infusion plasma levels of CCL17, a chemokine highly expressed by RNA-Seq in low NT ROCKET patients and in the Ph-like B-ALL datasets, were also significantly higher in the grade 0-1 versus grade 4-5 NT group (p < 0.05). **Conclusions:** This exploratory analysis suggests that B-ALL subtypes differ in risk for CD19 CAR T associated NT with Ph-like patients being at significantly lower risk than non Ph-like patients. Risk stratification by molecular subtype or gene expression signature could play an important role in identifying patients at elevated risk for severe NT.

7008 Oral Abstract Session, Sat, 3:00 PM-6:00 PM

Initial results of two phase I trials delivering mbIL-21 ex vivo expanded haploidentical NK cells after fludarabine/cytarabine for patients with relapsed/refractory myeloid leukemias. *First Author: Stefan O. Ciurea, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: NK cells play an important role in the control of malignancies but are ablated by high-dose chemotherapy. Thus, rapid recovery of NK cell number and function correlates with improved disease control. Haploidentical NK cells delivered after lymphodepleting chemotherapy can induce remission in patients with relapsed and/or refractory AML. **Methods:** We hypothesized that anti-leukemic activity could be increased without toxicity by adoptive transfer of expanded NK cells after reinduction with fludarabine, cytarabine, and G-CSF (FLAG), or mini-FLAG (4 days) for patients with low performance score. Haploidentical NK cell donors were selected by KIR ligand and/or KIR gene content. NK cells were expanded on feeder cells and cryopreserved in multiple aliquots. Patients received 3 NK-cell infusions per week for two weeks, beginning 3-10 days after chemotherapy. Response was assessed at day 30 after treatment. Parallel Phase I studies were opened using the same regimen and NK cell manufacturing platform at two centers (US and Brazil). **Results:** 13 patients have been treated to date, age 12-70 years (median 61y), with AML/MDS/CMML (11/1/1), having received 2-8 prior lines of therapy (median 4). 12 patients received 10^6 NK cells/kg/infusion, one received 5x10^6. One patient had no response and received other investigational therapy prior to formal disease assessment. One patient with pre-existing liver toxicity developed worsening hepatic dysfunction and died prior to day 30. Two patients achieved marrow remission but had residual CNS disease. The remaining 9 patients (69%) achieved $<$ 5% blasts by morphology, with/without peripheral count recovery, for overall marrow remission rate of 85%. One patient progressively improved in MRD status by PCR over a 4-month period after treatment, suggesting ongoing immunologic anti-leukemic activity. Immune correlative studies will be presented at the meeting. **Conclusions:** Multiple infusions of cryopreserved expanded NK cells can be safely delivered after high-dose chemotherapy, with encouraging responses on this first dose level. Clinical trial information: NCT01787474.

7009 Clinical Science Symposium, Mon, 4:30 PM-6:00 PM

A phase 1 dose escalation study of the *IDH1*m inhibitor, FT-2102, in patients with acute myeloid leukemia (AML) or myelodysplastic syndrome (MDS). *First Author: Justin M. Watts, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: *Isocitrate dehydrogenase 1* mutations (*IDH1*m) occur in 7-14% of AML patients (pts) and 3% of MDS pts. FT-2102 is a highly potent, selective small molecule inhibitor of *IDH1*m without anticipated CYP or QTc liabilities at the recommended phase 2 dose. **Methods:** A Phase 1/2 study was initiated to evaluate the safety, PK/PD, and clinical activity of FT-2102 alone or in combination with azacitidine (AZA) or cytarabine in *IDH1*m AML/MDS pts. Safety for all pts and efficacy for evaluable pts are reported. **Results:** At the data cutoff, 35 pts with a median of 2 prior regimens (range 1-9) had received FT-2102 in dose-escalation, including 22 single-agent (SA) and 13 AZA combination (CO) pts. Sixteen pts remain on treatment (SA, n = 10; CO, n = 6) with a median of 2 treatment cycles (range 1-16); 4 pts discontinued for transplant. FT-2102 has been well tolerated both as SA and in combination with AZA. Overall, regardless of causality, most treatment emergent AEs (TEAEs) were grade (gr) 1/2; most common ($>$ 20%) TEAEs were fatigue (34%), nausea (29%), and febrile neutropenia (23%). The most common ($>$ 15%) gr 3/4 TEAEs were febrile neutropenia (23%), anemia (20%), and pneumonia (17%). Five (14%) pts had gr 3 differentiation syndrome that was manageable and did not result in discontinuation. Steady-state exposure that exceeded the target IC90 of *IDH1*m was achieved at 150 mg BID, resulting in a reduction of 2-HG to normal levels in the majority of pts. Best response in all evaluable SA pts (n = 16) included: 2 (13%) complete remissions (CR), 4 (25%) complete remissions with incomplete hematologic recovery (CRi), and 5 (31%) clinical benefit (CB; stable disease lasting $\geq$8 weeks), including 2 with $>$ 50% reduction of marrow blasts (MB). Best response in evaluable CO pts (n = 11) included: 2 (18%) CR, 1 (9%) CRi, and 5 (45%) CB, including 2 with $>$ 50% reduction of MB. **Conclusions:** FT-2102 has shown favorable safety, PK/PD, and clinical activity in *IDH1*m AML/MDS with a single agent complete response rate (CR/CRi) of 38% and a complete response rate of 27% in combination with AZA. Current data support the continued evaluation of 150 mg BID in the expansion and Phase 2 stages of the study. Clinical trial information: NCT02719574.

7010 Clinical Science Symposium, Mon, 4:30 PM-6:00 PM

Durable response with venetoclax in combination with decitabine or azacitadine in elderly patients with acute myeloid leukemia (AML). *First Author: Courtney Denton Dinardo, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Venetoclax (VEN), an oral BCL-2 inhibitor, has synergistic activity when combined with hypomethylating agents. This clinical study explores the optimal dose and efficacy of VEN in combination with decitabine (DEC) or azacitadine (AZA) in elderly AML. **Methods:** This is an open-label, phase 1b, dose escalation and expansion study (NCT02203773) on the safety and efficacy of VEN, with DEC or AZA, in elderly patients ($\geq$65 years) with untreated AML. VEN was coadministered daily with 20 mg/m^2 of DEC on days 1-5 or 75 mg/m^2 of AZA on days 1-7, each 28 day cycle. VEN was dosed at 400, 800, or 1200 mg in the escalation phase, and 400 or 800 mg in the expansion phase. Complete remission (CR), CR with incomplete blood count recovery (CRi), overall survival (OS) and adverse events (AEs) were evaluated. **Results:** Data cutoff was July 7, 2017. Of 145 patients, 56% were male; the median age was 74 years (range: 65–86). Overall, 60, 74, and 11 patients received VEN at 400, 800, and 1200 mg, respectively. Key grade $\geq$3 AEs were febrile neutropenia (43%), thrombocytopenia (23%) and neutropenia (16%); pneumonia and bacteremia (all grades) occurred in 18% and 8% of patients, respectively. At 400mg of VEN, the rate of CR+CRi was 73% (76% with AZA and 71% with DEC); efficacy data are in the table. Minimal residual disease (MRD) assessment in marrow aspirates was performed at disease assessment in a central lab using multicolor flow cytometry assay; overall, 37% (36/97) of patients with CR/CRi had MRD levels below the 10^{-3} cutoff. Median follow up was 15.1 months. **Conclusions:** Preliminary data suggest that 400 mg of VEN has the optimal benefit-risk profile in combination with DEC or AZA, which demonstrated a tolerable safety profile with deep responses and durable outcomes in elderly patients with AML. Clinical trial information: NCT02203773.

		CR/CRi	Duration of CR/CRi	
Patient subgroup	n	n (%)	median months	OS
All VEN doses	145	97 (67)	11.3	17.5
Intermediate cytogenetic risk	74	55 (74)	12.9	NR
Poor cytogenetic risk	71	42 (59)	6.7	9.6
Secondary AML	36	24 (67)	NR	NR
Age ≥75 years	62	40 (65)	9.2	11.0
VEN 400 mg				
+ AZA	29	22 (76)	NR	NR
+ DEC	31	22 (71)	12.5	15.2
VEN 800 mg				
+ AZA	37	21 (57)	11.7	14.2
+ DEC	37	27 (73)	9.2	17.5

OS, overall survival; NR, not yet reached (if applicable)

Relationship of minimal residual disease (MRD) in acute lymphocytic leukemia (ALL) and putative leukemia stem cells (LSCs). *First Author: Jonathan Michael Gerber, Levine Cancer Institute, Atrium Health, Charlotte, NC*

Background: MRD has emerged as a significant prognostic factor in ALL, but even levels $<$ 0.1% still carry a risk of relapse. It is theorized that relapse is due to resistant LSCs, which survive after therapy. Consistent with this, MRD in acute myeloid leukemia patients was enriched for LSCs, which were CD34$^+$ CD38$^-$ with intermediate (int) levels of aldehyde dehydrogenase (ALDH) activity (CD34$^+$CD38$^-$ALDH^{int}) [Gerber, et al. *Blood*, 2012]. A similar CD34$^+$CD38$^-$ALDH^{int} putative LSC population was subsequently found in ALL [Gerber, et al. *ASH*, 2016]. We hypothesized that MRD in ALL would also be enriched for LSCs. **Methods:** Bone marrow specimens were collected on an IRB-approved protocol at diagnosis and/or post treatment from 32 patients with B cell ALL over a 3-year span. CD34$^+$ cells were isolated by magnetic bead/column selection, then analyzed by flow cytometry (FACS) for CD19, CD34, CD38, and ALDH. Student's *t*-test was used for statistical comparisons. **Results:** Twenty-four patients were followed post therapy, 5 of whom achieved complete remission with $<$ 0.1% detectable MRD by clinical flow cytometry and/or PCR. Whereas clinical FACS detected a mean of 0.0164 $\pm$ 0.0116% MRD in the 5 cases, the LSCs constituted 31.95 $\pm$ 13.51% of the CD34$^+$CD38$^-$ stem/progenitor cells, a nearly 2,000-fold increase ($p < 0.05$). In fact, in all cases with clinically detectable MRD by FACS and/or PCR, LSCs were reliably detected in the CD34$^+$CD38$^-$ stem/progenitor population, at levels as low as 1 in 10^6 mononuclear marrow cells. Furthermore, while the CD34$^+$CD38$^-$ALDH^{int} LSC population represented only 9.15 $\pm$ 4.07% of the total leukemic burden at diagnosis, it constituted 58.14 $\pm$ 18.63% in the MRD state ($p < 0.01$). Of note, CD19 was expressed on the CD34$^+$CD38$^-$ALDH^{int} population in all cases, both at diagnosis and in MRD. **Conclusions:** MRD was enriched for CD34$^+$CD38$^-$ALDH^{int} cells in ALL patients, implying that the putative LSCs are more resistant than the bulk leukemic cells to therapy. The LSCs expressed CD19, even in the MRD state, suggesting that therapies directed against CD19 could target LSCs and might prove curative. LSC detection may serve as a highly sensitive test for MRD. These findings merit validation in a larger cohort.

7013 Poster Discussion Session; Displayed in Poster Session (Board #73), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 11:30 AM-12:45 PM

Impact of minimal residual disease (MRD) status in clinical outcomes of patients with relapsed/refractory (R/R) acute lymphoblastic leukemia (ALL) treated with inotuzumab ozogamicin (InO) in the phase 3 INO-VATE trial. *First Author: Elias Jabbour, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: MRD negativity is a key prognostic indicator of patient (pt) outcome in ALL and is predictive of improved survival and disease-free status. In the INO-VATE ALL trial (Kantarjian, NEJM 2016), pts with R/R ALL who received InO vs standard chemotherapy (SC) achieved greater remission (CR/CRi; 81% vs 29%) and MRD-negativity (78% vs 28%, in pts with CR/CRi) and had improved overall survival (OS): 7.7 vs 6.7 months. This analysis was conducted to assess prognostic value of MRD negativity by end of treatment (EOT) with InO. **Methods:** INO-VATE pts who received InO (n = 164) were included. Among pts with CR/CRi, MRD status (by multiparametric flow cytometry at a central lab) was defined as negative (MRD–) if $< 1 \times 10^{-4}$ blasts/nucleated cells (n = 81), or as positive (MRD+; n = 83), based on assessment by EOT. OS, progression-free survival (PFS), and predictors of MRD status (by multivariate logistic regression) are reported from final study data as of Jan 4, 2017. **Results:** MRD– status with CR/CRi was associated with significantly improved OS and PFS (Table) vs MRD+ status with CR/CRi: unstratified HR 0.512; 1-sided P= 0.0009 for OS and HR 0.423; P< 0.0001 for PFS. Exploratory multivariate analyses indicated that 2nd salvage compared to 1st salvage (OR 0.499, 2-sided P= 0.058) was associated with lower likelihood of having MRD– status, while $< 1x10^9$/L absolute circulating blast count at baseline (OR 3.231, P= 0.002) and longer duration of remission (OR 1.033, P= 0.005) were associated with increased likelihood of having MRD– status. Clinical trial information: NCT01564784. **Conclusions:** Among pts who received InO in the INO-VATE trial, having CR/Cri and MRD– status at EOT was associated with the greatest survival outcomes. However, pts who achieved an MRD+ CR/CRi had much greater survival than those who did not have CR/CRi. In R/R ALL, use of InO may optimize chances to attain the primary goal of complete remission and MRD– status.

	CR/CRi and MRD– (n = 76)	CR/CRi and MRD+* (n = 45)	No CR/CRi (n = 43)
Median OS, mos [95% CI]	14.1 [8.6–23.0]	7.2 [5.8–10.8]	2.6 [1.9–3.6]
Median PFS, mos [95% CI]	8.6 [6.2–11.4]	5.4 [3.9–6.2]	1.4 [1.0–1.9]

Nivolumab (Nivo) maintenance (maint) in high-risk (HR) acute myeloid leukemia (AML) patients. *First Author: Tapan M. Kadia, The University of Texas MD Anderson Cancer Center, Department of Leukemia, Houston, TX*

Background: Frontline AML induction produces 60-70% complete remission (CR) rates but relapse is a major source of failure. Beside stem cell transplant (SCT), few options exist for post-CR maint in HR pts. Prior maint studies of cytotoxics were unsuccessful. Post SCT immune surveillance via tumor-specific cytotoxic T-cells may be important in suppressing AML relapse. Immune checkpoint inhibitors may restore host immune surveillance in post-CR maint. **Methods:** This is a pilot phase II study of nivo maint in HR AML pts in CR, ineligible for SCT. Pts ≥ 18 yrs with a HR feature in 1st CR (CR1) or any pt in 2nd CR (CR2) who received induction & ≥ 1 consolidation cycle & were within 12 months (mos) of CR were eligible. Treatment was: nivo 3mg/kg IV Q2 weeks for 6 mos, then Q4 weeks until 12 mos on study, & then Q3 mos until relapse. All pts had baseline cytogenetic (CG) & molecular testing, & minimal residual disease (MRD) assessment by flow cytometry. Blood & marrow samples were collected for immune correlatives. CR duration (CRd) is compared to a similar historical cohort with median (med) of 8 mos. **Results:** 14 pts (med age 56 yrs): 11 pts were in CR, CRp (1), & CRi (2) at enrollment; 11 pts (79%) were in CR1, 2 pts (14%) in CR2, & 1 pt (7%) in CR4 was treated. Baseline mutations: TP53 (n = 3), DNMT3a (2), IDH2 (2), NPM1 (2), TET2 (3). HR features: 5 (36%) persistent MRD, 4 (29%) adverse CG, 1 (7%) adverse mutation alone, 1 t-AML (7%) & 3 pts (21%) in ≥ CR2. Pts received a med of 4 (1-17) cycles of therapy. At med F/U of 11 mos (1.4 – 26), med CRd was not reached. 6- & 12-mo rates of CRd were 79% & 71%, respectively. The 12- & 18-mo estimated OS were 86% & 67%, respectively. Therapy was well tolerated; 5 pts had grade 3/4 immune-related events. 1 pt had thyroiditis, treated with steroids & hormone replacement; 1 pt with transaminitis responded to dose interruption; 2 pts had pneumonitis treated with steroids & dose interruption. All 4 pts resumed rx after interruption. 1 pt had autoimmune hemolytic anemia & came off study. Most pts have detectable MRD while on therapy & in CR; 1 pt cleared MRD & 1 pt normalized CG. **Conclusions:** Maint nivo is safe & feasible in HR AML. The study continues to surpass expected rate of 6-mo CRd of HR pts. Correlatives profiling the immune repertoire are being analyzed. Clinical trial information: NCT02532231.

7015 Poster Discussion Session; Displayed in Poster Session (Board #75), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 11:30 AM-12:45 PM

Profiling the immune checkpoint pathway in acute myeloid leukemia. *First Author: Paola Dama, University of Chicago, Chicago, IL*

Background: The immune checkpoint pathways in AML patients especially during the course of chemotherapy induction were seldom studied. This study was to characterize these pathways in AML patients treated on a prospective clinical trial to combine Selinexor with high-dose cytarabine (HiDAC) with mitoxantrone (Mito) (NCT02573363). **Methods:** Multiparameter flow-cytometry was utilized to monitor the changes in expression of immune checkpoint receptors using bone marrow and peripheral blood samples at diagnosis and following remission induction therapy in 26 patients with AML enrolled to the study. Expression of CD47, PD-L1, PD-L2 and Gal-9 was assessed on $CD34^+$ AML blasts and $CD34^-$ cell populations. In parallel, we evaluated expression of inhibitory (PD1, CTLA4, LAG3, TIM3) and stimulatory co-receptors (CD28, ICOS, CD137, OX40, CD40L, HLA-DR) on $CD4^+$ and $CD8^+$ T cell subsets. Flow cytometry data were analyzed with FlowJo-10 software. The Mann Whitney Test, Wilcoxon Rank test and Spearman's rank correlation analysis were applied. **Results:** The percentage of $CD34^-$ $Gal9^+$ cells was significantly higher in patients who experienced treatment failure (TF) after chemotherapy, comparing with those in complete remission (CR), with median of 36.9% (range: 1.7% -98.3%) versus a median of 3.8% (range: 0.18%-60.1%; $p < 0.05$). There was no difference of PD-L1 expression in these two patient groups. At the time of remission, we observed significant increase of expression of PD-L1 on BM CD34- cells, Tim3 on BM CD4+ and CD8+ T cells, as well as co-stimulatory checkpoint receptors: CD137 (4-1BB), HLA-DR on BM CD4+ cells, and OX40 on BM CD8+ T cells. In peripheral blood, the PD1 expression on CD4 cells was much higher at the time of remission comparing to that at the diagnosis. These data suggested an exhausted T cells status at the time of disease remission on the clinical trial treatment. **Conclusions:** Our small study demonstrated high level expression of Gal9 in CD34- cells in the BM at diagnosis in patients who failed induction chemotherapy. Increased expression of Tim 3 on CD4 and CD8 T cells in the BM and high PD-1 in peripheral CD4+ T cell at the disease remission suggested an exhausted immune status, which could be targeted with checkpoint inhibitors.

Treg infiltration and the expression of immune checkpoints associated with T cell exhaustion in AML. *First Author: Patrick Williams, University of Texas MD Anderson Cancer Center, Department of Cancer Medicine, Houston, TX*

Background: Better defining the immune checkpoint landscape of Acute Myeloid Leukemia will facilitate the rational selection of immune checkpoint targets and combination approaches for future clinical trials. **Methods:** Flow cytometry was performed on bone marrow aspirates (BMA) from 107 patients with AML treated at the MD Anderson Cancer Center. We evaluated the expression of inhibitory (PD1, CTLA4, LAG3, TIM3) and stimulatory receptors (GITR, OX40, 41BB, ICOS) on T cell subsets and the expression of their ligands (41BBL, B7-1, B7-2, ICOSL, PDL1, PDL2 and OX40L) on AML blasts. We correlated the expression of these markers with age, karyotype, a baseline next generation sequencing for 28 myeloid-associated genes including P53, DNA methylation proteins (DNMT3a, IDH1, IDH2, TET2) and FLT3, as well as prior treatment history. **Results:** When gating on $CD45^+$ cells, compared to healthy donors, patients with new and relapsed AML had an increased frequency for $CD3^+$ T cells (60.3% vs 78.0% vs 81.1%, P = 0.02), Tregs (1.7% vs 2.02 vs 3.02, P = 0.02), $PD1^+$ $CD8^+$ T cells (12.1% vs 27.3% vs 30.3%, P = 0.02) and $OX40^+$ $CD8^+$ T cells (0.62% vs 0.85% vs 2.26%, P = 0.03), $PD1^+$ $CD4^+$ T effector cells (13.2% vs 13.4% vs 25.5%, %, $P < 0.01$) and $OX40^+$ $CD4^+$ T effector cells (0.79% vs 4.81% vs 5.86%, P = 0.04). Compared to healthy donors, patients with new and relapsed AML had a higher incidence of exhausted $PD1^+$ $TIM3^+$ $CD8^+$ T cells (0.75% vs 1.36% vs 1.72%, P = 0.09), $PD1^+$ $TIM3^+$ $CD4^+$ T effector cells (0.75% vs 2.2% vs 2.8%, P = 0.16), $PD1^+$ $LAG3^+$ $CD8^+$ T cells (2.71% vs 4.69% vs 8.98%, $P < 0.01$) and $PD1^+$ $LAG3^+$ $CD4^+$ T effector cells (2.71% vs 14.3% vs 13.5%, P = 0.05), with bimodal distributions. The Treg to $CD8^+$ T cells correlated with increased frequencies of $PD1^+TIM3^+$ and $PD1^+LAG3^+$ $CD8^+$ T cells (P = 0.01). Blasts in BMAs from patients with TP53 mutated AML were more frequently positive for PD-L1 (6.95% vs 12.5%, P = 0.05). **Conclusions:** The increased Treg and exhausted T cell frequency in AML BMAs point to worsening exhaustion of the immune response. The dual contributions from Tregs and checkpoint ligand expression by blasts to immune suppression indicate that these pathways may play an important role in AML survival and therefore patients may benefit from checkpoint antibody therapy.

7017 Poster Discussion Session; Displayed in Poster Session (Board #77), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 11:30 AM-12:45 PM

Post hoc exploratory analysis of two phase 2 trials of quizartinib monotherapy in patients (pts) with *FLT3*-ITD–mutated (mu) relapsed/refractory (R/R) AML with or without prior 1st-generation FLT3 tyrosine kinase inhibitors (TKI) treatment. *First Author: Mark J. Levis, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD*

Background: First-generation (1st gen) FLT3 TKIs such as sorafenib (SOR) / midostaurin (M) are increasingly used for treatment of *FLT3*-mu acute myeloid leukemia (AML). Quizartinib (Q) is a highly potent and selective FLT3 inhibitor with strong clinical antileukemic activity in pts with *FLT3*-ITD mu R/R AML. Analyzing the clinical activity of Q in pts with prior TKIs may provide early insights into an important clinical question about potential benefit of agents with varying kinase and safety profiles. **Methods:** This post hoc exploratory analysis was done in two phase 2 trials of Q monotherapy in *FLT3* mu R/R AML (Studies (A) NCT01565668, (B) NCT00989261) to assess Q activity in pts w/ prior FLT3 TKI therapy. Pts with *FLT3*-ITD allelic frequency ≥ 3% were considered *FLT3*-ITD positive for this analysis. 27 of 261 *FLT3*-ITD mu pts received prior SOR and/or M (24 SOR, 1 SOR and M, 2 M) in Study A (Q 90, 135, or 200 mg/d). 11 of 72 *FLT3*-ITD mu pts received prior TKIs (10 SOR, 1 SOR and M) in Study B (Q 30 or 60 mg/d). In both studies, Q was given for 28-day cycles until relapse, intolerance, or proceeding to HSCT. **Results:** In Study A, composite complete remission (CRc = CR+CRp+CRi) and overall response rates (ORR = CR+CRp+CRi+PR) with Q were 33% (9/27) and 67% (18/27), respectively, in prior-TKI-treated pts, compared with 53% (117/221) and 75% (165/221), respectively, in the TKI-naive pts. In Study B, CRc and ORR were 36% (4/11) and 45% (5/11), respectively, in prior-TKI-treated pts, compared with 48% (29/61) and 69% (42/61), respectively, in the TKI-naive pts. Median survival durations in Study A were 24.6 wk for prior-TKI-treated pts and 24.7 wk for TKI-naive; in Study B they were 20.9 wk and 23.7 wk, respectively. **Conclusions:** This analysis demonstrates meaningful clinical activity of Q in *FLT3*-ITD mu R/R AML pts with prior 1st gen FLT3 TKI exposure. Limitations are small sample size and post hoc analysis. Further studies, including mutational analyses, are warranted to further characterize the potential mechanism/s of response to Q in pts who have failed prior FLT3 TKI. Clinical trial information: NCT01565668; NCT00989261.

7018 Poster Discussion Session; Displayed in Poster Session (Board #78), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 11:30 AM-12:45 PM

Erythropoietic cellular analyses in luspatercept-treated lower-risk myelodysplastic syndromes (MDS): Phase 2 PACE-MDS study. *First Author: Uwe Platzbecker, Universitatsklinikum Dresden, Dresden, Germany*

Background: Luspatercept (ACE-536) is a TGF-β family ligand trap promoting late-stage erythroid (E) differentiation and increases in hemoglobin. Endpoints of the ongoing, phase 2, open-label study in MDS include E response (IWG HI-E), RBC transfusion independence (RBC-TI, ≥8 weeks), and molecular/bone marrow (BM) morphological characteristics associated with response. **Methods:** MDS IPSS low or int-1 patients (pts) were treated every 3 weeks subcutaneously (up to 1.75 mg/kg) in the base/extension studies (NCT01749514/NCT02268383). BM and blood samples were analyzed prior to and at the end of 5 cycles of treatment (EOT) by central morphology and flow cytometry according to ELN guidelines to investigate E precursors, soluble transferrin receptor (sTfR), and reticulocytes (retics) in relation to response. **Results:** Data (as of 08Sept2017) were available for 49 pts (≥0.75 mg/kg) with evaluable flow and BM data. HI-E and RBC-TI responses were 61% (30/49 pts) and 55% (16/29 pts), respectively. At baseline, M/E ratio was lower and sTfR two-fold higher in R vs NR, mirrored by an increase in erythroid precursors. By EOT, retics were increased in R and remained unchanged in NR. **Conclusions:** These data suggest that expanded late-stage erythropoiesis at baseline is associated with a response to luspatercept. Responses were accompanied by further expansion of erythropoiesis (or activation of bone marrow) and increased release of reticulocytes, supporting luspatercept as an erythroid-maturation agent (EMA). Clinical trial information: NCT01749514, NCT02268383.

First-in-human study of ABBV-075 (mivebresib), a pan-inhibitor of bromodomain and extra terminal (BET) proteins, in patients (pts) with relapsed/refractory (RR) acute myeloid leukemia (AML): Preliminary data. *First Author: Gautam Borthakur, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Pts with RR AML have a poor prognosis. BET proteins bind acetylated histone tails, leading to the upregulation of oncogenic target genes; their inhibition can block aberrant transcription in tumor models. ABBV-075 is a pan-BET inhibitor with antitumor activity in vitro and in xenograft models of AML. This 2-part first-in-human study assesses the safety and PK of ABBV-075 at various monotherapy or combination dosing schedules (NCT02391480). In part 1, the recommended phase 2 dose for ABBV-075 monotherapy in pts with solid tumors was identified. Here, we report preliminary data from part 2 in pts with RR AML. **Methods:** Adult pts with RR AML received daily ABBV-075 as monotherapy (ABBV075-mono) or combined with venetoclax (ABBV075-VEN). The dose-limiting toxicity (DLT) period was 28 d (ABBV075-mono) or 21 d (ABBV075-VEN). Thrombocytopenia was not considered a DLT. **Results:** As of 1 Jan 2018, 19 pts (median age: 65 y [range, 30–78]; 14 pts had ≥3 prior therapies) were enrolled: 12 pts in ABBV075-mono, 7 in ABBV075-VEN cohorts. Median time on treatment was 39 d (range, 3–213). There were no DLTs; 16 pts experienced AEs. AEs irrespective of causality in > 3 pts were: anemia (11), fatigue (11), dysgeusia (10), nausea (9), diarrhea (7), decreased appetite (7), febrile neutropenia (6), thrombocytopenia (6), and dry mouth, vomiting, contusion, decreased platelet count, decreased weight, hyponatremia, and hemoptysis (4 each). 15 pts had grade ≥3 AEs (anemia [11]); 13 pts had serious AEs (febrile neutropenia [4]). 10 pts died of causes unrelated to ABBV-075, 5/10 pts due to AML progression. In ABBV075-mono cohorts, bone marrow blast count was ≤50% of baseline in 4/11 evaluable pts. 1 pt (female; normal cytogenetics; *STAG2* mut) reached complete remission with incomplete hematologic recovery (thrombocytopenia) in cycle 5, still maintained at 8 m from treatment start. At cutoff date, the median overall survival for all pts was 3.2 m, and 4 pts were still in treatment without progression for 1, 6, 20, and 24 w. Enrollment is ongoing. **Conclusions:** ABBV-075 was well tolerated and showed antileukemic effects in pts with RR AML. Clinical trial information: NCT02391480.

Analysis of anti-leukemic activity, predictive biomarker candidates, immune activation and pharmakodynamics in R/R AML and MDS in response to treatment with bemcentinib (BGB324), a first-in class selective AXL inhibitor, in a phase II open-label, multi-centre study. *First Author: Bjorn T. Gjertsen, Centre for Cancer Biomarkers CCBIO, Department of Clinical Science, University of Bergen, Bergen, Norway*

Background: Bemcentinib (BGB324) is a first-in-class, oral selective inhibitor of the RTK AXL currently in ph II clinical development across several cancer types. AXL overexpression has been established as an independent negative prognostic factor in AML whereas AXL inhibition via bemcentinib has shown anti-leukemic activity and immune activation in pre-clinical models of AML and other cancers. **Methods:** N = 35 R/R AML or MDS (interm-2 and high-risk) pts received bemcentinib monotherapy in this two part 3+3 dose escalation and cohort expansion study. Plasma protein biomarker levels were measured using the DiscoveryMap v3.3 panel (Myriad RBM) in a selection of pts pre-dose and at C2D1. Gene expression analysis was carried out by qPCR using TaqMan. Phosphorylation of AXL and downstream targets PLCγ1, Erk/MapK and Akt was carried out by single cell flow and mass cytometry. Clonal evolution was analysed by exome sequencing and TruSight myeloid panel. The TCRb- and IGH-repertoire was investigated using Biomed TCRb-A/B and Biomed2 FR-2/3 primer pools and NGS on an Illumina MiSeq platform. **Results:** Treatment was generally well-tolerated with most AEs being mild or moderate in severity. 2 pts achieved complete responses with incomplete recovery of peripheral counts (CRi) and 5 achieved partial responses (PR). 8 pts reported disease stabilisation for more than 4 months. Levels of plasma soluble AXL and angiogenin and BM SLFN-11 expression correlated with pt benefit. Whole exome sequencing analysis showed conservation of clones which may limit the evolution of resistant blasts. Immune activation was observed by T- and B-cell receptor diversification. PhosphoFlow analysis of AXL and downstream signalling intermediates evidenced target inhibition. **Conclusions:** Bemcentinib is well tolerated in MDS and AML pts and exhibits anti-leukemic activity through multiple mechanisms including immune modulation. Pt benefit (CRi/PR/SD > 4 mths) is predictable by measurement of plasma markers soluble AXL and angiogenin. Clinical trial information: NCT02488408.

Is there a benefit of re-induction therapy in adult patients with AML with <20% blasts? *First Author: Kavya Kannamma Kannan, Wake Forest University School of Medicine, Winston-Salem, NC*

Background: Decision on re-induction (RI) therapy in adult patients with newly diagnosed acute myeloid leukemia (AML) who have received induction chemotherapy (ICT) when there are less than 20% blasts on day 14 nadir bone marrow biopsy (NBMB), is difficult due to the lack of efficacy data and the toxicity associated with RI. We sought to determine the utility of RI in this group of patients. **Methods:** We identified 270 adults with AML treated at Wake Forest Baptist Health with ICT between 2002-2009. We excluded 37 patients who did not have a NBMB. NBMB were classified as negative (< 5% blasts), suspicious (< 5% blasts with morphological suspicion for residual disease or 5-20% blasts) and positive (> 20% blasts) for residual disease. Complete remission (CR) was achieved if recovery BM had < 5% blasts along with platelet recovery to at least 100,000 cells/microliter and absolute neutrophil count of at least 1000 cells/microliter. A CRi was defined as having either platelet or neutrophil recovery but not both. Kaplan Meier estimation was used to calculate the median OS and survival estimates at 1, 2, and 3 years post induction. **Results:** Of the 233 patients, 106 (45.5%) had NBMB findings suspicious for residual disease (sRD). Of these patients, 66 (62.3%) underwent RI and 40 (37.7%) did not. Of those who received RI, 52 of 66 (78.8%) achieved a CR/CRi. In the patients who did not receive RI, 32 of 40 (80.0%) achieved a CR/CRi. There was no statistical difference in median OS with and without re-induction in patients with sRD overall and when sub classified into favorable, intermediate and poor cytogenetic categories. **Conclusions:** Our retrospective analysis raises questions of the utility of RI in adult patients with AML with less than 20% blasts on nadir marrow. This finding warrants prospective trials for further validation.

Clonal evolution in acute myeloid leukemia (AML): Relapse after a long remission period. *First Author: Musa Yilmaz, Baylor College of Medicine, Houston, TX*

Background: Late relapse in AML occurring more than 5 years after achieving remission is uncommon and underlying biological events are poorly understood. We aim to determine the clonal events resulting in late relapse of AML. **Methods:** We identified patients (pts) with AML who received intensive induction chemotherapy between 1990 and 2010, achieved complete remission (CR), and remained in CR for at least 5 years. A total 349 pts were identified, and 15 (4%) relapsed beyond 5 years. Whole exome-sequencing was performed in diagnosis (dx) and 1st relapse bone marrow samples (available in 10 pts). **Results:** A total of 43 driver mutations were identified in 10 pts, of which 12 were primary tumor specific, 18 relapse-specific, and 13 were shared between primary and relapsed tumor (Table). Twenty-seven of 43 driver mutations (63%) were nonsynonymous SNV and 16 (37%) were indels. At relapse, 3 clonal evolution patterns were identified: pattern 1, the founding clone in the primary tumor gained additional mutations and evolved into the relapse clone and a subset of primary tumor mutations were not detected at relapse (UPN 1, 5, 6, and 7); pattern 2, the founding clone in the primary tumor gained additional mutations at relapse (UPN 9, 10, 12, and 14); pattern 3, relapsing clone harbored none of the primary tumor mutations, thus it represented a new clone (UPN 3 and 15). **Conclusions:** Relapse after a long remission in pts with AML is associated with persistence of the founding clone and acquisition of new relapse-specific mutations in the majority. Understanding the mechanisms of such quiescence may assist in increasing CR duration in pts with AML.

Driver mutations identified in 10 primary-relapse pairs.

