Long-term follow-up of brentuximab vedotin ± dacarbazine as first line therapy in elderly patients with Hodgkin lymphoma. *First Author: Jonathan W. Friedberg, University of Rochester Medical Center, Rochester, NY*

Background: Elderly patients (pts) with Hodgkin lymphoma (HL) have few treatment (tx) options and poor outcomes compared to younger pts. This phase 2, frontline, open-label trial studied brentuximab vedotin monotherapy (BV; ADCETRIS) and BV+dacarbazine (DTIC) in these pts (NCT01716806). We previously reported high response rates (92% and 100%, respectively) and complete remission rates (73% and 62%, respectively) as well as manageable safety profiles (Forero-Torres 2015, Friedberg 2017). **Methods:** Twenty-seven pts ≥ age 60 with classical HL not eligible for standard tx received 1.8 mg/kg BV; then 22 others received 1.8 mg/kg BV+375 mg/m^2 DTIC (12 cycles), then BV. Radiographic scans were done at Cycles 2, 4, 8, 12, 16 (for continued BV), end of tx, then per standard of care. Follow-up visits were every 3 months (mos). **Results:** Survival and peripheral neuropathy (PN) results are presented below. BV+DTIC resulted in 3-year (yr) PFS and OS rates of 52% and 90%, respectively, while BV alone rates were 34% and 71%. Most pts had tx-emergent PN and had either complete resolution or some resolution/improvement. Nearly all ongoing PN was Grade 1/2; 1 pt had ongoing Grade 3 PN. **Conclusions:** BV alone and BV+DTIC appear to induce long-term remissions for a subset of elderly HL pts. The addition of DTIC appears to increase durability of response and survival although not statistically assessed. PN resolution/improvement was observed for the majority of pts. These durable responses suggest that BV+DTIC may be an induction option for frail, elderly pts ineligible for standard tx. Clinical trial information: NCT01716806.

	BV (N = 27)	BV+DTIC (N = 22)
Median observation time from first dose[a], mos (range)	42.6 (4.6, 56.3)	37.8 (14.8, 44.8)

Survival by age in children and adolescents with Hodgkin lymphoma: A pooled analysis of Children's Oncology Group (COG) trials. *First Author: Justine M. Kahn, Columbia University Medical Center, New York, NY*

Background: The National Cancer Institute defines adolescent/young adult as 15-39y. Guidelines from ASCO and Friends of Cancer Research call for including children ≥12y on late phase trials spanning children and adults. We examined whether, in children and adolescents receiving response-based therapy for Hodgkin lymphoma (HL), age ≥12y would define a group with inferior outcomes compared to younger patients. **Methods:** This was a pooled analysis of individual patient-level data from three COG Phase 3 trials for intermediate, low, high-risk HL (AHOD0031, AHOD0431, AHOD0831). 5-yr event free survival (EFS) and overall survival (OS) by age were estimated via Kaplan Meier method. Cox regression models examined the influence of age on EFS and OS, adjusted for race/ethnicity, sex, insurance, histology, Ann Arbor stage, B symptoms, bulk, study, and radiation therapy (RT). **Results:** We included 2071 of 2155 patients, 1-21y enrolled from 2002 -2012. Mean age at diagnosis was 14.6y (±3.5) with 54% ≥15y (N = 1121) and 81% ≥12y (N = 1684). At median follow-up of 6.9 years, patients < 15y had statistically significantly better EFS (< 15y: 85% vs. ≥15y: 80%, p = 0.02). A difference in EFS was noted in those < 12y vs. ≥12y (87% vs. 81%, p = 0.0503). OS was significantly better in patients < 15y vs. ≥15y (98% vs. 95%, p = 0.006), but did not differ in < 12y vs. ≥12y (99% vs. 97%, p = 0.136). Cumulative incidence of second malignant neoplasm did not differ by age category. In multivariable models, older age was an independent predictor of treatment failure in both age categories (Table). **Conclusions:** With contemporary, response-based therapy on COG trials, adolescents ≥12 and ≥15y had worse EFS than younger groups. This suggests that children ≥12y may benefit from therapy escalation and inclusion in late phase trials of novel agents incorporating antibody drug conjugates or checkpoint inhibitors.

Multivariable cox model of 5-yr EFS and OS by age group.

7544 Poster Session (Board #181), Mon, 8:00 AM-11:30 AM

Radiation therapy in primary testicular lymphoma (PTL): Does practice match the standard of care? *First Author: Thomas Ollila, The Warren Alpert Medical School of Brown University, Providence, RI*

Background: National guidelines recommend contralateral testicular radiation as part of therapy for primary testicular lymphoma (PTL) regardless of stage, yet adherence to this in clinical practice is uncertain. We examined factors associated with receipt of radiation and overall survival (OS) of patients with PTL treated with or without radiation. **Methods:** Using data from the National Cancer Data Base (2004-2014), which contains > 80% of lymphomas diagnosed in the United States (US), we evaluated patients with diffuse large B-cell PTL who were treated with multiagent chemotherapy. We examined factors associated with receipt of radiation using log-binomial regression for relative risk (RR) with 95% confidence intervals (CI). OS was analyzed in a multivariable extended Cox model, accounting for immortal time bias. **Results:** Out of 1,821 patients, only 49.7% received radiation therapy. In a multivariable model, significant factors associated with lower use of radiation included black race (RR 0.66, 95%CI, 0.44-0.99), age 71-80 (RR 0.83, 95%CI, 0.75-0.93) or > 80 (RR 0.52, 95%CI 0.42-0.65) relative to age 60-70, Ann Arbor stage 2 (RR 0.78, 95%CI, 0.68-0.89) or 3/4 (RR 0.74, 95%CI, 0.66-0.84) relative to stage 1, and presence of comorbidities (RR 0.84, 95%CI, 0.75-0.95). There were no significant differences by income, insurance status, distance to hospital, or type of hospital (community or academic). Among patients who received radiation therapy, OS was 86% (95%CI, 83-88%) at 3 years (y) and 79% (95%CI, 75-82%) at 5 y, whereas for those who did not it was 66% (95%CI, 63-70%) at 3 y and 57% (95%CI, 53-60%) at 5 y. Receipt of radiation was associated with lower mortality adjusting for other factors (hazard ratio 0.68, 95%CI, 0.56-0.82). **Conclusions:** Nearly half of PTL patients in this "real-world" analysis do not receive radiation therapy despite a benefit supported by prospective trials. Association with socio-demographic factors and with survival suggest that delivery of radiation therapy may be an indicator of expertise or overall quality of care in PTL. Further research should examine if other components of PTL therapy like central nervous system prophylaxis are also suboptimally delivered in the US.

7545 Poster Session (Board #182), Mon, 8:00 AM-11:30 AM

Overall survival (OS) and transplantation (ASCT) utilization in real-world patients with relapsed/refractory diffuse large B-cell lymphoma (RR-DLBCL). *First Author: Chadi Nabhan, Cardinal Health Specialty Solutions, Dublin, OH*

Background: Many patients (pts) with RR-DLBCL treated in the real-world are not offered ASCT despite its curative potential. Understanding the impact of ASCT on OS in the real world is critical to better position novel therapies as an alternative to ASCT. **Methods:** We retrospectively analyzed real-world pts with RR-DLBCL treated between 1/1/10-12/31/16 in 126 community-based hematology/oncology practices across the US. Pts treated with first line (1L) R-CHOP or DA-EPOCH-R were grouped into 2 categories: early relapse (progressive disease [PD] on treatment within 365 days from completing last cycle) and late relapse (any 2L treatment 366-730 days from last cycle of 1L). Pts were stratified whether ASCT was performed after 2L. Pts receiving rituximab monotherapy in 2L or later were excluded from analysis. A period of ≥6 months of clinical inactivity at end of follow-up served as a proxy for death. Median (95% CI) OS were estimated by Kaplan-Meier method, and adjusted hazard ratios (HR) were estimated by Cox proportional hazard models to adjust for differences in pt characteristics (sex, age at DLBCL diagnosis, time to relapse (2L), 1L R-CHOP, and comorbidities). **Results:** For the 430 pts, median age was 65 (range 18-84) years and 61% were male. Following 1L, over 86% (n = 371) had early relapse, and 14% (n = 59) had late relapse. Across all lines, 33% (n = 144) pts received a salvage regimen intended for transplant, with 38% (n = 55) of these pts proceeding to ASCT. For all pts at first relapse, median OS was 13.8 mo. from initiation of 2L. Median OS was significantly longer among those who underwent ASCT compared to those who did not (21.4 mo. vs 10.5 mo.; adjusted $P < 0.01$); HR = 0.51 (95% CI 0.32-0.81). Median OS shortened with each subsequent line of therapy—more so for non-ASCT group with a median OS at 2L of 10.5 mo., 3L of 9.4 mo., and 4L+ of 3.9 mo. for non-ASCT. **Conclusions:** Although 33% of real-world pts with RR-DLBCL received salvage regimens intended for ASCT, only 13% of all evaluable pts eventually underwent ASCT. The low utility of ASCT and the poor OS rates in non-ASCT pts in this real-world population demonstrate an unmet need for novel therapies in this setting.

7546 Poster Session (Board #183), Mon, 8:00 AM-11:30 AM

A basal gene expression signature to predict for synergy of combined EZH2 and HDAC inhibition in EZH2 dysregulated lymphomas. *First Author: Jennifer Kimberly Lue, Columbia University Medical Center, New York, NY*

Background: EZH2 is the catalytic subunit of PRC2, and induces methylation of H3K27. Activating mutations and overexpression of EZH2 are found in NHL. Inactivating mutations in histone acetyltransferases (HATs) are also common in germinal center (GC) B-cell lymphomas and together with EZH2 mutations enforce a condensed chromatin state. Given the dysregulation of EZH2 and HATs in GC-B cell lymphomas, we hypothesized that dual inhibition of EZH2 and HDAC would be synergistic. **Methods:** Lymphoma cell lines (n = 21) were exposed to the EZH2 inhibitor GSK126 (G) and HDAC inhibitor romidepsin (R). Cell viability was assessed via Celltiter-Glo assay. Synergy was assessed by Excess over Bliss (EOB), where EOB > 10 defines synergy. A cutoff of > 20 was used. Western blot, mass spec and Co-IP were performed after exposure to G+R. Mice xenografts were enrolled in: 1. Control; 2. G (100mg/kg); 3. R (2mg/kg); 4. G+R. GSEA and differential gene expression of synergistic vs. non-synergistic cell lines was performed. **Results:** EZH2 mutation is associated with increased sensitivity to G ($p = 0.02$). HAT mutations do not predict sensitivity to R ($p = 0.2$). G+R treatment was highly synergistic in cell lines with EZH2 dysfunction. G+R led to increase acetylation and decrease methylation of H3K27 as well as decreased protein expression of PRC2 members as compared to single agent. Exposure to R or G+R led to dissociation of EZH2 from other PRC2 members as well as HDAC2 and DNMT3L, which is secondary to RbAP46/48 acetylation. A selective HDAC1/2 inhibitor, ACY957, was combined with G and showed synergy. G+R led to significant tumor growth delay compared to single agents ($p < 0.05$), and led to improved OS (Median OS G = 16 d; R = 16 d; G+R = 24 d; $p < 0.001$). Synergistic cells lines share a common basal gene expression signature which was validated in DLBCL via the TCGA database. Synergistic cell lines are enriched in pathways involved in chromatin silencing and remodeling, including epigenetic pathways (FDR < 0.2). **Conclusions:** G+R is highly synergistic. Responses are predicted by the presence of EZH2 dysregulation and a shared basal gene expression signature. G+R may serve as a targeted approach for NHL dependent upon EZH2 dysfunction.

7547 Poster Session (Board #184), Mon, 8:00 AM-11:30 AM

Acalabrutinib monotherapy in patients (pts) with relapsed/refractory (R/R) diffuse large B-cell lymphoma (DLBCL). *First Author: Martin JS Dyer, The Ernest and Helen Scott Haematological Research Institute, University Hospitals of Leicester NHS Trust, Leicester, United Kingdom*

Background: Acalabrutinib, a highly selective, potent, covalent BTK inhibitor, was assessed as monotherapy in pts with R/R de novo DLBCL. **Methods:** Eligible pts aged ≥18 y, with ECOG PS ≤2 and confirmed R/R non-germinal center (GCB) type DLBCL assessed by local IHC received oral acalabrutinib 100 mg bid until progressive disease (PD) or unacceptable toxicity. The primary endpoint was safety. Secondary endpoints included pharmacokinetics (PK), pharmacodynamics and investigator-assessed overall response rate (ORR; per Lugano criteria), duration of response (DOR) and progression-free survival (PFS). **Results:** 21 pts enrolled. To most recent prior therapy, 11 were relapsed (rel; partial response or better [≥PR], then PD), 10 were refractory (ref; no response/stable disease). Median age was 64 y (range 32-84); 86% had ECOG PS ≤1; 57% had extranodal disease; 81% had Ann Arbor stage III/IV; median no. of prior therapies was 3 (range 1-5). Median time on study was 3.9 mo (range 0.8-22.5); 1 pt continues therapy. Pts discontinued treatment primarily for PD (81%); 2 pts discontinued due to AEs (considered unrelated). PK was similar to prior studies, with rapid absorption and clearance; median steady-state BTK target occupancy was 97%-99% (n=5). ORR (≥PR) for all pts was 24% (5/21; 19% complete response [CR]). NanoString subtyping conducted on 15 pts revealed 5 GCB, 9 activated B-cell (ABC), and 1 unclassified DLBCL. The Table lists characteristics of the 5 responders. Common AEs (any grade) were diarrhea (43%), fatigue (43%), anemia (29%), cough (29%) and dizziness (29%); common Grade 3/4 AEs were anemia (24%), fatigue (10%) and abdominal pain (10%). Three pts had Grade 5 AEs (respiratory failure, meningeal progression, and sepsis); none were drug related. No atrial fibrillation, hypertension, TLS or Grade ≥3 bleeding AEs occurred. **Conclusions:** Acalabrutinib monotherapy was tolerable and had activity in difficult-to-treat DLBCL pts, including ref pts, supporting further studies in DLBCL. Clinical trial information: NCT02112526.

Pt	Subtype by Nanostring	Rel/ref	Prior therapies, #	Best response	DOR, mo	PFS, mo
1	ABC	Ref	3	CR	0.7+	2.6+
2	ABC	Rel	2	CR	13.7+	15.5+
3	ABC	Rel	2	PR	1.8	3.7
4 (ongoing)	GCB	Ref	3	CR	15.9+	20.3+

Results of real-time cell-of-origin subtype identification by gene expression profiling in patients with ABC-type diffuse large B-cell lymphoma in the phase III trial of lenalidomide plus R-CHOP vs placebo plus R-CHOP (ROBUST). *First Author: Grzegorz S. Nowakowski, Mayo Clinic, Rochester, MN*

Background: Gene expression profiling (GEP) is the gold standard in identification of activated B-cell-like (ABC) DLBCL, a subtype associated with inferior outcomes. The combination of lenalidomide + R-CHOP (R^2-CHOP) provided efficacy based on cell-of-origin (COO) in phase II DLBCL studies. ROBUST is a global, randomized, double blind, phase III study comparing R^2-CHOP vs placebo + R-CHOP in patients with previously untreated ABC-type CD20+ DLBCL (NCT02285062). **Methods:** ROBUST methods were previously described (Nowakowski, *Fut Oncol* 2016). Formalin-fixed paraffin-embedded excisional/surgical or core needle biopsy samples were analyzed by central pathology using the NanoString Lymphoma Subtyping Test (LST), based on the Lymph2Cx GEP assay (Scott, *Blood* 2014). Turnaround time was defined as number of days between central pathology sample receipt and results being provided to the study site. **Results:** From January 21, 2015 to August 3, 2017, 2093 patients were screened and 570 were enrolled in ROBUST. Three central pathology labs in China, USA and the UK received 2110 samples. Of 1798 successfully tested samples, COO was 788 (44%) ABC and 1010 (56%) non-ABC; 312 (15%) samples were non-processable for technical reasons (incorrect/insufficient slides or blocks, or low tissue RNA concentration and/or purity). According to geographic region of origin, the ABC-type DLBCL rate among successfully tested samples was 60% (241/404) from China/Japan/SK/Taiwan; 40% (441/1105) from Russia/Europe/Middle East; and 37% (106/289) from North America/Australia/New Zealand. Mean turnaround time was 2.4 days. **Conclusions:** Real-time COO assessment was feasible from multiple regions globally with a short turnaround time in the phase III ROBUST study, which minimizes the delay in receiving treatment. The percent of ABC-type DLBCL was similar to other reported studies of subtype analysis in the literature. Our findings impact the design and size estimation of future studies in newly diagnosed DLBCL utilizing COO as a biomarker, which provides a significant advance in precision medicine in DLBCL. Clinical trial information: NCT02285062.

7549 Poster Session (Board #186), Mon, 8:00 AM-11:30 AM

Acalabrutinib alone or in combination with rituximab (R) in follicular lymphoma (FL). *First Author: Nathan Hale Fowler, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Bruton tyrosine kinase (BTK) inhibition has shown clinical benefit in FL. Acalabrutinib is a highly selective, potent, covalent inhibitor of BTK. We evaluated acalabrutinib ± R in a Phase 1b study of patients (pts) with treatment-naive (TN) or relapsed/refractory (R/R) FL. **Methods:** Pts with R/R FL (≥1 prior treatment) were randomized to acalabrutinib (mono) or acalabrutinib + R (combo); TN pts received the combo. In 28-day cycles, R (375 mg/m^2 IV) was given weekly in Cycle 1 and on Day 1 of Cycles 2-6; acalabrutinib (100 mg PO bid [2 pts received 200 mg qd]) was given until progressive disease (PD) or intolerance. The primary endpoint was safety. Secondary endpoints included overall response rate (ORR), duration of response (DOR), pharmacokinetics (PK) and pharmacodynamics. **Results:** Thirteen TN and 27 R/R pts were treated. In all pts, the median age was 66 years (range 32-83), 98% of pts had ECOG PS ≤1, and 88% had stage III/IV disease. R/R pts received a median of 2 prior therapies (range 1-5). At a median follow-up of 22 and 7.6 months, 62% of TN and 26% of R/R pts, respectively, were still on treatment. Discontinuations were primarily due to PD (TN 15%; R/R 56%) and adverse events (AEs; TN 8%; R/R 11%). BTK occupancy and PK parameters were consistent with previous acalabrutinib studies. In all pts, common AEs (any grade) were fatigue (48%), headache (43%), diarrhea (40%), nausea (30%) and sinusitis (25%). Common Gr 3/4 AEs were hypertension (8%), increased alanine aminotransferase, increased aspartate aminotransferase, and cellulitis (all 5%), with no Gr 5 events. There were no cases of atrial fibrillation or Gr ≥3 hemorrhage. Efficacy outcomes are reported in the table. **Conclusions:** Acalabrutinib, alone and combined with R, was well-tolerated and yielded promising response rates in FL. These results support further evaluation of acalabrutinib in FL. Clinical trial information: NCT02180711.

	TN combo (n = 13)	R/R combo (n = 13)	R/R mono (n = 12)[a]

7550 Poster Session (Board #187), Mon, 8:00 AM-11:30 AM

90 yttrium-ibritumomab tiuxetan consolidation of first remission in advanced-stage follicular non-Hodgkin lymphoma: Updated results after a median follow-up of 8.5 years from the GOTEL trial. *First Author: Mariano Provencio-Pulla, Hospital Puerta de Hierro, Madrid, Spain*

Background: Relapse is the main cause of therapeutic failure in follicular lymphoma (FL). We report updated long-term efficacy and toxicity results of a multicenter phase II study (GOTEL-Provencio et al, Leuk Lymphoma 2014) to evaluate the role of consolidation with Yttrium-90 ibritumomab tiuxetan in patients with intermediate- and high-risk FL after 4 cycles of CHOP-R (cyclophosphamide, doxorubicin, vincristine, prednisone, rituximab) and 2 cycles of CHOP, without Rituximab. **Methods:** Patients older than the age of 18 with biopsy-proven, untreated, two-dimensionally measurable bulky stage II, III or IV FL (grade 1, 2 or 3) expressing the CD20 antigen were eligible for this trial. Patients were treated with standard CHOP-R immunochemotherapy every 21 days for 4 cycles, and 2 cycles of CHOP without rituximab. All patients achieving at least an unconfirmed partial response after four cycles of CHOP-R chemotherapy received treatment with two cycles of CHOP, without R. Consolidation treatment was with Yttrium-90 ibritumomab tiuxetan in a single dose. **Results:** Thirty patients were included. The overall response rate after consolidation therapy was 93%. The complete clinical response rate was 76.6%. With a median follow-up of 102 months (> 8-y). Twenty-three patients (77%) are alive without disease. 6 patients died (2 progressions, 1 AML, 3 others cause). The means for progression-free survival (PFS) and overall survival (OS) were not reached. OS at 5-year was 90% (IC 95%; 72-96%); PFS at 5-years was 70% (IC 95%, 50-83%). **Conclusions:** Our data support consolidation with Yttrium-90 ibritumomab tiuxetan as an effective treatment, which provides long progression-free and overall survival, in first line after a response to induction treatment in patients with intermediate- and high-risk FL. Updates on the long-term follow-up of these studies are needed because of the natural history of FL.

7551 Poster Session (Board #188), Mon, 8:00 AM-11:30 AM

Multi-center retrospective study evaluating outcomes of grade 3A follicular lymphoma (FL). *First Author: Kyle Greene, University of Utah Huntsman Cancer Institute, Salt Lake City, UT*

Background: Pathologic grading of FL (1, 2, 3A, 3B; based on increasing number of centroblasts) is prognostic and predictive. FL 3B is treated similarly to aggressive lymphomas with rituximab and anthracycline based chemo (RA). For FL 1-2, bendamustine and rituximab (BR) treatments are non-inferior to RA and better tolerated. Unfortunately, FL 3A was largely excluded from prospective trials and treatment with BR is extrapolated. We aimed to study pretreatment characteristics and the effect of treatment for FL 3A. **Methods:** We compiled disease characteristics of 178 patients (pts) with grade 3A FL from 1992-2017 from 6 academic institutions with sufficient follow-up. Those who were observed (n=15) were excluded. Data evaluated include: FLIPI Score (age, # involved sites, hemoglobin, stage) and gender. The outcomes were compared by treatment groups of: RA, BR, Rituximab only (RO) and other treatments (TX). Kaplan-Meier survival estimates were used to assess overall survival (OS) and progression free survival (PFS). Cox regression analysis was applied to remaining patient information. **Results:** We identified 163 treated pts (RA n=108, BR n=23, RO n=12, TX n=20.) Mean age was 59.8 (range 18-88) with 56% >60. Median OS and PFS were not reached, with the exception of PFS of 1.95 years for RO (p=0.03.) RO also had higher risk baseline features. No differences were observed between BR vs RA. Interestingly, age>60 trended towards better outcomes, but did not reach statistical significance (p=0.17.) Median follow-up was 3.5 years (range 21 days-27 years). Comparing 3-year PFS and OS of BR to RA (table 1), showed HR ~1 with high p-value suggesting similar efficacy. **Conclusions:** Controversy regarding optimal management of FL 3A continues. Age > 60 was protective and definitive therapy should be offered to all age groups when appropriate. Although limited by low pt numbers, our data suggest non-inferiority of BR to RA in FL 3A pts. Future prospective studies must include FL 3A pts so optimal treatments can be established.

Survival comparison with pts who received RA.

	HR	p-value	95% CI
3-Year PFS			
BR	1.09	0.881	0.49-2.85
TX	1.7	0.34	0391-4.83
RO	3.25	0.036	1.21-4.83
3 year OS			
BR	1.17	0.71	0.38-3.80
TX	2.1	0.081	0.57-5.14

7552 Poster Session (Board #189), Mon, 8:00 AM-11:30 AM

A proposal for a new staging system for extranodal natural killer T-cell lymphoma, nasal type, to predict the treatment strategy: A multicentre study from the Chinese Southwest Oncology Group and Asia Lymphoma Study Group. *First Author: Tongyu Lin, Cancer Center Sun Yat Sen University, Guangzhou, China*

Background: The survival of patients with extranodal natural killer T-cell lymphoma (ENKTL), a rare and highly aggressive malignancy, is not accurately predicted by the routine lymphoma Ann Arbor staging system (AASS). Therefore, an optimal staging system for ENKTL is warranted. **Methods:** A training cohort of patients with newly diagnosed ENKTL from 19 Chinese centres was assessed to develop a new staging system for ENKTL. The results were validated in an independent cohort including patients from Korea, Singapore and China. The new staging system was named the Chinese Southwest Oncology Group and Asia Lymphoma Study Group staging (CA) system. **Results:** Based on analyses of the 1168-patient training cohort, the CA system used the following classification scheme: stage I, lesions confined to the nasal cavity or nasopharynx without local invasiveness; stage II, non-nasal-type disease or lesions confined to the nasal cavity or nasopharynx with local invasiveness and without lymph node involvement; stage III, lesions with regional lymph node involvement; and stage IV, involvement of lymph nodes on both sides of the diaphragm or disseminated disease. The 5-year OS rates for stages I through IV were 60.7%, 42.9%, 17.5%, and 32.1% for the AASS and 70.8%, 53.1%, 38.6%, and 29.9% for the CA ($P < 0.001$). Patient distribution was more balanced with CA than with the AASS. The 985-patient validation cohort produced similar survival and distribution results to those of the training cohort. CA exhibited better prognostic value than the AASS for all 2153 patients (ROC, 0.69; 95% CI, 0.64-0.74 vs 0.62; 95% CI, 0.68-0.56; P = 0·01) and predicted that the best treatment choice based on non- anthracycline treatment was radiotherapy alone for stage I; chemotherapy combined with radiotherapy, regardless of the treatment sequence, for stage II; induction chemotherapy followed by radiotherapy for stage III; and intensive chemotherapy for stage IV patients. **Conclusions:** The CA system outperformed the AASS in staging ENKTL patients and could be useful for treatment strategy prediction and future clinical trial design.

7553 Poster Session (Board #190), Mon, 8:00 AM-11:30 AM

Lenalidomide with R-IMED (rituximab, ifosfamide, methotrexate, etoposide and dexamethasone) in refractory or relapsed non-GCB diffuse large B-cell lymphoma: A phase II clinical trial. *First Author: Tongyu Lin, Cancer Center Sun Yat Sen University, Guangzhou, China*

Background: The prognosis of refractory or relapsed(R/R) non-germinal center B cell (non-GCB) subtype diffuse large B cell lymphoma (DLBCL) is dismal without established standard salvage chemotherapy regimen. We designed a phase II trial to prospectively evaluate the efficacy and safety of the combination of lenalidomide and rituximab with the IMED (ifosfamide, methotrexate, etoposide and dexamethasone) regimen(L-R-IMED) in refractory or relapsed non-GCB DLBCL. **Methods:** Eligible participants were adults with non-GCB subtype, CD20 positive DLBCL who were refractory to or had relapsed after R-CHOP-based regimens. Patients received lenalidomide 10 mg orally per day on days 1 through 14 with R-IMED every 21 days for four to six cycles. The response was evaluated using PET-CT scan after every 2 cycles. The primary endpoint was objective response rate (ORR) and progression-free survival (PFS). **Results:** Between January 2014 and November 2017, 40 patients with non-GCB subtype, CD20 positive, R/R DLBCL were enrolled, and 40 were evaluable for response. The median age was 51 years (range 20–85 years) and 60% (24 of 40) were men and 40% (16 of 40) were women. 50% of the patient (n = 20) had refractory disease and 50% (n = 20) had relapsed disease. The ORR was 70% (28 of 40) with 55% (22 of 40) achieving a complete response. The median follow-up time was 14.8 months. The median PFS was 10.9 months (95% CI: 7.9-13.9 months) and the median PFS of patients had a complete response was 28.6 months (95%CI:8.6-48.5months). The median overall survival was not reached. The most common hematologic adverse event was neutropenia. The most common nonhematologic adverse event was fatigue. There was no treatment-associated death. None of our patients discontinued treatment due to significant hematological toxicities. **Conclusions:** Among patients with R/R non-GCB DLBCL, L-R-IMED showed promising efficacy and tolerability profile. The regimen needs to be further verified by phase III study.

7554 Poster Session (Board #191), Mon, 8:00 AM-11:30 AM

Breast Implant Associated-Anaplastic Large Cell Lymphoma (BIA-ALCL): The French Lymphoma Study Association (LYSA) registry data. *First Author: Corinne Haioun, CHU Henri Mondor, Créteil, France*

Background: BIA-ALCL is recognized as a distinct entity. In the French *Lymphopath* network with 59,356 lymphomas registered since 2010, 55 peripheral T-cell lymphomas (PTCL) out of 526 breast lymphomas were reviewed, that included 46 cases of BIA-ALCL. **Methods:** since 2016, a WebEx national multidisciplinary meeting has been implemented by the French Cancer Agency in order to define therapeutic strategies for newly diagnosed cases. BIA-ALCL registry funded by LYSA is collecting patient clinical data including reasons for breast implantation (breast augmentation, reconstruction), implant manufacturer, treatments and outcome. **Results:** 29 BIA-ALCLs have been analyzed so far. Median age was 62 y (29-77). In 15 out of 29 patients (pts) the first implant followed a mastectomy for breast cancer. Ten pts were implanted twice and 6 pts 3 times or more. Most implants were silicone-filled and textured. The median time between the first and last implant surgery and BIA-ALCL diagnosis were 10y [4-37] and 4y [0.2-8] respectively. The two clinical presentations i.e. effusion (n = 22) and breast tumor mass (n = 7) correlated with the 2 distinct histological subtypes (in situ or infiltrative). The majority of pts (84%) were stage IE (n = 21) or II (n = 1), whereas 7 pts were stage IV. Implant removal with capsulectomy was performed in 26 out of 29 patients with additional treatment based mostly on CHOP or CHOP-like chemotherapy regimens in 12 pts. After 2 years of median follow-up, 25 pts are alive and free of disease. Four pts with tumor mass presentation have died, either from lymphoma progression alone (n = 3) or with concomitant active breast cancer (n = 1). **Conclusions:** In situ BIA-ALCLs have an indolent clinical course and remain in complete remission mainly after implant removal. Infiltrative BIA-ALCLs have a more aggressive clinical course. Multiple implants and/or a past history of breast cancer could favor the occurrence of BIA-ALCL. New insights into the biology of BIA-ALCL might translate into more targeted and effective therapies.

7555 Poster Session (Board #192), Mon, 8:00 AM-11:30 AM

Primary testicular lymphoma: Treatment patterns and survival of 1740 men from the National Cancer Database. *First Author: Fernando Caumont, Virginia Mason Medical Center, Seattle, WA*

Background: The standard of care (SOC) for primary testicular lymphoma (PTL) is orchiectomy, chemotherapy (CHT) and radiation (RT) of the contralateral testis regardless of stage. PTL is rare and usually presents in elderly men; we hypothesized that men may not receive SOC and may have worse outcomes. To assess this, we queried the National Cancer Database (NCDB) which includes 70% of newly diagnosed US cancers, to analyze treatment patterns and survival of men with PTL in the rituximab era. **Methods:** Using NCDB data (2006 to 2013), we searched for men diagnosed with extra nodal lymphoma (N = 109210), primary site testis (N = 1865). Patients were analyzed in 2 treatment groups: 1) CHT + RT (SOC group); and 2) CHT alone, RT alone and orchiectomy alone, grouped as no-SOC. Kaplan-Meier (KM) survival plots were used to investigate 5-year overall survival (OS). Log rank test was used to estimate survival differences between treatments. **Results:** 1740 men with PTL underwent orchiectomy. Median age was 69. 794 (45.6%) were Stage 1, 217 (12.5%) were Stage 2, 88 (5.1%) were Stage 3, 274 (15.7%) were Stage 4. 367 men (21.1%) had no staging information available and were not included in the survival analysis. 619 (35.5%) received SOC, 692 (39.8%) had CHT alone, 54 (3.1%) had RT alone, and 375 (21.6%) received no further treatment. KM analysis by stage (Table 1) showed 5-year OS was significantly higher in the SOC group vs.non-SOC for Stage 1 (83.8% vs. 66.1%, $p < 0.001$), Stage 2 (78.2% vs. 58.7%, $p = 0.003$) and Stage 4 (64.3% vs. 54.5%, $p = 0.001$). Stage 3 patients receiving SOC had a non-significant trend toward survival advantage (74.1% vs 60.7%, $p = 0.07$). **Conclusions:** This study represents the largest PTL cohort reported to date and is reflective of current treatments. These data show that most US PTL patients do not receive guideline-recommended SOC, and OS is significantly worse across stages for those that do not receive SOC, highlighting the need for improved management of PTL

5-year OS analysis by stage.

	SOC*			No-SOC*			
Stage	Survival (%)	Alive (N)	Dead (N)	Survival (%)	Alive (N)	Dead (N)	P-values
I	83.9	260	50	66.1	320	164	< 0.001
II	78.3	54	15	58.8	87	61	0.003
III	74.1	20	7	60.7	37	24	0.07
IV	64.4	56	31	54.6	102	85	0.001

7556 Poster Session (Board #193), Mon, 8:00 AM-11:30 AM

Safety and efficacy of GVD and anti-PD-1 (SHR-1210) regimen with or without low-dose decitabine priming for refractory bulky and aggressive primary mediastinal large B-cell lymphoma. *First Author: Wenying Zhang, Bio-therapeutic Ward,Chinese PLA General Hospital, Beijing, China*

Background: Relapsed/refractory PMBCL (rrPMBCL) generally has limited treatment options and dismal prognosis. Recently, monotherapy of anti-PD-1 was reported to induce an effective and durable clinical response in nearly half PMBCL patients. However, the use of anti-PD-1 alone is notably unpractical for those with bulky aggressive lesions or life-threatening tumor mass given that anti-PD-1 alone always induce delayed tumor degradation. This ongoing, phase I/II study was aimed to evaluate the safety and efficacy of GVD chemo-regimen plus anti-PD-1 (SHR-1210) with or without low-dose decitabine priming in rrPMBCL patients with bulky aggressive lesions. **Methods:** This trial is enrolling patients with rrPMBCL who have bulky disease (minimum measurement must be > 75 mm in the longest diameter) with aggressive phenotype, rapid progression and fatal prediction. Enrolled patients were randomizedly assigned into 2 salvage treatment cohorts: GVD (Gemcitabine 0.8 g/m^2,Vinorelbine 30 mg/d, Doxorubicin 20 mg/m^2 , day 1, per 3 weeks) plus SHR-1210 (4 mg/kg, day 2, per 3 weeks) with (cohort 1) or without (cohort 2) low-dose decitabine priming (10mg/d, day -1 to -5, per 3 weeks). Safety was assessed by CTCAEv4.0, and clinical response by International Working Group (IWG) Response Criteria. **Results:** The prominent adverse event is ≤Grade 3 hematotoxicity in cohort 1. All enrolled 18 heavily-pretreated PMBCL patients had an effective control of disease progression after 1-cycle treatment and no death incident occurred so far. 11 patients had completed 4- to 8-cycle treatment, among them, 7 from cohort 1 were 2 CR, 4 PR, and 1 SD; 4 from cohort 2 were 3 CR and 1 PR. 6 patients who finished 8-cycle treatment had a 6- to 10-month ongoing progression-free survival so far. **Conclusions:** Both 2 regimens had comparably life-saving and durable clinical efficacy. Although all observed adverse events were tolerable in both groups, patients enrolled in the future will by treated by regimen without decitabine in view of the relatively lower treatment-associated toxicities. Clinical trial information: NCT03346642.

7557 Poster Session (Board #194), Mon, 8:00 AM-11:30 AM

Relationship between MRD and PET responses and PFS in previously untreated follicular lymphoma in the GALLIUM trial. *First Author: Judith Trotman, Concord Repatriation General Hospital, University of Sydney, Sydney, Australia*

Background: In GALLIUM (NCT01332968; 1202 follicular lymphoma pts), investigator-assessed progression-free survival (PFS) was significantly prolonged by first-line obinutuzumab (G)- vs rituximab (R)-based immunochemotherapy. Lymphoma activity by ^{18}F-FDG PET-CT (PET; Lugano 2014 criteria) showed complete metabolic response (CMR) at end of induction (EOI) to be prognostic for prolonged PFS and overall survival. Minimal residual disease (MRD) negativity in peripheral blood (PB) and/or bone marrow (BM) at EOI was prognostic for prolonged PFS. MRD is a sensitive measure of disease in PB and/or BM, and may add to the prognostic information provided by PET. **Methods:** Induction with G or R plus bendamustine, CHOP or CVP was followed by maintenance in responders. PET scans at baseline and EOI were assessed by an independent review committee. CMR was defined as a score of 1–3 on a 5-point scale. Baseline PB and BM were screened for MRD by consensus PCR for clonal t(14;18) translocation and/or Ig variable domain rearrangement. MRD at EOI was positive if allele- or translocation-specific real-time quantitative or nested PCR were positive in PB or BM. **Results:** Median follow-up was 44 months. At baseline, 595/609 pts with PET scans had detectable lesions and 815/1101 with MRD evaluable samples had a suitable MRD marker; 298 were evaluable for both at EOI. CMR was seen in 266 pts; 250 of these were MRD-negative (**Table**). For these pts, 2.5-year PFS from EOI was 85% (95% CI: 80–89). This group had the best PFS: Cox proportional hazard ratio (HR)=0.39 (95% CI: 0.17–0.93; p=0.03) vs CMR + MRD-positive; and HR=0.39 (95% CI: 0.19–0.81; p=0.01) vs non-CMR + MRD-negative. There were too few non-CMR + MRD-positive pts for analysis. **Conclusions:** Most evaluable pts achieved CMR and MRD-negativity, with a minority progressing despite a favorable prognosis. Risk of progression or death in pts achieving only CMR or MRD-negativity was 2.5-fold greater than in pts who achieved both, suggesting that EOI PET and MRD responses could provide complementary information. Clinical trial information: NCT01332968.