Impact of numerical variation, allele burden and mutation length on outcomes in acute myeloid leukemia with fms-like tyrosine kinase receptor-3 internal tandem duplication (FLT3-ITD) mutation. *First Author: Ahmad Ghorab, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: While high allelic burden is known to be associated with adverse outcomes in FLT3-ITD mutated AML, the impact of numerical variation and insert size on clinical outcome of AML patients (pts) is not well studied. **Methods:** Analysis included 330 newly diagnosed AML pts with FLT3-ITD mutation diagnosed between 3/1999 and 11/2015. Overall survival (OS) was calculated from the time of diagnosis to death/last follow up time (LFU). Relapse free survival (RFS) was calculated from response to relapse/LFU. **Results:** Table 1 summarizes patient characteristics, response and OS, RFS according to mutation number, size, allelic burden and stem cell transplantation (SCT). Because of the time frame, only 20% pts had frontline exposure to FLT3 inhibitors. **Conclusions:** Numerical variation and insert length had no significant impact on outcomes while lower allelic burden, FLT3 inhibitor therapy trended towards better RFS. SCT had a significant favorable impact on both OS and RFS.An expanded contemporary cohort analysis is ongoing.

Patient characteristics and outcomes:

iCare 1: A prospective clinical trial to predict treatment response based on genomics-informed computational biology in patients with acute myeloid leukemia (AML) and myelodysplastic syndromes (MDS). *First Author: Leylah Drusbosky, University of Florida, Gainesville, FL*

Background: Cytotoxic agents (7+3, HiDAC) and hypomethylating agents (HMAs) fail in the majority of MDS and AML pts. The aim of this study is to determine the predictive values of a genomics-informed computational biology method (CBM) in pts who are treated with standard of care (SOC) therapy. **Methods:** AML or MDS pts were recruited to a prospective clinical trial to assess predictive values by comparing CBM predictions of treatment response to actual clinical response. Genomic profiling was done by cytogenetics, whole exome sequencing, and copy number variation analysis. All genomic data were entered into CBM, which creates disease-specific protein network maps using PubMed. Digital drug simulations were done by measuring drug effect on a cell growth score. Each pt-specific protein network map was screened for the extent to which each pt's therapy reduced simulated disease growth. Clinical outcomes were prospectively recorded. For AML, CR+PR was used to define response (IWG 2003). For MDS, CR+PR+HI was used to define response (IWG 2006). Western blots were performed on pathway proteins. 2x2 tables and Fisher's exact tests were used to compare CBM prediction values vs empiric drug administration. **Results:** 135 pts were recruited, and 101 have had all genetic tests performed. 50/101 pts received 61 treatments and were eligible for efficacy evaluation. 33/50 had AML, 15/50 had MDS. Western blot validation showed correct prediction of 4 activated networks (Akt2, Akt3, PIK3CA, Erk1/2), with 89% accuracy. 55 drug outcome predictions were correctly matched to their actual clinical outcomes, resulting in 90% prediction accuracy, 93% PPV, 92% NPV, 93% sensitivity, and 88% specificity. The accuracy of CBM was significantly greater than empiric drug administration (p = 1.664e-05). **Conclusions:** CBM that models multiple genomic abnormalities showed high predictive value of protein network perturbations and clinical outcomes after SOC treatments. This technology could be used to establish eligibility criteria for precision enrollment in drug development trials, and will be used in upcoming precision medicine trials. Clinical trial information: NCT02435550.

7025 Poster Session (Board #85), Mon, 8:00 AM-11:30 AM

Determining the sensitivity of primary acute myeloid leukemia (AML) samples with FLT3-ITD or FLT3-D835 mutations to FLT3 inhibitors using an ex vivo drug sensitivity screen. *First Author: Mara Rosenberg, Oregon Health & Science University, Portland, OR*

Background: AML has high molecular complexity and certain markers are predictors of overall survival. Mutations in FLT3-ITD, for example, lead to a poor prognosis with outcomes further worsened by co-occurring mutations in DNMT3A. Small molecule inhibitors have been developed to target a select number of these mutations such as Midostaurin on FLT3-ITD and FLT3-D835. However, the impact of the specific FLT3 mutation or the effect of co-occurring mutations in DNMT3A and NPM1 on drug sensitivity is not fully known. **Methods:** We identified 503 primary AML samples tested with an ex-vivo drug sensitivity screen that includes 130 small-molecule inhibitors and over 10 FLT3 inhibitors. Mononuclear cells were screened, metabolic viability assessed, and drug response summarized by area under the curve (AUC). **Results:** FLT3-ITD was the strongest indicator for response to FLT3 inhibitors (Table 1). Sensitivities were similar with DNMT3A and/or NPM1 co-mutations. Further, FLT3-D835 mutant samples showed no increased sensitivity to FLT3 inhibitors compared to non-FLT3 mutated samples. **Conclusions:** The similar ex-vivo drug sensitivity profiles inFLT3-ITD AML with or without DNMT3A and/or NPM1 mutations suggest co-treatment with FLT3 inhibitors will allow for improved overall survival in these cohorts. Additional clinical testing may further characterize the effect of FLT3-D835 mutations on targeted therapies and the impact of co-mutations. Some FLT3-ITD inhibitors showed increased potency compared to Midostaurin suggesting alternative treatment choices for select AML patients.

Mean AUC values (± confidence interval) for each drug by sample classification.

Classification	Quizartinib	KW-2449	Cabozantinib	Sorafenib	Sunitinib	Midostaurin
ITD+	37(±3)*	55(±5)	45(±4)*	52(±4)	55(±4)	56(±4)
ITD+ / DNMT3A+	36(±5)*	55(±6)	41(±7)*	48(±7)	54(±7)	60(±7)
ITD+ / NPM1+	35(±4)*	52(±6)	39(±5)*	48(±5)	53(±4)	53(±6)
D835+	46(±8)*	70(±8)	53(±11)	59(±8)	61(±8)	69(±9)
FLT3-	57(±2)*	77(±2)	67(±2)*	73(±2)	74(±2)	75(±2)

*Drug AUC differs from Midostaurin ($p < 0.001$). Sample classification differs from FLT3 Negative cohort ($p < 0.001$).

7026 Poster Session (Board #86), Mon, 8:00 AM-11:30 AM

Initial report of a phase I study of LY2510924 with idarubicin and cytarabine (IA) in relapsed/refractory (R/R) AML. *First Author: Prajwal Boddu, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: LY2510924 is a peptide antagonist of CXCR4, a key component of the CXCR4/SDF-1 signaling axis that is critical for homing of stem cells in the bone marrow and activation of downstream pathways involved in cell proliferation and survival. In a preclinical AML model, LY2510924 showed significant activity as a single agent and in combination with chemotherapy (*Cho et al. Blood* 2015). **Methods:** A phase I study was designed to determine the safety and toxicity profile of combination therapy of LY2510924 with IA in patients (pts) with R/R AML. Pts aged 18 to 70 years who failed prior therapy (≤ salvage 3) were eligible. LY2510924 is administered from days 1-7 followed by IA starting day 8. In responders, 4-6 consolidation cycles were administered. Two dose escalation levels (10 and 20 mg) were planned, according to a 3+3 design; up to 12 pts to be enrolled in phase I portion. **Results:** Eleven pts have been enrolled with a median age of 55 (range, 19-70) years. Of 10 pts tested, 2 (20%) had complex cytogenetics. Median prior therapies were 1 (1-3). Six pts were treated at dose level '0' (10 mg) and 5 at dose level '1' (20 mg); 3 of 5 treated at dose level '1' were evaluable for response. Most non-hematologic toxicities were grade 1-2 in severity. At dose level '0', 1 pt experienced dose limiting toxicity (DLT) (2 grade 3 DLTs: rash and hypo-cellular marrow). No major toxicities occurred at dose level '1'. At '0' dose level, 1 pt had a CR and 2 had CRi; at dose level '1', 1 achieved CR; the overall response rate was 44%. By flow cytometry, 4 of 9 had ≥ 50% decrease in CXCR4 mean fluorescence intensity. **Conclusions:** Combination of LY2510924 with IA is safe in R/R AML pts. Dose-escalation to 40 mg of LY2510924 is planned to achieve > 90% blockade of CXCR4 receptor occupancy, followed at the expansion phase of the study at recommended phase 2 dose level. Clinical trial information: NCT02652871.

7027 Poster Session (Board #87), Mon, 8:00 AM-11:30 AM

CX-01, an inhibitor of CXCL12/CXCR4 axis and of platelet factor 4 (PF4), with azacitidine (AZA) in patients with hypomethylating agent (HMA) refractory AML and MDS. *First Author: Eric Huselton, Washington University in St. Louis, St. Louis, MO*

Background: Outcomes are poor for older patients with AML and MDS who progress on HMAs. Blocking the CXCL12/CXCR4 axis may be therapeutic as this is essential for retention of malignant stem cells in the bone marrow (BM), where they may be protected from the genotoxic stresses of chemotherapy. CX-01 is a low molecular weight heparin derivative with minimal anticoagulant activity that disrupts the CXCL12/ CXCR4 axis, and neutralizes the activity of PF4, a negative regulator of megakaryopoiesis. We hypothesized that CX-01 would re-sensitize patients with HMA-refractory AML and MDS to AZA and mitigate thrombocytopenia. **Methods:** Patients with HMA-refractory INT-1 or greater MDS and AML received 7 day continuous infusion of CX-01 with 7 day AZA 75 mg/m^2 in 28 day cycles. The primary objective was to assess the overall response rate (ORR). **Results:** To date, 20 patients were treated and 12 are evaluable for response with a BM biopsy after C2. The median age was 74 years. 9 patients had secondary AML, 7 had MDS INT-1, 2 had MDS INT-2, and 2 had de novo AML. 10 patients had poor risk cytogenetics and/or p53 mutations. Baseline BM showed a median 16% blasts. Patients were heavily pretreated, receiving a median of 6 cycles of prior HMA cycles (range 4-20) with 10 patients receiving > 1 prior line of therapy. Patients received a median of 2 cycles of CX-01 with AZA (range 0-5). Of the 12 evaluable patients, there was 1 complete response (CR), 3 marrow CRs (with incomplete count recovery), 7 stable disease, and 1 progressive disease for an ORR of 33%. There was no significant difference in baseline characteristics of responders and the rest of the cohort. 3 of 4 responders had hematologic improvement, 2 with normalization of platelet counts. Median duration of response is 212+ days, with 2 patients disease-free at 192 and 233 days, and all four responding patients still alive. CX-01 was well tolerated, with all severe AEs thought unlikely to be related to CX-01. **Conclusions:** CX-01 and AZA appears to have an encouraging response rate in HMA-refractory AML/MDS. Treatment was feasible with no instances of study related severe AEs. This trial is ongoing to evaluate the ORR and OS of all patients treated. Clinical trial information: NCT02995655.

7028 Poster Session (Board #88), Mon, 8:00 AM-11:30 AM

Inotuzumab ozogamicin (InO) treatment in patients with relapsed/refractory (R/R) acute lymphoblastic leukemia (ALL): Analysis from INO-VATE by bone marrow blast percentage (BMB%). *First Author: Anjali S. Advani, Leukemia Program, Department of Hematology and Medical Oncology, Taussig Cancer Institute, Cleveland Clinic, Cleveland, OH*

Background: InO is a calicheamicin-conjugated antibody targeting CD22 on ALL blast cells. Here we report outcomes in R/R ALL patients (pts) receiving InO or standard of care chemotherapy (SC) in the phase 3 INO-VATE trial according to baseline BMB%, an indicator of disease burden. **Methods:** Adults with CD22+ ALL due to receive salvage treatment were randomized 1:1 to InO (n = 164) or SC (n = 162). Dosing and methods were published previously (Kantarjian et al, NEJM 2016). BMB% was defined as low (< 50%), moderate (50–90%), and high (> 90%) at start of treatment. **Results:** At baseline, characteristics across all groups were balanced and median BMB% was 28%, 78%, and 95% in the low, moderate, and high disease burden subgroups. Complete remission rates were significantly higher in InO vs SC pts, with 74% vs 46%, 75% vs 48%, and 70% vs 17% achieving CR/CRi in low, moderate, and high BMB% subgroups. Significantly more pts in the InO arm achieved minimal residual disease negativity: 29/53 (55%), 52/79 (66%), and 16/30 (53%) for low, moderate, and high BMB% compared with 10/48 (21%), 11/83 (13%), and 2/30 (7%) for SC, respectively. InO-treated pts also had improved progression-free survival vs SC, with hazard ratios of 0.44 (97.5% CI, 0.26–0.74, 1-sided P= 0.0001) for low, 0.50 (97.5% CI, 0.34–0.75, P< 0.0001) for moderate, and 0.33 (97.5% CI, 0.16–0.69, P= 0.0002) for high BMB%. Overall survival (OS) was favored in the InO arm across groups (Table) with potentially the greatest difference seen in pts with high BMB% (HR = 0.60 [97.5% CI 0.32–1.129, 1-sided P= 0.03]). Clinical trial information: NCT01564784. **Conclusions:** InO treatment resulted in superior efficacy over SC across all BMB% subgroups out to 2 years follow-up, particularly in patients with the greatest disease burden by BMB%.

7029 Poster Session (Board #89), Mon, 8:00 AM-11:30 AM

Extensive safety profile of inotuzumab ozogamicin (InO) in relapsed/refractory acute lymphoblastic leukemia (ALL) patients enrolled in the phase 3 INO-VATE trial. *First Author: Ryan Daniel Cassaday, University of Washington School of Medicine and Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: In INO-VATE, patients (pts) treated with InO vs standard chemotherapy (SC) had significantly greater remission rates and longer overall survival (OS), with 23% reduced risk of death (Kantarjian et al, NEJM 2016). Here we report detailed safety outcomes from long-term follow-up. **Methods:** Study methods were previously published. Adults with CD22+ ALL in 1st or 2nd salvage were randomized 1:1 to InO (n = 164) or SC (n = 162). Data up to Jan 4, 2017 are reported. **Results:** Adverse event (AE) and serious AE rates were similar between arms even though more cycles of InO than SC were administered (Table). Grade (Gr) 3-4 AE rates were higher with SC, while more Gr 5 AEs occurred with InO vs SC (6% vs 2%); 5 cases (3%) were veno-occlusive disease (VOD). More pts taking InO discontinued due to AEs, most often from infections (10 [6%]) including pneumonia and sepsis, hepatobiliary disorders (7 [4%]), or blood/lymphatic disorders (BLD) including cytopenias (5 [3%]). For SC, discontinuations were most often from infections (6 [4%]) or BLD (3 [2%]). More hepatic AEs (any Gr) occurred with InO: 83 (51%) vs 52 (36%), including VOD (23 [14%] vs 3 [2%]). A lower percentage of death was seen with InO: 131 (80%) vs 126 (88%) for SC. Fewer InO pts died from ALL: 80 (49%) vs 100 (70%) for SC. Clinical trial information: NCT01564784. **Conclusions:** Safety data from the final report of INO-VATE are consistent with previous reports of data that also include greater efficacy (longer survival) seen with InO vs SC. Temporary discontinuation and dose reduction of InO were used to manage serious or severe AEs. Data suggest vigilant monitoring, treatment, and/or prevention for the most common events such as VOD and infections are needed to optimize outcomes.

	Treatment-emergent AEs (TEAEs)		Treatment-related TEAEs

7030 Poster Session (Board #90), Mon, 8:00 AM-11:30 AM

Outcomes with inotuzumab ozogamicin (InO) in patients with Philadelphia chromosome–positive (Ph+) relapsed/refractory (R/R) acute lymphoblastic leukemia (ALL). *First Author: Wendy Stock, Section of Hematology/Oncology, Department of Medicine, University of Chicago Pritzker School of Medicine, Chicago, IL*

Background: InO, a CD22-directed antibody-drug conjugate, is approved to treat adults with R/R ALL. Historically, patients (pts) with Ph+ ALL (~20–30%) have had poor prognoses compared with Ph− pts. **Methods:** Pts with R/R ALL received InO in a phase 1 dose-finding/phase 2 study (1010; DeAngelo et al, Blood Adv 2017) and a phase 3 trial (1022; Kantarjian et al, NEJM 2016) comparing InO vs standard chemotherapy (SC). We analyzed outcomes in Ph+ pts (Ph chromosome or BCR-ABL gene by FISH) treated with InO (InO-1010 or InO-1022) or SC based on final data from each study. **Results:** In 1010 and 1022, respectively, 16 and 22 Ph+ pts received InO; 27 Ph+ pts were randomized to SC in 1022 (22 received SC). Pts in 1010 were heavily pretreated. Among Ph+ pts in 1022, 19 (86%) InO pts and 26 (96%) SC pts had previous tyrosine kinase inhibitors (TKIs). Prior stem cell transplants (SCT) were 8 (50%) for InO-1010, 7 (32%) for InO-1022, and 9 (33%) for SC. Also, 15 (94%), 10 (45%), and 15 (56%) pts were treated in ≥2nd salvage for InO-1010, InO-1022, and SC, respectively. Efficacy outcomes are shown (Table). A total of 3 (19%) InO-1010 pts, 9 (41%) InO-1022 pts, and 5 (19%) SC pts proceeded to SCT after treatment. The most common non-hematologic grade 3-4 adverse events with InO in Ph+ pts were gastrointestinal disorders (31%) in 1010 and multi-organ laboratory abnormalities (41%) in 1022; 2 Ph+ pts in each InO study had veno-occlusive liver disease. Among SC pts, infections (55%) were the most common grade 3-4 nonhematologic events. Clinical trial information: NCT01363297. **Conclusions:** In Ph+ pts with R/R ALL who failed prior TKIs +/- SCT, InO-treated pts had higher rates of CR/CRi, MRD negativity, and subsequent SCT. However, overall outcomes in 1022 InO vs SC were still inferior to those reported in Ph– pts; thus additional treatment combinations should be explored.

Efficacy Endpoints	InO-1010 (n = 16)	InO-1022 (n = 22)	SC (1022) (n = 27)
Complete remission (CR/CRi), n (%)	9 (56)	16 (73)	15 (56)
Minimal residual disease (MRD) negativity, n (%)	10 (63)	14 (64)	5 (19)
Overall survival (mos), median (95% CI)	7.4 (4.3–11.3)	8.7 (3.6–14.1)	8.4 (5.0–14.3)
Progression-free survival (mos), median (95% CI)	4.4 (1.8–5.9)	3.9 (2.1–9.2)	3.1 (1.1–6.2)

7031 Poster Session (Board #91), Mon, 8:00 AM-11:30 AM

Phase 1 trial of pegzilarginase in patients (pts) with relapsed/refractory (R/R) AML or MDS refractory to hypomethylating agents (HMAs). *First Author: Geoffrey L. Uy, Washington University School of Medicine, St. Louis, MO*

Background: In vitro studies demonstrate that AML cells are arginine auxotrophs and are metabolically vulnerable to arginine depletion (PMID: 24018014 & 25896651). To test the clinical utility of arginine depletion in AML we performed a phase 1 trial of pegzilarginase, a pegylated, recombinant, cobalt-substituted, human arginase I in pts with R/R AML or MDS (NCT02732184). **Methods:** Pts with R/R AML or HMA-refractory MDS were enrolled in a phase 1 dose escalation study using a 3+3 design. The primary endpoint was MTD. Other endpoints included safety, PK, PD (arginine & ornithine), immunogenicity, preliminary clinical activity, and expression of ASS1, ASL, & OTC in blasts. **Results:** Twenty-one pts (19 AML, 2 MDS) were treated with weekly pegzilarginase 0.12 to 0.48 mg/kg. Low ASS1 expression was observed in the majority of pt samples by rtPCR. Eleven pts received at least 4 doses. One dose-limiting toxicity (DLT) of reversible G4 encephalopathy was observed at 0.48 mg/kg. Seven pts were then enrolled at 0.36 mg/kg. No DLTs were observed but 4 pts discontinued treatment before receiving 4 doses (3 - disease progression, 1 - withdrew consent). Related serious or ≥ Gr3 AEs in ≥2 pts were nausea and vomiting (3 pts each), and diarrhea and fatigue (2 pts each). Related AEs in ≥10% of pts included nausea (10 pts, 2 Gr 3), vomiting (9, 2 Gr 3), fatigue (7, 1 Gr 3), decreased appetite (6), diarrhea (3, 2 Gr 3), and dizziness (3, 1 Gr 3). The pegzilarginase $t_{1/2}$ was ~39 to 49 hr at ≥ 0.24 mg/kg and depleted arginine to ~10% of baseline for ≥48 hrs. One of 14 pts developed a low titer of anti-drug antibodies 4 weeks after start of treatment that was no longer detected at end of treatment (3 weeks after last dose). No clinical responses were observed. **Conclusions:** Pegzilarginase was well tolerated up to 0.36 mg/kg with a manageable safety profile. PK/PD data support weekly dosing, as confirmed by a rapid and sustained reduction in blood arginine. The observed results are consistent with a recent Ph 2 trial of arginine depletion in AML (PMID:28900115), suggesting depletion of arginine alone is insufficient for clinical activity in AML. Alternative approaches including combination therapy may be required. Clinical trial information: NCT02732184.

7032 Poster Session (Board #92), Mon, 8:00 AM-11:30 AM

A retrospective study of comorbidities and complications in elderly acute myeloid leukemia (AML) patients in the U.S. *First Author: Neil Dhopeshwarkar, Daiichi Sankyo, Basking Ridge, NJ*

Background: Treatment decisions are often influenced by comorbidity and functional capacity. Comorbidity burden in patients with AML has been shown to increase by age, but there is limited characterization of comorbidities and complications in elderly AML patients, who generally are underrepresented in clinical trials. We characterized elderly AML patients in terms of comorbidities and complications. **Methods:** Patients (≥ 65 years) with a primary diagnosis of AML (SEER ICD-O Recode 35021 and ICD-9 205.0x) were identified from the SEER-Medicare Linked Database (2000-2013) and were followed till end of 2014. AML patients were matched 1:1 to patients without cancer on age, sex, geographic region, and race. A subset of relapsed and/or refractory (R/R) AML patients was identified using a modified previously validated algorithm. Comorbidities were assessed using NCI index scores. Incidence rates were calculated for select complications. Cox Proportional Hazards models were used to assess risks of complications. **Results:** The median age in AML and matched non-cancer patients (3,911 matched pairs) was 77 years (65-101 years) with 54% being male. AML patients had more comorbidities (52.1 % vs. 48.3% with ≥1 comorbidity) and higher comorbidity scores (NCI scores: 0.97 vs. 0.84, $p < 0.01$) at baseline (up to 12 months prior diagnosis) compared to non-cancer controls. Among other complications, incidence rates (per 100 person years) of cardiovascular disease (CVD) (54.0 vs. 8.8, $p < 0.01$), type 2 diabetes (T2D) (25.4 vs. 4.8, $p < 0.01$), and stroke (17.0 vs. 5.7, $p < 0.01$) were higher among AML patients. After adjusting for age, sex, region, NCI score, and baseline myelodysplastic syndrome, AML patients had a significantly higher risk of CVD (HR 4.61, 95% CI 4.07-5.21), T2D (HR 3.85, 95% CI 3.35-4.42), and stroke (HR 2.60, 95% CI 2.32-2.92). Similar results were observed in the R/R AML group. **Conclusions:** Elderly AML patients had higher comorbidities and rates of complications compared to matched non-cancer patients. Clinical decisions should consider the presence of comorbidities and complications. Further research is needed to better understand the association between AML and chronic health outcomes.

7033 Poster Session (Board #93), Mon, 8:00 AM-11:30 AM

Hypomethylating agent (HMA) treatment as a bridge to allogeneic hematopoietic cell transplantation (HCT) for relapsed/refractory acute myeloid leukemia (RR-AML). *First Author: Michael Richard Grunwald, Levine Cancer Institute, Atrium Health, Charlotte, NC*

Background: Outcomes for patients (pts) with RR-AML are poor, with limited treatment options. Salvage HMA therapy has been explored for RR-AML but is often considered palliative. We examined response and survival in RR-AML pts treated with HMA therapy, including HCT rates and outcomes. **Methods:** All RR-AML pts initiated on HMAs at our institution between August 2013 and August 2017 were analyzed. Overall response rate (ORR) included complete remission (CR), CR with incomplete platelet recovery (CRp), CR with incomplete count recovery (CRi), and hematologic remission (defined by neutrophils $>$ 1000/μL, platelets $>$ 100k/μL, transfusion independence, and no peripheral blasts). We assessed the number of pts receiving HCT and their outcomes. Overall survival (OS) was estimated by Kaplan-Meier method. Log rank test was used for comparisons. **Results:** Fifty RR-AML pts received HMAs. Median age at HMA start was 58 years (range, 24-81); 54% of pts were male. NCCN risk categories at diagnosis were 14% favorable, 32% intermediate, and 54% unfavorable. FLT3-ITD mutations were present in 21% of pts, FLT3-TKD in 10%, and NPM1 in 31%. Most pts (72%) received azacitidine; 28% received decitabine. Concomitant with their HMA, 28% of pts received lenalidomide, and 16% (all FLT3-ITD) received sorafenib. Cytoreduction with hydroxyurea or cyclophosphamide was given to 20%. Among 37 evaluable pts, ORR was 57%. For the entire 50 pt cohort, ORR was 42%; median OS was 9.5 months. There was no correlation between survival and NCCN risk at diagnosis ($p = 0.98$) or at the start of HMA ($p = 0.85$). Most pts (84%) had received 1 prior line of therapy, while 16% had received 2 lines. Pts naïve to HMAs had OS superior to those with previous HMA exposure (median OS, 13.0 vs. 5.3 months; $p = 0.02$). Following HMA therapy, 14 pts (28%) underwent HCT. In this group with a median follow-up of 19.2 months, 1-year OS was 100%, and 2-year OS 78%. **Conclusions:** HMA therapy for RR-AML can yield response and survival rates comparable to other, more toxic therapies. Additionally, HMAs can be used to bridge RR-AML pts to HCT, with encouraging outcomes. These results warrant validation in a large prospective study.

7034 Poster Session (Board #94), Mon, 8:00 AM-11:30 AM

Treatment of relapsed/refractory (R/R) B-cell malignancies by chimeric antigen receptor T cells cultured from 50-100 mL peripheral blood in 7-10 days. *First Author: Lu Han, Department of Immunology, Affiliated Cancer Hospital of Zhengzhou University and Henan Cancer Hospital, Zhengzhou, China*

Background: Anti-CD19 chimeric antigen receptor (CAR) T cells for R/R B-cell malignancies has been remarkably effective in recent clinical trials. However, the training process is complex and long. We try to seek a method, which the preparation process is simple and short. **Methods:** We extracted 50-100 mL peripheral blood from patients (pts), and the CAR-T cells cultured 7-10 days to back to pts. All pts received a chemotherapy of cyclophosphamide and fludarabine followed by 1- 3x 10^6 CAR- T cells/kg, and were monitored for response. **Results:** CAR-T cells were capable of large numerical expansion in 7-10 days, up to about 5x10^8 magnitudes, and the culture success rate reached to 100%. We treated 29 pts with R/R B-cell malignancies (17 ALL and 12 B-cell lymphoma). Complete remissions (CRs) was achieved in 16 ALL pts (100%) 1 month after CAR-T cells infusion and CRs in 15 pts were MRD-negative, except 1 pt died in cytokine release syndrome (CRS). The CRs were 71.4% at 3 months and 56.0% at 6 months, respectively. 12 pts experienced CRS and severe CRS had 11.76% in ALL.Of 12 B-cell lymphoma, 4 achieved CR, 5 achieved PR, and 3 had progress disease (PD) when evaluated in 2 months. The CRs and overall response were 37.5% and 50.0% at 6 months, respectively. 2 pts were observed with CRS in lymphoma. **Conclusions:** Treatment of R/R B-cell malignancies with a high CRs by CAR-T cells, which cultured from 50-100 mL peripheral blood and achieved larger amount of amplification in short time. These results could be benefit for more high-risk pts. Clinical trial information: NCT02924753 NCT0310709.

7035 Poster Session (Board #95), Mon, 8:00 AM-11:30 AM

Quality of life and psychological distress in patients with acute myeloid leukemia (AML). *First Author: Julia Carp, Massachusetts General Hospital, Boston, MA*

Background: Older patients with AML face difficult treatment decisions as they can be treated either with multi-drug 'intensive' chemotherapy requiring a prolonged hospitalization, or 'non-intensive' chemotherapy. Although clinicians often perceive intensive chemotherapy as more burdensome, studies comparing older patients' quality of life (QOL) and psychological distress while receiving these treatments are lacking. **Methods:** We conducted a longitudinal study of older patients ($\geq$ 60 years) newly diagnosed with AML receiving intensive (i.e. 7+3: cytarabine/anthracycline combination) or non-intensive (i.e. hypomethylating agents) chemotherapy at two tertiary care hospitals. We assessed patient's QOL [Functional Assessment of Cancer Therapy-Leukemia], and psychological distress [Hospital Anxiety and Depression Scale [HADS]] at baseline and 2, 4, 8, 12, and 24 weeks after diagnosis. We compared the proportion of patients in each group reporting clinically significant depression or anxiety (HADS subscale cut off $\geq$ 7) and used mixed linear effects models to compare QOL and psychological distress longitudinally between groups. **Results:** We enrolled 75.2% (100/133) of eligible patients within 72 hours of initiating intensive (n = 50) or non-intensive (n = 50) chemotherapy. Baseline QOL, depression, or anxiety symptoms did not differ between the groups. At baseline, 33.33% (33/100) and 30% (30/100) of the overall cohort reported clinically significant depression and anxiety, respectively, with no differences between groups. At 4 weeks, 41.98% (34/81) of patients in the overall cohort reported clinically significant depression, with no differences between groups. In mixed linear effects models, there were no differences in QOL (β = -0.71, SE = 1.12, P = 0.527), depression (β = 0.24, SE = 0.20, P = 0.226), or anxiety (β = -0.16, SE = 0.19, P = 0.386) symptoms over all time points. **Conclusions:** Older patients with AML receiving intensive and non-intensive chemotherapy experience similar QOL and high rates of psychological distress. These findings underscore the need to develop supportive care interventions for older patients with AML, regardless of their initial treatment strategy.

7036 Poster Session (Board #96), Mon, 8:00 AM-11:30 AM

In acute myeloid leukemia patients CpG-methylation changes associate with resistance to induction chemotherapy. *First Author: Christian Dietger Niederwieser, Department of Internal Medicine IV, Hematology and Oncology, University Hospital Halle, Germany, Halle, Germany*

Background: Acute myeloid leukemia (AML) is a heterogeneous disease associated with epigenetic alterations targetable with demethylating agents. However, predictive response markers are missing. Here we analyzed the methylation changes of transcription factor (TF) binding motifs in resistant patients after treatment with or without azacytidine (Aza) followed by induction chemotherapy. **Methods:** Twenty refractory patients from the AML-AZA trial of the Study Alliance Leukemia receiving Aza followed by induction chemotherapy (n = 16/105) or chemotherapy alone (n = 4/109) were selected to perform genome wide DNA methylation analyzes using a 450K Illumina array (Illumina, San Diego, USA) before and on day 15 after therapy start. Methylation changes from day 0 to 15 corrected for %blasts were identified and motifs detected using HOMER software (Salk institute, San Diego, USA). Methylation variation was analyzed according to treatment with Aza and/or chemotherapy. **Results:** In the Aza/chemotherapy group, a total of 389 differentially methylated regions (DMRs), most of them single CpGs, were identified, 176 hyper- and 213 hypomethylated. In methylation clustering analyses, patients with a reduction/increase of blasts clustered separately together. Those with blast reduction were more likely female and *FLT3*-ITD mutated. The most highly represented *de novo* motifs (differential enrichment between 2 sets of sequences) were associated with 5 (hypermethylation) and 10 TFs (hypomethylation). The chemotherapy only group had 7181 DMRs, 5752 hyper- and 1429 hypomethylated. We found 24 and 12 TFs for the hyper- and hypomethylated loci in these patients, respectively. The *known* motifs (based on listing of motifs from previous data) in the Aza/chemotherapy group of the enriched TFs were analyzed [hyper-: 17 TFs (Jun-AP1 ($p = 1e-7$); hypomethylated: 4 TFs, GATA ($p = 1e-2$)]. For the chemotherapy group we found 90 TFs [EHF ($p = 1e-126$)] and 43 TFs [RUNX1 ($p = 1e-18$)] for hyper- and hypomethylated sites, respectively. **Conclusions:** DNA methylation of specific TF binding motifs may be associated with therapy resistance and could be used for response prediction of therapy with Aza and/or chemotherapy. Clinical trial information: NCT00915252.

7037 Poster Session (Board #97), Mon, 8:00 AM-11:30 AM

Factors influencing first-line therapy of acute myeloid leukemia (AML) patients (pts) in the Connect MDS/AML Disease Registry. *First Author: Christopher R. Cogle, University of Florida, Gainesville, FL*

Background: Historically, only about 40% of AML pts ≥ 65 y of age receive first-line therapy (1LTx) due to high adverse event and low 5-y survival rates. With the introduction of new agents to treat AML, we sought to identify current factors influencing 1LTx across clinical practice settings. **Methods:** The Connect® MDS/AML Registry (NCT01688011) is an ongoing US, prospective observational cohort study of pts with newly diagnosed AML (≥ 55 y) or MDS. Baseline demographics, median census income per capita (determined by ZIP code), disease characteristics, and genomic and treatment data were collected on AML pts enrolled from Dec 2013 to Oct 2017. Pts were categorized as receiving 1LTx (low- or high-intensity) or best supportive care (BSC) based on care provided ≤ 45 d after AML diagnosis (dx). Pts participating in clinical trials (n = 11) were excluded to focus on standard treatment practice. Uni- and multivariable logistic regression identified factors associated with 1LTx. **Results:** Data on 378 AML pts from 100 institutions (19 academic, 81 community/government) were analyzed. Median age was 70 y (range 55–92), 64% were male, and 83% were white. Most had private/Medicare insurance coverage (86%); average median income was USD 25,984. 77% of the cohort received 1LTx; 23% received BSC. 11% died ≤ 45 d after dx, of whom 90% had received 1LTx ($P < 0.05$). 77% had FISH or cytogenetic testing and 71% had molecular genetic testing, with 46% harboring ≥ 1 gene mutation. While age and comorbidities were predictors of 1LTx ($P < 0.1$) in univariable analyses, they were not independent predictors in multivariable analyses. In multivariable modeling, independent predictors of 1LTx were insurance coverage ($P < 0.01$), income ($P < 0.01$), and diagnostic genomic testing ($P < 0.05$). Probability of receiving 1LTx was lower in the Midwest ($P < 0.01$). **Conclusions:** In this preliminary analysis, 1LTx in AML pts was more strongly associated with diagnostic genomic testing and social determinants of health, such as income, insurance coverage, and geographic location. This highlights access and cost as potential barriers to AML pts receiving beneficial treatment. Clinical trial information: NCT01688011.