	MRD Status		
PET Response	**Negative (%)**	**Positive (%)**	**All (%)**
CMR	250/298 (84)	16/298 (5)	266/298 (89)
Non-CMR	24/298 (8)	8/298 (3)	32/298 (11)
All	274/298 (92)	24/298 (8)	298/298 (100)

7558 Poster Session (Board #195), Mon, 8:00 AM-11:30 AM

Outcomes in newly diagnosed diffuse large B cell lymphoma presenting with hepatic and/ or renal dysfunction. *First Author: Srinivasa Reddy Sanikommu, Levine Cancer Institute, Charlotte, NC*

Background: In DLBCL, hepatic and/or renal dysfunction may occur due to tissue infiltration with lymphoma, bulky lymphadenopathy leading to obstruction or tumor lysis leading to renal dysfunction. These patients are often excluded from clinical trials and there is paucity of data in this population. Recently, ASCO and Friends of Cancer Research joint statement emphasized to broaden the clinical trial eligibility criteria to make the results more representative. Therefore, we performed a retrospective study in this population. **Methods:** We obtained baseline characteristics, and assessed outcomes in patients with previously untreated DLBCL who presented with hepatic and/or renal dysfunction which led to ineligibility for prospective clinical trials at Levine Cancer Institute. Patients were treated with R-CHOP or R-EPOCH. Doxorubicin and vincristine were dose reduced for $\geq$ grade 3 hepatic dysfunction. Etoposide was dose reduced for either $>$ grade 3 hepatic dysfunction or CrCl $<$ 40ml/min. There were no dose reductions in cyclophosphamide or rituximab. **Results:** Of 146 contiguous patients screened, 20 met criteria for hepatic and/or renal dysfunction. Median follow up was 19.1 mo. Hepatic dysfunction, renal dysfunction or both were seen in 7 (35%), 9 (45%) and 4 (20%) patients respectively. Median time from consultation to starting treatment was 3 days. Cycle 1 was given as an inpatient in 18 (90%) patients. During cycle 1, dose reductions due to organ dysfunction were performed in 5 (25%) patients. Median time to reversal of impaired organ function was 12 days. By cycle 2, 18 (90%) patients received full dose chemotherapy. CR was obtained in 17 (85%) patients. The estimated 2-year OS was 80% (95% CI 62.5–97.5%). No deaths were due to organ dysfunction or drug toxicity. The results are comparable with chemoimmunotherapy in patients with DLBCL who present with normal hepatic and renal function. **Conclusions:** Rapid initiation of standard chemoimmunotherapy with dose adjustments based on degree of hepatic and/or renal dysfunction can lead to excellent outcomes in patients with DLBCL who present with organ dysfunction. Organ dysfunction related to lymphoma can reverse rapidly with chemoimmunotherapy.

7559 Poster Session (Board #196), Mon, 8:00 AM-11:30 AM

Outcomes in patients with marginal zone lymphomas undergoing transformation to high-grade lymphomas. *First Author: Juan Pablo Alderuccio, Sylvester Comprehensive Cancer Center, University of Miami, Miami, FL*

Background: Marginal zone lymphomas (MZLs) are characterized by a long overall survival (OS). High-grade transformation (HGT) to aggressive lymphoma negatively impacts OS. Thus, identifying patients predisposed to HGT is of utmost clinical importance. Given the paucity of data on HGT in MZL patients, we undertook a retrospective study of the largest cohort to date of MZL patients to identify risk factors for HGT and death, thought analyses of transformation-free survival (TFS) and OS. **Methods:** In the Florida Cancer Registry, we identified 564 biopsy proven MZL patients seen at our institution between 1/1990-12/2016. In 453 patients, diagnostic biopsies were reviewed and MZL diagnosis confirmed based on the WHO Lymphoma classification and these were studied. **Results:** Median follow-up of our cohort was 4.8 years (range 0.02-22.1yrs). The cases were classified as MALT (85.9%), splenic (7.7%) and nodal (6.4%) MZLs. 34 (7.5%) patients had biopsy proven HGT to diffuse large B cell lymphoma (DLBCL). The percentages of HGT was 17.2% in nodal, 11.4% in splenic, and 6.4% in MALT (p= 0.05). Among 34 HGT cases, the median time to HGT was 21 months (range: 0-135 months); HGT was present at the time of initial MZL diagnosis in 7(21%) patients. On multivariate analysis of TFS, patients with elevated LDH (HR 4.09,95%CI:1.91-8.76) and failure to achieve CR to initial therapy (HR 3.91,95%CI:1.80-8.48) had significantly higher risk for HGT. In separated models, IPI $>$ 2 (HR = 2.19,95%CI:1.01-4.74), and FLIPI $>$ 2 (HR = 2.52,95%CI:1.12-5.65) were significant predictors of higher risk for HGT. In the 34 patients with HGT, median OS from diagnosis was 129.6 months (95%LL = 55.2) and from HGT 87.6 months (95%LL = 14.4). Patients presenting with HGT within 12 months from MZL diagnosis had shorter OS compared to patients with late HGT [5-year OS rate 0.50 (95%CI:0.19-0.75) vs. 0.75 (95%CI:0.49-0.89), HR = 3.36, (p= 0.0192)]. **Conclusions:** In this largest single-institution study, HGT occurred in 7.5% of patients with higher proportion in nodal MZL (17.2%). Elevated LDH, FLIPI/IPI $>$ 2 and failure to achieve CR to initial therapy were identified as major risk factors for HGT. Patients transforming within 12 months from MZL diagnosis had worst survival.

7560 Poster Session (Board #197), Mon, 8:00 AM-11:30 AM

Randomized, open-label, phase II trial of everolimus versus thalidomide in patients achieving remission after first-line therapy for high-risk diffuse large B-cell lymphoma. *First Author: He Huang, Department of Medical Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Patients with diffuse large B-cell lymphoma (DLBCL) with a high International Prognostic Index (IPI) are at higher risk for relapse after a complete response (CR) to first-line rituximab-based chemotherapy. This study aimed to compare the efficacy and safety of everolimus (EVE) *v* thalidomide (THA) as maintenance therapy in patients with DLBCL in complete remission and with a high risk of relapse after rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone (R-CHOP). **Methods:** This was a single-center, phase II, randomized, open-label trial. Patients with stage II bulky or stage III to IV DLBCL, IPI $\geq$2, and a positron emission tomography/computed tomography-confirmed CR to first-line R-CHOP were randomized to receive EVE 5 mg/day for 1 year or THA 100 to 300 mg/day for 2 years or until disease relapse, unacceptable toxicity, or death. Eligible patients who refused any maintenance therapy were included as control group. Primary end point was disease-free survival (DFS). **Results:** A total of 102 patients were randomized to EVE (n = 50) or THA (n = 52). After a median follow-up of 34.2 months, 2-year DFS were 84.9% with EVE *v* 84.2% with THA (HR, 0.958; 95% CI, 0.370 to 2.484). 2-year overall survival (OS) were 93.4% with EVE *v* 91.4% with THA (HR, 0.711; 95% CI, 0.169 to 2.998). The control group included 137 patients, for whom 2-year DFS and OS was 62.4% and 81.6%, respectively. Both EVE and THA arms had a superior DFS (EVE *v* control, HR, 0.345; 95% CI, 0.165 to 0.722; THA *v* control, HR, 0.350; 95% CI, 0.174 to 0.706) and OS (EVE *v* control, HR, 0.216; 95% CI, 0.067 to 0.701; THA *v* control, HR, 0.335; 95% CI, 0.132 to 0.852) compared to control group. Grade 3 or 4 adverse events with EVE *v* THA were mucositis (8%), leukopenia (8%), thrombocytopenia (4%), infection (2%), and leukopenia (6%), thrombocytopenia (4%), infection (2%), respectively. **Conclusions:** The efficacy of everolimus and thalidomide as maintenance therapy was similar, both of which significantly improved DFS and OS in patients with high-risk DLBCL after achieving CR to R-CHOP. Everolimus administered 5 mg/day and thalidomide administered 100 to 300 mg/day were tolerated well.

7561 Poster Session (Board #198), Mon, 8:00 AM-11:30 AM

Dose-adjusted (DA)-EPOCH-R with high-dose methotrexate (HD-MTX) for newly diagnosed stage II-IV CD5-positive diffuse large B-cell lymphoma (CD5+ DLBCL): Primary analysis of PEARL5 study. *First Author: Kana Miyazaki, Mie University Graduate School of Medicine, Tsu, Japan*

Background: CD5+ DLBCL comprises 5-10% of DLBCL and is characterized by various aggressive clinical features and frequent CNS relapse. Our previous retrospective study (Miyazaki et al. Ann Oncol 2011) revealed that the 2-year (yr) PFS and CNS relapse rates in patients (pts) with newly diagnosed stage II-IV CD5+ DLBCL were 51% and 15%, respectively. An interim analysis of our multicenter phase II study for newly diagnosed stage II-IV CD5+ DLBCL (PEARL5 study) revealed that DA-EPOCH-R/HD-MTX provided a high CR rate (91%) with manageable toxicity (Miyazaki et al. ASH 2016). **Methods:** Pts with newly diagnosed stage II-IV CD5+ DLBCL between 20-75 yrs old and ECOG PS of 0-3 were eligible. Four cycles of DA-EPOCH-R followed by 2 cycles of HD-MTX (3.5 g/m^2) and additional 4 cycles of DA-EPOCH-R were planned as the protocol treatment. Cell-of-origin of DLBCL was determined by means of NanoString analysis system. The primary endpoint was 2-yr PFS. **Results:** From Aug 2012 to Nov 2015, 47 pts were enrolled in the study. All the pts were eligible and exhibited the following features: age, 37-74 yrs (median 62); M:F = 18:29; ECOG PS $>$ 1, 4%; stage III/IV, 53%; IPI HI/H, 47%; and ABC/GCB/unclassified, 39/4/3 (n = 46). With a median follow-up of 3.1 yrs (range, 2.0-4.9), the 2-yr PFS rate was 79% (95% CI, 64-88%). This compared favorably with the historical control of conventional R-chemotherapy (51%). The 2-yr OS rate was 89%. One pt in CR died in a traffic accident 0.8 yr after enrollment. The 2-yr CNS relapse rate was 9% (95% CI, 3-21%; n = 4). Among the 4 pts, 1 pt had primary testicular DLBCL. The remaining 3 pts experienced CNS relapse before HD-MTX. Two of these pts had high-grade B-cell lymphoma, NOS (WHO 2016) with *MYC* rearrangement, and the other pt discontinued the protocol treatment after the 1st rituximab due to grade 4 tumor lysis syndrome. The 2-yr PFS and OS rates in CD5+ ABC DLBCL (n = 39) were 77% and 87%, respectively. **Conclusions:** DA-EPOCH-R/HD-MTX is an effective treatment for newly diagnosed stage II-IV CD5+ DLBCL. Long-term efficacy and toxicity will be evaluated in a 5-yr follow-up in Nov 2021. Clinical trial information: UMIN000008507.

7562 Poster Session (Board #199), Mon, 8:00 AM-11:30 AM

Long term follow-up (FU) of lenalidomide plus R-CHOP therapy in patients with newly diagnosed diffuse large b-cell lymphoma (DLBCL): Combined analysis from two phase 2 trials. *First Author: Alessia Castellino, Department of Hematology, Mayo Clinic, Rochester, MN*

Background: The combination of lenalidomide (Len) with Rituximab-CHOP (R2CHOP21) has been shown to be safe and effective. These early results [Nowakowski et al. JCO 2014, Vitolo et al. Lancet Oncol 2014] led to two randomized trials. However, durability of response and safety have not been reported. Here, we present the long-term FU in de novo DLBCL patients (pts) who received R2CHOP21 in two independent phase 2 studies. **Methods:** We included newly diagnosed DLBCL pts enrolled in two R2CHOP21 phase 2 trials, conducted by Mayo Clinic (MC) and Italian Lymphoma Foundation (FIL). All pts received R-CHOP21 plus Len at 25 mg/d for 10 days/cycle and 15 mg/d for 14 days/cycle in MC and FIL trial respectively. We analyzed the long term FU outcome in terms of progression-free survival (PFS), time to progression (TTP), overall survival (OS) and the cumulative incidence of late toxicities and second tumors. **Results:** 108 DLBCL pts (59 MC, 49 FIL) were included. Main characteristics were: median age 69 years (y) (25 (23%) $\geq$ 75 y), stage 3-4 in 94 (87.0%) and International Prognostic Index (IPI) $\geq$ 3 in 60 (55.6%). At a median FU of 5.1 y, 5y PFS was 65.4%, 5y TTP 69.9% and 5y OS 77.4%. In total, 31 pts have relapsed, with only 4 cases occurring beyond 3y and only 2 CNS relapses. 5y PFS in germinal center (GCB) lymphomas vs non-GCB was 55.8% vs 65.7%, 5y TTP 62.3 vs 68.0 and 5y OS 71.7% vs 75.3% respectively. Only 4 pts had grade (gr) 4-5 late toxicities (1 gr 5 sepsis and 3 gr 4 neutropenia). Milder toxicities were infections (N 5 (4.6%), only 1 gr 3), thrombosis (N 1, gr 2) and persistent neuropathy (N 3, gr 1-2). Second neoplasia were 8 (6.4%): 1 acute myeloid leukemia, 2 second lymphoma (T-cell) and 5 other solid tumors. **Conclusions:** Long term FU shows that R2CHOP21 efficacy was maintained with high rate of PFS, TTP and OS, considering high risk features of patients included. The addition of len to RCHOP appears to mitigate the negative prognostic impact of non-GCB phenotype. The incidence of second tumors was low and no new worrisome safety signals were seen. This long -term analysis will aid interpretation of early results from randomized clinical trials, expected to be reported in near future.

7563 Poster Session (Board #200), Mon, 8:00 AM-11:30 AM

DEVEC metronomic schedule for aggressive B and T-cell lymphomas. *First Author: Maria Christina COX, Hematology Unit, Sant'Andrea Hospital, Roma, Italy*

Background: Metronomic chemotherapy (MC) is an emerging approach in solid tumours. Since MC has been poorly investigated in aggressive lymphomas in 2011, we formulated a new oral MC regimen termed DEVEC (Deltacortene, Etoposide, Navelbine, Cyclophosphamide). **Methods:** The DEVEC foresees an induction and a deescalated maintenance phase both consisting in 6 cycles. Rituximab is administered in CD20+ cases. Patients with aggressive B and T cell lymphomas, unsuitable for standard-chemotherapies, were enrolled in 6 Italian institutions. HIV+ and CNS involvement were excluded. Data were retrieved as of 31th January 2018 (EC approval n° 4640). **Results:** 58 patients started DEVEC between October 2011 and October 2017: the median follow-up time is 23 months. Median age was 79 years (26–93): 22 (37.9%) were refractory and 20 (34.5%) relapsed after previous treatments; 16 (27.62%) were treatment-naïve. Histology: DLBCL = 41(70.7%); PTCL = 15 (25.9%) and MCL = 2 (3.4%). By comprehensive geriatric assessment, patients scored as FIT = 7 (12%), UNFIT = 16 (27.6%), FRAIL = 23 (39.6%); Super-Frail (SF) = 10 (17.2%). In 53 evaluable cases the overall hematologic toxicity was mild and manageable with growth factors. Extra-hematologic toxicity of grade $\geq$3 was reported in 12/53 patients (22.6%) and were all classified as SAE: 6/12 cases occurred in SF. 5/12 patients discontinued DEVEC and died respectively 0, 1, 4, 4 and 5 months after treatment stop. In 50/53 patients, evaluable for outcome, the ORR was 68% and CR rate 44%. In the Naïve subset (n = 14) ORR = 92.8% and CR+CRu = 64%; in the Relapsed subset (n = 16): ORR = 93.7%; CR = 62.5%; in the Refractory subset (n = 20) ORR = 30%; CR = 10%. The estimated median OS and PFS were 15 (95%CI = 9.17-20.83) and 13 (CI 95% = 2.07-23.93) months, respectively. No significant differences in OS and PFS were observed in DLBCL vs PTCL. The direct cost of drugs of the oral DEVEC schedule was estimated 930 and 817 Euro (year 2016) for a single induction and maintenance cycle, respectively. **Conclusions:** To our knowledge this is the largest series of aggressive lymphoma treated with MC. DEVEC induced sustained CR in a substantial proportion of patients with very poor outlook and deserves further studies in aggressive lymphomas.

7564 Poster Session (Board #201), Mon, 8:00 AM-11:30 AM

A phase II trial of bevacizumab-GemAOD regimen for newly diagnosed extranodal NK/T cell lymphoma. *First Author: Zhiming Li, Sun Yat-Sen University Cancer Center, Guangzhou, China*

Background: Efficacy of L-asparaginase-based regimens has been confirmed for patients with extranodal natural killer/T-cell lymphoma (ENKTL). However, targeted therapy and optimal chemotherapy regimens for ENKTL remain to be determined. As high levels of vascular endothelial growth factor A (VEGF) is associated with a poor prognosis in ENKTL, we evaluated the efficacy and safety for bevacizumab (BEV) in the combination with gemcitabine, PEG-asparaginase, oxaliplatin and dexamethasone (BEV-GemAOD) regimen in untreated ENKTL in the Phase II Study (NCT 01921790). **Methods:** Patients with newly diagnosed ENKTL in stageI-IV from 18 to 80 years were eligible for enrollment. BEV-GemAOD regimen (bevacizumab 7.5 mg/kg d1; gemcitabine 1000 mg/m^2 d1, d8; PEG-aspargase 2500 U/m^2 d1; oxaliplatin 130 mg/ m^2 d1; dexamethasone 20 mg, d1-3; q3w) was planned as the protocol treatment. Patients with stage I/II received sandwich chemoradiation (BEV-GemAOD$\times$3 cycles followed by RT 50.4 Gy followed by BEV-GemAOD$\times$3 cycles). For stage III/IV, BEV-GemAOD regimen was repeated for six cycles. The primary endpoint was overall response rate (ORR) after six cycles of BEV-GemAOD. Secondary endpoints were progression-free survival (PFS), overall survival (OS), and toxicity. **Results:** 56 patients were enrolled from Oct 2013 to Feb 2018. 43 patients were evaluable for response: the median age, 37 years (range: 18-65 years); female, 25.6%; ECOG PS $>$ 1, 20.9%; stageIV, 37.2%; elevated LDH, 39.5%; elevated EBV DNA, 60.5%. After 2 cycles of BEV-GemAOD, ORR were 100%. CR rate (CRR) in stage I/II and III/IV were 88.9% (24/27) and 25% (4/16), respectively. After 6 cycles ORR were still 100%. CRR increased to 100% (27/27) and 87.5% (14/16), respectively. At median follow-up of 25.3 months, 2-year PFS and OS were 83.3% and 78.8%. The most common hematologic adverse event of grade 3/4 was neutropenia (32.6%). No patient died of treatment related toxicity. **Conclusions:** These results demonstrate that BEV-GemAOD regimen is feasible and provides high ORR, CRR and survival for either early- or late-stage patients with newly diagnosed ENKTL. Clinical trial information: NCT01921790.

7565 Poster Session (Board #202), Mon, 8:00 AM-11:30 AM

DLBCL outcomes in Malawi: Effect of HIV and derivation of a simplified prognostic score. *First Author: Matthew Painschab, Lineberger Comprehensive Cancer Center; University of North Carolina, Chapel Hill, NC*

Background: Prognostic factors for diffuse large B-cell lymphoma (DLBCL) in sub-Saharan Africa (SSA) are unknown. We report mature data from one of the first prospective DLBCL cohorts treated under real-world conditions in SSA. **Methods:** Patients ≥18 years with newly diagnosed DLBCL were enrolled in Malawi from 2013 to 2017. Participants were treated with CHOP chemotherapy, and concurrent antiretroviral therapy (ART) if HIV+. **Results:** 86 participants were enrolled with mean age 47 (SD 13). 54 (63%) were male, and 51 (59%) were HIV+, of whom 34 (67%) were on ART at DLBCL diagnosis. Median CD4 count was 113 cells/mL (IQR 62-227) and 25 (49%) had an HIV viral load < 400 copies/mL. HIV+ participants were younger and more urban, but otherwise similar to HIV-. 10 (12%) participants died before chemotherapy. Participants received a median 6 CHOP cycles (IQR 4-6). 28% of cycles were delayed or reduced for toxicity, more commonly in the HIV+ group, typically for neutropenia. No patients were lost to follow-up with median follow up 24 months (IQR 16-40) for patients still alive at administrative censoring. 2-yr overall survival (OS) was 38% (95% CI 28-49), and 42% (95% CI 30-53) for patients surviving to CHOP initiation. For those receiving CHOP, 13/43 (30%) deaths were treatment-related, and occurred primarily in patients with adverse baseline DLBCL characteristics. In multivariate analyses, only ECOG performance status (PS) ≥2 and lactate dehydrogenase (LDH) > 2x upper limit of normal (ULN) were associated with mortality. HIV was not associated with OS, but for HIV+ patients, being on ART prior to lymphoma diagnosis was associated with mortality. A simplified prognostic model of LDH > 2x ULN and PS≥2 outperformed the traditional age-adjusted IPI. **Conclusions:** DLBCL can be successfully treated in SSA and outcomes were not different for HIV+ and HIV- patients, although OS was worse than resource-rich settings. For HIV+ participants, those developing DLBCL on ART had worse OS, suggesting possible effects of the immunologic environment on tumor biology. A simplified prognostic model utilizing only PS and LDH may be optimal in resource-limited settings, where staging is imprecise, but requires additional validation.

7566 Poster Session (Board #203), Mon, 8:00 AM-11:30 AM

***Pd-l1* gene alterations to identify a subset of diffuse large B cell lymphoma that harbor a T cell inflamed phenotype.** *First Author: James K. Godfrey, University of Chicago, Chicago, IL*

Background: Programmed death – ligand 1 (PD-L1) expression on malignant cells is a dominant immune escape mechanism in cancer, and classically occurs as an adaptive response to the presence of activated T cells and interferon gamma in the tumor environment. Interestingly, a unique genetic mechanism underlying PD-L1 up-regulation has been described in a variety of lymphomas, in which the 9p24.1 chromosomal region encoding the PD-1 ligands is highly amplified. We sought to determine the incidence and immune landscape of *pd-l1* gene copy number alterations (CNA) in diffuse large B cell lymphoma (DLBCL). **Methods:** We utilized fluorescent in situ hybridization (FISH) to identify DLBCLs harboring *pd-l1* CNA, thereby enabling a characterization of the immunogenomic landscape of these lymphomas compared to those lacking *pd-l1* CNA. **Results:** Among 95 DLBCLs analyzed, 26% harbored *pd-l1* CNA (17 copy gain, 7 amplified, 1 translocation). *Pd-l1* CNA were highly enriched among DLBCLs with an activated B cell phenotype (75%). PD-L1 cell surface expression was strikingly enhanced in DLBCLs with *pd-l1* CNA versus those without, as assessed by PD-L1 H score. Furthermore, *pd-l1* CNA DLBCLs were associated with a pronounced infiltration by T cells with a restricted T cell receptor – beta repertoire, suggesting that lymphoma antigen-specific T cells had expanded in these samples. RNA-sequencing of *pd-l1* gene-altered versus non-altered DLBCLs revealed differential expression of *pd-l1*, as well as genes involved in T cell and cytokine signaling in the former, indicating that *pd-l1* CNA DLBCLs have been subjected to host immune surveillance. Lastly, whole exome sequencing of *pd-l1* gene altered versus non-altered DLBCLs is ongoing to identify potential differences in mutational loads and profiles. **Conclusions:** Our results indicate that *pd-l1* CNA identify a unique biological subset of DLBCL that has activated an endogenous anti-lymphoma immune response, and that may be more likely to respond to checkpoint blockade therapy with anti-PD-1 antibodies. We propose that a straightforward FISH analysis for *pd-l1* gene amplification may be useful as a predictive biomarker for immunotherapy responsiveness in DLBCL.

7567 Poster Session (Board #204), Mon, 8:00 AM-11:30 AM

Factors associated with duration of response after CD19-specific CAR-T cell therapy for refractory/relapsed B-cell non-Hodgkin lymphoma. *First Author: Jordan Gauthier, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: CD19-specific chimeric antigen receptor-modified T (CD19 CAR-T) cells achieve high complete remission (CR) rates in relapsed/refractory B-cell non-Hodgkin lymphoma (NHL), yet factors governing duration of response are unknown. **Methods:** We studied outcomes of 57 adults treated on a clinical trial (NCT01865617) with cyclophosphamide and fludarabine followed by 2 x 10^6 CD19 CAR-T cells/kg administered in a defined 1:1 ratio of CD4+/CD8+ CAR-T cells, and identified factors impacting progression-free survival (PFS) and overall survival (OS). **Results:** The median age was 56.5 years (range: 27 - 71) and the median number of prior therapies was 4 (range: 1 - 11). 25 patients (pts; 44%) had prior transplant, 47 (82%) had aggressive histology, and 46 (81%) had an IPI ≥ 2 at enrollment. The median lymph node burden (SPD) was 3343 mm^2 (range: 124 - 16765); 8 pts (14%) had bulky disease (diameter ≥ 10 cm). The median follow-up was 15.7 months. The best overall response and CR rates were 60% and 47%, respectively. Higher peak blood CAR-T cell counts (Cmax) and area under the curve (AUC) from day 0 - 28 after infusion by qPCR were associated with longer PFS (Cmax, HR = 0.48, P < 0.001; AUC, HR = 0.45, P < 0.001) and OS (Cmax, HR = 0.63, P = 0.03; AUC, HR = 0.61, P = 0.02). Higher CD8+, but not CD4+, CAR-T cell counts by flow cytometry correlated with longer PFS (Cmax, HR = 0.55, P < 0.001; AUC, HR = 0.53, P < 0.001) and OS (Cmax, HR = 0.62, P = 0.01; AUC, HR = 0.61, P = 0.01). SPD < median was associated with longer PFS (P = 0.004) and OS (P = 0.01). In multivariate analysis, low IPI (0-1 vs 3-4, HR = 0.11, P = 0.005) and indolent histology (HR = 0.05, P = 0.009) were associated with longer PFS; low IPI was associated with longer OS (0-1 vs 3-4, HR = 0.06, P = 0.007). In pts achieving CR after CAR-T cells, the probabilities of 1-year OS and PFS were 92% and 69%, respectively. In this subgroup, the median OS and PFS were not reached (median follow-up, 15 months). Multivariate analysis after adjusting for histology showed that the IPI and SPD adversely impacted PFS (IPI, P = 0.002; SPD, P = 0.007) and OS (IPI, P = 0.01; SPD, P = 0.02). **Conclusions:** Histology, IPI and CAR-T cell kinetics govern duration of response in NHL pts receiving CD19 CAR-T cells. Clinical trial information: NCT01865617.

7568 Poster Session (Board #205), Mon, 8:00 AM-11:30 AM

Phase II study of the PD1-inhibitor pembrolizumab for the treatment of relapsed or refractory mature t-cell lymphoma. *First Author: Stefan K. Barta, Fox Chase Cancer Center, Philadelphia, PA*

Background: PDL-1 is often expressed on tumor cells or in the microenvironment of T-cell NHL (Wilcox RA. Blood 2009) making inhibition of the PD1/PDL-1 axis a rational treatment target for T-cell NHL. **Methods:** We evaluated monotherapy with the PD1-inhibitor pembrolizumab (200mg flat dose q3weeks) for pts aged ≤18 with relapsed or refractory mature T-cell NHL in a multicenter prospective phase II trial. Primary endpoint was median progression-free survival (mPFS) defined as time from enrollment to either death or progression. The study was powered to demonstrate an improvement in mPFS from 3 to 6 months. **Results:** 18 pts were enrolled and included in the safety analysis. 17 pts were included in the survival analysis as 1 pt was found ineligible after central path review (n = 7 PTCL-NOS; n = 3 follicular T-cell lymphoma; n = 3 transformed MF; n = 1 MEITL, HSTCL, and AITL each; n = 1 ineligible histology). 2 pts came off study prior to response assessment for toxicities leaving 15 pts evaluable for response. Median age was 71 (18-88); 47% were male; median number of prior therapies was 2 (1-9); 76% were refractory to their last treatment. Response rate was 27% (4/15 pts; 95%CI 5-49%). All 4 responders (ALCL, MF, PTCL-NOS, FTCL) achieved a CR and were pts who had received ≤2 prior therapies. PDL1-expression was higher in responders, though not significantly (H-score 115 vs 68; p = 0.68). Median response duration was not reached with 2 of 4 responses ongoing > 9 months; 2 pts came off study in CR (n = 1 at 6 wks for toxicity; n = 1 at 6 mo for transplant). Median PFS and OS were 3.2 (95%CI 1.2-3.7) and 10.6 months (95%CI 3.2-100) respectively, with a median follow up of 5.9 months. 88% discontinued treatment early for PD (44%), toxicity (22%), pt choice, investigator choice, or transplant (6% each). Rash was the most common treatment attributable adverse event (AE) in 17% (n = 3). Most common AE ≥G3 were pneumonitis and rash (11% each). Treatment attributed SAE occurred in 11% (pneumonitis: n = 1; vasculitis: n = 1). Immune-related AE ≥G3 occurred in 5 pts (pneumonitis, rash: n = 2 each; vasculitis: n = 1). **Conclusions:** Pembrolizumab has moderate activity in T-cell NHL with acceptable toxicities. Combination therapies are being actively explored. Clinical trial information: NCT02535247.

7570 Poster Session (Board #207), Mon, 8:00 AM-11:30 AM

Copanlisib treatment in patients with relapsed or refractory indolent B-cell lymphoma: Subgroup analyses of diabetic patients from the phase II CHRONOS-1 study. *First Author: Martin H. Dreyling, Klinikum der Universität München LMU, Medizinische Klinik und Poliklinik III, Munich, Germany*

Background: Copanlisib is a pan-Class I phosphatidylinositol 3-kinase (PI3K) inhibitor with predominant PI3K-α and PI3K-δ activity recently approved in the US for treatment of relapsed follicular lymphoma. In the CHRONOS-1 trial, treatment of patients with relapsed or refractory indolent lymphoma resulted in an objective response rate of 59% (*JCO* 35:2169-2178, 2017). The most prominent adverse event following intravenous administration of copanlisib is transient hyperglycemia, thought to be due to impaired glucose uptake associated with PI3K-α isoform inhibition. We focus here on the diabetic mellitus (DM) patients enrolled in the phase II study. **Methods:** Indolent B-cell lymphoma patients with well-controlled DM were eligible and required to have fasting glucose < 160 mg/dL prior to each infusion. Patients received copanlisib 60 mg as a 1-hour infusion on days 1, 8, and 15 of a 28-day cycle. On C1D1, glucose was measured at pre-dose, and 3, 5, 6 and 8 hours after infusion. DM patients were instructed to check blood glucose at home 3x per day for 72 hrs after infusion until fasting glucose was < 160 mg/dL or non-fasting glucose was < 200 mg/dL. **Results:** Twenty patients with DM out of a total of 142 patients were enrolled; 17 patients with a history of DM, 1 with history of impaired glucose tolerance, and 2 diagnosed at screening. Comparing non-DM patients (n = 122) to DM patients, all-grade (G) hyperglycemia was 43% vs 85%, G3 31% vs 40%, and G4 2% vs 35%. In routine laboratory glucose assessments, G3 events were reported in 39% vs 70% and G4 in 2% vs 30%, non-DM vs DM respectively. Objective responses were observed in 9 of 20 patients (45%; 2 non-evaluable), including one complete response and stable disease in 8 patients (40%). Of note, 6 responders were on treatment > 300 days (or > 30 infusions), with 5 of these patients remaining on treatment at data cut-off. **Conclusions:** These results strongly suggest that the transient hyperglycemia seen with IV administration of copanlisib is also manageable in indolent lymphoma patients with DM as a comorbidity and should thus not preclude treatment of such patients. Clinical trial information: NCT01660451.

7571 Poster Session (Board #208), Mon, 8:00 AM-11:30 AM

Predictors of disease progression in smoldering Waldenström macroglobulinemia. *First Author: Saurabh Zanwar, Mayo Clinic, Rochester, MN*

Background: There are limited data on predictors of disease progression in patients (pts) with smoldering Waldenström Macroglobulinemia (SWM). We aim to address this issue in a large cohort of SWM with a long follow-up. **Methods:** Pts with Waldenström Macroglobulinemia (WM) seen at Mayo Clinic, Rochester from 1996-2013 were included. Time-to-progression (TTP) was defined as interval from diagnosis of SWM to initiation of WM-directed therapy per 2002 Consensus criteria or development of light chain amyloidosis (AL) or transformation. Cumulative incidence of progression (CIP) was calculated by competing risk analysis. Median values were chosen as cutoff for dichotomization of continuous variables for univariate analysis (UVA) and multivariate analysis (MVA). Kaplan Meier method was used for time-to-event-analyses. **Results:** Of 823 WM pts, 143 (17%) had SWM. After a median follow-up of 9.5 years (yrs) [95% CI 8-11.5 yrs], 110 (77 %) pts progressed (107 required therapy for WM, 3 developed AL). CIP was 11%, 37% and 52% at 1, 3 and 5 yrs, respectively. On UVA **(Table 1)**, hemoglobin (Hgb) ≤12.3 g/dL (p = 0.01) and beta-2 microglobulin (β2M) ≥2.7 ug/mL (p = 0.02) were significant predictors of TTP. On MVA, Hgb ≤12.3 g/dL [Risk ratio (RR) 1.9 (95% CI 1.1-3.5); p = 0.02] and β2M ≥2.7 ug/mL [RR 1.95 (95 % CI 1.1-3.6); p = 0.03] remained independent predictors of TTP. A score of 1 was assigned to both, giving a minimum score of 0 and maximum score of 2. The TTP was 9.3 yrs (95% CI 5.6-22.5 yrs), 4.1 yrs (95% CI 2.1-6 yrs) and 2.3 yrs (95% CI 1.5-4.5 yrs) for scores of 0, 1 and 2, respectively (p = 0.004). **Conclusions:** One-half of pts with SWM progress within five years from diagnosis. Pts with Hgb ≤12.3 g/dL and β2M ≥2.7 ug/mL at diagnosis have the shortest TTP.

Impact of baseline characteristics on TTP.

Parameter	Median (interquartile range)	P value (univariate)
Age (yrs)	64.3 (59-71.1)	0.76
MYD88^{L265P} mutated (%)	78	0.14
IgM (mg/dL)	2450 (1610-3590)	0.30
Marrow lymphoplasmacytic infiltrate (%)	30 (20-50)	0.88
LDH (U/L)	135 (106-157)	0.71
IgA (mg/dL)	64 (30-125)	0.56
IgG (mg/dL)	664 (486-997)	0.79
Involved/uninvolved serum free light chain ratio	9 (3.4-18.9)	0.07
Hemoglobin (g/dL)	12.3 (11.2-13.3)	**0.01**
Platelets (10^9/L)	264 (201-338)	0.52
β2M (ug/mL)	2.7 (2-3.7)	**0.02**

Early detection of post-transplant lymphoproliferative disorder using circulating tumor DNA. *First Author: Joanne Soo, Division of Oncology, Stanford University School of Medicine, Stanford, CA*

Background: Diffuse large B cell (DLBCL)-like post-transplant lymphoproliferative disorder (PTLD) affects 2-5% of transplant recipients. Although 50% of PTLDs can be related to Epstein-Barr virus (EBV) infection (Luskin et al., 2015) and high or increasing EBV viral load may precede EBV+ PTLD (Tsai et al., 2008), preemptive monitoring of EBV titers does not reliably predict development of PTLD (Dierickx et al., 2018). We aimed to assess the utility of circulating tumor DNA (ctDNA) for early detection of PTLD. **Methods:** We applied CAPP-Seq (Newman et al., 2014) to diagnostic tumor and plasma samples and matched germline in a cohort of 9 transplant recipients who developed PTLD to identify somatic alterations. We compared mutational patterns in PTLD to 149 de novo DLBCL cases sequenced by the same method as well 1112 published whole exome sequences (Pasqualucci et al, 2011; Reddy et al, 2017). We additionally sequenced serial post-transplant plasma samples preceding diagnosis in 5 patients and during or after treatment in 8 patients to determine the dynamics of ctDNA and compared these patterns to clinical outcome and EBV titers. **Results:** There was no significant difference in mutational burden between patients with PTLD and de novo DLBCL (median PTLD variants: 216, IQR = 79 – 321; median de novo DLBCL variants: 143.5, IQR = 45 – 243.8; p = 0.35), though there was a trend toward greater variant count in EBV- compared to EBV+ PTLD (p = 0.064). The prevalence of alterations in known driver genes including CREBBP, CARD11, MYD88, and EZH2 was similar between PTLD and de novo DLBCL. Prediagnostic plasma samples were available for 5 cases, including two EBV- PTLD, and we detected ctDNA in all patients prior to clinical diagnosis (mean lead time = 114 days). In the 3 EBV+ cases, EBV titers were concordant with ctDNA levels in EBV+ cases at all time points. In addition, ctDNA levels during and after treatment were concordant with clinical response in all patients. **Conclusions:** PTLD patients have detectable ctDNA prior to clinical diagnosis. Development of screening tools utilizing both ctDNA and EBV titers could facilitate early detection of PTLD in the transplant population.