7038 Poster Session (Board #98), Mon, 8:00 AM-11:30 AM

Low-toxic myeloablative conditioning regimen in haploidentical hematopietic stem cell transplantation for elderly patients with acute myeloid leukemia. *First Author: Cynthia Aristei, Radiation Oncology Section, Department of Surgery and Biomedical Sciences, University of Perugia and Perugia General Hospital, Perugia, Italy*

Background: Elderly candidates for hematopoietic stem cell transplantation (HSCT) cannot tolerate myeloablative conditioning regimens because of regimen-related toxicity and mortality rates. To lower them in elderly patients with acute myeloid leukemia (AML) who underwent 1-haplotype mismatched (haploidentical) HSCT, we designed a conditioning regimen with total marrow/total lymphoid irradiation (TMI/TLI) and low chemotherapy doses. The graft contained, as adoptive immunotherapy, a ratio of conventional T cells (Tcons) and T regulatory cells (Tregs) that induce a Graft versus Leukemia effect with a low incidence of Graft versus Host Disease (GvHD). **Methods:** July 2015-October 2017: 14 AML patients (median age 62 years, 6 in 1th and 7 in 2nd complete remission, 1 in partial remission) underwent haploidentical HSCT. Composite comorbidity/age scores were 1/2 in 7 patients and 3/4 in 8. TMI/TLI target volumes were skeletal bones, major lymph node chains and spleen. TMI/TLI was delivered from day -7 to day -4, in 2 daily fractions of 1.5 Gy (TMI) and 1.3 Gy (TLI) (total doses 13.5Gy and 11.7Gy respectively). Chemotherapy: tiothepa 2.5 mg/kg on days -10 and -9; fludarabine 30 mg/m^2 from days -10 to -6; cyclophosphamide 15 mg/kg on days -8 and -7. Haploidentical grafts consisted of 10x10^6/kg purified CD34+cells, 1x10^6/kg Tcons, 2 x10^6/kg freshly isolated Tregs. No post-transplant immunosuppression was given. **Results:** All patients sustained primary full-donor type engraftment and 11/14 are alive and relapse-free at a median follow-up of 18 months. Grade II-IV acute GvHD developed in 6 patients (43%) and chronic GvHD in none. Transplant-related causes of death were veno-occlusive disease (1), sepsis (1) and acute GvHD (1). Immune reconstitution was good, with peripheral blood T cells rapidly increasing. **Conclusions:** This innovative TMI/TLI-based conditioning with low dose chemotherapy and adoptive immunotherapy with Tcons and Tregs was efficacious as there have been no relapses to date. It was associated with low regimen-related toxicity and mortality. This exploratory analysis needs to be confirmed in a larger cohort of patients enrolled in a clinical trial.

7039 Poster Session (Board #99), Mon, 8:00 AM-11:30 AM

Characteristics and outcomes of acute myeloid leukemia (AML) with extramedullary disease (EMD). *First Author: Fevzi Firat Yalniz, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: EMD has been reported in 2.5-30% of AML patients (pts). The association with modern cytogenetic and molecular features and their prognostic value have not been fully explored. **Methods:** We reviewed medical records of all AML pts treated at MDACC from 8/12 to 1/2018. **Results:** Among 2388 pts, 88 (4%) had EMD; 30 were newly diagnosed. The sites involved were skin (n = 14), central nervous system (CNS) (n = 6), musculoskeletal (n = 4), nodal (n = 4) and intestinal (n = 2). 27/30 (90%) had concomitant marrow disease. Most relevant characteristics are in Table. Cytogenetics (CG) were not different between EMD and non-EMD pts (p = 0.1). Compared to non-EMD pts, pts with EMD had more *KIT* mutations (p = 0.003) but not *FLT3-ITD*, *NPM1*, *RAS* or *IDH*. The median overall survival (mOS) was shorter (6.1 vs 18.4 months; p = 0.004) in pts with EMD. On univariate analysis, the presence of any EMD (p = 0.02), skin involvement (p = 0.04) but not CNS (p = 0.9) was associated with shorter OS. There was no OS difference between *KIT*-mutated and wild-type EMD pts (p = 0.5). Of the 58 relapsed EMD (28 in 1st relapse and 30 in ≥2nd relapse), 13 had isolated EMD, 45 had concurrent marrow disease and 18 had prior SCT. The common sites involved were CNS (n = 32; 23 had isolated and 9 had ≥ 2 sites), skin (n = 11) and musculoskeletal (n = 6). Compared to non-EMD pts, there was no difference in CG and molecular characteristics. On univariate analysis, the mOS was not significantly different in pts with relapsed EMD compared to non-EMD pts (5.8 vs 5.9 months; p = 0.3), whether in first relapse (p = 0.3) or ≥2nd relapse (p = 0.5). **Conclusions:** AML with EMD carries a poor prognosis. The role of genetic and molecular markers warrants further investigation especially for treatment planning and clinical follow-up post remission.

7040 Poster Session (Board #100), Mon, 8:00 AM-11:30 AM

Outcomes by number of induction cycles with CPX-351 vs 7+3 chemotherapy in older adults with newly diagnosed, high-risk/secondary acute myeloid leukemia (sAML). *First Author: Tara L. Lin, University of Kansas Medical Center, Kansas City, KS*

Background: CPX-351, a liposomal encapsulation of cytarabine (C) and daunorubicin (D) at a synergistic ratio, is approved in the US for treatment of adults with newly diagnosed therapy-related AML or AML with myelodysplasia-related changes. In a phase 3 study, CPX-351 improved survival and remission rates vs 7+3 in patients (pts) aged 60-75 y with newly diagnosed high-risk/sAML. This exploratory analysis compared outcomes in 1 vs 2 induction phases. **Methods:** Pts were randomized 1:1 to receive 1-2 inductions of CPX-351 (100 units/m^2 [C 100 mg/m^2 + D 44 mg/m^2] on Days 1, 3, 5 [2nd induction: Days 1, 3]) or 7+3 (C 100 mg/m^2/d continuously for 7 d [2nd induction: 5 d] + D 60 mg/m^2 on Days 1-3 [2nd induction: Days 1-2]). Pts achieving complete remission (CR) or CR with incomplete platelet or neutrophil recovery (CRi) could receive up to 2 consolidations. **Results:** 304 pts were treated with CPX-351 (n = 153) or 7+3 (n = 151). A greater proportion of pts treated with CPX-351 achieved remission after 1 induction vs 7+3 (CR: 45% vs 28%; CR+CRi: 55% vs 34%; Table). Remission rates after 2 inductions were comparable between arms (CR: 21% vs 24%; CR+CRi: 31% vs 35%; Table). The frequency of grade 3-5 treatment-emergent adverse events (TEAEs) in pts with 1 induction was similar for CPX-351 (75/105 [71%]) vs 7+3 (74/100 [74%]). In pts with 2 inductions, fewer pts had grade 3-5 TEAEs with CPX-351 (38/48 [79%]) vs 7+3 (48/51 [94%]). Febrile neutropenia was the most common grade 3-5 TEAE with both CPX-351 and 7+3 (1 induction: 58% vs 57%; 2 inductions: 60% vs 80%). Serious TEAEs were similar with CPX-351 and 7+3 (1 induction: 33% vs 33%; 2 inductions: 29% vs 26%). **Conclusions:** Pts treated with CPX-351 were more likely to achieve remission after 1 induction vs 7+3; remission rates were similar after 2 inductions. Pts who received CPX-351 had a similar frequency of grade 3-5 TEAEs after 1 induction and fewer grade 3-5 TEAEs after 2 inductions vs 7+3 pts. Clinical trial information: NCT01696084.

7041 Poster Session (Board #101), Mon, 8:00 AM-11:30 AM

A phase 2 study of hyper-CVAD plus ofatumumab as frontline therapy in CD20+ acute lymphoblastic leukemia (ALL): Updated results. *First Author: Abdul Hamid Bazarbachi, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: In vitro studies showed that ofatumumab (O), a type I human antibody that targets a different CD20 epitope compared to rituximab, induces more potent antibody-dependent and complement mediated cell death. We hypothesized that substituting rituximab with ofatumumab, as part of Hyper-CVAD (HCVAD) regimen, may further improve outcomes in pts with Philadelphia chromosome (Ph) negative CD20+ ALL. **Methods:** Pts received 4 cycles (cy) of HCVAD [cy 1, 3, 5, 7 consisted of cyclophosphamide, doxorubicin, vincristine, and dexamethasone] alternating with 4 cy of methotrexate-cytarabine (MTX-ara-C, even cy 2, 4, 6, 8). Ofatumumab was infused on day 1 and 11 of cy 1 and 3; and day 1 and 8 of cy 2 and 4. For maintenance, pts received POMP, and late intensification with MTX/PEGylated asparaginase and O-HCVAD. Intrathecal MTX-Ara-C was used for CNS prophylaxis. Minimal residual disease (MRD) was assessed using multiparameter flow cytometry. **Results:** A total of 68 pts were enrolled (Table) and 65 were evaluable for response. Sixty-four pts (98%) achieved CR/CRp, 39/62 (63%) achieved negative MRD at time of CR, and 62/67 pts (93%) achieved negative MRD overall. Time to negative MRD was median 0.7 mo (range, 0.4-7.8). Pts received one to eight (median: 8) cy of intensive phase chemotherapy. The most common non-hematologic grade 3/4 toxicitiy was infection; occurred in 37 (56%) and 55 (81%) pts during induction and consolidation, respectively. At median 27 mo of follow-up (range 4-73), 51 pts (75%) are alive; 17 pts (25%) are receiving maintenance, 15 pts (22%) have relapsed, 14 pts (21%) have completed maintenance, and 12 pts (18%) have received ASCT in CR1. The 2-year CRD and OS were 79% and 81%, respectively. The 2-yr OS was 80% in both pts with $<$20% and $\geq$20% CD20 expression. **Conclusions:** O-HCAVD is highly effective and safe combination regimen in pts with CD20+ Ph-negative ALL. Clinical trial information: NCT01363128.

Mutant IDH (mIDH) inhibitors, ivosidenib or enasidenib, with azacitidine (AZA) in patients with acute myeloid leukemia (AML). *First Author: Courtney Denton Dinardo, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Ivosidenib (IVO; AG-120) and enasidenib (ENA; AG-221) are oral inhibitors of mIDH1 and mIDH2 proteins. *In vitro*, mIDH inhibitor + AZA combinations enhance cell differentiation and apoptosis. We report results of an ongoing phase 1b/2 study of mIDH inhibitors + AZA in patients (pts) with newly diagnosed (ND) AML (NCT02677922). **Methods:** Adult pts with m*IDH* ND-AML ineligible for intensive treatment (Tx) receive continuous IVO (mIDH1) 500 mg or ENA (mIDH2) 100 or 200 mg QD, plus SC AZA 75 mg/m^2 x 7d, in repeated 28d cycles. Response is defined by IWG 2003 AML criteria. **Results:** At data cutoff (Sep 1, 2017) 17 pts had received IVO 500 mg (n = 11) or ENA 100 mg (3) or 200 mg (3) + AZA in the phase 1b portion of the study; 11 were ongoing. *IVO:* Median age was 76 yrs. Median number of Tx cycles was 3 (range 1-13).Three pts discontinued Tx, 2 due to progressive disease (PD).AEs in $\geq$4 pts (any grade) were nausea (n = 8), constipation (6), fatigue (5) and diarrhea (4). Grade 3-4 hematological AEs (Table) occurred at similar frequency to what has been reported for AZA alone. Serious AEs in $>$ 1 pt were pneumonia, febrile neutropenia (n = 2 each). Eight of 11 pts responded, including 4 complete remissions (CRs). *ENA:* Median age was 68 yrs. Median number of Tx cycles was 9 (1-13). Three pts discontinued Tx, 2 due to PD. Most common AEs (any grade) were nausea and hyperbilirubinemia (n = 4 each). Serious AEs in $>$ 1 pt were pyrexia, bilirubin increase, pneumonia (n = 2 each). Four of 6 pts responded, including 2 CRs. **Conclusions:** mIDH inhibitor + AZA regimens were generally well tolerated in pts with ND-AML. Most AEs were grade 1-2 GI events and ENA-related indirect bilirubin elevations due to off-target UGT1A1 inhibition. Response rates are encouraging. Phase 1b enrollment completed in late 2017; updated data for all 23 IVO and 6 ENA pts will be presented, as well as longitudinal changes in m*IDH* variant allele frequencies. Enrollment continues in the phase 2 portion of this study (ENA + AZA) and the phase 3 AGILE study of IVO + AZA (NCT03173248). Clinical trial information: NCT02677922.

A randomized open label exploratory controlled trial of CLT-008 myeloid progenitor cells (MPC) to decrease infections during induction for AML. *First Author: Camille N. Abboud, Siteman Cancer Center, Washington University of St. Louis, St. Louis, MO*

Background: Induction chemotherapy for AML results in prolonged neutropenia and a high risk of infection. CLT-008 is a human off-the-shelf allogeneic MPC preparation manufactured by ex vivo culture expansion of CD34+ cells. Following infusion MPCs are expected to home to bone marrow (BM) and produce neutrophils. **Methods:** 163 subjects with de novo AML (age $\geq$55) and receiving HIDAC or 7+3 induction were randomized on Day 0 (first day of induction) to receive either CLT-008 (7.5x10^6 cells/Kg) on Day 9 + GCSF qd starting on Day 14 (treatment) or GCSF alone starting on Day 14 (control) qd until ANC recovery to 500/μL. Most endpoints were assessed from Day 9 to Day 28 and included days in a Febrile Episode (primary endpoint), microbiologically defined bacterial or fungal infections (MDI, adjudicated by a blinded independent committee), and days in hospital (to Day 42). The safety population (S-subjects) included those who received CLT-008 or GCSF. The evaluable population (E-subjects) included those who received CLT-008 or GCSF alone, were in study $\geq$ 28 days and did not receive additional chemotherapy before Day 28. **Results:** Baseline characteristics were balanced. The mean number of days in febrile episodes was 6.7 in treated and 7.1 in controls (NS) between the groups. In S-subjects, MDI was diagnosed in 14/70 treated vs 21/71 controls, a decrease of 32%. MDI with bacteremia was diagnosed in 7/70 treated vs 12/71 control subjects. MDI without bacteremia was diagnosed in 8/70 vs 11/71. In E-subjects, mean hospital stay was 3 days less in treated vs control. Remission rates and days to ANC recovery were similar in the two groups. All subjects assessed (n = 18) for chimerism had CLT-008 cells detected in peripheral blood on the day of infusion and 72% had CLT-008 detected in one or more of peripheral blood, BM or gingiva prior to ANC recovery. Infectious deaths occurred in no CLT-008 and 2 control subjects. GVHD was not observed. Antimicrobial use will be presented. **Conclusions:** Subjects receiving CLT-008 showed a decreased incidence of infections and days in hospital suggesting that myeloid progenitors may provide a new option to reduce infections in AML patients undergoing induction therapy. Clinical trial information: NCT02282215.

7044 Poster Session (Board #104), Mon, 8:00 AM-11:30 AM

Long-term survival of adults with B-cell precursor (BCP) acute lymphoblastic leukemia (ALL) after treatment with blinatumomab and subsequent allogeneic hematopoietic stem cell transplantation (HSCT). *First Author: Max Topp, Medizinische Klinik und Poliklinik II, Würzburg, Bayern, Germany*

Background: In BCP-ALL, blinatumomab has demonstrated efficacy in two phase 2 trials: MT 103 -203 (Gökbuget et al, Blood 2017) in minimal residual disease (MRD) and MT 102 – 211 in relapsed/refractory (R/R) disease (Topp et al Lancet Oncology 2104). We describe the long-term outcomes after blinatumomab followed by HSCT. **Methods:** Survival after blinatumomab and HSCT in continuous complete remission (CCR) was evaluated. In the MRD trial, 116 patients between Nov 2010 and Feb 2014 were treated with blinatumomab; in the R/R trial, 189 patients between Jan 2012 and Oct 2013 were treated. Follow up in both trials continued through 2017. **Results:** Most patients with HSCT in CCR in the MRD trial were $>$35 yrs of age whereas those in the R/R trial were younger (Table). After follow up of at least 3 yrs in the MRD trial of patients $\leq$35 yrs, 16/26 (62%) were alive with HSCT vs 2/9 (22%) for non-HSCT; in patients $>$35 yrs, 19/48 (40%) and 13/27 (48%) were alive with HSCT and for non-HSCT, respectively. Median overall survival (OS) from HSCT was not reached in patients $\leq$35 yrs in either trial (Table). **Conclusions:** These results suggest that in transplant-eligible patients in CCR, HSCT following blinatumomab is a potential option. Clinical trial information: NCT01466179, NCT01207388.

7045 Poster Session (Board #105), Mon, 8:00 AM-11:30 AM

Feasibility of HSCT vs consolidation therapy for AML patients aged 60-75 in CR1: A randomized phase III, multicentre EBMT study. *First Author: Dietger Niederwieser, Universitatsklinikum Leipzig AoR, Abt. Hamatologie und internistische Onkologie, Leipzig, Germany*

Background: AML has a particularly dismal prognosis in the elderly population. The OSHO, HOVON, SAKK and the French AML study groups performed a randomized phase III study comparing Hematopoietic Stem Cell Transplantation (HSCT) to conventional chemotherapy in these patients. **Methods:** Patients aged 60 – 75 years with AML CR1 (except FAB M3) were registered after induction(s) according to study group protocols. A donor search was initiated during consolidation. Patients with a related or matched unrelated donor were randomized within 150 days of diagnosis to receive either HSCT or non-HSCT in a 2:1 ratio. Patients in the HSCT arm were treated with Fludarabine/200 cGy total body irradiation followed by cyclosporine/mycophenolate mofetil. Patients in the non-HSCT arm continued therapy according to the study group protocols. Leukemia free survival was chosen as primary endpoint. Patients without a donor were included in the observation arm. **Results:** A total of 245 patients from 23 centers in five countries were registered and started consolidation. Sixty six patients (26.9%) exited the study before randomization because of relapse/no recovery (28), toxicities (10), consent withdrawal (10), patient choice (7), death (6) or miscellaneous reasons (5). Donors were identified for 135 (75.9%) of the 179 patients, 22.9% related and 77.0% unrelated. Ten patients with donors were allocated to the observation arm because of consent withdrawal, ineligibility, protocol violation or unknown reasons. Randomization proceeded for 125 (51,0%) patients. Of the 83 in the HSCT arm, 16 were not transplanted. Of the 42 patients in the non-HSCT arm, 6 did not receive the scheduled second consolidation and information is pending in 7. Endpoint analysis is due in 2020. **Conclusions:** The feasibility of HSCT for elderly patients with AML CR1 within 150 days from consolidation was demonstrated in a randomized European study. Donor identification and randomization was achieved for a large proportion of patients (75,9% and 51,0%). Despite a short treatment interval of $\leq$12 weeks from consolidation to HSCT/non-HSCT, relapse (n = 39) and toxicities (n = 14) were the most frequent cause of end of study. Clinical trial information: EudraCT Number 2007-003514-34.

7046 Poster Session (Board #106), Mon, 8:00 AM-11:30 AM

Impact of variant allele frequency of mutant *PTPN11* in AML: Single institution experience of 122 patients. *First Author: Mansour Alfayez, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Mutations in PTPN11, encoding tyrosine phosphatase SHP2, are present in 4-6% of AML. Largest report includes 27 patients (pts). **Methods:** Analysis included AML patients (pts) treated at MD Anderson Cancer Center between 2012 and 2017, positive for PTPN11 mutations by next generation sequencing. We evaluated baseline parameters, co-ocurring mutations,allelic burden and clinical outcome. **Results:** We identified 122 pts [62 (51%) male; median age 64.5 yrs (19-86)], among whom 64 (52.5%) treatment naïve and 58 (47.5%) salvage. In treatment naïve group, 26.6% had favorable risk (per ELN2017) [median overall survival (mOS) = 617 days (range 8-1151)], 23.4% intermediate [mOS = 336 days (Range 1-1403)] and 50% poor risk [mOS = 226 days (Range 3-540)] (P = 0.0086). Chr 3 abnormalities were present in 9 pts (14.1%), 14 pts (18.8%) had complex karyotype and 33 pts (39%) were diploid. Most common co-mutations were TET2 (51.9%), DNMT3A (33.3%), NPM1 (31.3%), and FLT3-ITD (26.6%), [Table]. Variant allelic frequency (VAF) for mutant PTPN11 with a cutoff of 0.4 further stratified poor risk AML into very poor (VAF $\geq$0.4; mOS = 194 days (Range 18-305)) and poor (VAF $<$ 0.4; mOS = 314 days (Range 3-645)), [P = 0.01; HR 6.16, CI 95% 1.5-24.6). Similarly among patients with non-diploid karyotype, the same VAF cut off stratified patient survival (p = 0.007, HR 3.27, CI 95% 1.2-8.7). In the salvage group also, VAF stratified pts for survival; [$\geq$0.4 vs $<$ 0.4 (P = 0.01, HR 5.14, CI 95% 1.48-17.8)]. **Conclusions:** We report the largest survey of PTPN11 mutations among adult leukemia patients. Reminiscent of experience with FLT3-ITD mutation, VAF appears to have impact on patient outcomes. Targeted therapies have the potential of improving outcomes.

7047 Poster Session (Board #107), Mon, 8:00 AM-11:30 AM

Molecular testing during AML treatment for early prediction of clinical response. *First Author: Hong Yuen Wong, Laboratory of Myeloid Malignancies, Hematology Branch, National Heart Lung and Blood Institute, National Institutes of Health, Bethesda, MD*

Background: Early prediction of response in acute myeloid leukemia (AML) patients undergoing cytotoxic chemotherapy may have clinical utility. Currently, measurable residual disease (MRD) testing *after* initial chemotherapy treatment can predict relapse and survival in AML. However, it has not been established if repeat molecular or genetic testing *during* chemotherapy can offer information regarding the chemotherapy sensitivity of the leukemic clone. **Methods:** Blood from 45 adult AML patients at day 1 and 4 of induction (n = 35) or salvage (n = 10) cytotoxic chemotherapy was collected for next generation sequencing ($>$ 500x) of 49 gene regions recurrently mutated in MDS/AML (Raindance Thunderbolts™ Myeloid Panel) and quantitative real-time PCR (qPCR) assessment (*WT1*) on IRB approved protocols. **Results:** The average age was 58 (23-78); 42% achieved a complete response. A median of 4 non-synonymous coding mutations (range 0-7) were detected in 45 patients by NGS in blood from day 1 (median VAF: 28%). Only 1 patient had no such mutations detectable. White blood cell (WBC) count decreased 75% on average from 10K/ul (range 0.3-60) on day 1 to 2.3K/ul (range 0.2-26) by day 4 of chemotherapy. All mutations found on day 1 remained detectable in blood on day 4 of therapy. Remarkably, the ratio of mutated to wild-type sequence was often maintained despite three days of intensive therapy, a phenomenon not limited to DNMT3A, TET2 and ASXL1. This surprising finding did not hold for *NPM1* (present only in responders, n = 5, mean decrease -44%, range -2% to -98%) or *TP53* (present only in non-responders, n = 9, mean increase 34%, range -38% to 94%). *WT1* was overexpressed on day 1 in 31 of 34 patients tested. In evaluable patients 7 of 12 responders had a 4-fold reduction in *WT1*/*Abl1* expression by day 4 compared with 7 of 19 non-responders. **Conclusions:** Molecular testing on day 4 of AML chemotherapy is not predictive of clinical response. The stability of NGS detectable mutations in blood suggests that cytotoxic therapy may have a limited therapeutic specificity for clones containing these mutations. *WT1* qPCR was uninformative for very early MRD assessment. Further validation is required to confirm the utility of *NPM1* and *TP53* monitoring in blood during cytotoxic therapy. Clinical trial information: NCT02527447.

7048 Poster Session (Board #108), Mon, 8:00 AM-11:30 AM

Phase 1 study of selinexor plus mitoxantrone, etoposide, and cytarabine in acute myeloid leukemia. *First Author: Bhavana Bhatnagar, The Ohio State Univ Comp Cancer Ctr, Columbus, OH*

Background: Patients (pts) with relapsed or refractory (R/R) acute myeloid leukemia (AML) have limited treatment options. Selinexor (SEL), an oral inhibitor of the nuclear transport protein XPO1, has shown promising single-agent activity in clinical trials of AML and preclinical synergy with topoisomerase (topo) II inhibitors. Hence, we tested the combination of SEL plus chemotherapy with topo II inhibitor in pts with R/R AML. **Methods:** This phase 1, open-label 3+3, dose escalation study tested SEL plus mitoxantrone, etoposide, and cytarabine (MEC) in pts aged $<$ 60 years with R/R AML (NCT02299518). The primary objectives were to evaluate the safety and preliminary efficacy of this combination. Pts received MEC IV on days 1-6, and up to 6 doses of SEL, across 3 dose levels ranging from 30-55 mg/m^2 on days 1, 3, 8, 10, 15, and 17. **Results:** We enrolled 23 pts (median age 47 years); 11 were treated on the dose escalation portion. Due to dose limiting hyponatremia in 2 pts on dose level 2 (SEL 40 mg/m^2), the maximum tolerated dose was 30 mg/m^2. However, based on the totality of safety data from other SEL trials in R/R AML, we established the RP2D of SEL in pts with AML to be 60 mg. We treated an additional 12 pts with 60 mg of SEL in combination with MEC. Common grade $\geq$3 toxicities for 21 treated pts for whom all analyses are complete (2 remain on therapy) are shown in Table 1. Of 21 pts, the overall response rate was 39% with 4 pts (19%) achieving complete remission (CR), 2 (10%) with CR with incomplete count recovery, and 2 (10%) with a morphologic leukemia-free state. Five responders proceeded to allogeneic stem cell transplantation. **Conclusions:** SEL plus MEC is a feasible treatment for pts with R/R AML. Toxicities of the combination are similar to cytotoxic chemotherapy alone. Clinical trial information: NCT02299518.

Grade $\geq$3 treatment-related adverse events occurring in $\geq$10% of pts (n = 21).

Adverse Event Term	no. (%)
Anemia	16 (76.2)
Thrombocytopenia	14 (66.7)
Leukopenia	11 (52.4)
Febrile neutropenia	9 (42.9)
Lymphopenia	7 (33.3)
Neutropenia	7 (33.3)
Catheter related infection	6 (28.6)
Diarrhea	5 (23.8)
Hyponatremia	4 (19.0)
Sepsis	4 (19.0)
Fatigue	3 (14.3)
Hyperglycemia	3 (14.3)
Hypotension	3 (14.3)
Agitation	2 (9.5)
Hypophosphatemia	2 (9.5)
Nausea	2 (9.5)
Respiratory failure	2 (9.5)

7049 Poster Session (Board #109), Mon, 8:00 AM-11:30 AM

Pharmacodynamic characterization of eryaspase (L-asparaginase encapsulated in red blood cells) in combination with chemotherapy in a phase 2/3 trial in patients with relapsed acute lymphoblastic leukemia (NCT01518517). *First Author: Iman El-Hariry, Erytech Pharma, Cambridge, MA*

Background: L-asparaginase (ASNase) is a key drug in the treatment of ALL. ASNase therapy aims to lower serum asparagine (ASN) levels, but no critical minimum value for efficacy has yet been established. ASN levels are difficult to measure accurately due to *ex vivo* depletion during the time required to harvest plasma from blood samples and to quench the enzyme, even if samples are immediately processed and stored on ice. Eryaspase is an investigational product under development. Following infusion of eryaspase, ASN is actively transported into RBCs, where it is hydrolyzed by the encapsulated ASNase. **Methods:** This randomized Phase 2/3 study enrolled pts with relapsed ALL. The co-primary endpoints were the mean duration of ASNase activity $>$ 100 U/L and incidence of allergic reactions during the induction phase. Secondary endpoints were safety, complete remission (CR), pharmacokinetics (PK), and pharmacodynamics (PD). Pts (n = 80, age: 1-55 years) were randomized to eryaspase or native ASNase. **Results:** The mean duration of ASNase activity $>$ 100 U/L measured in whole blood was significantly higher with eryaspase (18.9 $\pm$ 5.3 days) compared with native ASNase (8.5 $\pm$ 6.6 days). In both treatment arms, ASN depletion $\leq$2 μM was maintained for ~7 days in 75% of pts. The mean duration of ASN depletion $\leq$2 μM was 6.0 $\pm$ 5.0 and 11.6 $\pm$ 7.3 days with eryaspase and native ASNase, respectively. Exploratory receiver operating characteristic (ROC) analysis suggested that an optimal threshold of $\leq$ 7.55 μM ASN on Day 6 correlated with CR with a positive predictive value of 0.88. **Conclusions:** The assumed requirement for prolonged ASN depletion in patients receiving ASNase therapy is likely to be an overestimation caused by *ex-vivo* depletion that is observed with free ASNase. Measurement of ASN depletion in pts treated with eryaspase are less prone to such error. Accordingly, the efficacy of encapsulated ASNase cannot be accurately compared with that of free ASNase based on ASN depletion. ASN depletion $\leq$2 μM may not be needed with eryaspase, and a level $\leq$7.55 μM correlated with CR. Clinical trial information: NCT01518517.

7050 Poster Session (Board #110), Mon, 8:00 AM-11:30 AM

Relapse prevention with second generation tyrosine kinase inhibitors for Ph +ve acute leukemia after allogenic stem cell transplantation. *First Author: Faiz K. Anwer, University of Arizona, Tuscon, AZ*

Background: Relapse after allogeneic hematopoietic stem cell transplantation (AlloHSCT) for Ph+ve acute lymphoblastic leukemia (Ph+ ALL) remains the major cause of treatment failure. Use of tyrosine kinase inhibitors (TKIs) for post-transplant maintenance is not well defined. **Methods:** Database search using PubMed, Cochrane library, and Embase was performed on 08/10/2017 yielding 861 articles, 17 articles met inclusion criteria (n = 502). **Results:** Patients in seven prospective trials (n = 224) received imatinib post-transplant (PT) either prophylactically or pre-emptively for median duration of 3-12 months, at dose of 200–600 mg. Imatinib yielded a better overall survival (OS) (1.7 to 5-year OS was 30-86.7%), disease free survival (DFS) (30–81.5%) and low relapse rate (13 – 31.5%). Chen et al, in 2012 reported 52.4% higher OS (p = 0.0) with imatinib. Five retrospective trial patients (n = 221) received TKI PT either prophylactically or pre-emptively for median duration of 1-11 months, at dose of 300–800mg. TKI prophylactically led to better OS (1-year OS-100%, 2-year OS-66.7%), DFS (20-100%) and with the 3-year relapse rate of 63.6%. Three prospective trial patients (n = 28) received nilotinib PT prophylactically for a median duration of 0-20 month, at dose of 200-300 mg. Nilotinib prophylactically had a better OS (2-year OS was 69%, and mOS was 35.5 months) and DFS (56% in one study and median 34.1 months in another). Two retrospective trial patients (n = 29) received post-AlloHSCT dasatinib for median duration of 11-15 months, at dose of 50-100 mg. Patients who received dasatinib had a better OS (3-year 87% in one study, and median OS was 22 months in another study) and DFS (88%). **Conclusions:** Post-transplant prophylactic or maintenance TKIs in Ph+ ALL showed increase in OS, DFS and decrease in relapse rates. Limited data appears to favor a prophylactic rather than a pre-emptive strategy. In retrospective trials, use of dasatinib reported increase 3-year OS-87% whereas imatinib 3-year OS was 40% is post-transplant patients. The second generation TKIs have better outcomes in comparison to imatinib although further studies are needed to assess this fact definitively.

7051 Poster Session (Board #111), Mon, 8:00 AM-11:30 AM

Comparison of somatic mutations profiles from next-generation sequencing (NGS) of cell-free DNA (cfDNA) versus bone marrow (BM) in acute myeloid leukemia (AML). *First Author: Rita Elias Assi, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: NGS of cfDNA is a novel non-invasive strategy to define mutational profiles in many solid tumors, and can be used for real-time molecular monitoring of treatment and detection of resistance or disease recurrence. We examined the feasibility of cfDNA NGS in AML and compared mutation profiles to a BM NGS panel at multiple time points during therapy. **Methods:** Plasma cfDNA was collected and analyzed using a capture-based NGS assay (Qia275) targeting 275 genes. BM NGS was performed on DNA extracted from the sample in CLIA-certified molecular diagnostics laboratory for the detection of somatic mutations in the coding sequence of 28 or 81 genes. NGS profiles from cfDNA and BM were analyzed with an established bioinformatics pipeline to identify somatic variants. **Results:** 24 patients (pts) with median age of 42 years (24-61) were prospectively enrolled and 13 had serial cfDNA and BM samples for testing. NGS analysis of cfDNA detected a median of 3 deleterious somatic mutations (range 1-22) (allele frequency (AF) $>$ 0.1%, passing bioinformatic quality filters) with AF ranging from 1.5-96.5%. When matched to common mutations in both NGS panels, cfDNA harbored a median of 3 new mutations (1-8) in 83% (20/24) of pts, not detected in BM NGS panel. BM and cfDNA NGS detected identical mutations in 1/24 (4%) pt while BM NGS detected additional mutations in 3/24 (13%) pts where NGS cfDNA failed to do. Of the 20 pts on whom complete remission samples are available, 17 (85%) had a median of 3 alterations (2-8) by cfDNA including actionable mutations not detected by BM NGS. **Conclusions:** NGS of cfDNA is feasible in AML and successfully detects prior and novel mutations when BM sequencing shows absence of these mutations in a matched panel of genes. The discrepancies between BM and cfDNA mutation profiles seen in many pts may reflect leukemic evolution or intra-leukemic heterogeneity. Plasma cfDNA for genomic profiling is a promising and non-invasive strategy and further investigation of its utility is warranted in AML.

7052 Poster Session (Board #112), Mon, 8:00 AM-11:30 AM

Comparison of blast clearance in peripheral blood and day 14 bone marrow biopsy for evaluation of disease response after 7+3 induction in acute myeloid leukemia (AML). *First Author: Fahrettin Covut, Department of Medicine, Cleveland Clinic, Cleveland, OH*

Background: Peripheral blast clearance (PBC) and blast clearance in day 14 bone marrow biopsy (D14BM) are commonly used for early assessment of disease response after 7+3 induction in patients with AML. We compared both techniques in predicting disease response. **Methods:** We identified newly diagnosed AML patients (pts) between 2003 and 2016 at our institution. All pts underwent D14BM after median of 13 days (range: 12 - 17) from initiation of 7+3 induction and recovery bone marrow biopsy between days 28 and 42. PBC was defined as percentage of absolute count reduction after induction. Eventual outcome of induction was defined per Cheson criteria. Risk groups were determined by combining cytogenetic and molecular data based on the NCCN guidelines. Logistic regression analysis was performed to identify independent factors associated with complete remission (CR) at recovery biopsy. **Results:** Among 183 AML pts, 48 (26.2%) underwent early re-induction after D14BM, whereas 135 (73.8%) pts were observed without re-induction. Among observed pts, 105 (77.8%) pts had CR at recovery biopsy. On univariate logistic regression analysis, good/intermediate-risk versus poor-risk by cytogenetic and molecular data (OR 2.98, 95% CI 1.07 – 9.17, p = 0.042), per 1 g/dL increase in hemoglobin at diagnosis (OR 1.34, 95% CI 1.06 – 1.73, p = 0.015), day-3 PBC $>$ 85% (OR 9.21, 95% CI 2.74 - 37.41, p = 0.0006), $<$ 5% blast in D14BM (OR 5.10, 95% CI 1.93 - 13.63, p = 0.0009) and $\leq$10% cellularity in D14BM (OR 5.55, 95% CI 2.16 - 14.64, p = 0.0004) were more likely to achieve CR at recovery biopsy. On multivariate logistic regression analysis, only day-3 PBC $>$ 85% (OR 32.81, 95% CI 4.09 – 669.3, p = 0.004) was significantly associated with achieving CR at recovery biopsy. Day-3 PBC $>$ 85% was more sensitive (75% vs 44%) but less specific (75.4% vs 87.6%) compared to D14BM blast $<$ 5% in predicting CR at recovery biopsy. **Conclusions:** In our cohort, day-3 PBC $>$ 85% was only independent factor associated with CR. Our study suggests that PBC might be useful early non-invasive tool to evaluate disease response compared to blast clearance in D14BM, in patients with circulating blasts before initiation of 7+3 induction.