7573 Poster Session (Board #210), Mon, 8:00 AM-11:30 AM

AMC075: A randomized phase II trial of vorinostat with R-EPOCH in aggressive HIV-related NHL. *First Author: Juan Carlos Ramos, University of Miami Sylvester Comprehensive Cancer Center, Miami, FL*

Background: HIV+ individuals are at increased risk for developing aggressive NHL that are often EBV+ or HHV-8+. We recently reported a phase I study using the HDAC inhibitor vorinostat (V) with R-DA-EPOCH for untreated high-risk HIV-NHL. We hypothesized that V would enhance the anti-tumor effects of R-EPOCH, and transiently activate latent EBV, HHV-8, and HIV, thus targeting virus-infected reservoirs. The recommended phase II dose of V administered on days 1-5 with R-EPOCH was 300 mg. In 12 evaluable patients (pts), the complete response (CR) rate was 83% with a 1-yr event-free survival (EFS) of 83%. **Methods:** *Eligibility*: HIV+ pts with untreated high-risk non-Burkitt NHL (aa-IPI 2-3, or Ki-67 ≥ 80%, or DLBCL-ABC subtype, or other aggressive non-DLBCL NHLs) with CD4 count ≥ 50 cells/mm^3. *Randomized phase II (45 pts on each arm)*: The primary objectives were to determine safety and efficacy of R-DA-EPOCH +/- V using CR rate as the primary endpoint. Correlative studies compared treatment effects on HIV viral loads, T-cell subsets, and immunoglobulin (Ig) levels. Latent HIV reservoir was investigated longitudinally using quantitative viral outgrowth assay. **Results:** A total of 90 pts (93% male, median age = 48, median CD4 = 190 cells/mm^3) were treated; the most common NHLs were DLBCL (n = 31, 69%), plasmablastic lymphoma (PBL) (n = 8, 18%), primary effusion lymphoma (PEL) (n = 5, 11%) under VR-EPOCH arm vs. 35 (78%) DLBCL, 7 (16%) PBL, and 2 (4%) PEL under R-EPOCH. Grade 4 neutropenia and thrombocytopenia wer more common with VR-EPOCH (44% and 27%, respectively), vs R-EPOCH (16% and 2%, respectively). There were 2 treatment-related deaths (1 for each arm), and similar rates of febrile neutropenia (18% vs. 16%, respectively). CR rates were 65% for VR-EPOCH vs. 77% for R-EPOCH (1-sided P = 0.895). The 1-yr EFS rates (±standard errors) in evaluable pts for V-R-EPOCH (n = 43) vs. R-EPOCH (n = 45) were 75.6% (±6.4%) vs. 82.2% (±5.7%), with 1-yr overall survival of 77.6% (±6.3%) vs. 86.7% (±5.1%), respectively. V had no significant impact on HIV viral loads, latent reservoir, T-cell subsets, or Ig levels. **Conclusions:** This study demonstrated no clinical benefit of adding an HDAC inhibitor to concurrent curative chemotherapy in aggressive HIV-NHL upfront. Clinical trial information: NCT01193842.

7574 Poster Session (Board #211), Mon, 8:00 AM-11:30 AM

Radiotherapy (RT) to bulky (B) and extralymphatic (E) disease in combination with 6xR-CHOP-14 or R-CHOP-21 in young good-prognosis DLBCL patients: Results of the 2x2 randomized UNFOLDER trial of the DSHNHL/GLA. *First Author: Michael Pfreundschuh, University Saarland Medical Schooly, Homburg Saar, Germany*

Background: The role of RT to B and E for young patients with good-prognosis DLBCL is ill-defined. **Methods:** 18-60 year-old patients (aaIPI = 0 with B [≥7.5 cm], aaIPI 1) qualifying for radiotherapy to B or E were randomized to 6xR-CHOP-14 or 6x-R-CHOP-21 followed by RT (39.6 Gy) to B and E sites or observation in a 2x2 factorial design. Primary endpoint was event-free survival. **Results:** A planned interim analysis of the first 285 patients had revealed a significantly better EFS of patients assigned to RT (p = 0.004) resulting in the pre-defined closing of the non-RT arms. 305 pts (R-CHOP-21: 155; R-CHOP-14: 150) assigned to RT and 162 (R-CHOP-21: 81, R-CHOP-14: 81) assigned to observation were evaluable for this final analysis. There were no relevant differences in protocol adherence and toxicity between the two chemotherapy regimens. EFS, PFS and OS after R-CHOP-14 and R-CHOP-21 were not different. After 66 months median observation 3-year EFS was worse in pts not assigned to RT (68% vs. 84%; p = 0.001), due to a higher rate of PR (11% vs. 2%) triggering additional treatment (mostly RT) as an EFS event. 3-year PFS of pts assigned to RT was not significantly better (89% vs. 81%; p = 0.221) and 3-year OS (93% vs. 93%, p = 0.506) was not different, which was confirmed in a multivariate analysis adjusting for elevated LDH, stage III/IV, B and E involvement (HR_{EFS}= 0.5 [95%CI: 0.4-0.8], p = 0.001; HR_{PFS}= 0.7 [0.5-11], p = 0.174; HR_{OS}= 1.2 [0.6-2.2], p = 0.674). Results were not different when the analysis was restricted to patients with bulky disease only. **Conclusions:** There were no differences in outcome between R-CHOP-14 and R-CHOP-21. Patients assigned to observation had a worse EFS because of more events largely due to a higher PR rate triggering additional treatment with no differences in PFS and OS. These results highlight the difficulties in interpreting residual masses in DLBCL without a PET which has been shown to identify (elderly) patients with B who can be spared from radiotherapy without compromising their outcome [Pfreundschuh et al., ASCO 2017, #7506]. S*upported by Deutsche Krebshilfe, Amgen and Roche* Clinical trial information: NCT00278408.

7575 Poster Session (Board #212), Mon, 8:00 AM-11:30 AM

R-CHOP preceded by blood-brain barrier permeabilization (BBBp) by NGR-tumor necrosis factor (NGR-hTNF) in patients with relapsed or refractory primary CNS lymphoma (rrPCNSL): First results of the "INGRID" phase II trial. *First Author: Andres J. Ferreri, IRCCS San Raffaele Scientific Institute, Milano, Italy*

Background: PCNSL pts are treated with HDMTX-based chemo, which requires hospitalization and extensive expertise to manage toxicity. R-CHOP could overcome these troubles, but CNS access of related drugs is poor. TNF induces BBBp and improves CNS access of anticancer drugs. The addition of NGR peptide enhances biological properties of TNF without major toxicity. The hypothesis that NGR-hTNF can improve CNS availability and activity of R-CHOP in pts with rrPCNSL is being evaluated in a phase II trial. Herein, we report results of a per-protocol exploratory analysis. **Methods:** HIV-neg pts (age 18-80 y; PS ≤3) with PCNSL failed after HDMTX-based chemo were enrolled. Pts received 6 cycles of R-CHOP, preceded by NGR-hTNF 0.8 μg/m² in 1-hr inf in cycles 2-6. Response, microvasculature and vessel permeability were assessed by DCE- and DSC-MRI. Permeability was assessed in enhanced lesions and perilesional areas; results were expressed as Ktrans values normalized using contralateral white matter. R-CHOP drugs levels were assessed on matched CSF and serum/plasma samples. **Results:** The first 10 registered pts (median age 61 yo, range 41-68; 7 males) were analyzed. Pts were heavily pretreated: 7 had received ASCT, WBRT or both; 6 had refractory disease. Response to NGR-hTNF R-CHOP was complete in 5 pts and partial in 2; 3 pts experienced PD. All responding pts received consolidation (WBRT or ASCT); DoR was > 6 months in 6 pts, only one responding pt died. Treatment was well tolerated; no cases of g≥3 non-hematol toxicity, dose reduction or interruption were recorded. Neutropenia (54% of courses) and thrombocytopenia (15%) were the only g4 toxicities. NGR-hTNF delivery increased permeability as median (range) Ktrans of enhanced and perilesional areas raised from baseline values of 23.5 (6.8-98.8) and 2.5 (0.4-3.9) to 35.3 (23.9-887.7; p = 0.39) and 4.7 (2.2-37.7; p = 0.01), respectively. PK and perfusion data will be presented at the meeting. **Conclusions:** This exploratory study suggests that NGR-hTNF increases vascular permeability in pts with rrPCNSL. R-CHOP preceded by NGR-hTNF is safe and active in these pts. Clinical trial information: 201400153211.

7576 Poster Session (Board #213), Mon, 8:00 AM-11:30 AM

Circulating tumor DNA to predict timing of relapse in mantle cell lymphoma. *First Author: Mark J. Roschewski, Lymphoid Malignancies Branch, Center for Cancer Research, National Cancer Institute, Bethesda, MD*

Background: Mantle cell lymphoma is clinically heterogeneous. MRD- after frontline therapy improves PFS, but virtually all pts relapse. Surveillance after induction is not uniform and clinical decisions are empirical. Detection of ctDNA in the blood throughout therapy is promising. We used AdaptiveÕs next-generation sequencing assay to detect and quantify ctDNA in blood throughout therapy for MCL. **Methods:** Untreated MCL pts received bortezomib (BZ) + DA-EPOCH-R x 6 then randomized to obs vs. BZ maint x 18m. Pt serum collected pre-Tx, w/each cycle, and w/each surveillance visit paired w/CT scans at regular intervals for 5y. FFPE was analyzed for tumor-specific clonotypes. Tumor DNA was amplified using locus-specific primer sets for the Ig heavy-chain and light-chain loci, BCL1, and BCL2 translocations. Amplified products were sequenced, and pts w/o a high-frequency tumor clonotype excluded. Baseline ctDNA levels were compared to tumor burden and proliferation. Levels of ctDNA at EOI and during surveillance were analyzed for the ability to predict progression. **Results:** 53 MCL pts were treated between 1996 and 2013. After median f/u of 9.6y, 5-yr OS is 80.1% and median PFS is 30.7m. With FFPE available, 50 of 52 (96%) had an tumor-specific clonotype, and 46 of 48 pts (96%) had detectable ctDNA in serum prior to therapy. ctDNA was successfully tracked in 625 of 647 (97%) serum samples. Pre-treatment ctDNA levels more strongly correlated with total metabolic tumor volume (r_s= 0.74) than Ki-67 (r_s= 0.55) or serum LDH (r_s= 0.49). Overall, 47 pts responded to induction (44 CR; 3PR), and median TTP after EOI was 26m (range 0-131). 40 of 50 pts (80%) achieved MRD- at EOI, which was assoc with superior median PFS (45m vs. 25m, p = 0.001) and OS (NR vs. 40m, p = 0.01) vs. MRD+ pts. In 31 of 41 (76%) progressors, ctDNA was present prior to clinical progression with a median lead-time of 9m (range 0-38). Of 9 non-progressors, 8 remained ctDNA negative. BZ maint had no impact on PFS or OS. **Conclusions:** Nearly all pts with MCL have detectable baseline ctDNA. Achieving MRD- at EOI was associated with improved PFS and OS compared to MRD+ pts. ctDNA was detected a median 9m before progression. Clinical trial information: NCT00114738.

7577 Poster Session (Board #214), Mon, 8:00 AM-11:30 AM

Quality of life in cutaneous T-cell lymphoma subjects treated with anti-CCR4 monoclonal antibody mogamulizumab versus vorinostat: Results from the phase 3 MAVORIC trial. *First Author: Pierluigi Porcu, Thomas Jefferson University, Philadelphia, PA*

Background: Cutaneous T-cell lymphomas (CTCL) are rare non-Hodgkin's lymphomas that cause significant morbidity and adversely affect quality of life (QoL), most severely in Sezary syndrome (SS) patients (pts). **Methods:** A multicenter Phase 3 trial compared mogamulizumab (MOGA) vs vorinostat (VOR) in pts with Stage IB-IV CTCL who had failed ≥ 1 systemic therapy. Progression free survival was the primary endpoint. Validated QoL measurements included the Skindex-29 (SDX-29), Functional Assessment of Cancer Therapy-General (FACT-G) and EuroQol-5D. SDX-29 and FACT-G are reported here. Longitudinal modeling of symptoms, function, and QoL subdomains were evaluated using longitudinal mixed models on prespecified covariates. Meaningful change threshold (MCT) was evaluated and categorical change analyzed by group over time. Time to clinically meaningful worsening was defined using distribution-based minimally important difference thresholds. **Results:** 372 pts were randomized (186 in each arm). MOGA resulted in symptomatic and functional improvement with differences in SDX-29 Symptoms (Cycle, C3, C5, and C7; p < 0.05) and Functional (C3 and 5; p < 0.05) scales. The proportion of pts who improved by at least the MCT from baseline was significantly greater for MOGA vs VOR on SDX-29 Symptoms at C3 (61.1% vs 45.3%), C5 (64.5% vs 42.4%), C7 (67.1% vs 47.5%), and C11 (84.1% vs 50.0%) and SDX-29 Functioning domain at C5 (54.3% vs 28.8%). Significant difference in the FACT-G Physical Well-Being scale (C1, C3, and C5; p < 0.05) were observed in favor of MOGA and a greater proportion of pts declined by at least the MCT in favor of MOGA vs VOR at C1 (19.3% vs 34.7%), C3 (17.4% vs 42.9%), C5 (13.1% vs 43.3%), and C7 (15.9% vs 37.5%). The median time to worsening of symptoms on SDX-29 was 27.4 m for MOGA vs 6.6 m for Vor. In SS pts, the median time to worsening varied in favor of MOGA (p < 0.005) on all SDX-29 domains. In mycosis fungoides pts, time to worsening did not vary between arms. **Conclusions:** Symptoms, function, and overall QoL of CTCL pts favored MOGA over VOR across study time points. Pts with highest symptom burden and functional impairment derived the most QOL benefit from MOGA. Clinical trial information: NCT01728805.

7578 Poster Session (Board #215), Mon, 8:00 AM-11:30 AM

Efficacy of up-front hematopoietic cell transplantation in peripheral t-cell lymphoma, not otherwise specified (PTCL-NOS): A National Cancer Database analysis. *First Author: Bhagirathbhai R. Dholaria, Moffitt Cancer Center, Tampa, FL*

Background: Peripheral T cell lymphoma-not otherwise specified (PTCL NOS) is the most common subtype of mature T cell lymphoma in the Western World with inferior survival compared to the B-cell lymphomas. Herein, we studied the impact of up-front hematopoietic cell transplantation (HCT) on PTCL-NOS survival outcomes. **Methods:** The National Cancer Database (NCDB) with PTCL-NOS incident cases from 2004-2015 was used. We compared the outcomes of patients receiving chemotherapy only versus chemotherapy coupled with a consolidative autologous (auto) or an allogeneic (allo) HCT. Those without any form of chemotherapy treatment (n = 1823) were excluded from the analysis. **Results:** A total of 5252 PTCL-NOS patients were identified; 4812 received chemotherapy only and 440 received chemotherapy and a HCT (auto-HCT = 410; allo-HCT = 30). HCT recipients were more likely to be younger (median age, 55 vs. 63 years), had lower Charlson/Deyo co-morbidity score, of the white race, had a higher median household income, be treated at an academic facility and had private insurance. IPI and Ann-Arbor stage distribution were not significantly different between the groups. The median overall survival (OS) for all patients, chemotherapy alone and chemotherapy + HCT was 17.2 months, 14.7 months and not reached, respectively.($p< 0.001$) The 10-year OS was 15% and 52% for chemotherapy alone and chemotherapy + HCT group, respectively ($p< 0.001$). There was no significant difference in OS between auto-HCT and allo-HCT patients (p =0.93). After adjusting for baseline characteristics in Cox-regression model, HCT (Hazard ratio (HR) = 0.36, 95% confidence interval (CI): 0.20-0.65, p =0.001) was associated with improved OS. IPI-intermediate (HR = 1.9, 95% CI: 1.2-2.9, p =0.008) or IPI-high (HR = 3.5, 95% CI: 2.1-5.8, $p< 0.001$) were associated with poor OS. **Conclusions:** In this large US-based analysis, up-front HCT was an independent prognostic factor associated with improved OS of PTCL-NOS. Efforts to ensure early referral to transplant centers and education on the role of HCT to both our patients and hematologists to optimize the access to HCT are urgently needed.

7579 Poster Session (Board #216), Mon, 8:00 AM-11:30 AM

The effect of duvelisib, a dual inhibitor of PI3K-δ,γ, on components of the tumor microenvironment in previously untreated follicular lymphoma. *First Author: Carla Casulo, University of Rochester, Wilmot Cancer Institute, Rochester, NY*

Background: Duvelisib (DUV), an oral dual inhibitor of PI3K-d,g, is clinically active in hematologic malignancies, including follicular lymphoma (FL), CLL, and T cell lymphoma (Flinn, 2017). PI3K-δ inhibition directly targets malignant cells and PI3K-γ inhibition disrupts the supportive tumor microenvironment. In the CONTEMPO trial (NCT02391545), previously untreated FL patients (pts) treated with DUV+rituxumab had an ORR of 93% (36% CRR) and pts treated with DUV+obinutuzumab had an ORR of 89% (41% CRR). In both treatment arms chemokines reflective of the tumor microenvironment were inhibited (Casulo, 2016). **Methods:** *Ex vivo* whole blood assays were conducted from healthy volunteers and 32 FL pts enrolled in CONTEMPO [pre-and post-DUV]. *Ex vivo* and *in vitro* PI3K-γ assays [(fMLP-stim monocyte and CXCL12-stim human T cell pAKT(S473), murine bone marrow monocyte migration, and macrophage polarization quantified by ARG1 expression] and PI3K-δ assays [LPS-stimulated monocyte pAKT (S473)] with PI3K-δ-selective [idelalisib (IDELA), TGR-1202, IPI-3063] and PI3K-γ-selective [IPI-549] inhibitors were compared. **Results:** DUV (IC_{50} 0.4 ±0.1 mM) and IDELA (IC_{50} 1.0±0.2 mM) potently inhibited LPS-induced human monocytes via PI3K-δ compared with the PI3K-γ selective IPI-549 (IC_{50} 12±0.5 mM). For TGR-1202, the IC_{50} (25±8 mM) was below the RP2D clinical exposure. DUV (IC_{50} 0.5±0.2 mM) and IPI-549 (IC_{50} 1.6 ±0.2 mM) potently inhibited PI3K-γ dependent fMLP-stimulated human monocytes compared to IDELA (IC_{50} 9.4±2.3) and TGR-1202 (IC_{50} 55±16 mM). In FL pts treated with DUV, these PI3K-γ and PI3K-δ selective assays were inhibited 1-4 hours post treatment. Consistent with a PI3K-γ mechanism, both DUV and IPI-549 inhibited macrophage polarization to M2, reduced CXCL12-induced macrophage migration (DUV IC_{50} 51 nM; IPI-549 IC_{50} 85 nM), and blocked CXCL12-induced T cell migration (DUV EC_{50} 128±39 nM; IPI-549 EC_{50} 17±17nM), which was not observed with PI3K-δ inhibitor IPI-3063 (IC_{50} 630±71nM). **Conclusions:** The disruption of PI3K-d,g function in FL pts treated with DUV supports its inhibition of the tumor microenvironment through cancer-supportive macrophages and T cells. Clinical trial information: NCT02391545.

7580 Poster Session (Board #217), Mon, 8:00 AM-11:30 AM

Safety and efficacy of anti-CD20 immunotoxin MT-3724 in relapsed/refractory (R/R) B-cell non-Hodgkin lymphoma (NHL) in a phase I study. *First Author: Michelle A. Fanale, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: MT-3724 is a novel recombinant fusion protein consisting of a CD20 binding variable fragment (scFv) fused to Shiga-like toxin-I A1. The SLT-I A1 forces MT-3724 internalization and irreversibly inactivates ribosomes triggering cell death. We present interim results from a Phase I study in patients (pts) with B-cell NHL who relapsed after prior response to anti-CD20 Mab and chemotherapy (NCT02361346). **Methods:** 24 pts were treated by 13FEB2018: 21 pts (12 DLBCL) at 5-100 μg/kg/dose in 6 dose escalation cohorts and 3 pts (all DLBCL) at 75 μg/kg/dose in MTD expansion cohort. MT-3724 was given as six 2-hr IV infusions on Days 1-12 of each cycle (C) for up to 5 cycles. Investigator assessed tumor response after C2, C4 and C5 using Cheson criteria. **Results:** Demographics in 24 evaluable pts were: 54% female, mean age 66 yrs (range 34-78); ≥4 prior NHL therapies in 67%; ECOG status 0 in 42%, 1 in 46%, 2 in 4% and unknown in 8%. All pts had ≥1 AE (59 G≥3; 13 related), and 15 pts (63%) had 33 SAEs (23 G≥3; 4 related). The most common AEs were peripheral edema (67%), fatigue (43%), diarrhea (38%), myalgia (38%) and cough (33%). MT-3724 was not tolerated at 100 μg/kg/dose (2 pts had 1 DLT each: G2 pneumonia and G2 ileus). In dose escalation, no pts had DLT at doses ≤MTD of 75 μg/kg/dose. In the MTD expansion, 2 of 3 pts had G2 capillary leak syndrome (CLS) leading to dose delay and reduction. The CLS events occurred in obese pts (96 and 154 kg = high total of 7208 and 11572 μg/dose) and were reversible, but MTD was reduced to 50 μg/kg/dose and capped at 6000 μg/dose. Five pts (all DLBCL) had clinical benefit at 5-75 μg/kg/dose [1 CR and 2 PR (ORR 12.5%)' 2 SD with large tumor reduction (48% and 49%; DCR 21%)]. All pts with benefit had undetectable serum rituximab (RTX) level at screening. No pts with detectable screening RTX level had benefit, likely due to competitive inhibition of CD20 binding by prior RTX. **Conclusions:** MT-3724 showed clinical anti-tumor activity in heavily pre-treated pts with R/R B-cell NHL. Consistent with mechanism of action, MT-3724 had the best activity in rapidly growing DLBCL. Safety and efficacy assessment is ongoing at the adjusted MTD of 50 μg/kg/dose in DLBCL pts with undetectable screening RTX level. Clinical trial information: NCT02361346.

TPS7581 Poster Session (Board #218a), Mon, 8:00 AM-11:30 AM

Phase 3 zanubrutinib (BGB-3111) vs bendamustine + rituximab (BR) in patients (pts) with treatment-naïve (TN) chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL). *First Author: Peter Hillmen, St. James's University Hospital, Leeds, United Kingdom*

Background: Inhibition of Bruton's tyrosine kinase (BTK) has emerged as a strategy for targeting B-cell malignancies including CLL/SLL. Zanubrutinib has been shown to be a novel 2nd-generation, potent, and specific BTK inhibitor in clinical studies to date. Early clinical data suggest that zanubrutinib treatment in pts with TN (n = 16) or relapsed/refractory (R/R; n = 50) CLL/SLL induced deep and sustained responses, with a 94% overall response rate (ORR) including 6% and 2% complete response rates in TN and R/R CLL/SLL, respectively (ICML 2017). We hypothesize that zanubrutinib monotherapy may have superior efficacy and potentially improved safety vs standard BR chemoimmunotherapy in pts with TN CLL/SLL. **Methods:** This ongoing Phase 3, randomized, open-label, global study (NCT03336333, BGB-3111-304) compares the efficacy and safety of zanubrutinib vs BR in adult pts with TN CLL/SLL considered unsuitable for treatment with FCR (fludarabine, cyclophosphamide, rituximab). In Cohort 1, pts lacking del (17p) (n ≈ 420) are randomized 1:1 to oral zanubrutinib 160 mg twice-daily or BR x 6 cycles. Randomization is stratified by age (< 65 vs ≥ 65 y), Binet stage (C vs A/B), geographic region (North America vs Europe vs Asia-Pacific) and *IGHV* mutational status (mutated vs unmutated). In Cohort 2, pts with del(17p) (n ≈ 47) are enrolled and all receive zanubrutinib as in Cohort 1. Key inclusion criteria include histologically confirmed CD20+ CLL/SLL requiring treatment per iwCLL criteria, ECOG PS 0-2, and adequate hematologic function. The primary endpoint is progression-free survival (PFS) of zanubrutinib as compared to BR in Cohort 1 by independent review committee (IRC) according to iwCLL guidelines with modification for treatment-related lymphocytosis. The analysis of PFS between the 2 arms in Cohort 1 will be based on a log-rank test stratified by the randomization stratification factors. Key secondary end points include ORR, duration of response, overall survival, and safety in Cohorts 1 & 2. In Cohort 1, next-line treatment with zanubrutinib after IRC-confirmed progression on BR is included in the study design. Recruitment is ongoing. Clinical trial information: NCT03336333.

TPS7582 **Poster Session (Board #218b), Mon, 8:00 AM-11:30 AM**

The GAIA (CLL13) trial: An international intergroup phase III study for frontline therapy in chronic lymphocytic leukemia (CLL). *First Author: Von Tresckow Julia, Department I of Internal Medicine and Center of Integrated Oncology Cologne-Bonn, German CLL Study Group, University of Cologne, Cologne, Germany*

Background: Chemoimmunotherapy (CIT) is still standard of care in first line treatment of fit CLL patients (pts) without del(17p) or TP53 mutation. However, CIT is often associated with side effects caused by the general cytotoxicity of chemotherapy. Testing of chemotherapy-free treatment regimens with increased efficacy and superior toxicity profiles including CD20-antibodies and targeted drugs such as venetoclax (Ve) and ibrutinib (I) head to head with CIT is therefore warranted in this pt group. **Methods:** The trial is an investigator initiated trial of the German CLL Study Group in cooperation with the Nordic CLL Study Group, HOVON, SAKK, Cancer Trials Ireland and the Israeli CLL Study Group. Sponsor of the trial is the University of Cologne. It is registered at www.clinicaltrials.gov as # NCT02950051. 920 pts with a cumulative illness rating scale score ≤ 6 and a creatinine clearance $\geq$70ml/min who are diagnosed with previously untreated CLL according to iwCLL guidelines without del(17p) or TP53 mutation will be included and 1:1:1:1 randomized into four treatment arms. In the standard arm, six cycles of CIT with fludarabine, cyclophosphamide plus rituximab for pts $\leq$ 65 years or bendamustine plus rituximab for pts $>$ 65 years are given. In the experimental arms 12 cycles of Ve containing regimes are tested: Ve plus rituximab (RVe), Ve plus obinutuzumab (GVe) and Ve plus ibrutinib and obinutuzumab (GIVe). Two co-primary endpoints were defined: minimal residual disease (MRD) negativity for the comparison of CIT versus GVe and progression free survival (PFS) for the comparison of CIT versus GIVe. Secondary endpoints include comparisons of MRD and PFS for the other treatment arms, overall survival, safety parameters and health-related quality of life. Recruitment started in December 2016 and is estimated to take 33 months (m). The final analysis of the MRD endpoint is expected to be performed 49 m after trial initiation together with the interim PFS analysis. The final analysis of the PFS endpoint is expected to take place after 73 m, which will also be the formal end of trial. After the second meeting of the data safety monitoring board in February 2018 the trial continues recruiting as planned. Clinical trial information: # NCT02950051.

TPS7583 **Poster Session (Board #219a), Mon, 8:00 AM-11:30 AM**

KEYNOTE-667: Phase 2, open-label study of pembrolizumab in children and young adults with newly diagnosed classical Hodgkin lymphoma (cHL) with slow early response (SER) to frontline chemotherapy. *First Author: Christine Mauz-Korholz, Justus-Liebig University of Giessen, Giessen, Germany*

Background: High risk for relapse is observed in cHL patients (pts) with SER to initial chemotherapy and the burden of late organ toxicities may be higher following dose intensification. **Methods:** The phase 2, open-label KEYNOTE-667 (NCT03407144) study will enroll 400 pts aged 3 to 17 (children) or 18 to 25 years (young adults) with newly diagnosed, confirmed stage IA, IB, or IIA cHL without bulky disease (Group 1 [low-risk]) or stage IIEB, IIIEA, IIIEB, IIIB, IVA, or IVB cHL (Group 2 [high-risk]); measurable disease; and performance status per Lansky Play-Performance Scale $\geq$50 (age $\leq$16 years) or Karnofsky score $\geq$50 (age $>$ 16 years). Pts will receive induction with doxorubicin, bleomycin, vinblastine, dacarbazine (ABVD; Group 1) or vincristine, etoposide/etoposide phosphate, prednisone/prednisolone, doxorubicin (OEPA; Group 2) for 2 cycles, followed by early response assessment by PET/CT/MRI. Pts with rapid early response (Deauville score 1-3) will receive standard therapy. Pts with SER (Deauville score 4-5) will receive consolidation with pembrolizumab 2 mg/kg Q3W up to 200 mg (children) or 200 mg Q3W (young adults) plus 2 cycles AVD (Group 1) or 4 cycles cyclophosphamide, vincristine, prednisone/prednisolone, dacarbazine (COPDAC-28; Group 2). PET/CT for late response assessment (LRA) will be performed after consolidation. After LRA, Group 1 pts with SER will receive radiotherapy (RT); in Group 2, pts with Deauville score 4-5 will receive RT. All pts will receive maintenance with pembro Q3W concomitantly with RT. Pembro dosing will continue up to 17 administrations, with an option to stop after 24 weeks due to CR, or until progression, unacceptable toxicity, or withdrawal. The primary endpoint is objective response rate (ORR) per Cheson 2007 IWG criteria by group in SER pts. Secondary endpoints include SERs with PET negativity after consolidation, event-free survival (EFS), overall survival (OS), and radiotherapy frequency and details by group. ORR with 95% CI will be estimated using the Clopper-Pearson method. EFS and OS will be estimated by Kaplan-Meier methods. Safety will be assessed in all treated pts. Clinical trial information: NCT03407144.

TPS7584 **Poster Session (Board #219b), Mon, 8:00 AM-11:30 AM**

Phase I/II study to evaluate the safety and efficacy of tenalisib, a novel PI3K δ/γ dual inhibitor in combination with pembrolizumab in patients with relapsed/refractory classical Hodgkin lymphoma. *First Author: Rod Ramchandren, Barbara Ann Karmanos Cancer Institute, Detroit, MI*

Background: Despite impressive activity of PD-1/PD-L1 therapy in HL, proportions of patients do not respond and eventually progress. Growing evidence suggests that high infiltrations of immune-suppressive myeloid cells are responsible for anti-PD-1/PD-L1 therapy resistance. These observations suggest a need for an immunotherapeutic combination to overcome such resistance mechanisms. PI3K δ/γ isoforms are known to play a role in modulating the tumor microenvironment. Tenalisib demonstrated marked reduction of Tumor Associated Macrophages (TAMs) and angiogenesis and showed synergy with checkpoint inhibition in syngeneic mouse models. Tenalisib has demonstrated single agent activity in relapsed refractory heavily pre-treated cHL (ORR 29% CR 7% PR 21%). The proposed study hypothesizes that Tenalisib in combination with Pembrolizumab improve the depth and durability of responses to anti-PD1 therapy. **Methods:** The primary objective of this phase I/II, open label, 3+3 dose-escalation study is to evaluate the safety, tolerability, and identify the maximum tolerated dose of tenalisib in combination with Pembrolizumab in relapsed/refractory cHL. Patients will be enrolled in two escalating cohorts (Tenalisib 400/ 800 mg BID and Pembrolizumab 200 mg, IV) to determine MTD/ optimal dose. In Expansion part, two groups will be initiated. The first expansion group will enroll 18 patients who are naïve to anti-PD-1 therapy to explore the additive/synergistic effect of the combination by measuring efficacy parameters (ORR, DoR, PFS). The second group will enroll 27 patients who have received treatment with pembrolizumab for at least 6 months and have not demonstrated a complete response. The objective is to understand whether combination therapy will overcome PD-1 resistance by augmenting conversion rates (i.e., improvement from progressive disease to CR or from SD to PR) upon combination. Disease response assessments will be determined per the Lugano classification (Cheson 2014). Eligible subjects will receive Tenalisib BID orally and Pembrolizumab 200 mg, IV every three weeks in a 21-day cycle.

TPS7585 **Poster Session (Board #220a), Mon, 8:00 AM-11:30 AM**

ZUMA-7: A phase 3 randomized trial of axicabtagene ciloleucel (Axi-Cel) versus standard-of-care (SOC) therapy in patients with relapsed/refractory diffuse large B cell lymphoma (R/R DLBCL). *First Author: Olalekan O. Oluwole, Vanderbilt-Ingram Cancer Center, Nashville, TN*

Background: For pts with DLBCL who fail 1st-line therapy, the only potentially curative treatment is salvage chemotherapy followed by autologous stem cell transplant (ASCT). Only »50% of pts receiving salvage chemotherapy proceed to ASCT and 3-y progression-free survival (PFS) is 53% after ASCT (Gisselbrecht et al. *JCO.* 2010). In ZUMA-1, the pivotal, single-arm study of axi-cel, an autologous anti-CD19 chimeric antigen receptor (CAR) T cell therapy, the objective response rate (ORR) was 82% (58% complete response [CR] rate) in pts with refractory large B cell lymphoma; 40% remained in CR with 15.4-mo median follow-up (Neelapu & Locke et al. *NEJM.* 2017). This trial was primarily in pts with $\geq$ 2 prior lines of therapy and supported US FDA approval of axi-cel for the treatment of adult pts with R/R DLBCL after $\geq$ 2 prior lines of systemic therapy. ZUMA-7 investigates axi-cel as 2nd-line therapy for pts with R/R DLBCL. **Methods:** ZUMA-7 (NCT03391466) is a randomized (1:1) Phase 3, open-label, multicenter study of axi-cel vs SOC 2nd-line treatment in pts with R/R DLBCL. Planned enrollment is 350 pts. Eligible pts must have R/R DLBCL after 1st-line therapy (including an anti-CD20 antibody and an anthracycline) and intend to proceed to ASCT if they respond to 2nd-line therapy. Exclusion criteria include prior SCT, prior CD19-targeted therapy, or active infection. Pts randomized to axi-cel will undergo leukapheresis, then lymphodepleting chemotherapy (fludarabine 30 mg/m^2/d and cyclophosphamide 500 mg/m^2/d for 3 d), followed by a single infusion of axi-cel at 2×10^6 CAR T cells/kg. Corticosteroid bridging therapy is allowed for pts with high disease burden at screening. Pts in the SOC arm will receive investigator's choice of 2nd-line salvage therapy (R-ICE, R-DHAP, R-ESHAP, or R-GDP); pts who respond after 2–3 cycles will receive high-dose therapy and ASCT. The primary endpoint is event-free survival defined as time from randomization to disease progression, start of new lymphoma therapy, or death. Secondary endpoints include ORR, overall survival, PFS, duration of response, safety, and pt-reported outcomes. Accrual is ongoing. Clinical trial information: NCT03391466.

TPS7586 **Poster Session (Board #220b), Mon, 8:00 AM-11:30 AM**

A phase 1 open-label, safety, pharmacokinetic, and preliminary efficacy study of STRO-001, an anti-CD74 antibody drug conjugate, in patients with advanced B-cell malignancies. *First Author: Amrita Y. Krishnan, City of Hope, Duarte, CA*

Background: Sutro's cell-free antibody production system was used to make STRO-001, a novel CD74 targeting antibody drug conjugate. CD74 is expressed on B cells throughout differentiation, and is an attractive target for treatment of B cell malignancies. STRO-001 demonstrates potent cytotoxicity in non-Hodgkin lymphoma (NHL) and multiple myeloma (MM) cell lines and anti-tumor activity in xenograft models. Toxicology studies demonstrate dose-dependent B-cell depletion and reversible hematologic toxicity when STRO-001 is administered at up to 10 mg/kg. **Methods:** This study is a first-in-human Phase 1, open-label, multicenter, dose escalation (Part 1) study with dose expansion (Part 2) to identify the maximum tolerated dose (MTD), recommended phase 2 doses (RP2D) and to evaluate the safety, tolerability, and preliminary anti-tumor activity of STRO-001 in adults with B-cell malignancies (MM and NHL) who are refractory to, or intolerant of, all therapy known to provide clinical benefit. STRO-001 is given to all patients on study via intravenous infusion on Day 1 and Day 15 of each cycle until disease progression. Dose limiting toxicities will be assessed in the first cycle (Days 1-28) of dose escalation. In Part 1, 2 cohorts (1 for MM and 1 for NHL) will enroll 30 patients each to determine the MTD and RP2D for expansion while Part 2 will enroll 4 cohorts based on disease subtypes (MM, diffuse large B cell, mantle cell and follicular lymphomas). Efficacy will be evaluated per MM-specific or NHL-specific criteria. Key inclusion criteria include relapsed or relapsed/refractory disease, adequate bone marrow and renal function, and ability to comply with treatment, testing and pharmacokinetic (PK) schedules. NHL patients must have at least one measurable lesion. Key exclusion criteria include leukemic manifestations of lymphoma, need for ongoing anti-coagulants or immunotherapy including systemic corticosteroids and a history of CNS involvement. Samples will be collected to assess the PK and immunogenicity. No formal statistical hypothesis testing will be conducted in this study. This study is currently open for enrollment in the US. Clinical trial information: NCT03424603.

TPS7587 **Poster Session (Board #221a), Mon, 8:00 AM-11:30 AM**

ILyAD (Indolent Lymphoma and Vitamin D): A phase III double blind, prospective randomized trial to evaluate the supplemental effect of vitamin D on progression-free survival in patients with low tumor-burden indolent non-Hodgkin lymphoma treated with rituximab therapy. *First Author: Michael Brady, Wilmot Cancer Institute, University of Rochester Medical Center, Rochester, NY*

Background: Follicular lymphoma (FL) is the most prevalent lymphoma in the US. Though outcomes have improved substantially, this disease is characterized by an incurable clinical course requiring chronic, costly, often morbid therapy. Therefore, lower intensity and better-tolerated, cost-effective treatments are needed. In a recent study of newly diagnosed FL patients treated with standard chemotherapy plus anti-CD20 therapy, we reported a significant association between low vitamin D levels and clinical outcomes in two independent cohorts. The magnitude of this association is stronger than the individual clinical prognostic factors within the FL-IPI score and may be the strongest association reported to date of a pre-therapy prognostic factor in FL. These results strongly support a randomized trial to evaluate whether vitamin D supplementation can improve outcome in patients with indolent lymphoma treated with rituximab. **Methods:** This NIH-funded, multi-center, double-blind, randomized phase III study will enroll adult subjects with biopsy-proven indolent, low tumor burden FL, SLL, Marginal Zone or MALT histologies. Subjects will be randomized, 2:1, to vitamin D 2000IU daily or placebo daily for 3 years, or until disease progression, while receiving standard treatment with rituximab in 4 weekly doses. The primary endpoint is 3-year event free survival (EFS), secondary endpoints include response at week 13 and overall survival. Events are defined as lack of response at week 13, disease progression, initiation of new treatment or death. The study provides 81% power to detect HR of 0.55 at a 0.05 significance level, which corresponds to an increase in 3-year EFS from 40% to 60%. Correlative studies will identify if vitamin D levels can predict patients for whom supplementation is particularly effective and whole exome sequencing will determine whether key vitamin D related germline variations are critical determinants of outcome. The study is currently open and accruing with an enrollment goal of 210 subjects. Clinical trial information: NCT03078855.