7053 Poster Session (Board #113), Mon, 8:00 AM-11:30 AM

Validation of the ELN-2017 risk classification in younger adult patients (pts) with AML. *First Author: Prajwal Boddu, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The revised 2017 European Leukemia Net (ELN) classification of AML divides patients into 3 prognostic risk categories, with additional factors such as *FLT3*-ITD allele ratio (AR) considered for risk stratification. We evaluated the prognostic utility of ELN-2017 in comparison with ELN-2010 in younger pts with AML treated in our institution. **Methods:** Pts (< 60 years) who received idarubicin plus high dose cytarabine (IA) - based induction chemotherapy for newly diagnosed AML were reviewed. Cox regression analyses were fitted with baseline prognostic factors, including cytogenetic and molecular mutation status, with receipt of allogeneic transplant (SCT) as a time-dependent covariate. **Results:** According to ELN-2017 criteria, the number of pts in the favorable (fav), intermediate (int), and adverse (adv) categories were 198 (28%), 335 (47%), and 185 (26%), respectively. Overall survival (OS) at 5 years (yrs) in the fav, int, and adv groups was 57%, 37%, and 19%, respectively. In comparison, the 5-yr OS probabilities in the fav (n = 192), int-1 (n = 76), int-2 (n = 276), and adv (n = 185) ELN-2010 categories were 59%, 32%, 39%, and 15%, respectively. Although ELN-2010 historically distinguishes prognosis into int-1 and int-2 categories in younger pts, this difference was nullified in our cohort probably due to the use of high dose cytarabine (int-2 vs. int-1: HR 0.61 [0.37 - 1.01]; p = 0.06). By cox-regression, SCT was associated with decreased risk of mortality only in int and adv AML, but not in the fav subgroup. To evaluate whether *FLT3*-ITD AR impacted prognosis, we compared the two groups (*FLT3*-ITD^{low} and *FLT3*-ITD^{high} based on AR cut-off of 0.5) and found no significant differences in survival between these groups, in patients with *NPM1* mutated AML (p = 0.40) or in those with wild type *NPM1* treated with either with IA alone [n = 55] (p = 0.61) or in combination with FLT3 inhibitors [n = 16] (p = 0.73). **Conclusions:** The ELN-2017 more accurately distinguishes prognosis by replacing the ELN-2010 int-1 and int-2 groups with a single int category. Prognostic significance of the *FLT3*-ITD AR needs further evaluation. SCT should be considered in the post remission setting in IR and adv risk AML pts.

7054 Poster Session (Board #114), Mon, 8:00 AM-11:30 AM

Outcomes of patients with nucleoplasmin 1 (NPM1) mutated acute myeloid leukemia (AML) treated with hypomethylating agents (HMAs). *First Author: Mahesh Swaminathan, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Presence of NPM1 mutations (MU) is associated with improved outcomes in younger pts with AML treated with high doses of cytarabine. The outcomes of pts with NPM1 mutated AML treated with HMAs is unknown. It is important as HMAs are becoming standard of care in older pts with AML not candidates for intensive therapy. We investigated the outcomes of such group of pts treated with either azacitidine or decitabine or combinations at a single institution. **Methods:** We retrospectively analyzed outcomes of NPM1 mutated AML pts referred to a single institution from 2010 to 2017 treated with HMAs as monotherapy or in combination. **Results:** We identified 63 pts with median age of 68 (26-91); 34 pts (54%) were female. The median number of prior therapies was 0 (0-3). A total of 58/63 pts (92%) had available cytogenetics (CG). Thirty-seven pts (64%) had favorable, 20 (34%) had intermediate and 1 had adverse (2%) CG. All pts had NPM1 MU and 26 pts (41%) also had DNMT3A MU and 21 (33%) had FLT3-ITD. The overall response rate (ORR) was 75% (n = 47) [CR-30 (48%), CRp-5 (8%) and HIP-12 (19%)]; 73% in pts who received HMAs as monotherapy (n = 22) and 76% in combination therapy (n = 41). The median overall survival (OS) was 11.63 months and the relapse-free survival was 18.27 months. The ORR for pts with FLT-3 wild-type and FLT-3-ITD MU was 81% and 62% respectively, with median OS of 19.39 and 10.07 months, respectively. Thirty pts (48%) had MRD assessment available; 19 (63%) were negative and 11 (37%) were positive. Nine pts (14%) had NPM1 MU analysis at the time of response; 4 (44%) had no MU. Eleven pts (17%) had bone marrow transplant, of that 8 (73%) are alive; 3 (27%) died in CR, CRp and progressive disease due to sepsis, unknown cause and multi-organ failure (MOF) respectively. Two pts (3%) had early death due to MOF; 4 (6%) died, 2 from MOF and 2 from an unknown cause. **Conclusions:** This analysis indicates that although response rates are high in NPM1 mutated AML when treated with HMAs, survival maybe shorter than that reported with ara-C based therapies. Ara-C based therapy should therefore be used when possible but HMAs are an option. FLT-3 MU status is important for prognosis and may improve when adding FLT-3 inhibitor.

7055 Poster Session (Board #115), Mon, 8:00 AM-11:30 AM

Timed sequential therapy with high-dose cytarabine and mitoxantrone as an effective and safe induction regimen for acute myeloid leukemia. *First Author: Melissa L. Larson, Rush University Medical Center, Chicago, IL*

Background: Traditionally, patients eligible for induction chemotherapy for AML are treated with the "7+3" regimen, which includes standard doses of infusional cytarabine and an anthracycline, with historical CR rates of 50-60%. We conducted a retrospective analysis of an alternate induction regimen. Based on timed sequential therapy, it consists of a 2-day treatment with high dose cytarabine, which improves remission rates when used in induction, and dose intensified anthracycline therapy, which improves outcomes in younger patients. We present the analysis of the regimen and the response rates of patients based on risk stratification, history of prior MDS and age. **Methods:** 382 patients were treated from 1998-2015. The treatment consisted of 2 doses of cytarabine 2gm/m^2 (1.5 gm/m^2 for patients aged greater than 70 years) IVPB over 3 hours given 12 hours apart followed by one dose of mitoxantrone 30 mg/m^2 IVPB over 1 hour on days 1 and 5. Data regarding cytogenetics and MDS history was collected for each patient. IWG remission criteria were used to determine remission status. **Results:** Median age of the patients was 58 years (range 17-85). 205 were male; 177 were female. 25 patients had favorable risk; 200 had intermediate risk; 157 had unfavorable risk. A history of MDS was noted in 83 patients. 212 patients were under the age of 60 years; 170 were aged 60 years or older. The overall CR rate (CRR: CR+CRi+CRp) for all patients was 68.5%. The complete remission rates based on risk karyotypes were favorable 96%, intermediate 77%, and unfavorable 53%. Patients with no prior MDS had a CRR of 72.6% compared to 53% for patients with a history of MDS. Patients younger than 60 years had a CRR of 72.2% compared to 63.5% for aged 60 years or older. The 30 day induction death rate was 2.4%. **Conclusions:** This two-day induction regimen is a safe and effective treatment for *de novo* AML. There is a high response rate, particularly in patients with favorable and intermediate risk karyotypes, with a low rate of early mortality. The high response rates and tolerability noted with this regimen provides a platform for further clinical trials to enhance outcome by combining with novel targeted therapies for AML.

7056 Poster Session (Board #116), Mon, 8:00 AM-11:30 AM

Post-transplant cyclophosphamide (PT-Cy) based haploidentical transplantation (haploHCT) versus matched sibling (MSD) or matched unrelated donor (MUD) reduced intensity conditioning (RIC) HCT for diffuse large b-cell lymphoma (DLBCL): A CIBMTR and EBMT analysis. *First Author: Mehdi Hamadani, CIBMTR (Center for International Blood and Marrow Transplant Research), Department of Medicine, Medical College of Wisconsin, Milwaukee, WI*

Background: The outcomes of DLBCL patients undergoing PT-Cy based haploHCT have not been compared to those receiving MSD or MUD HCT **Methods:** Adult (≥18yr) DLBCL pts (n = 1438) undergoing RIC allogeneic HCT during 2008-15 were identified in the CIBMTR or EBMT registries. Pts were divided into 4 groups; haploHCT, MSD, MUD with (w) ATG/campath (A-C) and MUD without (w/o) A-C. Overall survival (OS) was primary endpoint. Secondary endpoints included acute (a) and (c) GVHD, non-relapse mortality (NRM), relapse/progression (R/P) and progression-free survival (PFS). **Results:** The baseline characteristics are shown in Table. The cumulative incidence of day 180 grade 3-4 aGVHD and 1 year cGVHD was 7%, 11%, 13% and 19% (p < 0.001) and 15%, 41%, 23% and 48% (p < 0.001) in the haploHCT **v** MSD **v** MUD w A-C **v** MUD w/o A-C groups, respectively. The 3 year post HCT univariate outcomes for the haploHCT, MSD, MUD w A-C and MUD w/o A-C cohorts were as follows: NRM (22% v 17% v 26% v 30%), R/P (41% v 47% v 38% v 34%), PFS (38% v 37% v 36% v 37%) & OS (46% v 50% v 43% v 46%). On multivariate analysis (MVA) compared to haploHCT, MSD (RR 3.1), MUD w A-C (RR 2.0) and MUD w/o A-C (RR 4.0) were associated with significantly higher risk of cGVHD (p < 0.001). Relative to haploHCT the 3 other groups did not have a significantly different R/P risk, but compared to MSD, the MUD w A-C pts had a significantly higher R/P risk (RR 1.45; p = 0.0008). MVA showed no significant difference between the 4 cohorts in terms of NRM (p = 0.08), PFS (p = 0.45) and OS (p = 0.53). **Conclusions:** Survival outcomes are comparable between RIC MSD, MUD and PT-Cy based haploHCT in DLBCL. cGVHD was significantly lower with haploHCT.

7057 Poster Session (Board #117), Mon, 8:00 AM-11:30 AM

Development and validation of a risk assessment tool for symptomatic BKV infection. *First Author: Ala Abudayyeh, Section of Nephrology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: BKV, is a member of the family Polyomaviridae. BKV has been associated with increased morbidity and mortality secondary to late hemorrhagic cystitis, ureteral stenosis, and nephropathy. In our retrospective published study of 2477 SCT patients, 38.1% had developed renal impairment, and BKV viruria was present in 25%. In addition, BKV was found to be an independent predictor of chronic kidney disease and poor survival. Using the same cohort we derived a risk grading system to quantify risk of symptomatic BKV without having to use a complex statistical model and further validated it with another retrospective cohort of 442 allogeneic SCT patients. We hypothesize that our risk grading system will accurately identify the patients at risk of symptomatic BKV at day 30 post allogeneic stem cell transplant. **Methods:** Using the three variables *(conditioning regimen, HLA donor status, & underlying cancer diagnosis)* that were significant predictors for symptomatic BKV derived from our initial study, *we* developed a risk scoring system, using the methods described by Sullivan and colleagues. A nomogram of the sub distribution hazard model with death as a competing risk was constructed as a visualizing aid to obtain predicted probability of BK infection manually. We further stratified the patients based on their risk score into low, moderate, and high risk using 33th percentile of the risk score as the cutoff point, and into low and high risk using 99th percentile of the risk score as the cutoff points **Results:** The risk score was significantly associated with symptomatic BKV ($P < 0.0001$). Specifically, at 30-days post STC, the Low risk (≤ 7) patients had 9% chance of developing symptomatic BKV, while the high risk top 1% (9 patients) of the population had 56% of developing symptomatic BKV. This was confirmed in the cohort of 442 allogeneic SCT patients. **Conclusions:** We have created and validated a grading system for symptomatic BKV to predict risk at day 30 post allogeneic SCT. Using this grading system we would hope to identify high risk patients for BKV and treat prophylactically using BKV Cytotoxic T cell therapies and prevent reactivation which is highly associated with increased morbidity, mortality, and kidney function decline.

7058 Poster Session (Board #118), Mon, 8:00 AM-11:30 AM

Cyclophosphamide (Cy) pharmacogenetics (PGx) in allogeneic stem cell transplant (SCT) patients (pts) receiving Cy, fludarabine, total body irradiation and post-transplant Cy (FluCyTBI-postCy). *First Author: Jai Narendra Patel, Levine Cancer Institute, Carolinas HealthCare System, Charlotte, NC*

Background: Cy is the backbone for many SCT conditioning regimens and is used post-SCT to prevent graft vs. host disease (GVHD). It has been proposed that genetic polymorphisms impact Cy exposure and clinical outcomes; however, no PGx studies have been performed in pts receiving FluCyTBI-postCy. **Methods:** Germline DNA from SCT pts receiving FluCyTBI-postCy was genotyped using a custom Ion AmpliSeq™ PGx Panel for polymorphisms in: *ALDH1A1* (*2), *ALDH3A1* (Pro329Ala), *GSTA1* (135T > C), *GSTM1* (null), *GSTP1* (Ile105Val, Ala114Val), *CYP2B6* (*2, *4, *5, *6, *18, *22), *CYP2C8* (*2, *3), *CYP2C9 (*2, *3, *8, *11), *CYP2C19 (*2, *3, *17), *CYP3A4* (*1B, *22), and *CYP3A5* (*3, *6, *7). Phenotypes (poor [PM], intermediate [IM], normal [NM], and rapid metabolizers [RM]) were inferred based on literature. Cy 14.5 mg/kg IV was given on days -6 & -5 pre-SCT, and 50 mg/kg on days +3 & +4 post-SCT. Univariate logistic regression was used to investigate the association between polymorphisms and any grade cardiotoxicity, hemorrhage cystitis [HC], liver toxicity, and/or acute GVHD up to day +100. Univariate Cox proportional hazards regression was used to investigate the association between polymorphisms and overall [OS] & progression-free survival [PFS]. **Results:** In 59 evaluable pts, the median age was 57 (24-77), 61% were male, 73% received haploidentical SCT and 27% matched related donor SCT. The table summarizes significant findings ($P < 0.05$). **Conclusions:** Several genes involved in the activation (*CYPs*) and inactivation (*ALDHs* & *GSTs*) of Cy and its metabolites were associated with SCT outcomes and toxicities. Prospective studies exploring the combined effects of these genes on outcomes are needed to validate findings.

7059 Poster Session (Board #119), Mon, 8:00 AM-11:30 AM

Effect of donor type in patients with AML or MDS undergoing reduced intensity hematopoietic cell transplant. *First Author: Nahid Rashid, Washington University in Saint Louis, Saint Louis, MO*

Background: Haploidentical (haplo) hematopoietic cell transplants (HCT) are a promising option for patients. Overall survival (OS) is comparable in patients receiving haplo vs matched unrelated donor (MUD) HCT. We are specifically interested in patients receiving peripheral blood (PB) HCT with a reduced intensity conditioning (RIC). Studies comparing AML/MDS patients who received only PB HCT and RIC are lacking. Based recent data, we hypothesized that enhanced graft-versus-leukemia effect may lead to lower relapse in RIC haplo verus MUDs. **Methods:** Our study included patients aged $\geq$ 18 undergoing MUD or haplo-HCT at Washington University between January 2010 and September 2017. Data was retrospectively collected via chart review. The primary outcome was OS, compared via the Kaplain-Meier method. Secondary outcomes included the cumulative incidence of relapse, treatment-related mortality (TRM), acute graft-versus-host disease (aGVHD), neutrophil (NE) and platelet engraftment (PE), analyzed via the method of Fine and Gray. **Results:** Our study included patients aged $\geq$ 18 undergoing MUD or haplo-HCT at Washington University between January 2010 and September 2017. Data was retrospectively collected via chart review. The primary outcome was OS, compared via the Kaplan-Meier method. Secondary outcomes included the cumulative incidence of relapse, treatment-related mortality (TRM), acute graft-versus-host disease (aGVHD), neutrophil (NE) and platelet engraftment (PE), analyzed via the method of Fine and Gray. **Conclusions:** There is no significant difference in OS, PFS, relapse, or TRM in haplo versus MUD between the two groups. This indicates that haplo are a reasonable alternative to MUD in patients receiving RIC. More data needs to be collected to determine if there is a significant difference in outcomes favoring haplo over MUD.

	Haplo	MUD	p value
1 year			
OS	49% (36 -61%)	42% (33 – 50%)	0.63
Relapse	38% (26 – 50%)	29% (21 – 36%)	0.14
TRM	22% (12 – 31%)	34% (26 – 42%)	0.08
Day + 30			
NE	88% (81 – 95%)	94% (90 – 98%)	< 0.001
Day +100			
aGVHD (II-IV)	17% (8 – 26%)	10% (5 – 15%)	0.14
aGVHD (III-IV)	7% (1 – 13%)	6% (2 – 11%)	0.52

7060 Poster Session (Board #120), Mon, 8:00 AM-11:30 AM

Efficacy and safety of moxetumomab pasudotox (moxe) in adult patients (pts) with relapsed/refractory hairy cell leukemia (HCL) in relation to drug exposure, baseline disease burden, and immunogenicity. *First Author: Denison Kuruvilla, MedImmune, Mountain View, CA*

Background: Moxe is an immunotoxin targeting CD22 on B cells leading to cell death. The objectives of this analysis were to characterize the pharmacokinetics (PK) and evaluate the exposure-efficacy/safety of moxe in pts with HCL. **Methods:** Data from two HCL studies (Ph1: 49 pts dosed at 5, 10, 20, 30, 40 & 50 μg/kg IV; Ph 3: 80 pts dosed at 40 μg/kg IV) were pooled to develop a population PK model. The model derived C_{max} and AUC were then used to evaluate the exposure-efficacy/safety relationship in the 2 studies independently due to differences in bioactivity of materials (Ph1 50 μg/kg was bioactive equivalent to Ph3 40 μg/kg). Efficacy endpoints included complete response (CR), durable CR (Ph3 only) and objective response rate (ORR). Safety parameters included hemolytic uremic syndrome (HUS), capillary leak syndrome (CLS), ≥Gr 2 increased creatinine (CRE), and Gr 3/4 adverse events (AE). **Results:** Moxe PK was linear from 5-50 μg/kg with PK well-described by a 1-compartment model. Day 1 clearance (CL) was higher than for later doses (22 vs 4 L/hr), attributed to CD22+ B cell depletion with repeated dosing. Ph3 pts with anti-drug antibody (ADA) titers > 10240 had ~4-fold increase in CL. High CL was associated with high baseline B cells. High baseline B cells/low PK were associated with lower response rate, but clinical benefit was still observed. In Ph3, rates of CR and durable CR were 56-58% and 50-53% in high (≥median) PK exposure group vs 31-34% and 14-17% in the low PK exposure group. In Ph1, rate of CR was 67-71% in high vs 46-50% in low PK exposure groups. Pts with ADA titer > 10240 had lower CR and durable CR, but clinical benefit was still observed. Pts with high PK exposure had higher incidence of CLS and CRE in Ph3 but not in Ph1. HUS incidence in both studies was low and was not evaluated further. Pts with high PK exposure in Ph1 had higher rates of Gr 3/4 AE. Incidence of Gr 3/4 AE in Ph3 40 μg/kg was consistent with that of Ph1 50 μg/kg. **Conclusions:** Moxe CL decreased with repeated dosing, consistent with B cell depletion. ADA titer > 10240 increased CL by ~4-fold. Pts with high PK exposure had better response but had a slightly higher incidence of Gr 3/4 AE. Clinical trial information: NCT01829711 and NCT00586924.

7061 Poster Session (Board #121), Mon, 8:00 AM-11:30 AM

Pharmacokinetics (PK), pharmacodynamics (PD) and immunogenicity of moxetumomab pasudotox (Moxe), an immunotoxin targeting CD22, in adult patients (Pts) with relapsed or refractory hairy cell leukemia (HCL). *First Author: Kemal Balic, MedImmune, Mountain View, CA*

Background: Moxe is a recombinant immunotoxin that specifically binds to CD22 on the B cell surface and internalizes leading to cell death. The PK, PD, and immunogenicity of moxe were evaluated in a pivotal study (NCT01829711) in pts with HCL. **Methods:** Eighty pts were enrolled and received moxe (40 μg/kg IV) on days 1, 3, and 5 of each 28-day cycle. Samples were collected for assessments of PK, circulating CD19+ B cell counts and immunogenicity. PK parameters were estimated by non-compartmental approach. B cell counts were evaluated by flow cytometry. Immunogenicity testing utilized a tiered strategy: screen, neutralization followed by characterization of domain specificity (*Pseudomonas* exotoxin A [PE38], CD22) and titer. **Results:** Moxe concentrations peaked shortly after infusion followed by rapid elimination in a monophasic fashion (half-life = 1.38 hr; clearance = 44.6 mL/hr/kg). PK exposure increased from Dose 1 to Dose 3, likely due to post-treatment depletion of B cells expressing CD22. Moxe caused rapid and sustained depletion of circulating CD19+ B cells (mean 89% reduction from baseline on day 8). PK exposure revealed an inverse relationship with baseline CD19+ B cells. Higher PK exposures were significantly associated with low baseline CD19+ B cell counts. After dosing, CD19+ B cells were almost fully depleted and a weakened relationship with PK was observed. Anti-drug antibody (ADA) incidence and prevalence rates were 66% and 88%, respectively. Neutralizing antibodies (Nab) were detected in 84% of total pts. Among Nab+ pts, 99% and 54% of ADA exhibited specificity to PE38 and CD22 binding domains, respectively. Median titers were generally low at baseline but increased with time. Reduced PK exposure was observed at later cycles (≥ Cycle 3), consistent with increasing titer levels. **Conclusions:** Moxe exhibited rapid clearance and was highly immunogenic, as expected for a bacterial immunotoxin. This CD22 targeted therapy elicited rapid and potent B cell depleting activity in pts with HCL. Overall, these properties support moxe as a promising new approach for the treatment of relapsed/refractory HCL. Clinical trial information: NCT01829711.

7062 Poster Session (Board #122), Mon, 8:00 AM-11:30 AM

Cross-intolerance with bosutinib after prior tyrosine kinase inhibitors (TKIs) in patients (pts) with Philadelphia chromosome–positive (Ph+) leukemia: Phase 1/2 study update. *First Author: Carlo Gambacorti-Passerini, University of Milano-Bicocca, Monza, Italy*

Background: Bosutinib has a distinct adverse event (AE) profile vs other TKIs used to treat Ph+ leukemia. **Methods:** Pts with chronic phase (CP) chronic myeloid leukemia (CML; n=403) or accelerated/blast phase CML or Ph+ acute lymphoblastic leukemia (ADV; n=167) previously treated with imatinib ± dasatinib and/or nilotinib received bosutinib (starting dose 500 mg QD) in a phase 1/2 study (NCT00261846). Cross-intolerance (AEs leading to discontinuation of both prior TKI and bosutinib) and AEs causing prior TKI intolerance and recurring as grade 3/4 AEs with bosutinib were assessed after ≥4 y of follow-up. **Results:** In imatinib-intolerant and dasatinib-intolerant pts, respectively, 18% and 24% in the CP CML group and 18% and 5% in the ADV group had cross-intolerance with bosutinib, which was most commonly due to hematologic AEs (Table). Cross-intolerance in imatinib-intolerant pts with CP CML due to AEs common with imatinib was low (rash 6%; diarrhea 10%; edema/fluid retention 0; myalgia 0); cross-intolerance due to pleural effusion was low in dasatinib-intolerant pts with CP CML (13%) and dasatinib-intolerant ADV pts (0). No deaths occurred due to cross-intolerance. **Conclusions:** Cross-intolerance with bosutinib was low and largely due to hematologic AEs, supporting bosutinib use in pts with Ph+ leukemia intolerant to prior TKIs, including those with intolerance due to rash or diarrhea. Clinical trial information: NCT00261846.

Long-term treatment-free remission (TFR) following frontline (1L) nilotinib in patients (pts) with chronic myeloid leukemia in chronic phase (CML-CP): ENESTfreedom 144-wk results. *First Author: Jerald P. Radich, Clinical Research Division, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: ENESTfreedom (NCT01784068) is a phase 2 study evaluating TFR following 1L nilotinib in newly diagnosed CML-CP pts. We previously reported 48- and 96-wk TFR rates of 51.6% and 48.9%. Long-term data (144-wk; data cutoff, Oct 11, 2017) on TFR durability are now available. **Methods:** Pts with $MR^{4.5}$ (*BCR-ABL1* ≤ 0.0032% on International Scale [$BCR\text{-}ABL1^{IS}$]) and ≥ 2 y of 1L nilotinib entered a 1-y consolidation phase; pts with sustained deep molecular response were eligible for TFR. Treatment was restarted after loss of major molecular response (MMR; $BCR\text{-}ABL1^{IS}$ ≤ 0.1%). Results are from the 144-wk analysis, in which all pts completed ≥ 144 wk of TFR, restarted nilotinib, or discontinued the study. **Results:** At data cutoff, 89 of 190 pts entering the TFR phase remained in TFR (144-wk TFR rate: 46.8%, 95% CI 39.6-54.2%). 94 pts (49.5%) discontinued TFR due to loss of MMR (91 restarted nilotinib), and 7 (3.7%) discontinued TFR for other reasons. 4 pts in TFR at 96 wk were no longer in TFR at 144 wk (3 had first loss of $MR^{4.5}$ within 8 wk in TFR). Of 91 pts who restarted nilotinib, 90 (98.9%) and 84 (92.3%) regained MMR and $MR^{4.5}$, respectively (1 discontinued the study without MMR, 5 discontinued with MMR but not $MR^{4.5}$, 1 remained in reinitiation phase with MMR but not $MR^{4.5}$). Of 84 pts who regained $MR^{4.5}$, 70 (83.3%) had stable $MR^{4.5}$ 48 wk later, 11 (13.1%) discontinued the study < 48 wk after regaining $MR^{4.5}$, and 3 (3.6%) remained in reinitiation phase with < 48 wk of follow-up after regaining $MR^{4.5}$. No pt had disease progression. 10 pts died (consolidation, 2; TFR, 1; reinitiation, 4; discontinuation, 3), none of causes attributable to CML. 144-wk treatment-free survival rate was 48.7% (95% CI 41.4-55.6%). Among 94 pts remaining in TFR for > 96 wk, any-grade musculoskeletal pain–related AE rates were 16.0%, 40.4%, 9.6%, and 4.3% in the consolidation phase and first, second, and third 48 wk of TFR, respectively; cardiovascular event rates were low across these periods. **Conclusions:** These results suggest the durability and safety of TFR following 1L nilotinib, with a 144-wk TFR rate of 46.8%. There were no disease progressions, and musculoskeletal pain appeared transient. Clinical trial information: NCT01784068.

7064 Poster Session (Board #124), Mon, 8:00 AM-11:30 AM

Intensive chemotherapy (IC) versus hypomethylating agents (HMA) for the treatment of younger patients with myelodysplastic syndrome (MDS) and elevated bone marrow blasts. *First Author: Paolo Strati, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The AZA-001 trial has shown a survival advantage for patients with high-risk MDS treated with HMA as compared to IC. However, this study was conducted mainly in an older population. **Methods:** We retrospectively analyzed the characteristics and outcomes of patients with MDS, younger than 60 years of age, with ≥ 10% bone marrow blasts who received frontline treatment with HMA or anthracycline-cytarabine-based IC at our institution between 10/1993 and 12/2017. **Results:** One-hundred and six patients were included in the study, 57 treated with HMA and 49 with IC. Use of IC was associated with shorter time to response (1 vs 2 months; $p < 0.001$) and higher overall response rate (ORR; 82% vs 60%, p = 0.02). On univariate analysis (UA) age younger than 50 (p = 0.03) and use of IC (p = 0.02) were associated with ORR, but on multivariate analysis (MVA) only use of IC maintained its association (OR 4.3, 95% CI 2-9.1; $p < 0.001$). Rates of treatment discontinuation secondary to early death or toxicity were comparable; 31% of patients on HMA and 33% on IC proceeded to stem cell transplant (SCT). After a median follow-up of 15 months (range, 1-178 months), 38 (51%) out of 74 patients lost their response, and median response duration (RD) was 19 months (range, 1-166 months). Factors associated with longer RD on UA were lack of unfavorable cytogenetics (p = 0.04), consolidation with SCT in first remission (p = 0.009) and use of IC (p = 0.03); on MVA, use of IC maintained its association (HR 2.9, 95% CI 1.4-5.8, p = 0.03). Eight (8%) patients transformed to acute myeloid leukemia during frontline treatment, 7 (12%) on HMA and 1 (2%) on IC (p = 0.07). At most recent follow-up, 65 (61%) patients died, median overall survival was 21 months (range, 1-178 months) and was significantly longer for patients treated with IC (43 vs 15 months; p = 0.05). **Conclusions:** IC is more effective than HMA for younger patients with MDS and bone marrow blasts ≥ 10%, irrespective of other baseline characteristics. Strategies combining targeted agents with either HMA or IC should be investigated, to determine whether this advantage will be maintained.

7065 Poster Session (Board #125), Mon, 8:00 AM-11:30 AM

PU.1 and JDP2 expression in myelodysplastic syndromes to predict treatment response and leukemia transformation. *First Author: Kristian Boasman, University of Lincoln, Lincoln, United Kingdom*

Background: Myelodysplastic syndromes (MDS) are malignant disorders leading to acute leukaemia (AML). Recent breakthroughs identified down-regulation of PU.1 in high risk MDS and AML, with work within NPM1 mutated AML cells showing PU.1 relocates in the cytoplasm causing differentiation arrest. Microarray analysis in PU.1 overexpressing K562, revealed Jun Dimerization Protein 2 (JDP2), downstream to PU.1 was significantly suppressed. In this study we investigated PU.1 and JDP2 expression during different stages of MDS progression/AML evolution and in patients responding to Azacitidine. **Methods:** Gene expression of PU.1 and JDP2, in total bone marrow and selected CD34+ cells, from 12 newly diagnosed MDS patients stratified according to IPSS-R (6-low, 3-intermediate, 3-high risk), 2 AML and 10 controls was undertaken. Samples were enriched for the mononuclear fraction by Ficoll separation and RNA analysed by RT-PCR for PU.1 and JDP2 expression. Protein expression was analysed by western blot. Results obtained were compared with Bloodspot MDS gene expression data. PU.1-knockdown was performed in K562 using PU.1 short interfering RNAs. **Results:** We revealed PU.1 and JDP2 are down regulated in MDS patients. PU.1 and JDP2 expression inversely correlates with disease progression, consistently reducing in IPSS-R groups. Investigating PU.1 and JDP2 expression data in MDS vs normal samples from a large Bloodspot pool confirmed our findings. To understand if JDP2 suppression is a direct result of reduced PU.1 we performed PU.1-knockdown. This revealed only a partial reduction in JDP2 expression suggesting a more complex regulatory mechanism. PU.1 and JDP2 expression levels in CD34+ cells, significantly and progressively reduces towards AML transformation. Furthermore, we demonstrated a significant upregulation in PU.1 and JDP2 expression in patients achieving a response to Azacitidine, suggesting PU.1/JDP2 could be targets of this drug. **Conclusions:** PU.1 and JDP2 expression correlates with patient's prognosis and leukaemia transformation in MDS, highlighting a potential role as new diagnostic and prognostic markers in MDS.

7066 Poster Session (Board #126), Mon, 8:00 AM-11:30 AM

Omacetaxine mepesuccinate for patients with higher-risk MDS and CMML after failure of hypomethylating agents: A phase II clinical trial. *First Author: Gabriela Sanchez-Petitto, University of Texas Health Science Center at Houston, Houston, TX*

Background: Hypomethylating agents (HMAs) are the standard of care for patients (pts) with higher-risk myelodysplastic syndromes (MDS) and chronic myelomonocytic leukemia (CMML); however, outcomes after HMA failure are poor. We designed a phase II trial to evaluate omacetaxine mepesuccinate (OM) in pts with MDS and CMML after HMA failure. **Methods:** Eligible pts were $>$ 18 years of age, and had intermediate-1- or higher-risk MDS or CMML by the International Prognostic Scoring System (IPSS) and/or bone marrow (BM) blasts 5-30%, that had not responded to, progressed on, or relapsed after HMA therapy. OM was given at 1.25 mg/m^2 SQ every 12 hours for 3 days on a 28-day cycle, until progression or unacceptable toxicity. Primary endpoints were overall response rate (ORR) and overall survival (OS). **Results:** From 6/2015 to 11/2017, 42 pts were enrolled. Median age was 76 years (range, 61-87); 8 pts (19%) had CMML. 17 pts (40%) had adverse-risk cytogenetics, and 19 pts (45%) had received 2 or more prior therapies. Median BM blasts was 10% (range, 2-20%). The median duration of follow-up was 25 months, and the median number of cycles of OM received was 3 (range, 1-23). The ORR was 33%; 3 pts achieved CRp, 10 achieved CRi and 1 achieved HI with a median number of cycles to best response of 2 (range, 1-9 cycles). Response rates for pts with MDS and CMML were 35% (12/34) and 25% (2/8), respectively. Response rates for pts with diploid and adverse-risk cytogenetics were 58% (7/12) and 24% (4/17), respectively (P = 0.057). Of the 14 responders, 5 remain on study, 6 relapsed, 2 died while in response, and 1 was lost to follow-up. The median OS was 7.5 months, and the 1-year OS rate was 25%. The median RFS was 4.9 months, and the 1-year RFS rate was 14%. Two pts are alive with ongoing response after $\geq$2 years of treatment; both had MDS with diploid cytogenetics and a *RUNX1* mutation. Overall, the treatment was well-tolerated. Among 39 pts who received $\geq$2 cycles of OM, 8 (21%) required dose reduction. The 30-day and 60-day mortality rates were 10% and 14%, respectively. **Conclusions:** In patients with MDS and CMML with prior HMA failure, OM resulted in an ORR of 33% with a median OS of 7.5 months. Some pts had long-term responses to OM. Clinical trial information: NCT02159872.