TPS7588 **Poster Session (Board #221a), Mon, 8:00 AM-11:30 AM**

A phase 1, open-label, multicenter, non-randomized study to assess the safety, tolerability, pharmacokinetics, and preliminary antitumor activity of AZD4573, a potent and selective CDK9 inhibitor, in subjects with relapsed or refractory hematological malignancies. *First Author: Simon Rule, Department of Haematology, Derriford Hospital, Plymouth, United Kingdom*

Background: Cyclin-dependent kinase 9 (CDK9) belongs to the group of transcription-regulating CDKs and promotes transcription elongation through phosphorylation of RNA Polymerase II at serine 2 (pSer2-RNAPII). Studies using multi-CDK inhibitors with CDK9 activity demonstrated that transient inhibition of CDK9 can modulate expression of oncogenes with short-lived transcripts and proteins (e.g. MCL1, MYC), providing an intriguing therapeutic rationale. Transient and selective inhibition of CDK9 is key to preferentially kill tumor cells dependent on survival proteins without causing broad toxicity due to prolonged transcription suppression. Multi-CDK inhibitors, e.g. Dinaciclib (Flynn et al., Leukemia 2015) have been progressed in early trials and shown to reduce levels of MCL1 and induced clinical responses attributed to CDK9 inhibition. However, a more potent and selective CDK9 inhibitor that has appropriate pharmacokinetics for tuneable target engagement and an optimal dose/schedule, leading to improved efficacy, is warranted. We developed a selective CDK9 inhibitor, AZD4573, with nanomolar potency that exhibits anticancer activity across a diverse set of hematological models. Pre-clinical experiments demonstrated a rapid, dose-dependent decrease in pSer2 RNAPII with concomitant depletion of MYC and MCL1 mRNA and protein leading to induction of cleaved caspase/PARP. AZD4573 induced significant antitumor activity in xenograft models when given as monotherapy or in combination (Cidado J et al, AACR 2018). These data suggest clinical progression of AZD4573 for treatment of hematological malignancies. **Methods:** This study is a multicenter, open-label, first in human phase 1 dose-escalation study including an intra-subject ramp-up. The purpose is to assess the safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD) and preliminary antitumor activity of AZD4573 in subjects with relapsed/refractory haematological malignancies. Study enrolment is ongoing. Clinical trial information: NCT03263637.

TPS7589 **Poster Session (Board #222a), Mon, 8:00 AM-11:30 AM**

A phase 3 study comparing polatuzumab vedotin plus R-CHP versus R-CHOP in patients with DLBCL (POLARIX). *First Author: Herve Tilly, Centre Henri Becquerel, University of Rouen, Rouen, France*

Background: R-CHOP remains the standard of care in patients (pts) with previously untreated diffuse large B-cell lymphoma (DLBCL). However, pts with high-risk disease have poorer outcomes with R-CHOP. Polatuzumab vedotin (pola) is an antibody-drug conjugate targeting CD79b; it delivers the antimitotic agent MMAE and is being evaluated as a replacement strategy for vincristine within the R-CHOP regimen. In a phase Ib/II study in higher risk DLBCL pts, pola + R-CHP produced promising efficacy across different subtypes of DLBCL and a safety profile similar to that observed in the R-CHOP arm of the GOYA study (Tilly H, et al. Hematol Oncol 2017; Vitolo U, et al. J Clin Oncol 2017). **Methods:** This is a multicenter, randomized, double-blind, placebo-controlled, phase 3 study in pts with previously untreated DLBCL. Pts (planned N = 875) aged 18-80 years with CD20-positive DLBCL (including DLBCL not otherwise specified [NOS], germinal center B-cell like [GCB], and activated B-cell like [ABC] subtypes), ECOG performance status 0–2, and IPI score 2–5, will be randomized 1:1 to one of two treatment groups, stratified by IPI score (2 versus 3–5), bulky disease and geographical region. Arm A will receive pola 1.8 mg/kg on Day 1 plus R-CHP (standard dosing schedule) plus vincristine placebo for 6 cycles; Arm B will receive R-CHOP (standard dosing schedule) with pola placebo for 6 cycles. In both arms, R will be administered as monotherapy in cycles 7 and 8. The primary endpoint is progression-free survival, as assessed by the investigator, using the Lugano classification (Cheson B, et al. J Clin Oncol 2014). Secondary endpoints include PET-CT complete response rate at end of treatment assessed by an independent review committee, event-free survival due to efficacy reason, 2-year PFS rate, and overall survival. PET-CT and CT scans will be obtained at screening, after 4 cycles (planned interim assessment), and 6–8 weeks after end of study treatment. Patient follow-up will continue for 5 years after end of treatment. Enrolment began November 2017. Clinical trial information: study is funded by F. Hoffmann-La Roche Ltd; Clinical trial information: NCT03274492.

TPS7590 Poster Session (Board #222b), Mon, 8:00 AM-11:30 AM

The PRIMO study: A phase 2 study of duvelisib efficacy and safety in patients with relapsed or refractory peripheral t-cell lymphoma (PTCL). *First Author: Steven M. Horwitz, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Duvelisib is an oral dual inhibitor of phosphoinositide 3-kinase (PI3K)-δ and PI3K-γ being developed for the treatment of hematologic malignancies. In preclinical investigations, duvelisib potently killed TCL cell lines with constitutive phospho-AKT (S473) and reprogrammed tumor-associated macrophages from an immunosuppressive to immunostimulatory phenotype in PTCL mouse xenograft models (Horwitz, Blood 2017). In a Phase 1 study duvelisib monotherapy demonstrated encouraging clinical activity and an acceptable safety profile (Flinn, Blood 2017), with an overall response rate (ORR) of 50% (3 complete responses [CRs], 5 partial responses [PRs]) in patients (pts) with PTCL (n = 16). These results suggest duvelisib monotherapy may provide a meaningful benefit in relapsed/refractory (RR) PTCL, a population in need of new and effective therapies. **Methods:** This Phase 2, open-label, study of duvelisib monotherapy in adult pts PTCL employs a Dose Optimization Phase (DOP) and an Expansion Phase (EP) (NCT03372057). The primary objectives are to identify the optimal dose of duvelisib and examine the efficacy, safety, and tolerability of duvelisib at the optimal dose. The study will enroll up to 120 pts with histologically confirmed PTCL subtypes of PTCL-NOS, angioimmunoblastic TCL, anaplastic large cell lymphoma, and natural-killer TCL. Disease responses will be measured by ^{18}FDG-PET-CT scanning as assessed by an independent review committee per IWG criteria. The DOP, to be conducted at 4-6 centers in the U.S., will include 20 pts randomly assigned to 1 of 2 parallel cohorts. Cohort 1 will receive a starting dose of 25 mg duvelisib PO BID, with potential sequential escalation to 50 mg and then 75 mg based on responses and tolerance of therapy. Pts in Cohort 2 will receive 75 mg duvelisib PO BID. The EP, to be conducted globally at ~40 centers, will include pts treated at the optimal dose as determined from the DOP. The primary endpoint is ORR (CR + PR) in all pts receiving the optimal dose for at least 1 cycle in either phase. Secondary endpoints include AEs, duration of response, and PFS. This study is open for enrollment. Clinical trial information: NCT03372057.

8000 Oral Abstract Session, Fri, 2:45 PM-5:45 PM

Once-weekly vs twice-weekly carfilzomib (K) dosing plus dexamethasone (d) in patients with relapsed and refractory multiple myeloma (RRMM): Results of the randomized phase 3 study A.R.R.O.W. *First Author: Maria-Victoria Mateos, Hematology, Hospital Clinico Universitario de Salamanca-IBSAL, Salamanca, Spain*

Background: Twice-weekly K at 20/27 mg/m^2 is approved for the treatment of RRMM. To develop a more convenient K regimen, once-weekly K plus d was assessed in the phase 1/2 CHAMPION-1 study, establishing a maximum tolerated dose of K 20/70 mg/m^2 for RRMM pts. We present results from the pre-planned interim analysis of the phase 3 study A.R.R.O.W. comparing Kd once-weekly at 20/70 mg/m^2 (once-weekly group) vs twice-weekly at 20/27 mg/m^2 (twice-weekly group). **Methods:** Pts with 2–3 prior therapies and prior exposure to proteasome inhibitor and immunomodulatory agent were eligible. Pts were randomized 1:1 to receive either once- or twice-weekly K plus d. The once-weekly group received K (30-min IV) on days (D) 1, 8, and 15 of all cycles (20 mg/m^2 on D1 [cycle 1]; 70 mg/m^2 thereafter). The twice-weekly group received K (10-min IV) on D1, 2, 8, 9, 15, and 16 (20 mg/m^2 on D1 and 2 during cycle 1 and 27 mg/m^2 thereafter). All pts received d at 40 mg on D1, 8, 15 (all cycles), and 22 (cycle 1–9 only). Treatment was given in 28-day cycles until disease progression or unacceptable toxicity. The primary endpoint was progression-free survival (PFS). Secondary endpoints were overall response rate (ORR), overall survival, safety, and pharmacokinetics. **Results:** Baseline characteristics were generally balanced. Median PFS (once- vs twice-weekly) was 11.2 mo vs 7.6 mo (hazard ratio = 0.69; 1-sided P= 0.0014). ORR (once- vs twice-weekly) was 62.9% vs 40.8% (P< 0.0001); 7.1% vs 1.7% had a complete response or better. Grade ≥3 adverse events (AEs) occurred in 67.6% (once-weekly) and 61.7% (twice-weekly). Treatment-related grade 5 AEs occurred in 5 pts (2.1%) (once-weekly) and 2 pts (0.9%) (twice-weekly). The incidence of grade ≥3 hypertension and cardiac failure (once- vs twice-weekly) was 5.9% vs 5.5% and 2.9% vs 4.3%, respectively. **Conclusions:** Once-weekly Kd at 20/70 mg/m^2 significantly improved PFS and ORR vs twice-weekly Kd at 20/27 mg/m^2. The incidence of AEs was comparable between groups. No new safety risks were found in the once-weekly group. Overall, once-weekly Kd showed favorable benefit-risk profile with a convenient dosing regimen vs twice-weekly Kd. Clinical trial information: NCT02412878.

8001 Oral Abstract Session, Fri, 2:45 PM-5:45 PM

Pomalidomide (POM), bortezomib, and low-dose dexamethasone (PVd) vs bortezomib and low-dose dexamethasone (Vd) in lenalidomide (LEN)-exposed patients (pts) with relapsed or refractory multiple myeloma (RRMM): Phase 3 OPTIMISMM trial. *First Author: Paul G. Richardson, Jerome Lipper Multiple Myeloma Center, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA*

Background: POM, a standard-of-care treatment (Tx) in RRMM, has demonstrated synergistic anti-myeloma activity with dexamethasone (DEX) and proteasome inhibitors (PIs). POM + DEX is indicated for RRMM after ≥ 2 prior Txs including LEN and a PI, and is the only Tx to be investigated exclusively after LEN. As LEN becomes increasingly established in up-front Tx of MM, pts who have exhausted the benefit of LEN represent a clinically relevant unmet medical need. In preclinical studies, POM inhibited proliferation of LEN-resistant cells. Here we report final PFS and safety data from the first phase 3 POM triplet trial comparing PVd vs Vd in an entirely post-LEN treated population. **Methods:** Pts with RRMM, 1-3 prior Tx lines, and ≥ 2 cycles (c) of prior LEN were randomized 1:1 to receive PVd or Vd. In 21-d c, pts received POM 4 mg/d on d 1-14 (PVd arm only); BORT 1.3 mg/m² on d 1, 4, 8, and 11 of c 1-8 and on d 1 and 8 of c 9+; and DEX 20 mg/d (10 mg if aged > 75 yrs) on the days of and after BORT. The primary endpoint was PFS. **Results:** 559 pts were enrolled: 281 PVd and 278 Vd. Median age was 67 and 68 yrs, respectively. All pts had prior LEN (71% vs 69% LEN refractory), 72% vs 73% had prior BORT, and 70% vs 66% were refractory to last Tx. Median prior Tx lines was 2; 40% in PVd and 41% in Vd arm had 1 prior Tx line. After a median follow-up of 16 mos, PVd significantly reduced the risk of progression or death by 39% vs Vd (Table). OS data are not mature. Most common grade 3/4 treatment-emergent AEs were neutropenia (42% vs 9%), infections (31% vs 18%), and thrombocytopenia (27% vs 29%). **Conclusions:** To date, OPTIMISMM is the only phase 3 study in early RRMM to report a significant and clinically meaningful PFS improvement in pts who were entirely LEN exposed and 70% LEN refractory. Furthermore, the results showed improved benefit in pts with only 1 prior Tx line. POM safety remained manageable, consistent with its known profile. Clinical trial information: NCT01734928.

Efficacy.

	ITT		1 Prior Tx Line

8002 Oral Abstract Session, Fri, 2:45 PM-5:45 PM

Daratumumab (DARA) in combination with carfilzomib and dexamethasone (D-Kd) in lenalidomide (Len)-refractory patients (Pts) with relapsed multiple myeloma (MM): Subgroup analysis of MMY1001. *First Author: Ajai Chari, Tisch Cancer Institute, Mount Sinai School of Medicine, New York, NY*

Background: Len-refractory pts have poor outcomes, highlighting an unmet medical need. In the phase 1b MMY1001 study (NCT01998971), D-Kd induced deep responses and was well tolerated in pts with relapsed MM. We examined the safety and efficacy of D-Kd in len-refractory pts. **Methods:** In total, 85 carfilzomib (carf)-naïve pts with 1-3 prior lines of therapy were enrolled. Pts received carf (20 mg/m^2 on Cycle 1 Day 1 [C1D1] and 70 mg/m^2 on C1D8+) on days 1, 8, and 15 of 28-day cycles and dexamethasone 40 mg QW. DARA was given QW C1-C2, Q2W C3-C6, and Q4W thereafter; 10 pts received a standard first dose of DARA (16 mg/kg) on C1D1, and 75 pts received a split first dose of DARA (8 mg/kg on C1D1 and C1D2). Refractoriness was defined as progression ≤60 days of completion of last line of therapy. **Results:** Among len-refractory pts (n = 51) in the MMY1001 D-Kd arm, median age was 66 yrs (range 38-85 yrs). Pts had received a median of 2 (range 1-4) prior lines of therapy; 98% had received bortezomib (bort), 18% had received pomalidomide (pom), 43% were refractory to bort, and 18% were refractory to pom. In total, 20 pts (39%) discontinued due to progressive disease (26%), adverse events (AEs; 6%), pt withdrawal (6%), or physician decision (2%). The most common hematologic grade 3/4 treatment-emergent AEs (TEAEs; ≥10%) were thrombocytopenia (37%), anemia (29%), neutropenia (28%), and lymphopenia (26%). Infusion-related reactions were observed in 37% of pts (43% for standard first DARA dose; 36% for split first DARA dose); none were grade 3/4. With 8.3 months of median follow up, median PFS was 14.1 months (95% CI 9.4-not estimable); the 12-month PFS rate was 69% (95% CI 49-82). ORR and MRD-negative rates are summarized in the Table. Median time to MRD negativity (10^{-5}) was 5.1 months. **Conclusions:** The combination of DARA and weekly Kd was well tolerated and demonstrated promising efficacy in len-refractory pts. Updated data will be presented. Clinical trial information: NCT01998971.

8003 Oral Abstract Session, Fri, 2:45 PM-5:45 PM

Randomized phase 3 trial of ibrutinib/rituximab vs placebo/rituximab in Waldenström's macroglobulinemia. *First Author: Meletios A. Dimopoulos, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece*

Background: Single-agent ibrutinib (ibr) is highly active in relapsed Waldenström's Macroglobulinemia (WM) and is approved in the US and EU for WM. We report the results of a multinational, prospective, randomized trial of ibr/rituximab (IR) vs placebo/rituximab (R) in WM at a preplanned interim analysis. **Methods:** Pts with confirmed symptomatic WM were randomized to daily ibr (420 mg) or placebo, both with R (375 mg/m^2/wk IV for infusions at wks 1-4 and 17-20). Pts treated with a prior R-based regimen required a response (≥MR) to the last R therapy. The primary endpoint was PFS by IRC. We also report response rates, Hb improvement, TTnT, OS, and safety. **Results:** For 150 randomized pts, median age was 69 y; 38% had a high IPSSWM; 45% were treatment-naïve. MYD88^{L265P} and CXCR4^{WHIM} mutations were found in 85% and 36% of 136 pts with available data. At median follow-up of 26.5 mo, IR prolonged PFS compared with R (median PFS, not reached [NR] vs 20 mo; HR, 0.20; CI: 0.11-0.38, P < 0.0001); 30-mo PFS rates were 82% vs 28%. PFS improved in all relevant subgroups, including treatment-naïve (HR, 0.34; CI: 0.12-0.95), relapsed (HR, 0.17; CI: 0.08-0.36), MYD88^{L265P}/CXCR4^{WT} (HR, 0.17; CI: 0.06-0.49), MYD88^{L265P}/CXCR4^{WHIM} (HR, 0.24; CI: 0.09-0.66), and MYD88^{WT}/CXCR4^{WT} (HR, 0.21; CI: 0.04-1.1). Overall (≥MR) and major (≥PR) response rates by IRC were higher for IR vs R, 92% vs 47% and 72% vs 32% (both P < 0.0001). Improvements in Hb were seen in 73% vs 41% of IR and R patients (P < 0.0001). 75% of IR pts continued on treatment. Median TTnT was NR for IR and 18 mo for R (HR, 0.096; P < 0.0001). The 30-mo OS rates were 94% vs 92% in the 2 arms. With median time on treatment of 25.8 mo for IR, grade ≥3 treatment-emergent AEs occurred in 60% vs 61% of pts on each arm. Serious AEs occurred in 43% vs 33% of pts on IR vs R, whereas no fatal AEs occurred with IR and 3 with R. Meaningful reductions in any grade IgM flare (8% vs 47%) and grade ≥3 infusion reactions were observed (1% vs 16%) with IR. **Conclusions:** The IR combination demonstrated superior efficacy to R, producing significant improvements in PFS for all WM patients regardless of prognostic or genotypic factors with a predictable toxicity profile. IR should be considered a standard therapeutic option for patients with WM. Clinical trial information: NCT02165397.