7067 Poster Session (Board #127), Mon, 8:00 AM-11:30 AM

A pilot trial of anti-KIR antibody with or without 5-azacitidine for myelodysplastic syndrome. *First Author: Fevzi Firat Yalniz, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Experimental and clinical data suggest that enhancement of NK cell activity by a surrogate of KIR blockage improves the outcomes in myeloid malignancies. Lirilumab (LIRI) is a human IgG4 monoclonal antibody that blocks KIR/HLA-C interaction and augments NK cell activity. We designed a phase 2 study to evaluate the safety and efficacy of LIRI as a single agent and in combination with 5-Azacitidine (AZA) in patients (pts) with myelodysplastic syndrome (MDS). **Methods:** Adult pts with MDS of any risk who had not received prior therapy with a hypomethylating agent, adequate performance status (ECOG $\leq$ 2) and organ function were included. Lower risk MDS pts (low and intermediate-1 by IPSS) were given LIRI at the dose of 3 mg/kg in every 4 weeks. Higher risk MDS pts received AZA at the dose of 75 mg/m^2 on days 1-7 in combination with LIRI 3 mg/kg on day 7 of 28 day cycle. Responses were evaluated on day 28 of course 1 and afterwards every 3 months or as indicated according to IWG-2006 criteria. **Results:** A total of 10 pts including 8 with higher and 2 with lower risk MDS were enrolled. The median age was 70 years (range, 50-84) and 40% of pts had complex cytogenetics. All pts had baseline next generation sequencing and frequently identified mutations included TP53 (n = 5), TET2 (n = 3) and NRAS (n = 2). The median follow up was 5 months (range, 3-15) and pts received a median of 4 (range, 2-13) and 9 (range, 5-14) cycles of treatment with AZA plus LIRI and single agent LIRI, respectively. Two pts achieved complete remission (CR), 5 marrow CR and 3 had stable disease. Two achieved cytogenetic CR (20%) and 4 had hematologic improvement. Reasons for study discontinuation included disease progression (n = 4), stem cell transplantation (n = 3) and toxicities (myocarditis, non-therapy related, n = 1). The median duration of CR/mCR responses were 3 months (range, 1-5). Grade 3/4 toxicities included 3 episodes of neutropenic infections, 2 pneumonia, 2 infectious colitis and 1 elevated bilirubin. Nine serious adverse events reported of which 6 possibly related to LIRI. **Conclusions:** LIRI either as a single as well as in combination with AZA was well tolerated in pts with MDS. A large scale multicenter study is warranted to confirm our findings. Clinical trial information: 02599649.

7068 Poster Session (Board #128), Mon, 8:00 AM-11:30 AM

The impact of clonal size on the revised international prognostic scoring system (R-IPSS) in myelodysplastic syndromes (MDS) with a single cytogenetic abnormality. *First Author: Omar Alkharabsheh, Mayo Clinic, Rochester, MN*

Background: Cytogenetics is the backbone of the R-IPSS for MDS, contributing the most points (0 to 4) to the total scoring system. The current R-IPSS cytogenetics does not factor in the clone size or the number of abnormal metaphases. The International System for Human Cytogenetic Nomenclature (ISCN) in 2016 defined the clone by the presence of a structural rearrangement in at least 2 metaphases or 3 metaphases in case of monosomies. **Methods:** This is a retrospective study from the Mayo Clinic records for patients with confirmed MDS by a hematopathology review. Analysis included patients with adequate karyotyping of 20 metaphases only. Patients were divided into 3 groups (grp) based on their R-IPSS cytogenetics category (Intermediate, Poor and Very Poor). Patients with a single abnormal clone only were included. The size of the abnormal clone was calculated by dividing the number of abnormal metaphases by 20. The overall survival (OS) of each R-IPSS grp with different clonal percentage was compared to the diploid cytogenetics (DC) group. The Good and Very good R-IPSS cytogenetics were excluded. Survival estimates were calculated by Kaplan-Meier curves and log-rank testing using JMP v.13. **Results:** Of 1301 patients, 36.5% (n = 475) had a DC, 49% (n = 637) had an abnormal karyotype and 15% (n = 189) had no available cytogenetic results. Of those with abnormal karyotype, 58% (n = 372) had a single clone. Of those with a single clone, 70% (n = 260) had a single chromosomal abnormality. The OS of the 3 groups was statistically different and consistent with their R-IPSS score. OS was higher in the DC group (OS = 54 months, n = 474) compared to the Intermediate (OS = 30.5 months, n = 121), Poor (OS = 21.1 months, n = 49), and Very poor (OS = 8.7 months, n = 75), $p < 0.005$ for all grps. The clone size had no impact on overall survival above 5% when combining the 3 grps, the lowest threshold to make statistical conclusions was 10% (p = 0.01). **Conclusions:** The clonal percentage of any abnormality detected by conventional karyotype did not affect OS in patients with MDS that have an R-IPSS risk of intermediate or above. Therefore, any chromosomal abnormality should be included in the R-IPSS cytogenetics.

7069 Poster Session (Board #129), Mon, 8:00 AM-11:30 AM

Characteristics and outcomes of myelodysplastic syndrome (MDS) with chromosome (chr)3q abnormalities. *First Author: Mansour Alfayez, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Balanced and unbalanced chr 3q21;q26.2 abnormalities result in aberrant expression of the oncogene ecotropic viral integration site 1 implicated in leukemogenesis, and correlate with poor outcomes in acute myeloid leukemia (AML). These abnormalities occur in < 1% of MDS. **Methods:** We retrospectively reviewed the baseline characteristics of MDS patients (pts) with inv(3)(q21q26)/t(3;3)(q21;q26)/unbalanced abnormalities, diagnosed between 2000 and 2017, and assessed its impact on treatment response, overall survival (OS) and transformation to AML. **Results:** 56 patients [53% male; median age 66.5 yrs (29-85)] were included. 21 (38%) had therapy-related MDS and 51 (91%) were High/Very High risk by IPSS-R. Isolated Chr 3q21-26 abnormalities were seen in 18 (32%) pts; 38 (68%) had additional abnormalities the most common being chr 7 (24 pts (63%)). The median number of additional chr alterations per pt was 2 (1–25). Common molecular markers were *TP53* (8/19; 42%), *ASXL1* (2/6; 33%), *RAS* (5/44; 11%), *RUNX1* (3/6; 50%) and *PTPN11* (3/9; 33%). Of 34 pts received HMA-based therapy, 29% achieved CR/CRi/CRp compared to 40 % (4/10) in non-HMA group (8 pts received high intensity chemotherapy, including 2 pts with SCT) (p = 0.7); the median duration of response was 5.5 months (mos) in HMA-treated pts vs 19.25 mos in non-HMA group (p = 0.057). The median OS was 13.2 mos in the HMA-treated group vs 7.5 mos in non-HMA based therapy, showing a trend of higher early mortality in the latter (p = 0.042; HR 1.3, 95% CI 0.6-3.0). Stratified by IPSS-R, OS was 11.2 mos, 13.8 mos and 21.1 mos in Very High, High and Intermediate risk group; respectively (p = 0.03). Of the 48 pts with available follow-up, AML transformation was seen in 27 pts (56%): 23/35 (66%) in HMA-treated and 4/13 (31%) in non-HMA group (median time to transformation: 5.5 mos vs 4.75 mos, respectively; p = 0.4). **Conclusions:** MDS with chr 3q21;26.2 abnormalities is an aggressive disease with high risk of transformation to AML. Additional cytogenetic abnormalities are common including –7/7q, and relationship with specific molecular abnormalities is unclear. Treatment with HMA does not seem to affect survival or transformation to AML and novel therapeutic approaches are needed.

7070 Poster Session (Board #130), Mon, 8:00 AM-11:30 AM

Effect of enforced expression of *cxcl8* by hematopoietic stem and progenitor cells on niche interactions and hematopoietic progenitor cells in adult zebrafish. *First Author: Bradley Wayne Blaser, Ohio State University Comprehensive Cancer Center, Columbus, OH*

Background: *Cxcl8* is an angiogenic chemokine that is highly expressed in a subset of patients with MPN or clonal hematopoiesis of indeterminate potential (CHIP), a finding which is associated with poor outcomes. Our recent work has discovered a novel role for *cxcl8* and its receptor, *cxcr1*, in supporting colonization of hematopoietic stem and progenitor cells (HSPCs) within the sinusoidal endothelial cell niche of the embryonic zebrafish known as the caudal hematopoietic territory (CHT). We hypothesized that enforced expression of *cxcl8* by HSPCs would alter HSPC-niche interactions and expand HSPCs in adults. **Methods:** Expression of *cxcl8* was enforced in zebrafish HSPCs by microinjecting DNA constructs containing the HSPC-specific *Runx1+23* enhancer/promoter element into HSPC (*Runx1+23:mCherry*) or endothelial cell (*kdrl:mCherry*) reporter zebrafish. Time lapse fluorescence video microscopy and single-cell tracking was performed on embryonic zebrafish HSPCs within the CHT niche. Kidney marrow was harvested from adult zebrafish and hematopoietic cell populations were identified by flow cytometry. **Results:** Enforced expression of *cxcl8* by HSPCs nearly doubled the amount of time they resided within the CHT when compared to expression of GFP as a control (3.8 ± 0.5 vs 2.1 ± 0.3 h, p = 0.005, N = 108 tracked cells). Enforced expression of *cxcl8* increased the percent of time individual HSPCs spent closely interacting with a single group of CHT endothelial cells by 30% (87% vs 57%, p = 0.001). Flow cytometric analysis of whole kidney marrow in adult zebrafish at 3 months of age showed that *cxcl8* expression caused a skewing of the hematopoietic progenitor cell:lymphoid cell ratio in favor of the progenitor compartment (1.96 ± 0.15 vs 1.61 ± 0.10, p = 0.048). **Conclusions:** Taken together, these data support a model in which pre-malignant HSPC clones aberrantly express *cxcl8*, acquire a selective advantage over normal clones through enhanced interactions with the endothelial cell niche, and progress over time to a neoplastic state.

7071 Poster Session (Board #131), Mon, 8:00 AM-11:30 AM

Impact of ruxolitinib in myelofibrosis post allogeneic stem cell transplant: A pilot study. *First Author: Joyson Poulose, Penn State Hershey Medical Center, Hershey, PA*

Background: Allogeneic stem cell transplant (SCT) is the only potentially curative treatment for intermediate and high-risk myelofibrosis (MF). The use of Ruxolitinib (Rux) in the pre-SCT setting has demonstrated significant improvements in constitutional symptoms and splenomegaly. However, the optimal time of starting Rux and the effects of post-SCT Rux maintenance are still unclear. **Methods:** We analyzed outcomes of patients diagnosed with MF at our center who never received Rux (Cohort A), received only pre-SCT Rux (Cohort B), and received post-SCT Rux (Cohort C) between 6/2012 and 6/2017. **Results:** This study analyzed 16 patients, 11 male and 5 female, with median age of 59 years (range 47-72) at the time of SCT. The MF scores ranged from 2 to 3 (WHO Grade) at diagnosis. All patients had constitutional symptoms and splenomegaly at diagnosis except 1 who had prior splenectomy. There were 3 patients in cohort A, 9 patients in cohort B, and 4 patients in cohort C (3 patients received both pre- and post-SCT Rux; 1 received only post-SCT Rux). The median duration of Rux pre-SCT was 8 months (5-20); the mean duration of Rux post-SCT was 20 months (4-32). A JAK2V617F mutation was detected in all patients in cohort A, 7 patients in cohort B, and 3 patients in cohort C. All patients received reduced intensity conditioning regimen. The median time (days) for neutrophil engraftment (ANC>500) was 17 (13-18) in group A, 15 (0-74) in group B, and 12.5 (12-16) in group C. The median time (days) to transfusion independence was 148 (118-1140), 72 (11-105), and 24.5 (13-101) for patients in cohorts A, B, and C respectively. CMV/EBV viremia was detected in 8 patients before day 100, 3 of them in cohort A. Grade II-III acute GVHD was seen in all patients in cohort A and 4 patients in cohort B, but none in cohort C. The median spleen size reduction post-SCT was 17% in cohort A, 11% in cohort B, and 32% in cohort C. At the time of last follow up, an overall response was seen in 4 patients in cohort B, 2 with CR. All patients in cohort C achieved a CR and are alive. No one in group A achieved a remission. **Conclusions:** In this pilot study, patients treated with Rux pre- and post-SCT showed better outcomes and fairly good tolerability. Further studies on a larger patient population are warranted.

7072 Poster Session (Board #132), Mon, 8:00 AM-11:30 AM

The effect of pre-transplant JAK 1/2 inhibitors on outcomes of myelofibrosis patients who receive allogeneic stem cell transplant. *First Author: Kathleen Miller, Harvard Medical School, Boston, MA*

Background: The use of JAK 1/2 inhibitors (JAKi) for myelofibrosis (MF) treatment is becoming commonplace, but their impact on outcomes after hematopoietic stem cell transplant (SCT) is not well studied. We conducted a retrospective analysis of 132 patients who underwent SCT for primary or secondary MF at two partner institutions to assess the impact of receiving pre-SCT JAKi on several outcomes, including overall survival (OS), progression free survival (PFS), and GVHD-free and relapse-free survival (GRFS). **Methods:** 132 patients with MF who received allogeneic SCT between 2004 and 2017 at Massachusetts General Hospital or Dana Farber Cancer Institute were identified. The use of this data was approved by the local Institutional Review Board. We limited our final analysis to the 116 patients who were intermediate-1 (41) and intermediate 2 risk (75) by DIPSS prior to SCT, as there were very few patients in the high or low risk groups. Cox proportional hazard regressions were fit to estimate the association between the use of pre-SCT JAKi and OS, PFS, and GRFS after SCT, adjusting for baseline ECOG performance status, conditioning intensity and DIPSS status. **Results:** Of the 116 DIPPS-intermediate patients in the study, 41 received a JAKi prior to SCT and 75 patients did not. Patients who received pre-SCT JAKi had increased OS (75% vs 41%) and increased PFS (73% vs 44%) but not in GRFS (17% vs 14) in unadjusted analysis. In models adjusted for baseline ECOG performance status, conditioning regimen intensity, and DIPPS status, the use of JAKi prior to SCT was associated with a marginally-significant improvement in PFS [hazard ratio (HR) = 0.54, 95% CI 0.27 – 1.07, p = .075] and OS [HR = 0.53, 95% CI 0.26 – 1.07, p = .077], and was not associated with an improvement in GRFS [HR = 0.77, CI 0.49 – 1.23, p = .28]. **Conclusions:** Our data suggest that the use of JAKi prior to SCT may improve survival outcomes for patients with MF intermediate risk 1 or 2 who undergo SCT. However, further investigation with a larger sample size is needed to better understand the effect of pre-SCT JAKi use on patient outcomes after SCT. Future investigation should also focus on the use of post-SCT JAKi given their exhibited activity for GVHD.

TPS7073 Poster Session (Board #133a), Mon, 8:00 AM-11:30 AM

Phase 3, randomized, placebo-controlled trials evaluating glasdegib in combination with intensive or nonintensive chemotherapy in patients with untreated acute myeloid leukemia. *First Author: Jorge E. Cortes, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Glasdegib is an oral Hedgehog pathway inhibitor with clinical activity in patients (pts) with untreated AML or higher-risk MDS, and improved survival when combined with low-dose cytarabine (AraC) in unfit pts with AML. BRIGHT AML1019 comprises two Phase 3, randomized (1:1), double-blind trials evaluating glasdegib 100 mg once daily (QD) or placebo (PBO) + chemotherapy in untreated adult AML (NCT03416179). The protocol includes 2 parallel, simultaneous trials: 1 with intensive chemotherapy (IC) and 1 with nonintensive chemotherapy (nIC). **Methods:** Both trials include pts aged ≥18 y with untreated AML (WHO 2016), including AML evolved from MDS or antecedent hematologic disease, or secondary AML. Key exclusions: inadequate organ function, acute promyelocytic leukemia, active CNS leukemia. Assignment to IC or nIC trial is per Investigator. In the IC trial, 400 pts are randomized (1:1) to glasdegib 100 mg QD or PBO on Day 1 and continue for up to 2 y or until post consolidation minimal residual disease (MRD)-negative status. Glasdegib or PBO are administered with 7+3 induction (AraC 100 mg/m^2 IV for 7 days + daunorubicin 60 mg/m^2 for 3 days); induction 2, if needed, will use 7+3 or 5+2. Consolidation consists of single-agent AraC 1 or 3 g/m^2 IV over 3 h twice daily on Days 1, 3 and 5 every 28 days for ≤4 cycles; eligible patients may receive hematopoietic stem cell transplant. In the nIC trial, 320 pts are randomized (1:1) to glasdegib 100 mg QD or PBO, each with azacitidine 75 mg/m^2 daily SC or IV for 7 days, in 28-day cycles. Treatments continue until disease progression, unacceptable toxicity, withdrawal or death. In both trials, glasdegib and PBO continue regardless of chemotherapy dose modifications/delays. The primary endpoint is overall survival. Secondary endpoints include response, time to and duration of response, event-free survival, safety, patient-reported outcomes and pharmacokinetics. Clinical trial information: NCT03416179.

TPS7074 Poster Session (Board #133b), Mon, 8:00 AM-11:30 AM

AGILE: A phase 3, multicenter, randomized, placebo-controlled study of ivosidenib in combination with azacitidine in adult patients with previously untreated acute myeloid leukemia with an IDH1 mutation. *First Author: Eytan Stein, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Acute myeloid leukemia (AML) is a hematologic malignancy with limited treatment options for patients who are ineligible for intensive chemotherapy, corresponding to a median overall survival ≤1 year (Dombret et al. 2016). Mutations in isocitrate dehydrogenase 1 (*IDH1*) occur in 6–10% of AML cases (Xu et al. 2017). Ivosidenib (IVO; AG-120) is a first-in-class, oral, targeted inhibitor of the mutant IDH1 (mIDH1) enzyme that has demonstrated robust clinical activity and a manageable safety profile as a single agent in patients with AML. A phase 1 study of IVO in combination with azacitidine (AZA) is ongoing (NCT02677922). As of September 11, 2017, 11 treatment-naïve patients with mIDH1 AML have been treated with IVO 500 mg QD + AZA 75 mg/m^2 subcutaneously (SC) for 7 days in a 28-day schedule (DiNardo et al. ASH 2017). Patients have been treated for a median of 3 cycles (range 1–13) and adverse events are consistent with the AML monotherapy experiences of IVO and AZA. One case of IDH differentiation syndrome has been reported. The objective response rate (ORR) was 8 of 11 patients, including 4 patients who achieved a complete remission (CR). **Methods:** AGILE is a global, randomized, double-blind, placebo-controlled trial in patients with previously untreated mIDH1 AML who are candidates for nonintensive treatment (NCT03173248). 392 patients are being randomized 1:1 to receive either IVO 500 mg QD + AZA 75 mg/m^2 SC or intravenously for 7 days in 28-day cycles, or matched placebo + AZA. Randomization is stratified by region and by *de novo* versus secondary AML. Key eligibility criteria include patients with previously untreated mIDH1 AML (according to WHO criteria) who are not candidates for or not willing to receive intensive chemotherapy, ECOG performance status 0–2, and no prior treatment with a hypomethylating agent or mIDH1 inhibitor. The primary outcome measure is overall survival, and key secondary outcome measures include event-free survival, CR rate, CR + CR with partial hematologic recovery (CRh) rate, and ORR. AGILE is currently open for enrollment globally. Clinical trial information: NCT03173248.

TPS7075 Poster Session (Board #134a), Mon, 8:00 AM-11:30 AM

A phase 3, trial of gilteritinib, as maintenance therapy after allogeneic hematopoietic stem cell transplantation in patients with *FLT3*-ITD$^+$ AML. *First Author: Mark J. Levis, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD*

Background: *Fms*-like tyrosine kinase 3 internal tandem duplication (*FLT3*-ITD) mutations in acute myeloid leukemia (AML) are a common indication for allogeneic hematopoietic stem cell transplant (HSCT) in first complete remission (CR1). Despite HSCT, relapses are common and cure rates are limited thereafter. The use of FLT3 inhibitors as post-HSCT maintenance therapy has not been prospectively evaluated. Gilteritinib is a highly selective, potent FLT3/AXL inhibitor with robust activity and favorable tolerability in relapsed/refractory AML. Several gilteritinib trials in AML include single arm post-HSCT gilteritinib maintenance therapy to establish the feasibility of this strategy. This trial will compare the safety and efficacy of 2-year maintenance therapy with gilteritinib versus placebo in patients with *FLT3*-ITD$^+$ AML in CR1 after allogeneic HSCT. **Methods:** This Phase 3, randomized, double-blind, placebo-controlled multicenter trial (NCT02997202; Blood and Marrow Transplant Clinical Trials Network Protocol 1506), to be conducted at 149 sites worldwide, will enroll 532 adult subjects (aged ≥18 years) with *FLT3*-ITD$^+$ AML in CR1 who are ≥30 days and ≤90 days from scheduled allogeneic HSCT. Of these 532 subjects, 346 subjects who have achieved successful engraftment without uncontrolled graft-versus-host disease (GVHD) or other serious toxicity will be randomized (1:1; stratified by conditioning regimen intensity, time from HSCT [Day 0] to randomization [30–60 days vs 61–90 days], and presence of minimal residual disease [MRD] in the pre-transplant bone marrow sample) to receive oral gilteritinib (120 mg) or matching placebo as maintenance therapy for 2 years. The primary endpoint is relapse-free survival (RFS) in the two treatment arms; RFS will be assessed from the time of randomization to the time of death or morphologic leukemia relapse (as defined by Revised IWG criteria). Overall survival is a key secondary endpoint. Other endpoints include safety/tolerability, non-relapse mortality, event-free survival, incidences of acute/chronic GVHD, and MRD. As of January 30, 2018, 47 patients have been enrolled and 11 have been randomized. Clinical trial information: NCT02997202.

TPS7076 Poster Session (Board #134b), Mon, 8:00 AM-11:30 AM

An open-label, first-in-human, dose escalation study of a novel CD3-CD123 bispecific T-cell engager administered as a single agent by intravenous infusion in patients with relapsed or refractory acute myeloid leukemia, B-cell acute lymphoblastic leukemia, or high risk myelodysplastic syndrome. *First Author: Nicolas Boissel, Hôpital Saint-Louis, Paris, France*

Background: Persistence of leukemic stem cells is an important cause of relapse in patients with acute myeloid leukemia (AML). CD123 (α-chain of the interleukin-3 receptor) is highly expressed on myeloid leukemic stem cells and blasts, and is present on B-cell acute lymphoblastic leukemia (B-ALL). With the goal of developing a therapeutic molecule active against leukemic stem cells and blasts, a novel bispecific T-cell engager (TCE) has been engineered incorporating the proprietary Cross-Over-Dual-Variable-Domain (CODV) format, a fully humanized Fc-silenced IgG1 backbone, and variable domains from two antibodies, targeting CD3 (T-cell co-receptor) and CD123, respectively. In nonclinical experiments, the TCE exhibited T-cell mediated cytotoxic activity against AML cells in vitro and in mouse models. **Methods:** This first-in-human trial will enroll patients with relapsed or refractory AML, B-ALL, or high risk myelodysplastic syndrome. The trial is starting at the minimum anticipated biological effect level (MABEL) dose, followed by an intrapatient dose escalation to a steady-state dose. The drug will be administered intravenously on a weekly basis with specific precautions to prevent and mitigate cytokine release syndrome. One patient will be treated at each of the first two dose levels, while subsequent dose levels will enlarge to a 3+3 design. Patients will be assessed for response, safety, and pharmacodynamic and pharmacokinetic endpoints. The primary objective of the dose escalation study is to determine a recommended phase 2 dose for a subsequent expansion cohort.

TPS7077 Poster Session (Board #135a), Mon, 8:00 AM-11:30 AM

Phase 3 study of first line pevonedistat (PEV) + azacitidine (AZA) versus single-agent AZA in patients with higher-risk myelodysplastic syndromes (HR MDS), chronic myelomonocytic leukemia (CMML) or low-blast acute myelogenous leukemia (AML). *First Author: Mikkael A. Sekeres, Leukemia Program, Department of Hematology and Medical Oncology, Taussig Cancer Institute, Cleveland Clinic, Cleveland, OH*

Background: PEV is a first-in-class small molecule inhibitor of NEDD8-activating enzyme, with single-agent clinical activity in patients with relapsed/refractory AML (Swords et al. *Br J Haematol* 2015;169:534–43). In preclinical AML models, PEV in combination with AZA resulted in synergistic antitumor activity compared with either agent alone (Visconte et al. *Leukemia* 2016;30:1190–4). A phase 1b study reported that PEV+AZA was well tolerated and showed clinical activity in patients ≥60 years with untreated AML (Swords et al. *Blood* 2018; Epub). These results provided the rationale for this phase 3 study to compare the efficacy and safety of PEV+AZA versus single-agent AZA as first line treatment for patients with HR MDS, CMML, or low-blast AML. **Methods:** This is a global, multicenter, randomized, controlled, open-label, phase 3 study (NCT03268954). Eligible patients (N = ~450 planned) are adults with a confirmed diagnosis of HR MDS, CMML, or low-blast AML with no prior treatment, who are ineligible for intensive chemotherapy and/or allogeneic stem cell transplantation and do not have acute promyelocytic leukemia or a history of central nervous system involvement by AML. Patients are stratified by IPSS-R risk group (MDS/CMML) and low-blast AML, and randomized 1:1 to receive PEV 20 mg/m^2 intravenously on days 1, 3, and 5, plus AZA 75 mg/m^2 (intravenous or subcutaneous) on days 1–5, 8, and 9, or AZA alone, in 28-day cycles until progression, transformation to AML, or unacceptable toxicity. Primary endpoints are overall response rate by cycle 6 and event-free survival; overall survival is a key secondary endpoint. Other secondary endpoints include survival rates at 6 months and 1 year; rate/duration of response; time to AML transformation; rate of complete remission (CR); time to first CR or partial remission; rate of hematologic improvement; rate/duration of red blood cell and platelet transfusion independence; time to relapse, progression, or death; pharmacokinetics; and health-related quality of life. Recruitment is currently ongoing. Clinical trial information: NCT03268954.

TPS7078 Poster Session (Board #135b), Mon, 8:00 AM-11:30 AM

A phase 3, randomized study of pracinostat (PRAN) in combination with azacitidine (AZA) versus placebo in patients ≥18 years with newly diagnosed acute myeloid leukemia (AML) unfit for standard induction chemotherapy (IC). *First Author: Guillermo Garcia-Manero, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: AML is associated with poor survival rates in patients ineligible for IC or stem cell transplant due to advanced age, comorbidities, and/or disease risk factors. Non-intensive therapies, including the hypomethylating agent AZA, are frequently used in this setting; however, response rates/survival remain dismal. Pre-clinical studies in myeloid malignancies indicate that inhibition of DNA hypermethylation and histone deacetylation induces re-expression of silenced genes in a synergistic fashion. In a Phase 2 study in AML patients ≥65 years not eligible for IC, PRAN, a novel oral histone deacetylase (HDAC) inhibitor, in combination with AZA showed promising efficacy (Garcia Manero, Blood 2016) with a 64% overall response rate and 19.1 months median overall survival. **Methods:** This phase 3, randomized, double-blind study (NCT03151408) is evaluating the efficacy and safety of PRAN plus AZA in patients ≥18 years with newly diagnosed AML unfit to receive IC. Ineligibility for induction CT is based on either 1) age ≥75 years or 2) age < 75 years plus a protocol-defined comorbidity. A total of 500 patients (randomized 1:1 to either PRAN + AZA or placebo + AZA) are planned to be enrolled at ~130 study centers worldwide. Randomization is stratified by cytogenetic risk (intermediate vs. unfavorable-risk) and ECOG Performance Status (0-1 vs. 2). Treatments are administered as 28-day cycles, with PRAN/placebo given orally 3x/week for 3 weeks followed by one week off and AZA administered for 7 days of each cycle. Study treatment is to be continued until disease progression or unacceptable toxicity. A minimum of 6 cycles may be required to achieve a CR. The primary endpoint is overall survival; secondary endpoints include morphologic and cytogenetic CR rates, CR without minimal residual disease and transfusion independence. Overall survival will be tested for superiority of PRAN using the stratified log-rank test at the alpha = 0.025 level of significance (one-sided). Enrollment opened in July 2017. Clinical trial information: NCT03151408.

TPS7079 Poster Session (Board #136a), Mon, 8:00 AM-11:30 AM

Trial in progress: An open-label, multicenter, phase 3b study to assess the safety and efficacy of midostaurin in patients (pts) aged ≥ 18 y with newly diagnosed (ND) *FLT3*-mutated acute myeloid leukemia (AML) who are eligible for 7+3 or 5+2 chemotherapy (chemo). *First Author: Adolfo Fuentes, Novartis Pharmaceuticals Corporation, East Hanover, NJ*

Background: *FLT3* mutations, found in ≈30% of pts with AML, are associated with a poor prognosis. Midostaurin is a multikinase inhibitor that targets FLT3 and other kinases involved in AML pathogenesis. In the phase 3, randomized, placebo-controlled RATIFY trial, midostaurin + chemo significantly improved OS and EFS in adults (aged 18-59 y) with ND *FLT3*-mutated AML. The chemo regimen in RATIFY was 7+3 induction (1-2 cycles of cytarabine [Ara-C] 200 mg/m^2/d on d1-7 + daunorubicin 60 mg/m^2/d on d1-3) and consolidation (≤4 cycles of Ara-C 3000 mg/m^2/d every 12 h on d1, 3, 5). Midostaurin + chemo was approved in the United States and Europe for pts aged ≥18 y with ND *FLT3*-mutated AML. However, many institutions use different chemo regimens as the standard of care (SOC). The aim of this new study is to assess the safety and efficacy of midostaurin 50 mg bid in combination with different SOC chemo regimens and as single-agent maintenance. **Methods:** CPKC412A2408 (NCT03379727) is an open-label, single-arm, multicenter, phase 3b study in adults aged ≥18 y and fit for chemo with ND AML per WHO 2008 classification, ECOG performance status of ≤2, and a documented *FLT3* internal tandem duplication or tyrosine kinase domain mutation (estimated enrollment, 300). Pts must start their first induction chemo cycle with 7+3 (Ara-C 100-200 mg/m^2/d on d1-7 + daunorubicin 60-90 mg/m^2/d or idarubicin 12 mg/m^2/d on d1-3) or 5+2 (a reduced-dose regimen with these agents) per investigator's discretion and enroll by d7 of the first induction cycle. Once pts start on 7+3 or 5+2, they may not switch. Pts will receive consolidation with Ara-C, with dose per investigator's choice. Midostaurin 50 mg bid will be administered on d8-28 of each 28-d induction and consolidation cycle and daily for ≤12 cycles of maintenance. Pts will discontinue the study if not in complete remission (CR) or CR with incomplete hematologic recovery (CRi) at the end of induction or consolidation or if they receive a stem cell transplant. The primary and secondary endpoints are safety and the proportion of pts achieving CR/CRi, respectively. Clinical trial information: NCT03379727.

TPS7081 Poster Session (Board #137a), Mon, 8:00 AM-11:30 AM

Clinical development of asciminib (ABL001) in chronic myeloid leukemia (CML): A randomized phase 3 study vs. bosutinib. *First Author: Michael J. Mauro, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Several tyrosine kinase inhibitors (TKIs) targeting the BCR-ABL1 ATP-binding site are available to treat CML. However, new options are needed for patients (pts) with resistance/intolerance to these TKIs or who do not achieve treatment goals with them. Asciminib is a novel, potent and specific BCR-ABL1 inhibitor that targets the myristoyl pocket (Wylie, *Nature* 2017). Due to its distinct binding site, asciminib maintains activity against BCR-ABL1 mutants that confer resistance to ATP-binding site TKIs and offers the possibility for combination therapy with these TKIs. It therefore has the potential to address unmet needs in CML, including use in pts for whom ATP-binding site TKIs have failed or for combination with these TKIs in earlier lines, and in Philadelphia chromosome–positive acute lymphoblastic leukemia. In an ongoing phase 1 study in pts with resistance/intolerance to ≥ 2 TKIs (Hughes, *Blood* 2016 [abst 625]), asciminib has been well tolerated; 42% of pts achieved a major molecular response (MMR) by 12 mo with single-agent twice-daily asciminib. A recommended dose for asciminib monotherapy was identified for pts without T315I mutations (40 mg twice daily); in separate cohorts, dosing in select pt groups and combination dosing with ATP-binding site TKIs continues to be evaluated. Now, a phase 2 study of asciminib add-on therapy in pts without a deep molecular response on long-term frontline imatinib is planned, and a randomized phase 3 study of asciminib monotherapy vs bosutinib (an ATP-binding site TKI approved for third-line therapy) in the third or later line is enrolling. Here we describe this ongoing, open-label, phase 3 study (NCT03106779). **Methods:** Pts with CML in chronic phase (planned enrollment, N = 222) are randomized 2:1 to receive asciminib 40 mg twice daily or bosutinib 500 mg once daily. Eligible pts are ≥ 18 y old, previously treated with ≥ 2 TKIs, with failure/intolerance to the previous TKI, and have *BCR-ABL1*^{IS} ≥ 1%. Pts with T315I or V299L mutations are excluded. MMR rate at 24 wk will be compared between arms (primary objective). The 96-wk MMR rate, progression-free and overall survival, safety, tolerability, and asciminib pharmacokinetics will also be evaluated. Clinical trial information: NCT03106779.

TPS7082 Poster Session (Board #137b), Mon, 8:00 AM-11:30 AM

Phase 1b study of venetoclax in combination with azacitidine in patients with treatment-naïve higher-risk myelodysplastic syndromes. *First Author: Chun Yew Fong, Austin Health/Olivia Newton-John Cancer Research & Wellness Centre, Heidelberg, Australia*

Background: Myelodysplastic syndromes (MDS) are characterized by ineffective hematopoiesis leading to cytopenias and potentially transform to acute myeloid leukemia (AML). Treatment (tx) with hypomethylating agents (HMAs) is the standard of care for patients (pts) with tx-naïve higher-risk (HR) MDS who are not candidates for intensive chemotherapy/allogeneic stem cell transplant. Currently, azacitidine (AZA) is the only drug shown to prolong survival in tx-naïve HR MDS. However, ~50% of pts treated with HMA alone do not derive clinical benefit. Venetoclax (VEN) is a potent, orally bioavailable BCL-2-specific inhibitor, VEN plus AZA has demonstrated a tolerable safety profile and promising efficacy in elderly pts with tx-naïve AML (incl. secondary AML) ineligible for intensive chemotherapy. Preclinical data indicate activity of VEN in HR MDS (Jilg, 2016). Thus, the unmet medical need in HR MDS as well as relevant clinical data with VEN in AML provide a rationale for assessing VEN plus AZA in pts with tx-naïve HR MDS. **Methods:** This open-label, Phase 1b dose-escalation study evaluates VEN in combination with AZA for tx-naive HR MDS (NCT02942290) and consists of 2 portions, an initial dose-escalation (~24 pts) and a safety expansion (~20 pts) at the recommended Phase 2 dose (RPTD). Key eligibility criteria are no prior therapy for MDS, an overall International Prognostic Scoring System score of $\geq$1.5 (Int-2 and HR), bone marrow blasts $\geq$5% and $<$ 20%, and ECOG score of $\leq$2. VEN will be administered at starting dose level of 100 mg daily for 14 days/cycle (28 days) and may be escalated up to 400 mg for subsequent dose-level cohorts. AZA will be administered at the standard dose (75 mg/m^2) for 7 days/cycle. Primary study objectives are to assess safety and pharmacokinetics, and to determine the RPTD and dosing schedule of VEN plus AZA. Secondary objectives incl. rates of overall response, hematologic improvement, transfusion independence, and cytogenetic response, as well as duration of response, progression-free survival, overall survival, and time to transformation to AML. Exploratory objectives include patient-reported outcomes and translational biomarkers of response and resistance. Clinical trial information: NCT02942290.

TPS7083 Poster Session (Board #138a), Mon, 8:00 AM-11:30 AM

A phase 2, multicenter, open-label study of the safety and efficacy of luspatercept in subjects with myeloproliferative neoplasm (MPN)-associated myelofibrosis and anemia with or without RBC transfusion dependence. *First Author: Ruben A. Mesa, UT Health San Antonio Cancer Center, San Antonio, TX*

Background: Anemia is an important complication of MPN-associated myelofibrosis. There are few effective therapies other than RBC transfusions, and responses to other therapies are typically brief. Anemia and RBC transfusion dependence are independent adverse prognostic and predictive variables for survival. Luspatercept is a fusion protein consisting of a modified type IIB activin receptor linked to the Fc domain of human IgG1. Luspatercept acts as an erythroid maturation agent by binding specific TGFβ superfamily ligands such as GDF11, blocking their inhibitory effect and leading to increased RBC production. Luspatercept ameliorated anemia in preclinical models and preliminary data have shown it is effective and well tolerated in subjects with lower-risk myelodysplastic syndromes and anemia, with or without RBC transfusion dependence. **Methods:** Eligible subjects have MPN-associated myelofibrosis, are aged $\geq$18 y, and have anemia (hemoglobin $<$ 9.5 g/dL) or RBC transfusion dependence (defined as receiving 2–4 U RBC/28 d averaged over 84 d). There are 3 cohorts: (1) cohort 1: 20 subjects with anemia only, no ruxolitinib received in the past 112 d; (2) cohort 2: 20 subjects with RBC transfusion dependence, no ruxolitinib; and (3) cohort 3: 30 subjects with anemia or RBC transfusion dependence receiving a stable ruxolitinib dose. Luspatercept is given subcutaneously at a starting dose level of 1.0 mg/kg every 3 w for 8 cycles. The primary endpoint is anemia response, defined as a hemoglobin increase of $\geq$1.5 g/dL from baseline or RBC transfusion independence for $\geq$84 d. Responders can continue therapy in an extension phase. Secondary endpoints include time to response, response duration, health-related quality of life, and safety. Response rates with 95% confidence interval will be calculated. The statistical analyses are descriptive. Enrollment began November 2017. Clinical trial information: NCT03194542.

TPS7084 Poster Session (Board #138b), Mon, 8:00 AM-11:30 AM

Clinical activity, safety and tolerability of ASN002, a dual JAK/SYK inhibitor, in patients with non-Hodgkin lymphoma (NHL), myeolfibrosis (MF), chronic lymphocytic leukemia (CLL) and solid tumors. *First Author: Stefan K. Barta, Fox Chase Cancer Center, Philadelphia, PA*

Background: ASN002 is a novel, potent inhibitor of Janus Kinases (JAK) and Spleen Tyrosine Kinase (SYK). Pre-clinical studies indicate that ASN002 has low nM IC50s against SYK and JAK, decreases proliferation in ibrutinib-resistant cell lines, and suppresses tumor growth in rodent xenograft models of NHL and other hematologic malignancies. **Methods:** This Phase 1/2 clinical trial in patients with solid tumors and hematologic malignancies evaluated escalating ASN002 oral doses of 10, 20, 30, 40, 50 and 75 mg BID and 80 and 120 mg QD. Phase 1 allowed patients with solid tumors or hematologic malignancies; Phase 2 allows only patients with mantle cell lymphoma (MCL), myelofibrosis (MF), Peripheral T-cell Lymphoma (PTCL) and Chronic Lymphocytic Leukemia (CLL). Endpoints include safety, tolerability, pharmacokinetics, serum markers of inflammation, and response using Lugano criteria (NHL), IWG-MRT (MF), or IWG-CLL. **Results:** Forty-six patients have enrolled in the study at doses of 10 –75 mg BID and 80-120 mg QD. All patients had multiple prior lines of treatment (range: 2 – 8). ASN002 was well tolerated at doses up to 75 mg BID. The DLT at 100 mg BID was Grade 3 infection. 75 mg BID was the recommended Phase 2 dose. Most drug-related adverse events were Gr 1/2 (e.g. headache, fatigue). Steady-state systemic exposure was high (C_{max}, AUC (0-12h)) and increased in a dose related manner up to 100 mg BID. Robust reduction of inflammatory markers CRP, IL-18, MIP1β, VCAM-1, TNFR2 was observed at all dose levels. Stable disease (9+ months) in a patient with primary peritoneal cancer, about 50% reduction in target lesions at 3 months in a FL patient, stable disease and reduction of pruritus in a PTCL patient after 2 months, and significant disappearance of skin lesions in another PTCL patient after one month were observed. Early improvement in symptoms within 2 weeks of treatment in MF has also been reported in an ongoing patient. Accrual of patients continues. Conclusions: ASN002 was safe and well tolerated. Encouraging preliminary evidence of efficacy in NHL and MF patients was observed. Updated and detailed results will be presented. Clinical trial information: NCT02440685.

7500 Oral Abstract Session, Sun, 9:45 AM-12:45 PM

RELEVANCE: Phase III randomized study of lenalidomide plus rituximab (R^2) versus chemotherapy plus rituximab, followed by rituximab maintenance, in patients with previously untreated follicular lymphoma. *First Author: Nathan Hale Fowler, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Immunochemotherapy induction followed by rituximab maintenance is the standard of care in previously untreated symptomatic FL. Phase II studies of chemo-free combination immunotherapy with lenalidomide and rituximab (R^2) show promising activity. **Methods:** RELEVANCE is a global, randomized, phase III trial (NCT01650701) of R^2 vs R-chemo followed by rituximab in previously untreated grade 1-3a FL patients requiring therapy according to GELF criteria. Lenalidomide dose was 20 mg/d, d2-22/28 for 6-12 cycles (c), continued in responders at 10 mg/d for a total of 18 c. Rituximab dose was 375 mg/m^2 weekly c1 and d1 c2-6 and continued in responders for 12 additional c (q8wk). R-chemo was given per investigator's choice of standard R-CHOP, R-bendamustine (R-B), or R-CVP, followed by 12 c of rituximab (q8wk). Co-primary endpoints of CR/CRu at 120 wk and PFS (50% interim analysis by 1999 IWG) are reported here. **Results:** As of 31May2017, 1030 patients with high tumor burden were randomized to R^2 (n = 513) and R-chemo (n = 517; 72% R-CHOP, 23% R-B, 5% R-CVP); baseline characteristics were similar in both groups. At a median follow-up of 37.9 mo, superiority for R^2 over R-chemo was not established for both co-primary endpoints (Table). Toxicity profiles for R^2 vs R-chemo differed, with higher grade 3/4 lab (34% vs 50%) and febrile (2% vs 6%) neutropenia with R-chemo, and higher grade 3/4 cutaneous events (7% vs 1%) with R^2. SPMs were reported in 7% R^2 and 9% R-chemo patients and grade 5 AEs were 1% for both. 69% R^2 and 71% R-chemo patients completed treatment. **Conclusions:** In the first randomized phase III comparison of a chemo-free regimen vs standard R-chemo followed by rituximab maintenance in previously untreated FL, R^2 showed similar efficacy and a different safety profile to R-chemo. Clinical trial information: NCT01650701.

Primary efficacy results of R^2 vs R-chemo in previously untreated FL.

7501 Oral Abstract Session, Sun, 9:45 AM-12:45 PM

Acalabrutinib in patients (pts) with Waldenström macroglobulinemia (WM). *First Author: Roger Owen, St. James's University Hospital, Leeds, United Kingdom*

Background: Bruton tyrosine kinase (BTK) is a clinically validated target in WM. Acalabrutinib is a highly selective, potent, covalent BTK inhibitor that we evaluated in a Phase 2 study of pts with treatment-naive (TN) or relapsed/refractory (R/R) WM. **Methods:** Pts with TN or R/R WM received 100 mg acalabrutinib BID (or 200 mg QD [n=6], later switched to 100 mg BID) in 28-day cycles until progressive disease (PD) or intolerance. The primary endpoint was investigator-assessed overall response rate (ORR). Secondary endpoints included duration of response (DOR), progression-free survival (PFS), overall survival (OS), safety and PK. **Results:** One hundred six pts (14 TN and 92 R/R) were treated; median age was 69 y (range 39-90); 94% had ECOG PS $\leq$1; median serum IgM was 3615 mg/dL (range 291-9740). R/R pts had a median of 2 prior therapies (range 1-7). At a 25-mo median follow-up, 7 (50%) TN and 70 (76%) R/R pts remain on treatment. Discontinuations were primarily due to PD (TN 0 pts; R/R 9 pts), adverse events (AEs; TN 3; R/R 3), and investigator decision (TN 2; R/R 4). BTK occupancy and PK parameters were consistent with previous acalabrutinib studies. Efficacy outcomes are listed in the Table. Common AEs (any grade) were headache (39%), diarrhea (31%), contusion (29%), and dizziness (25%). Common Gr 3/4 AEs were neutropenia (16%), pneumonia (7%), anemia, increased ALT, and hyponatremia (each 5%). Atrial fibrillation occurred in 3 pts (1 Gr 3). Bleeding events occurred in 57% of pts (commonly contusion [29%] and epistaxis [13%]); 4 events were Gr 3/4: epistaxis, hematuria, dysfunctional uterine bleeding, and retinal hemorrhage. There were 5 Gr 5 events: pneumonia, glioblastoma multiforme, esophageal carcinoma, myocardial ischemia, and intracranial hematoma. **Conclusions:** Acalabrutinib is a highly effective treatment for WM with durable responses and limited toxicity. Clinical trial information: NCT02180724.

Modified 3rd Intl workshop on WM criteria (Kimby 2006).

7502 Oral Abstract Session, Sun, 9:45 AM-12:45 PM

Phase 2 CAPTIVATE results of ibrutinib (ibr) plus venetoclax (ven) in first-line chronic lymphocytic leukemia (CLL). *First Author: William G. Wierda, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Ibr, a first-in-class, once-daily BTK inhibitor, is approved in the US and EU for CLL treatment, including del17p. Early studies support synergistic antitumor activity with combined ibr and ven, a BCL-2 inhibitor approved by FDA for relapsed del17p CLL. Single-agent ibr lead-in may lower tumor lysis syndrome (TLS) risk by debulking prior to adding ven. PCYC-1142 (CAPTIVATE) is a multicenter, phase 2 study of ibr + ven (I+V) in first-line CLL (NCT02910583) evaluating if remission with undetectable minimal residual disease (MRD(-)) after I+V can provide pts treatment holidays. **Methods:** Treatment-naïve pts <70 y with active CLL/SLL by IWCLL criteria receive single-agent ibr (420 mg/d PO) lead-in (3 x 28 d cycles) before initiating ven ramp-up to 400 mg/d PO. MRD (<0.01% by flow) is assessed in peripheral blood (PB) after 6 cycles I+V. MRD and response in bone marrow (BM) are assessed after 12 cycles I+V with planned randomization and intervention based on MRD status. **Results:** 163 pts were enrolled (median 58 y; 14% del17p; 15% del11q; 33% longest lymph node diameter [LDi] ≥5 cm). The first 14 pts enrolled for safety run-in completed ≥6 cycles I+V (median treatment duration, 9.9 mo ibr, 7.2 mo ven). No dose-limiting toxicities occurred during safety run-in; response was seen in 14/14 (CR confirmed in 1/5 early BM; 13/14 PR); PB was MRD(-) in 9/11 assessed pts. 97 pts (including 14 safety run-in pts) completed ibr lead-in plus ≥1 dose of ven (I+V Exposed). AEs in ≥20% of I+V Exposed pts were diarrhea (39%), fatigue (23%), nausea (23%) and arthralgia (21%); grade ≥3 AEs in ≥3% were neutropenia (10%), hypertension (3%) and thrombocytopenia (3%). No clinical TLS occurred; lab TLS was seen in 1/163 pts. In I+V Exposed pts with baseline LDi ≥5 cm, LDi decreased to <5 cm in 19/30 pts (63%) after ibr lead-in. TLS risk shifted from high to medium/low in 17/22 pts (77%); overall, proportion of high-risk TLS decreased from 23% at baseline to 3% after ibr lead-in. **Conclusions:** Early data show promising activity of I+V oral regimen with MRD(-) response in 82% in first-line CLL. Safety was consistent with AE profiles of single-agent ibr or ven. The protocol-specified efficacy analysis in the first 30 pts will be presented. Clinical trial information: NCT02910583.

7503 Oral Abstract Session, Sun, 9:45 AM-12:45 PM

Randomized phase III study comparing an early PET driven treatment de-escalation to a not PET-monitored strategy in patients with advanced stages Hodgkin lymphoma: Final analysis of the AHL2011 LYSA study. *First Author: Olivier Casasnovas, CHU Le Bocage Service d'Hématologie Clinique, Dijon, France*

Background: Escalated BEACOPP (BEA) improves PFS but not OS in pts with advanced HL compared to ABVD and is associated to a higher risk of hematological toxicity, secondary leukemia and infertility. PET performed after 2 cycles of BEA (PET2) might identify a population with a better outcome suitable for de-escalation treatment without impairing the disease control. **Methods:** AHL 2011 (NCT01358747) was designed to evaluate in 16 to 60 y HL pts with stage III, IV or high risk IIB, a treatment strategy driven by PET after 2 BEA cycles, delivering 4 cycles of ABVD for PET2 negative pts and 4 cycles of BEA for PET2 positive pts. This PET driven strategy (arm B) was randomly compared to a standard treatment delivering 6 cycles of BEA (arm A). The allocation of treatment in the experimental arm was based on the central review of PET2 interpreted according to Deauville criteria. PFS was the primary endpoint with a hypothesis of non-inferiority of the PET driven arm compared to the standard arm. **Results:** 823 pts were registered including 413 and 410 pts in the arms A and B respectively. Pts characteristics were well balanced in both arms. PET2 positivity rate was similar in arms A (12%) and B (13%). Based on PET2 results, 346 (84%) pts received 4 cycles of ABVD and 51 (12%) 4 additional cycles of BEA in the experimental arm. The treatment toxicity was significantly higher in pts receiving 6 cycles of BEA compared to those who received 2 cycles of BEA + 4 cycles of ABVD with more frequent grade ≥3 AE (anemia (11% vs 2%), leukopenia (85% vs 74%), thrombocytopenia (44% vs 15%), and sepsis (7% vs 3%)) and SAE (45% vs 28% ($p < 10^{-4}$). With a median follow up of 50 months, the 5y-PFS was similar in the standard (86.2%) and the PET driven arms (85.7%; p = 0.68). PET2 positivity was related to a significantly lower 5y-PFS compared to PET2 negative pts (70.7% vs 88.9%; $p < 0.0001$). OS was similar in both arms. **Conclusions:** PET performed after 2 cycles of BEA can be safely used to guide subsequent treatment and supports the response-adapted strategy delivering ABVD for pts with negative PET2 reducing the treatment-related immediate toxicity without impairing the disease control. Clinical trial information: NCT01358747.

7504 Oral Abstract Session, Sun, 9:45 AM-12:45 PM

Activity and tolerabilty of the first-in-class anti-CD47 antibody Hu5F9-G4 with rituximab tolerated in relapsed/refractory non-Hodgkin lymphoma: Initial phase 1b/2 results. *First Author: Ranjana H. Advani, Stanford Cancer Institute, Stanford, CA*

Background: Targeted non-cytotoxic therapies are needed in relapsed/refractory (r/r) NHL. Hu5F9-G4 (5F9) is a first-in-class humanized antibody targeting CD47, a protective "don't eat me" signal on cancers, that stimulates tumor cell phagocytosis and an anti-tumor T cell response. Preclinically, 5F9 synergizes with rituximab to eliminate lymphoma by enhancing Fc receptor-mediated antibody-dependent cellular phagocytosis. This trial is the first to explore clinical activity of an anti-CD47 antibody+ rituximab. **Methods:** This Phase 1b/2 enrolled r/r NHL patients in a 3+3 dose escalation design (NCT02953509). A 1 mg/kg 5F9 priming dose with higher weekly maintenance doses was used to mitigate on-target toxicities, specifically anemia. Maintenance doses were escalated from 10 to 30 mg/kg with standard dose rituximab. **Results:** 22 heavily pre-treated patients with r/r DLBCL (n = 15) and FL (n = 7) were enrolled in Phase 1b. Patients had a median of 4 prior therapies (range 2-9), 90% were rituximab-refractory. 5F9+ rituximab was well-tolerated. Common treatment-related AEs were chills (41%), headache (36%), anemia (32%), and fever (27%). All were grade 1-2 except 3 G3 AEs (chills, fever, anemia). Prime/maintenance 5F9 dosing significantly mitigated on-target anemia, a mostly first dose effect with spontaneous recovery. Only 2 patients required a one-time transfusion. The MTD was not reached up to 30 mg/kg weekly of 5F9 dosing. > 90% CD47 receptor occupancy was achieved on peripheral blood cells, showing high target saturation. A Phase 2 dose of 30 mg/kg 5F9 Q2 weeks after cycle 1 was selected. Across all doses, the ORR was 50%, 32% achieved CR. %ORR/CR was 40/27 in DLBCL and 71/43 in FL, respectively. As of 1/16/2018, 90% of responding patients continued in response (4.4 month median follow up), including 1 patient for 13+ months. **Conclusions:** 5F9 + rituximab is a novel immunotherapy that inhibits a key macrophage/cancer checkpoint. It is well tolerated with no MTD reached and has promising clinical activity in rituximab-refractory DLBCL and FL patients including multiple CRs. Phase 2 cohorts are ongoing in indolent lymphoma and DLBCL Clinical trial information: NCT02953509.

7505 Oral Abstract Session, Sun, 9:45 AM-12:45 PM

Updated safety and long term clinical outcomes in TRANSCEND NHL 001, pivotal trial of lisocabtagene maraleucel (JCAR017) in R/R aggressive NHL. *First Author: Jeremy S. Abramson, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Lisocabtagene maraleucel (liso-cel; JCAR017) is a CD19-directed 4-1BB CAR T cell product administered in defined composition at a precise dose of CD8 and CD4 CAR T cells. A multicenter seamless design pivotal phase 1 trial of liso-cel in R/R B-NHL (NCT02631044) has enrolled; long-term follow up of the nonpivotal cohort will be presented here. **Methods:** Pts with R/R DLBCL, PMBCL, FL3B, or MCL and adequate organ function are eligible. Treatment includes lymphodepletion with fludarabine and cyclophosphamide, followed by liso-cel. Multiple dose levels (DLs) and administration schedules were evaluated; DL2 (10^8 CAR T cells) was chosen for the pivotal cohort. The nonpivotal FULL dataset includes all pts in the DLBCL cohort (DLBCL NOS, PMBCL, FL3B) treated with liso-cel at all DLs; CORE dataset includes only pts meeting inclusion criteria for the pivotal cohort, including DLBCL NOS (de novo or transformed from FL) and high grade lymphoma. Study objectives include safety, PK, and antitumor response. **Results:** As of Oct 9, 2017, 91 pts were treated and evaluable for safety, 88 for efficacy. Pt characteristics were previously reported (Abramson ASH 2017). CRS was seen in 35% of pts; a single pt (1%) developed grade 3-4 CRS. Neurotoxicity (NT) developed in 19% of pts including 12% grade 3-4; all but one event resolved at time of data snapshot. Median onset of CRS and NT was 5 and 10 days respectively. Nineteen pts (21%) received tocilizumab and/or dexamethasone. Long term safety, including B cell aplasia, infections, and cytopenias, will be reported. Best ORR in FULL and CORE was 74% (65/88) and 80% (52/65), respectively; best CR was 52% (46/88) in FULL and 55% (36/65) in CORE. A higher rate of durable response at DL2 was observed in the CORE population, with 6-month ORR and CR of 50% and 50% (7/14) vs 40% (8/20) and 30% (6/20) at DL1. Long term efficacy, including 6-/12-month follow up from ~95/~55 pts, will be reported. **Conclusions:** Liso-cel shows durable responses in pts with heavily pretreated R/R DLBCL and trends toward more durable responses at DL2. Observed acute toxicities have been manageable at all DLs tested and long-term safety from the nonpivotal cohort will be reported. Clinical trial information: NCT02631044.

7507 Oral Abstract Session, Sun, 9:45 AM-12:45 PM

Randomized phase 2 trial of polatuzumab vedotin (pola) with bendamustine and rituximab (BR) in relapsed/refractory (r/r) FL and DLBCL. *First Author: Laurie Helen Sehn, BC Cancer Agency, Vancouver, BC, Canada*

Background: Pola is an antibody-drug conjugate targeting CD79b+ cells in B-NHL. Early results led to FDA breakthrough therapy status and EMA PRIME designation. We now report combined results for safety and efficacy from the randomized r/r FL and DLBCL cohorts of a phase 1b/2 study (ClinicalTrials.gov NCT02257567). **Methods:** 80 FL and 80 DLBCL transplant-ineligible patients (pts) were randomized 1:1 to pola 1.8 mg/kg + BR (B: 90mg/m^2 x 2 days; R: 375mg/m^2) or BR for 6 cycles (q28 days FL, q21 days DLBCL). Primary endpoint: PET-CR, 6–8 weeks after treatment end, by independent review committee (IRC) using modified Lugano criteria. **Results:** For FL pts (pola+BR *v* BR), median age was 65 *v* 63 years, both arms had median 2 prior therapies, 41% *v* 42% were refractory to last therapy, and 64% *v* 37% had FLIPI 3–5. At 24 Oct 17, median follow up was 15 months. DLBCL characteristics and follow up were previously described (Sehn, ASH 2017). The most common grade 3–5 AEs higher in pola+BR *v* BR were cytopenias, febrile neutropenia, and infections. SAEs higher in pola+BR *v* BR were febrile neutropenia (FL, DLBCL) and infection (FL). Grade 5 AE rates were similar between treatment arms: 5% (FL) and 18% (DLBCL). PET-CR and PFS were similar between FL arms. In DLBCL, pola+BR showed significantly higher PET-CR rates (p = 0.012) and longer median (m) PFS (p < 0.0001) and mOS (p = 0.0008) (Table). In DLBCL, longer PFS and OS were seen for pola+BR in 2nd-line (2L), 3rd-line plus (3L+), relapsed, and refractory pts. mPFS (pola+BR *v* BR [months]): 2L (11.1 *v* 3.7), 3L+ (6.0 *v* 2.0), relapsed (11.1 *v* 5.1), refractory (6.0 *v* 1.9). mOS: 2L (not reached [NR] *v* 5.9), 3L+ (11.5 *v* 3.8), relapsed (NR, NR), refractory (11.5 *v* 3.8). **Conclusions:** The toxicity of pola+BR was manageable. In FL, pola+BR did not improve PET-CR rate; longer follow up is necessary to assess survival. In contrast, in DLBCL, pola+BR led to significantly higher PET-CR rates and notably longer PFS and OS *v* BR regardless of prior treatment status. Clinical trial information: NCT02257567.

Efficacy (ITT).

7508 Oral Abstract Session, Sun, 9:45 AM-12:45 PM

High, durable minimal residual disease negativity (MRD–) with venetoclax + rituximab (VenR) in relapsed/refractory (R/R) CLL: MRD kinetics from phase 3 MURANO study. *First Author: Peter Hillmen, St James's University Hospital, Leeds, United Kingdom*

Background: Survival with chemoimmunotherapy is associated with MRD–, but the importance of MRD with targeted agents and in R/R setting remains unclear, mostly due to low MRD– rates. In MURANO, VenR showed superior PFS (hazard ratio 0.17) and peripheral blood (PB) and bone marrow (BM) MRD– vs bendamustine + R (BR) in R/R CLL pts. We now report MRD kinetics. **Methods:** Pts randomized to VenR for 6 mo. followed by single-agent Ven ≤1.5 y, or BR for 6 mo. PB samples serially collected and BM at end of combination treatment (EOCT; Mo. 9) or at best response; MRD analyzed centrally by ASO-PCR and/or flow cytometry; MRD–: < 1 CLL cell/10^4 leukocytes. **Results:** Higher concordance in MRD– between BM and PB in VenR (45/50 [90%]) vs BR (3/10 [30%]) in pts with paired samples. Thus, we focus on PB MRD and outcome. Best MRD– rates were higher with VenR (84% vs 23% in BR), and were independent of high-risk factors only for VenR: del(17p), IGVH unmutated and mutated TP53 (present vs non-present: 83% vs 87%, 82% vs mutated 89% and 73% vs unmutated 88% respectively). PB MRD kinetics for VenR are shown in Table. Among 121/194 (62%) pts on VenR and MRD– at EOCT: 100 (83%) maintained MRD– and were PFS free at median follow-up (f/u) of 13.8 (5.6–23.0) mo.; 2 developed PD; 2 died (unrelated); 2 developed Richter's (with one MRD+ directly before); and 15 (12%) converted to confirmed MRD+ (2 serial assay positive) at median MRD+ f/u of 5.6 (0.03–11.2) mo. (1 MRD ≥10^{-2} with PD, 14 MRD 10^{-4}– < 10^{-2} with 2 PD, 1 death and 11 PFS free). MRD kinetics by arm will be presented graphically. **Conclusions:** Robust PB MRD and high concordance with BM MRD with VenR confirms value of PB MRD for correlation with clinical outcome. VenR achieves high, early, deep, durable PB MRD–regardless of risk features, unlike BR. Some reemergence of MRD+, mainly intermediate level, is seen only in a small number of pts, and may not lead to clinical PD, consistent with PFS benefit observed. Clinical trial information: NCT02005471.

Romidepsin activity in T follicular helper(TFH)-phenotype PTCL versus non TFH treated on the same clinical trials. *First Author: Paola Ghione, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Histone-deacetylase inhibitors are active agents for peripheral T-cell lymphomas (PTCL). Anecdotally, angioimmunoblastic T-cell lymphoma (AITL) may respond better to romidepsin than PTCL-NOS. The cell of origin of AITL and a subset of PTCL-NOS are understood to originate from a follicular helper T-cell (TFH). We characterized PTCL-NOS in terms of TFH phenotype and analyzed responses to romidepsin in AITL, TFH-PTCL, and non-TFH-PTCL. **Methods:** We analyzed 41 patients with PTCL treated with romidepsin alone or in combinations at MSKCC between 7/2012 to 1/2018. We re-reviewed the pathology of all PTCL-NOS to identify TFH-PTCL. We estimated survival with Kaplan-Meier method and differences in survival with Log-Rank. Differences between groups were estimated with Mann Whitney and Fisher's Exact tests. **Results:** Patients characteristics are in the table. Median FU was 43.6 months. Patients received romidepsin after at least one line of prior therapy (range 1-5) as single agent in 21 (11 TFH, 10 non-TFH), or combination in 20 (13 TFH, 7 non-TFH) with duvelisib, lenalidomide or lenalidomide+carfilzomib. Three PTCL-NOS were TFH, 2 PTCL-NOS were re-classified as AITL. Romidepsin therapies had 58% ORR in TFH compared to 30% in non-TFH (p = 0.11). Median time-to-progression was 6 months for TFH vs 2months for non-TFH (p = 0.0046, HR 0.31, 95% CI 0.14–0.70). Six patients sufficiently responded to romidepsin to proceed to alloSCT (5 TFH, 1 non-TFH). **Conclusions:** Our results suggest that romidepsin, and combinations, may have superior activity in TFH-PTCL compared to non-TFH. If this observation is confirmed in prospective studies, it could help in the development of subtype-specific PTCL therapy.

Tenalisib, a dual PI3K δ/γ inhibitor: Safety and efficacy results from an on-going phase I/Ib study in relapsed/refractory T-cell lymphoma. *First Author: Yasuhiro Oki, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Tenalisib is a novel, next generation, highly specific, dual equi-potent PI3K δ/γ inhibitor. Early results demonstrated an acceptable safety profile with encouraging clinical activity in relapsed/refractory TCL (NCT02567656). **Methods:** An open-label, Phase 1/1b study consists of dose escalation cohorts followed by two expansion cohorts enrolling patients with peripheral TCL (PTCL) and with cutaneous TCL (CTCL). The primary objective is to determine the MTD, and to describe the safety and pharmacokinetic profiles. The secondary objectives are assessment of the overall response rate (ORR) and duration of response (DoR). Responses were evaluated for PTCL and CTCL based on IWG criteria (Cheson 2007) and the mSWAT respectively. **Results:** As of January 10, 2018, a total of 55 patients (27 PTCL and 28 CTCL) have been enrolled. 19 patients across dose escalation (200 mg - 800 mg BID) and 36 patients in dose expansion (at MTD, 800 mg BID Fasting) were enrolled and the results presented are the pooled data across both parts. At the time of analysis, safety assessment of 55 patients receiving at least one dose of Tenalisib demonstrated an acceptable safety profile. The most common drug related AEs were transaminitis, diarrhea, and fatigue. Related Grade ≥ 3 AE (≥ 5%) includes transaminitis (20%) and rash (5%). These events were reversible and managed by withholding study drug. Seven of 14 patients who had transaminitis were treated with steroids and only one patient discontinued therapy due to a drug related transaminitis. Drug related SAEs were pyrexia, elevated INR, sepsis, and diplopia secondary to neuropathy. Efficacy assessments of the 32 evaluable patients receiving at least two cycles of tenalisib showed an ORR of 47% (15/32, 3 CR, 12 PR and 10 SD). Indication specific analysis showed an ORR of 50% (7/14, 3 CR, 4 PR) in PTCL and 44% (8/18, 8 PR) in CTCL. Twelve patients discontinued treatment due to a rapid progression before the first efficacy assessment. **Conclusions:** Tenalisib shows acceptable safety and encouraging clinical activity in relapsed/refractory TCL. Recruitment in the expansion cohort is close to completion. Clinical trial information: NCT02567656.

The dual SYK/JAK inhibitor cerdulatinib demonstrates rapid tumor responses in a phase 2 study in patients with relapsed/refractory B- and T-cell non-Hodgkin lymphoma (NHL). *First Author: Paul A. Hamlin, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Cerdulatinib is a selective, potent inhibitor of SYK, JAK1, JAK3, and TYK2. Preclinical and clinical data suggest that combined SYK/JAK inhibition may have activity in B- and T-cell NHL. SYK is a key regulator of BCR signalling (upstream of BTK and PI3K), and is also expressed in T-cell lymphomas. Preclinical studies suggest it may be an oncogenic driver in PTCL. Frequent activating JAK/STAT mutations are observed in B and T cell NHL. A phase 1 dose escalation study of cerdulatinib in 43 patients with r/r CLL and NHL was completed in 2016. Complete inhibition of SYK and JAK was well tolerated and consistent antitumor activity was seen in CLL and FL. **Methods:** This phase 2a study intended to confirm the safety and efficacy of cerdulatinib dosed 30 mg orally BID in patients with r/r B- and T-cell lymphoma. Dose reductions were permitted to a minimum of 15mg BID. Response was assessed by Lugano Classification criteria. **Results:** 99 patients enrolled (FL: 36, CLL/SLL: 28, PTCL: 18, marginal zone lymphoma: 8, aggressive: 5, Waldenstrom's macroglobulinemia: 4). Median age is 68 (42-93) and median # of prior therapies is 3 (1–13). 30 patients had prior BTK, PI3K or BCL-2 inhibitor therapy. The most common AEs of any grade are diarrhea (42%), fatigue (36%), and nausea (32%). Grade 3+ AEs occurring in ≥5% patients are neutropenia (18%), lipase increase (15%), pneumonia (12%), diarrhea (10%), and fatigue (7%). 5 patients have had Grade 5 infections considered related to study drug (3 of 5 in the CLL cohort). The target PK range has been achieved with an average SSCmin of ~0.8 μM. Broad activity seen: 61% ORR in CLL/SLL, 50% in FL, and 43% in PTCL (4 CRs, 2 PRs in 14 patients). The first PTCL patient achieved a CR and is on drug at 11 months. Responses typically occurred after 2 cycles of treatment. Durable PRs have occurred in patients who relapsed on BTK inhibitor (CLL, 5+ months, WM, 7+ months, FL, 12 months), venetoclax (SLL, 18+ months), and tenalisib (PTCL, 3+ months) therapy. Updated PK/PD, safety and efficacy will be presented. **Conclusions:** The cerdulatinib phase 2 dose of 30 mg BID demonstrates good tolerability and efficacy in heavily pre-treated r/r B and T cell NHL. Clinical trial information: NCT01994382.

Durability of response to venetoclax (VEN) in patients with CLL relapsed/refractory to ibrutinib and/or idelalisib. *First Author: John C. Byrd, The Ohio State University, Division of Hematology, Columbus, OH*

Background: Therapies are urgently needed for patients (pts) with CLL relapsed/refractory (R/R) to BCRi. We report outcomes for the full trial population from an ongoing phase 2 trial with VEN monotherapy, including the impact on detectable minimal residual disease (MRD). **Methods:** Pts with CLL R/R to ibrutinib and/or idelalisib received 400 mg daily VEN after initial dose ramp up. Results are from a data cut on 28Nov2017. **Results:** Pts (N = 127) had received a median of 4 prior therapies (1 – 15). Del(17p) was noted in 40% (50/126) and 28% (34/122) of pts had mutated *TP53*. After a median of 17 (.1 – 36) months on VEN, the best overall response rate was 66% (84/127; CR/CRi – 10%, nPR/PR – 56%) per investigators (INV) and 70% (89/127) by independent review committee (IRC). Per INV (median follow up, 16 [.03 – 33] months), estimated median progression-free survival (PFS) was 25 months (18-month rate, 66%); neither median duration of response (18-month rate: 75%) nor median overall survival (18-month rate: 88%) was reached. 36/77 pts assessed (47%; 28% [36/127] by intent to treat) had undetectable blood MRD, 9/26 assessed were also undetectable in marrow (2 CR/CRi, 7 PR). Median PFS was longer for pts with undetectable MRD in blood vs positive (not reached vs 21.9 months; HR, .148 [.04 – .49], p= .0019). 64 pts discontinued VEN, most commonly for CLL progression (n = 35; median time, 10 months [.1 – 29]), AEs (n = 8), and Richter's transformation (n = 6; median time, 13 months [4 – 19]). Common any-grade AEs were GI AEs (diarrhea [50%], nausea [49%]) and cytopenias (anemia [43%], neutropenia [41%], thrombocytopenia [28%], decreased white blood cell count [28%]). **Conclusions:** Based on longer follow up, VEN monotherapy demonstrates robust activity, with good tolerability in pts with CLL R/R to ibrutinib and/or idelalisib. Though most pts achieved PR, outcomes appear durable with undetectable MRD. Clinical trial information: NCT02141282.

Comparison of different phase II studies using sequential combinations of targeted agents for treating chronic lymphocytic leukemia. *First Author: Von Tresckow Julia, Department I of Internal Medicine and Center of Integrated Oncology Cologne-Bonn, German CLL Study Group, University of Cologne, Cologne, Germany*

Background: The German CLL study group (GCLLSG) performed three similar phase-II-trials combining a CD20-antibody, ofatumumab (O) or obinutuzumab (G, for GA-101), with ibrutinib (I) or venetoclax (A) in an all-comer population of treatment-naïve or relapsed/refractory CLL patients (pts). **Methods:** In all 3 trials, pts with high tumor burden received optional bendamustine debulking (BD). Subsequent induction therapy consisted of 6 cycles of I plus O (BIO trial), or I plus G (BIG) or A plus G (BAG). Induction therapy was followed by a maintenance phase using the same drugs until achieving a minimal residual disease (MRD) negative complete remission or up to 24 months. The primary endpoint was the overall response rate (ORR) at the end of induction; secondary endpoints were MRD and safety. **Results:** 66 pts each were enrolled in the 3 trials. Pts with < 2 induction cycles were excluded from the analysis as per protocol, resulting in 65, 61 and 63 evaluable pts in BIO, BIG and BAG, respectively. The primary endpoint was met in all trials. BD achieved an ORR of 61 % across all trials. During combination therapy one fatal adverse event occurred in each trial; during induction 46 SAEs occurred in BIO, 29 in BIG and 59 in BAG. Patients characteristics and major results are shown in the Table. **Conclusions:** The sequential combination concept shows very good efficacy and tolerability. BD reduced the number of IRR. Combination therapies with G seemed more efficient when compared to O. Additionally, combining A plus G seemed to evoke deeper responses than I plus G. Clinical trial information: NCT02689141, NCT02401503 and NCT02345863.

Depth of response and progression free survival in CLL patients on ibrutinib. *First Author: Audrey Sigmund, The Ohio State University, Department of Internal Medicine, Columbus, OH*

Background: While it has been established that attainment of a complete response (CR) after chemoimmunotherapy improves progression free survival (PFS), this has not been proven with the BTK inhibitor ibrutinib (IB). Most patients (pts) receiving IB achieve a partial response (PR) at best, and multiple trials have focused on deepening responses. Here we investigate the association of depth of response at one year and PFS in CLL pts on IB. **Methods:** This was a retrospective study of pts with CLL enrolled in 4 sequential clinical trials of IB as a single agent or in combination with ofatumumab at the Ohio State University. Response was evaluated by two independent investigators using International Workshop on CLL 2008 guidelines if bone marrow was available; if no marrow was available, clinical response was used. A landmark analysis was performed at response assessment at 12 +/- 2 months. PFS was calculated from this response assessment to progression or death. The method of Kaplan-Meier and Cox models were used to estimate PFS. **Results:** The cohort was comprised of 237 pts enrolled between July 19, 2010 and March 24, 2014 with median number of prior therapies 3 (range 0-13). Median age was 65; 82% IGVH unmutated, 36% with del(17p), and 54% with complex karyotype. At month 12 assessment, 5% of pts had CR, 3% CR with incomplete marrow recovery (CRi), 77% PR, 12% PR with lymphocytosis, and 3% stable disease. With a median follow-up of 48 months, the median PFS was 52 months (95% CI: 42-70) with no significant difference among response groups (p = 0.23). However, PR pts with lymph nodes (LN) ≥3cm had significantly higher risk of progression than pts with LN < 3cm (median PFS 42 vs. 68 months; hazard ratio = 1.6, p = 0.03 from multivariable model). **Conclusions:** There was no significant difference in PFS between CR and other response groups. However, a significant difference was found in PR pts with LN ≥3cm vs. LN < 3cm. This suggests that, unlike with chemoimmunotherapy, attainment of a CR with IB is not critical, however, those patients with significantly enlarged nodes after 1 year of therapy have shorter PFS. Combination therapy studies without the goal of therapy discontinuation may focus on elimination of bulky nodal disease rather than attainment of CR for all patients.

7515 Poster Discussion Session; Displayed in Poster Session (Board #152), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 1:15 PM-2:30 PM

Two years rituximab maintenance vs. observation after first line treatment with bendamustine plus rituximab (B-R) in patients with marginal zone lymphoma (MZL): Results of a prospective, randomized, multicenter phase 2 study (the StiL NHL7-2008 MAINTAIN trial). *First Author: Mathias J. Rummel, Department of Haematology and Oncology, Justus-Liebig Universität, Giessen, Germany*

Background: Rituximab (R) maintenance is part of a standard treatment for follicular lymphoma. In MZL, however, it is not yet common practice. In this study we compared the effect of 2 years of R maintenance vs. observation after first-line treatment with B-R in patients with previously untreated MZL. **Methods:** Patients had stage II (bulky disease > 7 cm), III, or IV disease. Nodal and splenic MZL were included but not MALT lymphomas. Primary endpoint was progression free survival (PFS). Secondary endpoints included response rates, overall survival (OS), and toxicity. For induction patients were treated with up to 6 cycles of B-R plus 2 additional R cycles. Only patients responding to B-R were then randomized to either R maintenance (q 2 months for 2 years) or observation. **Results:** Median time of follow-up after registration was 76 months at the time of this analysis (February 2018). 119 patients with a median age of 65 years were evaluable for response. 108 (91%) responded to B-R induction, with 23 patients (19%) achieving a complete remission. Of 104 randomized patients, 53 (51%) were randomized to R maintenance and 51 (49%) to observation. Median age of randomized patients was 64 years, patient characteristics and toxicity were similar for both groups. PFS was superior for 2 years of R maintenance, with the median not yet reached vs. 92.2 months for observation (hazard ratio (HR) 0.35, 95% CI 0.17 – 0.76, p = 0.008). The OS rate at 6 years was 92% for R maintenance vs. 86% for observation. The difference in OS was not statistically significant (HR 0.52, 95% CI = 0.20 – 1.39). **Conclusions:** Our results demonstrate a statistically significant PFS improvement of a 2-year R-maintenance vs. observation after B-R induction in patients with MZL. Clinical trial information: NCT00877214.

Response rate to lenalidomide plus rituximab (R^2) as independent of number of prior lines of therapy: Interim analysis of initial phase of MAGNIFY phase IIIb study of R2 followed by maintenance in relapsed/refractory indolent NHL. *First Author: David Andorsky, Rocky Mountain Cancer Centers, US Oncology Research, Boulder, CO*

Background: In the relapsed/refractory (R/R) setting for indolent non-Hodgkin lymphoma (iNHL), duration of response (DOR) to and types of prior therapy are important factors in predicting outcomes to subsequent therapy. Lenalidomide plus rituximab (R^2) has shown promising efficacy and tolerability in multiple NHL studies. This report explores the association between prior number of therapies and response to R^2. **Methods:** MAGNIFY (NCT01996865) is a phase IIIb, multicenter, global study of R/R NHL patients, including follicular lymphoma (FL) grade 1-3a and marginal zone lymphoma (MZL). Patients receive 12 cycles of R^2 (lenalidomide 20 mg/d, d1-21/28 + standard rituximab). Patients with stable disease or better are then randomized 1:1 to maintenance with R^2 vs rituximab alone. This analysis focuses on the initial period before randomization (12 cycles R^2) for patients with <2 (<2L) vs ≥2 lines (≥2L) of prior systemic anti-lymphoma therapies. **Results:** As of May 1, 2017, 232 patients with FL gr1-3a (n = 186) and MZL (n = 46) were enrolled for the initial treatment period. Overall, median age was 66 years (range 35-91) and 89% were stage III/IV. Patients received a median of 2 prior systemic treatments (31% ≥3) and 97% received prior rituximab-containing regimens. Analyzed subgroups included 43% <2L (n = 99) and 57% ≥2L (n = 133) with generally similar baseline characteristics. In efficacy-evaluable patients, the overall response rates (70% and 66%) and complete response (51% and 36%) were similar in <2L and ≥2L patients. Median time to response was 2.8 months (range, 2-12) for both groups. For <2L and ≥2L groups, 1-year rates for PFS were 68% and 70%, and DOR were 77% and 81%, respectively. The most common grade ≥3 treatment-emergent adverse events for <2L and ≥2L patients, respectively, were neutropenia (29%; 37%), thrombocytopenia (10%; 6%), and leukopenia (4%; 7%). **Conclusions:** R^2 therapy showed favorable activity and tolerable safety profiles in patients who had R/R FL and MZL, regardless of the number of prior anti-lymphoma therapies. Enrollment in MAGNIFY is ongoing. Clinical trial information: NCT01996865.

Role of ofatumumab (OFA) maintenance treatment in relapsed chronic lymphocytic leukemia (CLL): Final analysis of PROLONG study. *First Author: Marinus Van Oers, Department of Hematology, Academic Medical Center, Amsterdam, the Netherlands, on behalf of the HOVON CLL Working Group, Amsterdam, Netherlands*

Background: An interim analysis of the PROLONG phase 3 study in patients (pts) with CLL showed a significant increase in progression free survival (PFS) with OFA maintenance without unexpected side effects (van Oers, et al, 2015). Here, we present the final analysis of the study. **Methods:** Pts in complete or partial remission after 2nd or 3rd line treatment for CLL were randomized 1:1 to OFA (300 mg followed 1 week later by 1000 mg every 8 weeks for up to 2 years) or to observation (Obs) arm. The primary endpoint was investigator-assessed PFS. Secondary endpoints included time to next treatment (TTNT), overall survival (OS), and safety. **Results:** Overall, 480 pts were randomized to either OFA arm or Obs arm. Baseline characteristics were similar between the 2 arms. Median duration of OFA treatment was 608 days. Median follow-up was 40.89 months (mo). Median PFS was 34.17 mo for OFA (95% confidence interval [CI]: 29.70, 38.01) and 16.89 mo (95% CI: 12.98, 20.37) for Obs (Hazard ratio [HR] = 0.55; 95% CI: 0.43, 0.70; $P < 0.0001$) arm. Median TTNT was 37.36 mo (95% CI: 30.55, 42.61) for OFA and 27.56 mo (95% CI: 23.52, 32.62) for Obs (HR = 0.72; 95% CI: 0.57, 0.91; $P < 0.0044$). The OS data although not yet mature, do not show a difference (HR = 0.99; 95% CI: 0.72, 1.37). Death rate was similar in both the arms (32% in OFA vs. 29% in Obs). Adverse events (AEs) were reported in 92% of pts in OFA arm vs. 82% in Obs arm; 62% of pts in OFA arm had ≥grade 3 AEs vs. 51% in Obs arm. Serious AEs (SAEs) were reported in 48% of pts in OFA vs. 46% in the Obs arm. Most common (> 5% of all pts) ≥grade 3 AEs were neutropenia (OFA: 23% vs Obs: 10%), pneumonia (OFA: 13% vs Obs: 12%), febrile neutropenia (OFA: 6% vs Obs: 4%), and pyrexia (OFA: 5% vs Obs: 2%). Due to AEs, 12% of pts discontinued OFA permanently. Up to 60 days after the last treatment, there were 5 SAEs leading to death in the OFA arm vs 7 in the Obs arm; none were considered to be related to the study drug. **Conclusions:** This final analysis confirmed the results of the interim analysis, the treatment effect of maintenance OFA was maintained with more mature data. A significant clinical benefit was observed in pts with relapsed CLL after OFA maintenance. Treatment was well tolerated without unexpected toxicities. Clinical trial information: NCT01039376.

Acalabrutinib combined with PI3Kδ inhibitor ACP-319 in patients (pts) with relapsed/refractory (R/R) B-cell malignancies. *First Author: Paul M. Barr, Wilmot Cancer Institute, University of Rochester, Rochester, NY*

Background: Acalabrutinib, a selective, covalent inhibitor of Bruton tyrosine kinase (BTK), was evaluated in combination with the PI3Kδ inhibitor ACP-319 in pts with R/R B-cell malignancies. **Methods:** Pts with ≥1 prior therapy & ECOG PS ≤2 received oral acalabrutinib 100 mg bid and ACP-319 in escalating doses (25/50/100 mg bid; Part 1) or 50 mg bid (expansion cohort; Part 2) until progressive disease or unacceptable toxicity. The primary endpoint was safety (including dose-limiting toxicity [DLT; Part 1]). Secondary endpoints were PK/PD, overall response rate (ORR), duration of response (DOR) & progression-free survival (PFS). **Results:** Part 1 pts (8 CLL/SLL, 3 FL, 3 MCL, 3 diffuse large B-cell lymphoma [DLBCL], 1 WM) had median age 65 y (range 48-77) & ECOG PS ≤1. One pt had a DLT in the ACP-319 50-mg group (maculopapular rash [MR]); 2 had DLTs in the 100-mg group (MR; febrile neutropenia, diarrhea & pneumonitis). The maximum tolerated dose for Part 2 was ACP-319 50 mg bid with acalabrutinib 100 mg bid. Pts with CLL/SLL were switched to acalabrutinib monotherapy in 2016 due to reduced benefit:risk ratio with added ACP-319. Herein, 25 DLBCL pts (3 in Part 1, 22 in Part 2) were analyzed; by IHC (Hans algorithm), 9 had germinal center B-cell (GCB) & 16 had non-GCB DLBCL. Median age was 70 y (range 55-90); median no. of prior therapies was 2 (range 1-5). Common AEs (≥40%) were increased AST/ALT (48%/52% [Grade ≥3, 28%/20%]), diarrhea (52% [12%]), fatigue (40% [0%]) & rash (40% [12%]); 22 pts discontinued (5/7 due to AEs with acalabrutinib/ACP-319); no deaths were due to AEs. ORR is in Table. ACP-319 exposure was dose proportional with higher/variable exposure to an inactive metabolite. Acalabrutinib exposure was slightly higher at ACP-319 100 (vs 25/50) mg. Median BTK occupancy at trough was 95%; p-AKT inhibition was ACP-319 dose dependent. **Conclusions:** The combination of acalabrutinib + ACP-319 was tolerable with manageable AEs; in DLBCL, response rate was high in non-GCB pts. Clinical trial information: NCT02328014.

Initial results of a dose escalation study of a selective and structurally differentiated PI3Kδ inhibitor, ME-401, in relapsed/refractory (R/R) follicular lymphoma (FL) and chronic lymphocytic leukemia (CLL)/small lymphocytic lymphoma (SLL). *First Author: Jacob Drobnyk Soumerai, Massachusetts General Hospital, Boston, MA*

Background: ME-401, an oral tyrosine kinase inhibitor highly selective for PI3Kδ was studied in a phase 1b trial for patients (pts) with R/R FL or CLL/SLL. The starting dose was based on pharmacokinetic and pharmacodynamic data from a study in healthy volunteers. **Methods:** Eligible adult pts had ECOG ≤2, no prior PI3K therapy, and no prior progression of disease (POD) on BTK therapy. ME-401 was given once daily on days 1-28 of 28-day cycle until POD or unacceptable toxicity. All pts received PJP prophylaxis and CMV monitoring was mandatory. At least 6 evaluable pts were treated at each dose level, with option to expand to 12 pts for efficacy assessment. Dose limiting toxicities (DLT) were assessed up to Day 56. Response was assessed after Cycles 2 and 6. **Results:** 31 pts (21 FL, 10 CLL/SLL) received ME-401 and 30 were evaluable for DLT: 12 at 60 mg, 12 at 120 mg, and 6 at 180 mg. Median age was 65 (range: 47-79), 14/30 (47%) pts received ≥2 prior therapies, and 9/21 (43%) pts with FL had POD < 24 months after initial chemoimmunotherapy (POD24). Of 29 pts evaluable for response, the overall objective response rate was 83% (24/29), with 75% (15/20) in FL, including 9/9 (100%) with POD24, and 100% (9/9) in CLL/SLL, occurring by Cycle 2 in 20/24 responders. No DLTs were reported and escalation above 180 mg was closed given frequent responses across lower dose levels. With a median follow-up of 20 weeks (range: 2-53 weeks) 3 pts had POD at 8, 14 and 17 weeks after starting therapy. Five pts discontinued MEI-401 due to adverse events (AEs): rash (n = 3), colitis (n = 1), and cardiomyopathy (n = 1), and 2 pts discontinued for personal reasons. Most common AEs (all grades/grade ≥3) were diarrhea (32%/16%), fatigue (29%/0%), cough (29%/0%), rash (29%/10%), and nasal congestion (26%/0%). All grade ≥3 AEs were reported in Cycle 3 or later. **Conclusions:** ME-401 was well tolerated with high early response rates among R/R FL and CLL/SLL pts. No DLTs were reported. An alternative dosing (ME-401 days 1-7 of 28-day cycle starting with Cycle 3) is being evaluated, including dosing ME-401 at 45 mg and at 60 mg in combination with rituximab. Clinical trial information: NCT02914938.

7520 Poster Discussion Session; Displayed in Poster Session (Board #157), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 1:15 PM-2:30 PM

Phase I/II clinical trial of ibrutinib and buparlisib in relapsed/refractory diffuse large B-cell lymphoma, mantle cell lymphoma, and follicular lymphoma. *First Author: Connie Lee Batlevi, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Bruton's tyrosine kinase (BTK) and PI3K inhibitors synergize effectively in both in vitro and in vivo models of B-cell non-Hodgkin lymphoma (Griner, et al, PNAS, 2014; Erdmann et al, Blood, 2017). We report on a phase I/II clinical trial of ibrutinib (BTK inhibitor) and buparlisib (pan-PI3K inhibitor) in patients with relapsed/refractory diffuse large B-cell lymphoma (DLBCL), follicular lymphoma (FL), and mantle cell lymphoma (MCL). **Methods:** Patients (pts) were eligible if they had relapsed/refractory DLBCL, FL, or MCL, ECOG ≤2, and adequate organ function. Ibrutinib and buparlisib were given daily by mouth on a 28-day cycle with dose reductions permitted after cycle 1 unless a DLT was noted. Tumor response was based on a modified Lugano classification with CRs requiring FDG-PET resolution and ≥ PR by CT. **Results:** 37 pts were enrolled (DLBCL N = 14, FL N = 5, MCL N = 18) with median prior systemic therapies being 3 for DLBCL (range 1-7), 2 for FL (all had 2 prior regimens), and 1 for MCL (range 1-3). Ibrutinib 560 mg and buparlisib 80 mg was selected for dose expansion cohort based on rash and diarrhea requiring dose reductions. Thirty-six pts were evaluable for toxicity while 1 pt was not evaluable for progression within one week of therapy. Grade 3/4 adverse events related to therapy included rash (22%), hyperglycemia (16%), diarrhea (11%), hypertension (11%), anorexia (8%), mood changes (8%), ALT elevation (5%), lipase elevation (5%), anemia (5%), and hyponatremia (5%). Five pts discontinued buparlisib but continued ibrutinib for neurocognitive toxicities related to buparlisib. Thirty-five pts were evaluable for response with best overall response rate (ORR) as follows: DLBCL 31% (N = 13, 3 CR, 1 PR), FL 20% (N = 5, 1 CR), MCL 88% (N = 17, 11 CR, 4 PR). **Conclusions:** Combination of BTK and PI3K inhibition such as ibrutinib and buparlisib demonstrate a reasonable safety profile and promising clinical activity, especially in MCL. Long term follow-up and correlative analysis of tumor targeted sequencing and cell free DNA analysis is ongoing. Clinical trial information: NCT02756247.

7521 Poster Session (Board #158), Mon, 8:00 AM-11:30 AM

Prognostic role of beta-2 microglobulin (B2M) in relapsed/refractory (R/R) chronic lymphocytic leukemia (CLL) patients (pts) treated with ibrutinib (ibr). *First Author: William G. Wierda, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: B2M is often elevated in pts with CLL and correlates with disease stage and burden. Normalization of B2M at 6 mo during ibr treatment was associated with improved progression-free survival (PFS) (Thompson et al 2016). We evaluated B2M changes over time, factors associated with B2M normalization, and correlations between B2M status and PFS in pts with R/R CLL treated with ibr. **Methods:** Data were pooled from 2 clinical trials of single-agent ibr (420 mg/d) in pts with R/R CLL. Pts in RESONATE were randomized 1:1 to ibr or ofatumumab. All pts in RESONATE-17 received ibr. Univariate (UVA) and multivariate (MVA) analyses were used to examine baseline (BL) factors associated with B2M normalization. PFS from time of the 6-mo B2M visit was compared based on B2M status; exploratory analyses evaluated PFS by 9-, 12-, and 15-mo B2M status. **Results:** In the combined ibr population (N = 339), BL elevated B2M (79% ≥3.5 mg/L; median 5.4 mg/L), del17p (61%), and unmutated *IGHV* (58%) were common; 15% had del11q, and 25% had creatinine clearance (CrCl) < 60 mL/min. Pts had a median of 2 prior lines of therapy. Median B2M decreased rapidly, by ~40% at 3 mo, in all patients. Overall, 50% of pts normalized B2M during ibr. Median time to B2M normalization was 17 mo and was non-significantly shorter for pts with del17p vs without del17p (14 vs 26 mo; *P*= 0.220). In UVA, BL B2M < 3.5 mg/L, age < 65 y, and CrCl ≥60 mL/min were significantly (*P*≤0.0002) associated with B2M normalization at 6 mo, while del17p was not significant. In MVA, BL B2M < 3.5 mg/L (*P*= 0.0002) and CrCl ≥60 mL/min (*P*= 0.034) were significant factors. PFS did not differ when assessed by 6-mo B2M normalization status (HR 0.699 [95% CI 0.452, 1.080]; *P*= 0.105), nor by 12- or 15-mo B2M status, but was significantly different by 9-mo B2M status (HR 0.579 [95% CI 0.366, 0.915]; *P*= 0.018); median PFS was not reached in either group. For B2M normalization at 9 mo, CrCl was significant in MVA, but age and BL B2M were not. **Conclusions:** Pts treated with ibr had a rapid decrease in median B2M regardless of BL parameters. BL B2M < 3.5 mg/L and CrCl ≥60 mL/min were associated with B2M normalization at 6 mo in MVA. B2M normalization status at 9, but not 6, mo predicted PFS. Clinical trial information: NCT01578707 and NCT01744691.

7522 Poster Session (Board #159), Mon, 8:00 AM-11:30 AM

Achievement of complete remission (CR) as an endpoint for patients with chronic lymphocytic leukemia (CLL) treated with ibrutinib. *First Author: Paolo Strati, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Achievement of a deep response with chemoimmunotherapy associates with prolonged survival in patients with CLL. However, it remains unclear whether this is a desirable endpoint also for patients treated with ibrutinib, who generally achieve partial remissions (PR) rather than CRs. **Methods:** We analyzed the characteristics and outcomes of patients with CLL enrolled in a phase 2 study (NCT02007044) of frontline or salvage continuous ibrutinib therapy, with or without 6 cycles of Rituximab, at our institution between 12/2013 and 10/2016. Progression-free survival (PFS) was defined as time from treatment initiation to disease progression and/or death secondary to CLL-related complications. **Results:** Two-hundred and six patients were included in this study and response was achieved in 186 (99%) of 188 evaluable patients, including PR with lymphocytosis. Six (3%) patients achieved a CR with negative minimal residual disease (MRD), 40 (21%) CR with positive MRD, 3 (2%) nodular PR, 119 (63%) PR, and 18 (10%) PR with lymphocytosis. No significant differences were observed among the baseline characteristics of the 46 patients achieving CR as compared to the 140 patients achieving PR. Achievement of CR was associated with a significantly prolonged PFS (1 event out of 46 patients, 3-year PFS 97%) as compared to PR (14 events out of 140 patients; 3-year PFS 78%)(p = 0.04). None of the baseline characteristics associated with prolonged PFS. Overall, after a median follow-up of 22 months (range, 2-37 months), median PFS was not reached and 19 patients (9%) progressed and/or died of CLL-related complications. Among patients in CR, 1 (2%) with positive MRD died of metastatic melanoma, after 19 months on treatment. Among patients in PR, 13 (8%) developed progressive CLL (1 with Richter transformation), 1 (0.5%) died of metastatic colon cancer, and 4 (1%) died of severe infections. **Conclusions:** This is the first study showing that achievement of CR is a desirable endpoint for patients with CLL treated with ibrutinib, associating with prolonged PFS. Our results support the development of future combination studies, aimed at achieving higher rates of CR in patients treated with ibrutinib. Clinical trial information: NCT02007044.

7523 Poster Session (Board #160), Mon, 8:00 AM-11:30 AM

Association of *ATM* mutation and unmutated IGHV status with shorter time to first treatment (TTFT): An analysis of multigene mutation profiling and standard prognostic clinical markers in 384 treatment-naive (TN) chronic lymphocytic leukemia (CLL). *First Author: Boyu Hu, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Somatic mutations (MUTs) in CLL play important roles in leukemogenesis and affect both response to treatment and survival outcomes. Correlation of somatic MUTs with TTFT remains limited. In this study, we associated somatic MUT results from a 29-gene panel and known prognostic factors with TTFT. **Methods:** DNA from either peripheral blood or bone marrow that contained ≥ 10% CLL cells from 384 TN pts underwent next generation targeted sequencing of a 29-gene panel. Concurrent clinical characteristics such as Rai/Binet staging, FISH abnormalities, cytogenetics and *IGHV* MUT were analyzed in univariable (UA) and multivariable (MVA) analyses with MUT data. TTFT was defined as time from diagnosis to initial treatment; untreated pts were censored at last follow up. **Results:** With a median follow up of 24.3 months (m), the median TTFT for all pts was 61.7m (95% CI 47-74.5m). Compared to pts with no MUTs, pts with a single MUT in *ATM* (p < 0.001), *BIRC3* (p < 0.001), *CXCR4* (p < 0.001), *NOTCH1* (p < 0.001), *SF3B1* (p = 0.02) and *SPEN* (p = 0.04) had shorter TTFT. Pts with 2-5 MUTs also had shorter TTFT by 39m compared to pts with 0-1 MUT (p < 0.001). Location of the MUT in various domains of *TP53* gene along with "hotspot" MUTs in *SF3B1* and *NOTCH1* were not associated with differences in TTFT. Additionally, del(17p) was not associated with shorter TTFT. In UA, MUT in *ATM* (p < 0.001), *NOTCH1* (p < 0.001) and *SF3B1* (p = 0.002) as well as unmutated *IGHV* (p < 0.001), del(11q) (p < 0.001) and trisomy 12 (p < 0.001) and advanced Rai (p = 0.05) and Binet (p < 0.001) stages were associated with shorter TTFT. In MVA, *ATM* MUT (p < 0.001), unmutated *IGHV* (p < 0.001) and advanced Binet stage (p = 0.01) remained significant; del(11q) was not significant in the model. **Conclusions:** Somatic MUT in *ATM* and unmutated *IGHV* are important independent prognostic factors for shorter TTFT. Other somatic MUTs, like *CXCR4* and *SPEN* whose clinical significance have not been fully elucidated, correlated to shorter TTFT although not independently. Somatic gene MUTs, especially *ATM,* are associated with disease progression in TN pts.

7524 Poster Session (Board #161), Mon, 8:00 AM-11:30 AM

Distinct immune signatures in chronic lymphocytic leukemia (CLL) and Richter's syndrome (RS). *First Author: Yucai Wang, Mayo Clinic, Rochester, MN*

Background: Immune checkpoint blockade with PD-1 inhibitor pembrolizumab was effective in RS but not CLL in a phase 2 study (NCT02332980). Analyzing the immune signatures including PD-L1 expression and T cell diversity is important for understanding the differential responses. **Methods:** 15 CLL and 14 RS patients in NCT02332980 were included. Expression of PD-L1 in lymph node (LN) was analyzed by immunohistochemistry staining. Peripheral blood (PB) and LN T cell diversity was analyzed using the ImmunoSEQ platform (Adaptive Biotechnology), which quantifies the clonailty of T cells by deep sequencing of the CDR3 region of T cell receptor (TCR). Data analysis (Student's t-test and Mann-Whiney U test) was done by GraphPad Prism (v7). **Results:** PD-L1 expression was significantly lower in CLL (n = 6) *vs* RS (n = 12) patients (mean 5.5% *vs* 22.9%, *P*= 0.003). A control CLL cohort (n = 11, Mayo CLL tissue registry) also had lower PD-L1 expression (7.7%, *P*= 0.002 *vs* RS). RS Patients progressed on ibrutinib or chemotherapy had similar PD-L1 expression (25.3% vs 19.6%, *P*= 0.416). PB TCR clonality at trial baseline was significantly lower in RS (n = 13) *vs* CLL (n = 13) patients (median 0.098 *vs* 0.342, *P*= 0.026). Patients progressed on ibrutinib or chemotherapy had similar TCR clonality (CLL: 0.34 *vs* 0.24, *P*= 0.524; RS: 0.11 *vs* 0.09, *P*= 0.534). 5 RS patients achieved an objective response (1 CR, 2 PR, 1 CMR and 1 PMR), 4 of which were after progression on ibrutinib. For CLL patients, only 1 nodal reduction was seen. 4 RS patients had prior CLL samples available for TCR analysis. 2 patients had a notable decrease of TCR clonality (0.21-0.04 and 0.17-0.03) from CLL (PB) to RS state (LN), and achieved CR and PR, respectively. 2 other patients with stable clonality (0.04-0.05 and 0.03-0.08) had SD and PMR, respectively. PB TCR clonality did not change significantly with pembrolizumab (CLL [n = 11]: *P*= 0.775; RS [n = 11]: *P*= 0.830; paired t-test). **Conclusions:** RS patients had higher expression of PD-L1 and lower TCR clonality (more diverse T cells) compared with CLL patients. The distinct immune signatures may explain their differential responses to PD-1 blockade. The dynamic changes of TCR clonality during Richter's transformation may predict a response to PD-1 blockade.

7525 Poster Session (Board #162), Mon, 8:00 AM-11:30 AM

Rapid progression of disease following ibrutinib discontinuation in patients with chronic lymphocytic leukemia. *First Author: Paul Joseph Hampel, Mayo Clinic, Rochester, MN*

Background: The clinical characteristics, management, and outcomes of patients (pts) with chronic lymphocytic leukemia (CLL) who develop rapid progression of disease following ibrutinib discontinuation are not well described. **Methods:** We identified all CLL pts at Mayo Clinic who discontinued ibrutinib therapy. Clinical symptoms, exam and radiographic findings, and laboratory changes associated with discontinuation were ascertained. **Results:** Of 281 ibrutinib treated pts, 82 (29%) discontinued therapy. Reasons for discontinuation and the median time to discontinuation include: toxicity (n = 30, 37%, 8 months), CLL progression (n = 18, 22%, 25 months), Richter's transformation (n = 9, 11%, 6 months), other (n = 11, 13%), and death (n = 14, 17%). In total, 61 pts had adequate records for review within 4 weeks after discontinuing ibrutinib. Among these, 15 (25%) had progressive worsening in > 2 clinical domains (i.e., symptoms, exam/imaging, labs) post discontinuation, including 13 pts who discontinued due to progression or transformation and 2 pts who discontinued due to toxicity or other. Clinical findings included sudden worsening of constitutional symptoms (n = 14, 93%), worsening lymphadenopathy or splenomegaly (n = 10, 67%), and increasing lactate dehydrogenase or lymphocytosis (n = 12, 80%). We defined these clinical symptoms as ibrutinib stop sequela. Next line therapy was started the next day after ibrutinib discontinuation for 6 pts, after gap in treatment in 4 pts (median 13 days, range 5-36), and overlapped with ibrutinib in 2 pts. Three pts did not receive subsequent therapy. Next line therapy included idelalisib (n = 3), venetoclax (n = 3), steroids with anti-CD20 therapy (n = 2), pembrolizumab (n = 1) and multi-agent chemotherapy (n = 3). Age, sex, *TP53* disruption, and *IGHV* mutation status did not predict the occurrence of the described worsening on univariate analysis. The median overall survival for the entire group was 35 months. **Conclusions:** Multiple ibrutinib stop sequela were seen in 1 out of 4 patients after stopping ibrutinib, occurring despite prompt next line salvage therapy. Parameters to better define the post-ibrutinib interval and optimal ways for its management are required.

7526 Poster Session (Board #163), Mon, 8:00 AM-11:30 AM

Mitigation of tumor lysis syndrome (TLS) complications with venetoclax (VEN) in CLL. *First Author: Matthew Steven Davids, Dana-Farber Cancer Institute/Harvard Medical School, Boston, MA*

Background: VEN can cause rapid tumor debulking in patients (pts) with relapsed/refractory CLL. Current VEN dosing schedule with TLS prophylaxis/monitoring averts overt TLS, but further data on emergent biochemical changes during VEN initiation are needed to guide practice. **Methods:** Pts were included from phase 2 trials of VEN for CLL with del(17p) (n = 51) or prior BCRi therapy (n = 117). VEN started at 20 mg QD with ramp up to 400 mg over 5 wk. Pts were categorized as low (L) TLS risk (nodes < 5 cm and ALC < 25), medium (M; node ≥5 – < 10 cm or ALC ≥25), or high (H; node ≥10 cm or ≥5 cm and ALC ≥25). Laboratory values, AEs, and relevant concomitant medications during ramp up were analyzed. **Results:** TLS risk was categorized as 36% L, 36% M, and 27% H (see Table). 96% of pts completed ramp up; most in 5 wk. TLS AEs were reported in 4 pts (2 M; 2 H), with no clinical TLS and 1 laboratory TLS meeting Howard criteria (HC*). During VEN ramp up, 114 pts had potassium (K) > upper limit of normal (ULN) (1 K > HC); 21 were treated for rising or sustained K > ULN. 16 of these 21 had pre-VEN initiation K > ULN. 5/21 pts interrupted VEN for 1 day and all restarted VEN. 119 pts had phosphate (P) > ULN. 20 pts received P binder for P > HC during VEN ramp up and all others resolved without additional medication. Most instances were isolated; 4 pts had concurrent calcium (Ca^{2+}) or uric acid (UA) changes, and P was not treated in these cases. 70% of pts received allopurinol and 20% allopurinol and rasburicase at VEN start. 6 pts received rasburicase in addition to ongoing prophylaxis. Though 144 pts had Ca^{2+} < lower limit of normal (LLN), only 6 were treated. **Conclusions:** Despite the frequency of K > ULN, treatment was applied in 13% of pts for rising or sustained elevation, and most had pre-VEN K > ULN. Most cases of P > ULN were isolated, asymptomatic, and resolved without intervention. VEN causes rapid tumor cytoreduction consistent with analyte changes, though clinical sequelae are rare and mitigated by approved dose ramp up, TLS prophylaxis/monitoring, and timely intervention. Clinical trial information: NCT01889186, NCT02141282.

7527 Poster Session (Board #164), Mon, 8:00 AM-11:30 AM

Economic evaluation for the US of venetoclax (VEN) versus ibrutinib (IBR) versus allogeneic hematopoietic stem-cell transplantation (HSCT) for patients (pts) with relapsed or refractory (R/R) chronic lymphocytic leukemia (CLL) with 17p deletion (del 17p). *First Author: Nimer Alsaid, University of Arizona College of Pharmacy, Tucson, AZ*

Background: Prior to targeted agents, HSCT was the primary treatment for R/R CLL del 17p. VEN and IBR have been shown to improve progression free (PFS) and overall survival (OS). We performed an independent economic evaluation of VEN versus IBR versus HSCT in R/R CLL del 17p from the U.S. payer perspective. **Methods:** From published trial data we constructed a life-time horizon Markov model with 3 states: PFS; progression; and death. Kaplan-Meier PFS and OS curves for VEN, IBR and HSCT were digitized, and Weibull distributions fitted. The wholesale acquisition cost of VEN and IBR were sourced from RedBook. Costs of the HSCT (procedure, pre-conditioning, post-procedural adverse events [AE]) were estimated from published prediction equations and a claims database. EQ-5D utility values were sourced from literature. AE disutility values were assumed the same for the 3 interventions. Discount of 3% was applied. The life years (LY) and quality adjusted LY (QALY) for each treatment were estimated, and the incremental cost-effectiveness (ICER) and cost-utility ratios (ICUR) were determined. **Results:** IBR prevailed in PFS over VEN and HSCT until ~190 weeks (3.7 years) when curves crossed and VEN prevailed over both IBR and HSCT. VEN prevailed in OS over IBR and HSCT over the full life time horizon. The Table below presents the BCA and PSA estimated costs and (QA)LYs gained. VEN was cost saving over IBR and HSCT and yielded higher (QA)LY gains. IBR was cost saving over HSCT and yielded higher (QA)LY gains. The ICERs and ICURs for VEN over IBR and HSCT were cost saving per (QA)LY gained. For IBR, the ICER and ICUR revealed incremental costs per LY and QALY gained. **Conclusions:** Over a life time horizon, VEN showed cost savings while achieving higher (QA)LYs over IBR and HSCT. IBR achieved higher (QA)LYs over HSCT but at incremental cost.

7528 Poster Session (Board #165), Mon, 8:00 AM-11:30 AM

Change in tumor lysis syndrome risk after lead-in treatment in a phase 1b/2 study of obinutuzumab, ibrutinib, and venetoclax for chronic lymphocytic leukemia. *First Author: Kerry Anne Rogers, The Ohio State University, Division of Hematology, Columbus, OH*

Background: Venetoclax (VEN) is highly effective for the treatment of chronic lymphocytic leukemia (CLL). Tumor lysis syndrome (TLS) during VEN initiation is a major risk and management, including hospitalization for high risk patients, increases treatment burden and limits use. Strategies to decrease TLS risk are of interest. We reviewed our phase 1b/2 study of combination obinutuzumab (OBIN), ibrutinib (IBR), and VEN to understand how lead-in OBIN and IBR change TLS risk. **Methods:** All study patients who completed 3 cycles (C) of treatment were included. Agents were started sequentially over C1-3 with OBIN C1 (C1 D1: 100mg, C1 D2: 900mg, C1 D8, D15: 1,000mg, C2-8 D1: 1,000mg), IBR C2 (C2-14 D1-28: 420mg), and VEN C3. Risk for TLS was assessed according to the VEN US label at baseline and prior to C3. We recorded absolute lymphocyte count (ALC) and lymph node (LN) sum of the product of longest diameters (SPD) and tested for changes in TLS risk between C1 and C3 using the Wilcoxon signed-rank test. **Results:** 61 patients were included: 36 relapsed or refractory and 25 treatment naïve. ALC and LN (C1-3) and TLS risk (baseline, C3) are in Table 1. ALC significantly decreased from C1 to C3 ($p < 0.0001$) with a median change of -93.2% (range -99.6-194.5%). LN similarly decreased ($p < 0.0001$). OBIN attenuated IBR lymphocytosis with a median ALC change C2 to C3 of 2.1 (range -0.3-46.7). Twelve (20%) patients reduced TLS risk from high to medium, 26 (43%) from medium to low, and 23 (38%) had no change. There were no incidents of clinical or laboratory TLS. **Conclusions:** Lead-in OBIN and IBR decreased TLS risk in the majority of high (12/19, 63%) or medium (26/34, 76%) risk patients when reassessed prior to VEN. This strategy may improve the safety of VEN initiation, allow some initially high risk patients to avoid hospitalization, and expand settings where VEN is used. Clinical trial information: NCT02427451.

CLL burden and TLS risk (n = 61).

ALC in k/uL, median (range)	-

7529 Poster Session (Board #166), Mon, 8:00 AM-11:30 AM

Management and outcomes of 222 CLL patients (pts) treated with venetoclax (VEN) in the real world. *First Author: Chadi Nabhan, Cardinal Health Specialty Solutions, Dublin, OH*

Background: VEN is an oral bioavailable BCL-2 inhibitor approved by the FDA in April 2016 for use in CLL. More data are needed to understand real world initiation, management and outcomes of CLL pts treated with VEN. **Methods:** This was a retrospective cohort study of CLL pts who initiated VEN. Investigators from 25 community centers provided pt-level data from medical records including demographics, clinical characteristics, ramp up management and outcomes. Tumor burden was assessed per FDA label, tumor lysis syndrome (TLS) was defined by Howard criteria and response was based on iwCLL criteria. The primary endpoint was response. Characteristics and outcomes were summarized by descriptive statistics. **Results:** 222 VEN pts were included, of whom 22% used VEN in combination with ibrutinib (7%) or an anti-CD20 (14%). Median age was 64 years (range 57-71); 82% had *TP53* interruption ; 84% had ≥1 prior line of therapy (median 1; range 0-6); 62% had prior kinase inhibitor (KI) use; and 4% had prior use of 2 KIs. At baseline, 11%, 49% and 40% had low, medium and high tumor burden, respectively, and 27% initiated VEN as inpatient. During ramp up, 6% had a dose interruption; no dose modifications were reported due to hematologic abnormalities. TLS events occurred in 6% of pts (n = 13) with 2 pts experiencing clinical TLS, mainly among high risk pts. 34 pts (15%) discontinued VEN, mainly due to relapse (n = 5), refractoriness (n = 9), or in setting of disease response (n = 8). Maximum dose of 400mg was achieved in 53% of pts and 46% (n = 103) were maintained at doses < 400mg following ramp up. With a median follow up of 6.1 months, ORR was 75% (CR: 26%). Median time to best response was 3 months. Responses were not negatively affected by TLS or maintenance doses < 400mg. Among 38 pts assessed for minimal residual disease (MRD) during VEN, 23 (61%) were MRD negative. Resolution of baseline lymphadenopathy, lymphocytosis, or B symptoms were reported among 93%, 95%, and 96%, respectively. **Conclusions:** In this study, most VEN-treated CLL pts completed the ramp up, few experienced a TLS /hematologic event, and responses were comparable to clinical trials. Inpatient management deviated from the FDA label suggesting opportunity to improve adherence to initiation guidance.

7530 Poster Session (Board #167), Mon, 8:00 AM-11:30 AM

A phase 2 study to assess the safety and efficacy of umbralisib (TGR-1202) in pts with CLL who are intolerant to prior BTK or PI3Kδ inhibitor therapy. *First Author: Anthony R. Mato, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Although KI therapies are generally well-tolerated, intolerance is the most common reason for discontinuation, thus representing an unmet medical need. Umbralisib (TGR-1202), a next generation PI3Kδ inhibitor, has a discontinuation rate due to adverse events (AEs) of < 10%. **Methods:** We report results from a Ph 2 study assessing the safety/efficacy of umbralisib in CLL pts who were intolerant (defined per protocol) to a prior KI within 12 mos. AEs must have resolved to ≤ GR 1 prior to umbralisib therapy. Umbralisib (800mg QD) administered until progression or toxicity. Primary endpoint is progression-free survival (PFS). **Results:** 40 pts were treated as of 2/2018 (36 BTK & 4 PI3Kδ intolerant). Baseline demographics: median (med) age 69 yrs (range 52-96), med prior therapies 2 (1-7), 55% male, ECOG 0-1 (92%), del17p (20%), del11q (23%), IGHV unmutated (60%). 80% required treatment within 6 mos of prior KI discontinuation. Most AE's leading to KI discontinuation were: arthralgia, rash (9 events each), A-fib (6), diarrhea (4), bleeding, fatigue and weight loss (3 each). AEs on umbralisib are listed in the table: GR ≥3 PI3Kδ-associated AE's were limited: AST/ALT (3%); diarrhea (7.5%); rash (3%). 4 pts discontinued umbralisib due to intolerance (rash, pneumonia, pneumonitis, pancreatitis), and 1 pt due to study noncompliance. No pt discontinued umbralisib as a result of a prior KI intolerant AE. 3 pts (7.5%) had dose reductions (headache, hematologic, and colitis) and were successfully re-challenged (colitis pt on study in PR now 12 mos). Med PFS not reached with 90% of pts progression free at a med follow up 6.5 mos (range 1–15). **Conclusions:** Umbralisib appears to be safe and effective in KI intolerant CLL pts. These are the first data to confirm that switching from KI to an alternate PI3Kδ (umbralisib) can result in disease control (PFS) without recurrence of KI intolerance toxicities. BTK mutations and CYP polymorphisms are being assessed. Clinical trial information: NCT02742090.

Umbralisib AEs (all causality) in > 15% pts (n = 40).

7531 Poster Session (Board #168), Mon, 8:00 AM-11:30 AM

B-cell acute lymphoblastic leukemia (B-ALL) in CLL patients treated with lenalidomide. *First Author: Moritz Fuerstenau, Department I of Internal Medicine and Center of Integrated Oncology Cologne-Bonn, German CLL Study Group, University of Cologne, Cologne, Germany*

Background: The immunomodulatory drug lenalidomide (len) has shown clinical activity in CLL. It has been associated with an increased rate of second primary malignancies (SPM) in multiple myeloma (MM). In MM degradation of transcription factors Ikaros and Aiolos leads to its anti-tumor activity and T-cell activation; in CLL, its mechanism of action has not been determined yet. In our CLLM1 trial, 2 of 56 pts developed BCR-ABL positive B-ALL during or after len maintenance; there were no B-ALL cases in the placebo group. **Methods:** We screened all phase III trials using len in CLL pts for reported B-ALL cases, obtained reports of B-ALL cases in CLL from the FDA Adverse Event Reporting System (FAERS) and analysed available data for B-ALL cases in five non-len GCLLSG trials in order to estimate the incidence of B-ALL in CLL pts not exposed to len. In the 2 CLLM1 pts, PCR was performed for detection of BCR-ABL before B-ALL diagnosis and clonal relationships of B-ALL and CLL will be assessed by NGS. **Results:** In 3 phase III trials (CLLM1, CONTINUUM, ORIGIN) evaluating the use of len in CLL, a total of 846 pts were enrolled, 438 receiving len monotherapy. Five out of 438 pts (1,1%) developed B-ALL during treatment (n = 1) or after discontinuation (n = 4). No B-ALL cases were reported in the control groups including 408 pts. Of the 5 pts, 2 received len as firstline and 3 as maintenance therapy, median length of exposure was 32 months (range 15-47), median age at B-ALL diagnosis was 69 years (range 60-82). Both CLLM1 pts were categorized as 'high risk' or 'very high risk' according to CLL-IPI, 1 pt featuring a TP53 mutation, both with unmutated IGHV. BCR-ABL could not be detected at any time point before ALL diagnosis, clonal relationship of B-ALL and CLL is currently being analysed. In 2015 pts treated within 5 non-len GCLLSG trials, only 2 cases of B-ALL were identified (0,1%); this underscores the assumption that secondary B-ALL is usually a rare event in CLL. **Conclusions:** According to a large GCLLSG cohort and in accordance with published data on SPM in CLL, B-ALL is a rare event in CLL patients. In CLL patients treated with len either as firstline or maintenance therapy following chemotherapy, an increased number of B-ALL was observed, the reason for this increase is unknown.

7532 Poster Session (Board #169), Mon, 8:00 AM-11:30 AM

A U.S.-based survey: The experiences of 1147 chronic lymphocytic leukemia (CLL) patients (pts). *First Author: Brian Koffman, CLL Society Inc, Claremont, CA*

Background: The CLL literature focuses largely on the objective aspects of diagnosis (dx), active observation (AO), prognosis and management. While health care providers (HCPs) try to effectively educate and reassure pts, the literature on pts' subjective experience through the continuum of care is limited. **Methods:** We utilized an online or paper 64 question survey directed to CLL pts to capture more information on their experience with CLL. The survey was IRB-approved and took place between October-December 2017. All analyses here are descriptive in nature. **Results:** 1147 pts from 48 states completed the survey. Median age was 65 (range 28-86), 46% male, 96% Caucasian. 33% of pts do not recall education by their HCP at dx. Following education, 66% of pts report a good understanding of sources of information on CLL, 64% of disease characteristics and 62% of therapy indications. At disease progression, only 23% of pts report education from their HCPs. Effects of treatment and clinical trial opportunities are well understood by 43% and 35% respectively. At dx, 48% were told they had the "good" cancer. When AO was recommended, pts report anxiety (56%), relief (52%) and confusion (31%). 34% and 16% of pts report that discussing prognostics increased their anxiety and confusion respectively. During AO pts report fatigue (51%), enlarged nodes (47%), anxiety (39%), depression (21%), and night sweats (21%). Also during AO, 653 pts (66%) utilize herbals and other non-traditional interventions for CLL management (Table). When pts declined participation in a clinical trial, the reasons cited were preference for a "proven" treatment (38%), distance from the trial site (29%), fear (20%), and frequent imaging (20%). **Conclusions:** To our knowledge, this is the largest survey of CLL pts. Much can be learned by detailed surveying of CLL pts throughout their disease. These include previously unrecognized suboptimal interactions between the CLL pt and the HCP. Understanding how pts experience their disease is critical to improve communication between pts and their HCPs, which will ultimately advance CLL outcomes.

During AO	% used
Green tea or derivatives	60
Vitamin D	56

7533 Poster Session (Board #170), Mon, 8:00 AM-11:30 AM

The efficacy of duvelisib monotherapy following disease progression on ofatumumab monotherapy in patients with relapsed/refractory CLL or SLL in the DUO crossover extension study. *First Author: Bryone J. Kuss, Flinders Medical Centre, Bedford Park, Australia*

Background: Duvelisib, an oral dual inhibitor of PI3K-δ,γ, is being developed for the treatment of hematologic malignancies, including relapsed/refractory (RR) CLL/SLL. In the Phase 3 DUO study (NCT02004522) duvelisib monotherapy demonstrated significant improvement compared to ofatumumab monotherapy (PFS 13.3 vs 9.9 mo. $p < 0.0001$; ORR 74% vs 45% $p < 0.0001$) with a manageable safety profile (Flinn, ASH 2017). Study IPI-145-12 (NCT02049515) is an open-label, optional, crossover extension study where pts with confirmed progressive disease (PD) on DUO were given the option to receive the opposite treatment. Herein we present data for the 89 pts who voluntarily rolled over following PD on ofatumumab on DUO and received duvelisib on Study IPI-145-12. **Methods:** Eligible pts were enrolled within 3 months of PD on the DUO study (excluding Richter's transformation or prolymphocytic leukemia), and maintained adequate renal and hepatic function and an ECOG PS of 0-2. Duvelisib 25 mg BID was administered until PD, intolerance, death, or study withdrawal. Responses were determined by investigators using modified IWCLL/IWG criteria. **Results:** Median age was 68 yrs (range: 39-89), 63% were male, and 90% Caucasian. Nearly half (49%) had Rai Stage III/IV or Binet Stage C, and 23% had del(17p) and/or *TP53* mutation. Median prior anticancer therapies was 3 (range: 2-8). Median exposure to duvelisib was 32 weeks on the extension study. The ORR for pts treated with duvelisib in the crossover was 73% (95% CI: 64, 82) (all PRs) compared to 28% (95% CI: 19, 37) (1% CR, 27% PR) when previously treated with ofatumumab in DUO. The median PFS for duvelisib was 15 mo. (95% CI: 10, 17) compared to 9 mo. (95% CI: 9, 11) for prior ofatumumab. **Conclusions:** In an extension study, duvelisib monotherapy achieved robust and durable responses in 89 RR CLL/SLL pts with PD following ofatumumab treatment in the DUO study (ORR: duvelisib 73%; prior ofatumumab 28%), with a longer PFS with duvelisib than prior ofatumumab (PFS: duvelisib 15 mo.; prior ofatumumab 9 mo.). These data further support duvelisib monotherapy as an effective oral treatment option for pts with RR CLL/SLL. Clinical trial information: NCT02049515.

7534 Poster Session (Board #171), Mon, 8:00 AM-11:30 AM

Improving outcomes with brentuximab vedotin (BV) plus chemotherapy in patients with newly diagnosed advanced stage Hodgkin lymphoma. *First Author: David J. Straus, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: ECHELON-1 is a phase 3 study of BV plus doxorubicin, vinblastine, and dacarbazine (A+AVD) vs ABVD as frontline therapy in untreated advanced HL (NCT01712490). G-CSF primary prophylaxis (G-PP) was administered at the investigators' discretion, and during the study was formally recommended by an independent data monitoring committee (IDMC) for patients (pts) receiving A+AVD. For pts receiving A+AVD, G-PP was associated with fewer infections and ≥ Grade 3 AEs, including neutropenia (70% without vs 29% with G-PP) and febrile neutropenia (21% vs 11%). **Methods:** Exploratory analyses assessing outcomes and exposure in pts who received G-PP on the A+AVD arm compared with those who did not were conducted. G-PP was defined as use of G-CSF by Day 5 of treatment (tx); non-G-PP pts included pts who received G-CSF secondary prophylaxis. **Results:** 1334 pts with advanced HL were randomized 1:1 to receive A+AVD or ABVD. In 662 pts treated with A+AVD, G-PP was given to 42 of 499 pts who started tx prior to, and 41 of 163 pts who started tx after the IDMC recommendation. Across tx arms, baseline characteristics were similar between the subgroups. G-PP, compared with no G-PP, was associated with a lower rate of BV dose delays (35% vs 49%) and dose reductions (20% vs 26%), and decreased hospitalization rates (pts with at least 1 hospitalization 29% vs 38%). Of the 7 neutropenia-associated deaths during A+AVD tx, none occurred in pts who received G-CSF prior to the onset of neutropenia. A+AVD with G-PP was associated with a decreased risk of a modified progression free survival event (mPFS; Connors, 2018) by 25% compared to A+AVD without G-PP and by 42% compared to ABVD. Clinical trial information: NCT01712490. **Conclusions:** Concomitant administration of G-PP with A+AVD in pts with advanced HL reduced AEs and frequency of tx delays. Though the sample size is small, G-PP with A+AVD may be associated with improved efficacy and a decrease in early, neutropenia-associated deaths; a prospective clinical trial to further assess the safety and efficacy in pts receiving G-PP with A+AVD is planned.

	A+AVD		
	With G-PP	Without G-PP	ABVD
N	83	581	670
2-year mPFS %	84.6	81.7	77.2
95% CI	73.7, 91.3	78.1, 84.8	73.7, 80.4
Hazard ratio vs ABVD	0.58	0.79	-
95% CI	0.31, 1.07	0.62, 1.02	

7535 Poster Session (Board #172), Mon, 8:00 AM-11:30 AM

Limited stage nodular lymphocyte predominant Hodgkin lymphoma (NLPHL): A subgroup analysis of the HD.6 clinical trial. *First Author: Bethany Monteith, Queen's University, Kingston, ON, CA*

Background: NLPHL is a rare subtype of Hodgkin lymphoma (HL) accounting for 5% of cases. It is rarely studied in prospective clinical trials and treatment is controversial. **Methods:** In the Canadian Cancer Trials Group HD.6 phase 3 trial, individuals with newly diagnosed non-bulky stage IA or IIA HL were randomly assigned to treatment with ABVD chemotherapy (CT) alone, or to radiation based (CMT/RT) therapy *[Meyer NEJM 2012]*. From this we identified all patients with NLPHL. A classical Hodgkin lymphoma (cHL) comparison cohort was constructed using propensity score matching 3:1 for age, sex, stage, treatment arm and number of nodal sites. Event free survival (EFS), overall survival (OS) and freedom from disease progression (FFP) were as defined in the original trial. The NLPHL cohort was analyzed according to treatment arm and compared with the cHL cohort using log-rank statistics. Secondary endpoints included toxicity and second malignancies. **Results:** Of 405 individuals enrolled in HD.6, 29 (7.2%) had NLPHL. Of these, median age at diagnosis was 42 yrs, 24 (83%) were male and 15 were assigned to RT. Median follow up was 120 months. For patients with NLPHL, 12-yr EFS for CMT/RT vs CT was 58% vs. 85% (HR 0.46, 95% CI 0.09-2.37) and FFP was 70% vs 85% (HR 0.72, 95% CI 0.12-4.33), respectively. There was one death in the CMT/RT arm; OS analysis by treatment arm was not conducted due to insufficient events. Eighty-seven pts were identified for the matched cHL cohort. 12-yr OS in the NLPHL and cHL groups was 95% and 87% (HR 3.43, 95% CI 0.44-26.5), EFS 70% and 81% (HR 0.73, 95% CI 0.30-1.76), FFP 78% and 90% (HR 0.51, 95% CI 0.17-1.57). Over the entire course of follow-up, there was 1 (3%) death in the NLPHL group due to unknown cause and 12 (14%) deaths in the cHL group – 3 treatment-related toxicity, 6 secondary malignancy, 3 other causes. **Conclusions:** We present the only prospective assessment of early-stage NLPHL treated with ABVD alone. Acknowledging limitations including small sample size, outcomes of pts with NLPHL appear very good when treated with ABVD chemotherapy alone. Clinical trial information: NCT 00002561.

7536 Poster Session (Board #173), Mon, 8:00 AM-11:30 AM

Sintilimab (IBI308) in relapsed/refractory classical Hodgkin lymphoma: A multicenter, single-arm phase 2 trial in China (ORIENT-1 study). *First Author: Yuankai Shi, Department of Medical Oncology, Beijing Key Laboratory of Clinical Study on Anticancer Molecular Targeted Drugs, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Classical Hodgkin's lymphoma (cHL), characterized by chromosome 9p24.1 alteration and PD-1 ligands overexpression, is sensitive to PD-1/PD-L1 blockage in previous studies. This study will confirm the efficacy and safety of sintilimab (IBI308), a promising anti-PD-1 monoclonal antibody, in Chinese patients with relapsed/refractory (R/R) cHL. **Methods:** ORIENT-1 (NCT03114683) is a multicenter, single-arm, phase 2 study. Patients who failed 2 or more lines of systemic therapy, including autologous hematopoietic stem cell transplantation (HSCT) were enrolled. Sintilimab was given 200 mg intravenously every 3 weeks, until disease progression, death, unacceptable toxicity, or withdrawal from study. The primary endpoint was objective response rate (ORR) assessed by independent radiological review committee (IRRC) according to 2007 IWG criteria. The cut-off date for this analysis was Feb 8, 2018. **Results:** Among 96 treated patients enrolled between Mar 30th 2017 and Nov 1st 2017, the median number of previous chemotherapies was 3 (range: 1~13). 54.2% patients received prior radiotherapy and 18.8% failed HSCT. With median treatment cycles of 9 (range: 1~14), ORR was 74.0% (71/96, 97%CI: 64.2%, 83.7%) per IRRC review. 23 patients (24.0%) achieved complete response (CR). The median duration of response has not been reached. At the time of analysis, 64 of 71 complete and partial response patients had an on-going response. The most common treatment-related adverse event (TRAE) was pyrexia (43.8%, 42/96), and 92.9% were grade 1~2. Most of pyrexia happened in the day of first infusion and recovered within 1 day. Other common TRAEs were hypothyroidism (13.5%) and TSH increase (11.5%), and all were grade 1~2. The most common grade 3~4 TRAEs were pyrexia (3.1%) and thrombocytopenia (2.1%). No patient died. **Conclusions:** Till now, ORIENT-1 study is the largest cHL study in China. Patients in our study were sensitive to sintilimab, with 74.0% ORR and 24.0% CR rate. The safety profile was consistent with the findings of other anti-PD-1 monoclonal antibodies in cHL patients. Sintilimab could be a new treatment option for R/R cHL patients in China. Clinical trial information: NCT03114683.

7537 Poster Session (Board #174), Mon, 8:00 AM-11:30 AM

Safety and efficacy of decitabine-primed anti-PD-1 (SHR-1210) treatment in patients with relapsed/refractory classical Hodgkin lymphoma. *First Author: Chunmeng Wang, Bio-therapeutic Department, Molecule & Immunology Department, Chinese PLA General Hospital, Beijing, China*

Background: More than 50% unprecedented objective clinical response rate led to a rapid approval of anti-PD-1 antibodies by FDA using in patients with relapsed/refractory classical Hodgkin lymphoma (r/r cHL). However, anti-PD-1 monotherapy can induce complete remission (CR) only in about 10% patients. Decitabine, a demethylating agent, was documented to directly boost T cell function and also possibly delay/reverse PD-1-blocked T cell exhaustion. This Phase I/II study was designed to assess the safety and efficacy of decitabine-primed anti-PD-1 (SHR-1210, a novel humanized IgG4/kappa monoclonal antibody) treatment in r/r cHL patients. **Methods:** Enrolled patients without anti-PD-1 history were 1:2 assigned into SHR-1210 monotherapy (4 mg/kg per 3 weeks) cohort 1 or decitabine (10mg/d on day 1-5) plus SHR-1210 (4mg/kg, day 8, per 3 weeks) cohort 2. Patients refractory to anti-PD-1 monotherapy were allocated into cohort 2. Safety was assessed by CTCAEv4.0, and clinical response by PET-CT referred to standard international criteria. **Results:** A total of 57 patients with heavily treated history (14-cycle median systemic treatment or with average 8-cycle anti-PD-1 monotherapy) were enrolled and 41 completed serial response evaluation by the end of Jan. 2018. The most common adverse events were clinically negligible cherry hemangioma (75% in cohort 1 and 93% in cohort 2), and unattended leukocytopenia (32% in cohort 2). Six from 13 patients in cohort 1 were evaluated as 1 CR (17%), 2 PR (34%), and 3 SD. Twenty cases from cohort 2, before enrollment were evaluated to be refractory to anti-PD-1 alone therapy, 17 were evaluated and showed 4 CR (23%), 5 PR (30%), 4 SD, and 4 PD. Eighteen of 26 patients without anti-PD-1 history before enrollment were evaluated as 12 CR (67%), 4 PR (22%), and 2 SD. So far, 88% evaluated patients had a $>$ 24-week progression-free survival. **Conclusions:** Addition of decitabine not only largely increased the CR rate of anti-PD-1 therapy in r/r cHL, but significantly reversed the resistance of anti-PD-1 therapy. Combination therapy had an acceptable safety profile. Clinical trial information: NCT02961101 and NCT03250962.

Immune toxicity in post autologous transplant patients treated with brentuximab vedotin in combination with immune checkpoint blockade. *First Author: Catherine S. Magid Diefenbach, Perlmutter Cancer Center at NYU Langone Health, New York, NY*

Background: Emerging data suggests that checkpoint blockade therapy (CBT) subsequent to stem cell transplant (SCT) may cause significant immune-related toxicity. We evaluated whether increased patterns of immune toxicity were seen in post SCT patients treated on Arms A-F of E4412: A Phase I Study with an Expansion Cohort of the Combinations of Ipilimumab, Nivolumab and Brentuximab Vedotin in Patients with Relapsed/Refractory Hodgkin Lymphoma **Methods:** Transplant status of patients treated with brentuximab vedotin (BV) + ipilimumab (Ipi) (Arms A-C) or BV + nivolumab (Nivo) (Arms D-F) was recorded at study entry. Toxicity was graded according to CTCAE v4.0. **Results:** Eighteen of 42 patients enrolled on Arms A-F were post SCT; 15 autologous (ASCT) and 3 allogeneic (AlloSCT). There were no demographic differences between the SCT and all patients. No patients had active GVHD. In Arms A-C grade 3 toxicities (rash and allergic reaction), occurred in 20% (2/10) of SCT patients (8 ASCT, 1 AlloSCT) compared with 39% (9/23) of all patients; there were no grade 4 toxicities in SCT patients compared to 4% (1/23) of all patients. A higher incidence of grade-1-2 rash was noted in ASCT patients 70% vs 39% all patients; however there was no increase in diarrhea, arthritis, or uveitis. In Arms D-F there were no significant differences in high grade toxicities in ASCT 16% (1/6) vs. 21% (4/19) all patients; 50% (1/2) AlloSCT patients experienced grade 3 toxicity (pneumonitis, typhlitis). A second pneumonitis, grade 5, occurred in the non SCT population. There remainder of toxicities were grade 1-2 and were not significantly increased in the SCT patients. A transient and clinically insignificant elevation in transaminases was not increased in SCT 16% (3/19) compared to all patients 47% (9/19). **Conclusions:** CBT in combination with BV was well tolerated in the ASCT population, however larger studies are required to confirm this finding for AlloSCT patients. Investigation of dual CBT (Ipi + Nivo) in combination with BV in this population continues. Evaluation of the safety of CBT + BV in E4412 in the pre SCT setting is ongoing and will be combined with this data by the ASCO meeting. Clinical trial information: NCT01896999.

7539 Poster Session (Board #176), Mon, 8:00 AM-11:30 AM

Brentuximab vedotin with chemotherapy for stage III or IV Hodgkin lymphoma (HL): Impact of cycle 2 PET result on modified progression-free survival (mPFS). *First Author: Robert W. Chen, Department of Hematology and Hematopoietic Cell Transplantation, City of Hope National Medical Center, Duarte, CA*

Background: The ECHELON-1 trial demonstrated improved outcomes for patients (pts) with advanced HL who received frontline A+AVD (brentuximab vedotin, doxorubicin, vinblastine, dacarbazine) vs ABVD (doxorubicin, bleomycin, vinblastine, dacarbazine), with 2-year mPFS rates of 82% and 77%, respectively. Here we report a post-hoc analysis of mPFS outcomes and clinical characteristics by Cycle 2 PET (PET2) status per independent review facility (IRF). **Methods:** Pts were randomized 1:1 to A+AVD or ABVD on Days 1 and 15 for up to six 28-day cycles. PET scans were conducted at the end of Cycle 2 and end of treatment. PET2 results guided an optional switch to alternative therapy at the treating physician's discretion for pts with a Deauville score of 5. A switch to alternate therapy was not considered an event. The primary endpoint, mPFS, was defined as time to progression, death, or absence of a complete response with subsequent anticancer therapy, per IRF. **Results:** PET2 negativity rates (Deauville $\leq$3) were 89% (588/664 pts) in the A+AVD arm and 86% (577/670) with ABVD. Baseline characteristics were well-balanced across arms, with no significant differences in PET2– vs PET2+ pts in either arm. PET2 positivity rates (Deauville $\geq$4) were 7% (47/644) in the A+AVD arm and 9% (58/670) with ABVD; 5 total pts with a Deauville score of 5 switched to alternative frontline therapy. Subgroup analyses showed a favorable treatment effect for both subgroups in favor of A+AVD (Table 1), with 2-year mPFS (PET2– vs PET2+) of 85.2 vs 57.5% in the A+AVD arm, and 80.9 vs 42.0% in the ABVD arm. Outcomes for PET2+ pts were relatively poor in both arms, as previously reported. **Conclusions:** Overall, ECHELON-1 demonstrated a treatment effect in favor of A+AVD over ABVD. This post-hoc analysis showed a similar treatment effect on mPFS consistently in favor of A+AVD regardless of PET2 status. Clinical trial information: NCT01712490.

Summary of mPFS by PET2 Status.

	2-year mPFS (per IRF), %			
	A+AVD	ABVD	HR	P-value
Overall	82.1	77.2	0.77	0.035
95% CI	78.8–85.0	73.7–80.4	0.603–0.983	
N	664	670		
PET2–	85.2	80.9	0.774	0.070
95% CI	81.9–88.0	77.3–84.0	0.586–1.022	
N	588	577		
PET2+	57.5	42.0	0.609	0.089

7540 Poster Session (Board #177), Mon, 8:00 AM-11:30 AM

Prognostication of older Hodgkin lymphoma (HL) patients (pts): Findings from a multicenter phase II study. *First Author: Andrew M. Evens, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ*

Background: Outcomes have been historically poor for older HL pts (ages $\geq$ 60 years (yr)). Furthermore, there are sparse data regarding prognostication. **Methods:** Untreated older HL pts received 2 initial doses of single agent brentuximab vedotin (Bv) 1.8 mg/kg q 3 weeks followed by 6 cycles of doxorubicin, vinblastine & dacarbazine (AVD); responding pts received 4 Bv consolidation doses. 48 pts enrolled (42 evaluable for response). Univariate (UVA) & multivariate (MVA) analyses were performed with Cox proportional hazard regression for survival. **Results:** Median age was 69 yrs (60-88); 63% male; ECOG PS 0: 40%, 1: 42%, 2: 20%; 82% stage III/IV; 60% IPS 3-7; median Cumulative Illness Rating Scale-Geriatric (CIRS-G) comorbidity score 6 (52% grade 3/4); & 12% had baseline loss of instrumental activities of daily living (iADL). 52% of pts completed all intended cycles & 65% received at least 1 Bv consolidation; the median CIRS-G for pts who completed all intended therapy vs not was 4 vs 8, respectively (P= 0.03). ORR to initial Bv was 87% (CR 30%). After AVD, ORR & CR rates were 95% and 90%, respectively. Among all 48 pts, 2 yr PFS was 85% with 94% OS. Response to the initial 2 doses of Bv (CR/PR vs SD) was associated with 2 yr PFS rates of 100% vs 50%, respectively (P= 0.002). On UVA, increasing age and CIRS-G score & loss of iADLs were significant for PFS (Table). On MVA of all factors, only iADLs loss remained significant for inferior PFS (HR 8.19, 95%CI 1.2-57.6, P= 0.03). 2 yr PFS rates based on loss of iADLs vs not were 25% vs 94%, respectively ($P<$ 0.0001) with 2 yr OS 67% vs 97%, respectively (P= 0.01). Pts with loss of iADLs received a median of 6.5 vs 12 intended cycles on study (P= 0.01); 67% vs 39% had a serious adverse event (P= 0.20); and CR rate was 60% vs 95% (P= 0.06). **Conclusions:** Outcomes for older HL pts treated with sequential Bv/AVD were overall excellent. The most dominant factor associated with divergent pt outcomes was baseline functionality, as assessed by iADLs. Clinical trial information: NCT01476410.

7541 Poster Session (Board #178), Mon, 8:00 AM-11:30 AM

Brentuximab vedotin (BV) plus chemotherapy in patients with newly diagnosed advanced stage Hodgkin lymphoma (HL): North American results. *First Author: Rod Ramchandren, Barbara Ann Karmanos Cancer Institute, Detroit, MI*

Background: ECHELON-1 is a global, phase 3 study of BV plus doxorubicin, vinblastine, and dacarbazine (A+AVD) vs ABVD as frontline therapy in patients with advanced HL (NCT01712490). The primary endpoint was modified PFS (mPFS) per independent review facility (IRF) defined as progression (PD), death, or the receipt of additional treatment for patients not achieving CR at the completion of frontline therapy. A+AVD was superior to ABVD (HR = 0.77, p = 0.035) with 2-year mPFS rates of 82.1% and 77.2%; as previously reported. **Methods:** Efficacy and safety of A+AVD vs ABVD in North America (NA) was examined. mPFS in NA was a prespecified analysis. Traditional PFS by investigator, where only PD or death were counted as events, was a sensitivity analysis of the primary endpoint. **Results:** 497 pts in NA with advanced classical HL were randomized 1:1 to receive up to six cycles of A+AVD or ABVD. There was a significant improvement in mPFS by IRF and by INV for pts who received A+AVD compared with ABVD (Table). 2-year traditional PFS by INV was also improved with A+AVD. Across subgroups, a benefit for A+AVD was consistently observed, including in pts with Stage III (HR = 0.64; 95% CI: 0.33, 1.24) and Stage IV (HR = 0.55; 95% CI: 0.33, 0.94) disease. Clinical trial information: NCT01712490. Adverse event rates for A+AVD vs ABVD (all grades) were: interstitial lung disease 3% vs 10%, peripheral neuropathy, 80% vs 56%; neutropenia, 62% vs 54%; febrile neutropenia (FN), 20% vs 9%. In A+AVD pts receiving G-CSF primary prophylaxis, FN was 9%. Two NA pts died during treatment with A+AVD vs 7 with ABVD. **Conclusions:** For pts treated in NA on the ECHELON-1 trial, the absolute difference between A+AVD and ABVD at 2 years for mPFS by IRF was 10.6% and for PFS by INV was 11.7%. A prospective clinical trial is planned to confirm these safety and efficacy findings in advanced stage HL pts treated with A+AVD in the NA community setting.

	mPFS IRF		mPFS INV		PFS INV