8004 **Oral Abstract Session, Fri, 2:45 PM-5:45 PM**

Phase 2 study of venetoclax plus carfilzomib and dexamethasone in patients with relapsed/refractory multiple myeloma. *First Author: Luciano J. Costa, University of Alabama at Birmingham, Troy, AL*

Background: The BCL-2 inhibitor venetoclax (VEN) has demonstrated efficacy, as monotherapy and combined with PI bortezomib, in relapsed/refractory (R/R) multiple myeloma (MM). We report preliminary data for VEN combined with second generation PI carfilzomib and dexamethasone (VENKd) in R/R MM. **Methods:** In this ongoing phase 2, dose escalation study (NCT02899052), pts with R/R MM received VENKd on 28-d cycles: VEN 400 mg/day + K 27 mg/m^2 d1,2,8,9,15,16+ dex 40 mg d1,8,15,22 (Cohort 1), same regimen but with VEN 800 mg/day (Cohort 2), VEN 800 mg/day + K 70 mg/m^2 d1,8,15 + dex 40 mg d1,8,15, 22 (Cohort 3/expansion cohort), or VEN 800 mg + K 56 mg/m^2 d1,2,8,9,15,16 + dex 40 mg d1,2,8,9,15,16,22,23 (optional Cohort 4; no data available at cutoff). Treatment continued until progressive disease (PD) or unacceptable toxicity. **Results:** As of 01Dec2017, 26 pts were enrolled. Median age was 67.5 years (40 – 79), 68% had ISS II/III disease, and 23% had t(11;14). Pts received a median of 1 prior therapy (1 – 3); no pts had prior K exposure, 96% had received prior PI (54% refractory), 62% were IMiD refractory, and 35% double refractory. At data cut off, 23 pts were on therapy for 0.3 – 10 months and 3 pts discontinued the study for PD, physician decision, and death. 85% of pts had an AE, grade 3/4 AEs were neutropenia (15%), hypertension (12%), thrombocytopenia (8%), decreased white blood cells (8%), and nausea (4%). 7 serious AEs occurred, but no dose-limiting toxicities were reported. Maximum tolerated dose was not reached and Cohort 3 is being expanded. VEN pharmacokinetics with Kd were comparable to VEN plus bortezomib and dexamethasone. Of 17 pts evaluated after completing ≥2 cycles, 3 had complete response (CR), 2 very good partial response (VGPR), 3 partial response (PR), 3 stable disease, and 2 PD (awaiting response data for 4 pts). Median time to first response was 1 month. Of 5 evaluable pts with t(11;14) MM, 1 achieved CR, 1 VGPR, 3 PR. **Conclusions:** VENkd is well tolerated with promising preliminary efficacy that supports study in pts with R/R MM. Accrual continues with 34 pts enrolled to date. Updated safety and efficacy results will be available for presentation. Clinical trial information: NCT02899052.

8005 **Oral Abstract Session, Fri, 2:45 PM-5:45 PM**

A phase 1 trial of ruxolitinib, lenalidomide, and methylprednisolone for relapsed/refractory multiple myeloma patients. *First Author: James R. Berenson, Institute for Myeloma & Bone Cancer Research, West Hollywood, CA*

Background: Preclinical studies from our laboratory have demonstrated that ruxolitinib (RUX) in combination with lenalidomide (LEN) and dexamethasone shows marked anti-myeloma effects both *in vitro* and *in vivo*. Furthermore, MUC1 is responsible for LEN resistance in MM cells, and RUX blocks its expression in MM cells. Thus, RUX may restore sensitivity to LEN. Therefore, a phase 1 trial was conducted to determine the safety and efficacy of RUX in combination with LEN and methylprednisolone (MP) for relapsed/refractory (RR)MM patients (pts) who had previously been treated with LEN/steroids and a PI and showed progressive disease at study entry. **Methods:** A traditional 3+3 dose escalation design was used to enroll subjects in four cohorts with planned total enrollment to be 28 pts. Subjects received RUX twice daily continuously, LEN daily on d1-21 of a 28-d cycle and MP orally every other day. In DL0, pts received RUX 5 mg, LEN 5 mg, and MP 40 mg. In DL+1 and +2, both doses of LEN and MP remained unchanged and RUX was escalated to 10 and 15 mg, respectively. DL+3 escalated LEN to 10 mg with MP unchanged and RUX at 15 mg. **Results:** As of February 1, 2018, 28 pts had been enrolled, and 21 were evaluable. The median age was 66 years (range, 63-81), and 29 (55%) were male. Pts received a median of 6 prior treatments (range, 2-11). No DLTs occurred, and DL+3 was expanded. Among evaluable pts, the CBR and ORR were 48% and 33%, respectively (1 CR, 6 PR and 3 MR), and 7 and 4 showed SD and PD. G3 AEs included transient thrombocytopenia (14.3%), anemia (9.5%) and gastrointestinal bleeding (9.5%). SAEs included a humeral fracture (4.8%), a cerebral vascular accident from a pt with atrial fibrillation who discontinued his anticoagulation (4.8%), renal insufficiency (4.8%), sepsis (4.8%), and neutropenic sepsis (4.8%). **Conclusions:** This Ph 1 trial demonstrates for the first time that a JAK inhibitor, RUX, can overcome refractoriness to LEN and steroids for RRMM pts. These promising results are leading to other clinical trials with immunomodulatory agents and steroids with RUX as well as expansion of the current clinical trial to 49 pts, and may represent a new therapeutic approach for treating MM. Clinical trial information: NCT03110822.

Phase II study of ex vivo expanded cord blood natural killer cells for multiple myeloma. *First Author: Nina Shah, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Multiple myeloma (MM) is an incurable disease with immune dysregulation and exhaustion. Remissions in some patients (pts) after allo-stem cell transplant (SCT) suggest a graft versus myeloma effect; however toxicity limits its widespread use. Allogeneic natural killer (NK) cells are safe and potentially active against various hematologic malignancies, including MM. We previously demonstrated safety of ex vivo expanded cord blood (CB) derived NK cells in doses up to 1 e8 cells/kg in the setting of high dose melphalan and auto-SCT (ASCT) (Shah et al, Br J Haematol 2017). Here we present results of the phase II portion of our study. **Methods:** Pts with symptomatic MM who were appropriate candidates for ASCT were eligible. CB units with at least 4/6 match at HLA-A, B and DR were chosen for each pt. When possible, CB units with potential NK alloreactivity (KIR-HLA mismatch) were prioritized. Due to pre-clinical data demonstrating synergy between lenalidomide and NK cells, patients received lenalidomide (10 mg daily) from days (-8) to day (-2). Melphalan 200 mg/ m^2 was given intravenously on day (-7). Freshly expanded CBNK cells were infused on day (-5). Autologous peripheral blood progenitor cells were infused on day (0). **Results:** 33 patients were enrolled. 24/33 (74%) pts had at least 1 of the following adverse features: high risk cytogenetics/FISH (del1p, amp1q, t(4;14), t(14;20), t(14;16), del (17p), cyotgenetic del (13)), history of progression/relapse or ISS III disease. Successful expansion to target dose (1 e8 cells/ kg) was achieved in all but 3 patients (who received 5 e7 cells/kg). There were no toxicities associated with the CB NK cell infusions. Responses at 3 months were CR:18/33 (55%); VGPR: 4/33 (12%); PR: 7/33 (21%). Best response was CR: 21/33 (65%); VGPR: 6/33 (18%); PR: 3/33 (9%). With a median follow-up time of 22 months, 10 pts have progressed and 3 have died. Median PFS has not been reached. By DNA microsatellite chimerism analysis, donor CB-NK cells were detected 1-13 days after infusion for 25/33 (76%) pts. **Conclusions:** In this relatively high risk MM population, CBNK cells in the setting of auto-SCT is a promising adjunct immunotherapy. Updated data and correlative analyses will be presented at the annual meeting. Clinical trial information: NCT01729091.

bb2121 anti-BCMA CAR T-cell therapy in patients with relapsed/refractory multiple myeloma: Updated results from a multicenter phase I study. *First Author: Noopur S. Raje, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: bb2121 is a second-generation chimeric antigen receptor (CAR) T cell therapy targeting B cell maturation antigen (BCMA) to redirect T cells to recognize and kill malignant myeloma cells. Initial data from the dose-escalation (DE) phase of CRB-401, a first-in-human study of bb2121 in relapsed/refractory multiple myeloma (RRMM), have shown promising efficacy and safety. We report updated safety and efficacy results on 43 patients (pts) enrolled in this ongoing study. **Methods:** CRB-401 (NCT02658929) is a 2-part, phase I study of bb2121 in pts with RRMM. DE pts had received ≥ 3 prior lines of therapy including a proteasome inhibitor and an immunomodulatory agent, or were double refractory, and had ≥ 50% BCMA expression on plasma cells. In the dose-expansion (Exp) phase, pts had to have received daratumumab and been refractory to last line of therapy; no BCMA expression was required. Following lymphodepletion with Flu (30 mg/m^2)/Cy (300 mg/m^2) given daily for 3 days, pts received 1 infusion of bb2121. **Results:** As of 02 Oct 2017, 21 pts had received bb2121 in the 4 DE cohorts (median follow-up, 35 weeks); no DLTs and no grade ≥ 3 neurotoxicities (NTX) were observed. Cytokine release syndrome (CRS), primarily grade 1-2, was reported in 15 of 21 (71%) pts; 2 pts had grade ≥ 3 CRS that resolved in 24 hours. There were 2 deaths on study; both pts had achieved complete response (CR) and had not progressed. Overall response rate in the 18 evaluable pts in DE cohorts ≥ 150 × 10^6 CAR T cells was 94%; 10 of 18 (56%) pts had CR or unconfirmed CR; 9 of 10 evaluable pts were MRD-negative. With a median follow-up of 40 weeks in ≥ 150 × 10^6 DE cohorts, median response duration and progression-free survival (PFS) had not been reached; PFS rates at 6 and 9 months were 81% and 71%, respectively. Doses of 150 to 300 × 10^6 CAR T cells were selected for the Exp phase. Results from an additional 5 months of follow-up and initial data from ~20 pts from the Exp cohort will be presented. **Conclusions:** bb2121 shows promising efficacy at dose levels ≥ 150 × 10^6 CAR T cells with deep and durable ongoing responses and manageable CRS and NTX. These data support the potential of bb2121 anti-BCMA CAR T cell therapy as a new treatment paradigm for RRMM. Clinical trial information: NCT02658929.

8008 Oral Abstract Session, Fri, 2:45 PM-5:45 PM

FDA analysis of pembrolizumab trials in multiple myeloma: Immune related adverse events (irAEs) and response. *First Author: Aviva C Krauss, US Food and Drug Administration, Silver Spring, MD*

Background: Development of irAEs with checkpoint inhibition may be associated with response in some disease settings. **Methods:** We evaluated overall survival (OS), safety and objective response rates (ORR) among patients who developed irAEs and those who did not in two trials of pembro in MM. KEYNOTE 183 (KN183) evaluated pomalidomide and dexamethasone (PomDex) with or without pembro in patients with relapsed/refractory (RR) MM, and KEYNOTE 185 (KN185) evaluated lenalidomide and dexamethasone (LenDex) with or without pembro in patients with newly diagnosed (ND) MM ineligible for autologous stem cell transplant. FDA placed both trials on clinical hold in July 2017 due to worse OS in the pembro-containing arms. **Results:** Using a June 2, 2017 data cut-off: median follow-up on KN183 was 8.1 months, 249 patients were randomized. There were 29 deaths in the pembro arm and 21 in the control arm, for an OS hazard ratio (HR) of 1.61 (95% CI: 0.91, 2.85). ORR was 34% in the pembro arm and 40% in the control arm. Median follow-up on KN185 was 6.6 months, 301 patients were randomized. There were 19 deaths in the pembro arm and 9 in the control arm, for an OS HR of 2.06 (95% CI: 0.93, 4.55). ORR was 64% in the pembro arm and 62% in the control arm. Neither trial showed a difference in time-to-progression between arms. In KN183, 58% of patients on the pembro arm developed an irAE, with an ORR of 37%, not significantly different than the 31% in those without an irAE. A trend was noted for improved ORR (49%) in those on the control arm (PomDex) with an irAE, compared to 33% in those without an irAE. In contrast, ORR in patients with NDMM in KN185 who developed an irAE were higher than in those who did not. **Conclusions:** The utility of immunotherapy in patients unable to mount adequate immune responses merits further study, as does the worse OS observed in both trials.

8009 Poster Discussion Session; Displayed in Poster Session (Board #18), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 3:00 PM-4:15 PM

Updated efficacy data and MRD analysis according to risk status in newly diagnosed myeloma patients treated with carfilzomib + lenalidomide or cyclophosphamide (FORTE trial). *First Author: Francesca Maria Gay, Myeloma Unit, Division of Hematology, University of Torino, Torino, Italy*

Background: Carf plus Len-Dex (KRd) or Cyclo-Dex (KCd) is effective in NDMM. Treatment of high-risk pts is an unmet medical need. **Methods:** NDMM pts ≤65 yrs were randomized (1:1:1; stratification ISS and age) to ARM A: 4 28-day induction cycles with KCd (Carf: 20/36 mg/m^2 IV days 1,2,8,9,15,16; Cyclo: 300 mg/m^2 days 1,8,15; Dex: 20 mg days 1,2,8,9,15,16) followed by MEL200-ASCT and consolidation with 4 KCd; ARM B: 4 28-day cycles with KRd (Carf: 20/36 mg/m^2 IV days 1,2,8,9,15,16; Len: 25 mg days 1-21; Dex: 20 mg days 1,2,8,9,15,16) followed by MEL200-ASCT and 4 KRd; ARM C: 12 KRd cycles. Primary endpoint was VGPR rate with KRd vs KCd induction. For this analysis, the 2 KRd arms were pooled (2:1), as treatment was the same until that point. Enrollment was completed in March, 2017; data cut-off was November 30, 2017. **Results:** 474 pts were randomized (KRd, n = 315; KCd, n = 159). Pts characteristics were well balanced: 49% of KRd pts vs 49% of KCd pts had ISS Stage 2-3 at baseline, 31% vs 35% had high-risk chromosomal abnormalities [del17 and/or t(4;14) and/or t(14;16) by FISH], 68% vs 74% had Revised ISS Stage 2-3. Rates of sCR/CR (14% vs 3%; P = 0.0004), ≥nCR (33% vs 21%; P = 0.0106) and ≥VGPR (75% vs 60%; P = 0.0017) were significantly higher with KRd vs KCd. The advantage of KRd was consistent in all subgroups; ≥VGPR, ≥nCR in high-risk pts treated with KRd were comparable to the overall population. MRD evaluation (8 color second generation flow cytometry, sensitivity 10^{-5}) was available in a subset of pts: 144 KRd and 56 KCd. Rate of MRD negativity in evaluable pts was 56% with KRd vs 29% with KCd (P = 0.008). MRD negativity in high-risk pts treated with KRd was comparable to the overall population (Table). Treatment was well tolerated, as previously shown (Gay F ASCO 2017). **Conclusions:** KRd induction significantly improved sCR/CR, ≥ nCR, ≥VGPR rates and MRD negativity vs KCd with similar efficacy in high-risk pts. Clinical trial information: NCT02203643.

A phase 3 randomized study of pembrolizumab (pembro) plus lenalidomide (len) and low-dose dexamethasone (Rd) versus Rd for newly diagnosed and treatment-naive multiple myeloma (MM): KEYNOTE-185. *First Author: Saad Zafar Usmani, Levine Cancer Institute, Charlotte, NC*

Background: KEYNOTE-185 (NCT02579863) evaluated Rd ± pembro in patients (pts) with newly diagnosed, ASCT-ineligible MM. **Methods:** Pts were randomized 1:1 to pembro (200 mg Q3W) + Rd (len 25 mg [days (d) 1-21] + 40 mg dex [weekly] every 28d) vs Rd until progression (PD), unacceptable toxicity, or withdrawal. Randomization stratified by age (< 75 vs ≥75 y), and disease stage (ISS I or II vs III). Primary end point was PFS per 2011 IMWG; secondary end points included OS and safety. On July 3, 2017, based on interim data presented to the DMC, the FDA halted KEYNOTE-185. **Results:** 301/640 pts enrolled (151, pembro-Rd; 150, Rd), with median (range) age: 74 y (53-89) vs 74 y (57-91); 24 (16%) pts in pembro-Rd am vs 10 (7%) pts in Rd arm had high-risk cytogenetics. Median (range) drug exposure was 131.0 d (1-485) in pembro-Rd arm vs 162 d (1-467) in Rd arm; median 6.0 cycles. AEs with ≥5% difference between arms: constipation, pyrexia, rash, vomiting, decreased appetite, pneumonia, oral candidiasis, pruritus, hypo-/hyperthyroidism. No SAEs with ≥5% difference between arms. In pembro + Rd arm, immune-mediated AEs (≥2%): hypothyroidism (7%), hyperthyroidism (6%), colitis (2%), and skin reactions (13%). 19 (13%) pts died in the pembro-Rd arm (6 from PD, 13 from AEs); 5/19 deaths were high risk. 9 (6%) pts died in the Rd arm (1 from PD, 8 from AE); 0/9 were high-risk. 6 (4%) treatment related deaths occurred; 4 (3%) [1 cardiac arrest, 1 pneumonia; 1 myocarditis, 1 cardiac failure]) were related to pembro. Median duration of follow-up was 6.4 mo vs 6.9 mo. Median TTP was not reached in either arm. Median PFS was not reached in either arm; HR, 1.22 (95% CI, 0.67-2.22); *P*= 0.75. Median OS was not reached in either arm; HR, 2.06 (95% CI, 0.93-4.55); *P*= 0.97. A retrospective random forest analysis and a subsequent multivariable Cox regression analysis led to no conclusive results due to the small number of death events (< 10%) at time of analysis. **Conclusions:** Benefit-risk profile for combination of pembro-Rd is unfavorable for newly diagnosed MM. Evaluation of T-cell subsets and cytokines along with long-term safety and survival follow-up is ongoing. Clinical trial information: NCT02579863.

8011 Poster Discussion Session; Displayed in Poster Session (Board #20), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 3:00 PM-4:15 PM

Subcutaneous daratumumab (DARA SC) plus cyclophosphamide, bortezomib, and dexamethasone (CyBorD) in patients (Pts) with newly diagnosed amyloid light chain (AL) amyloidosis: Safety run-in results of andromeda. *First Author: Ray Comenzo, Division of Hematology/Oncology, John C. Davis Myeloma and Amyloid Program, Tufts Medical Center, Boston, MA*

Background: Systemic AL amyloidosis is characterized by disposition of insoluble amyloid fibrils into tissues and organs via clonal expansion of CD38$^+$ plasma cells. The safety run-in of DARA SC + CyBorD in ANDROMEDA (NCT03201965) is presented. **Methods:** Eligible pts had ≥1 involved organs, ECOG score ≤2, absolute neutrophil count ≥1.0 × 10^9/L; hemoglobin ≥8.0 g/dL; platelet count ≥50 × 10^9/L; estimated glomerular filtration rate ≥20 mL/min/1.73m^2, and NT-ProBNP ≤8,500 ng/L. In the safety run-in, pts received a concentrated co-formulation of DARA (1,800 mg in 15 mL) and recombinant human hyaluronidase enzyme (rHuPH20; 30,000 U) in a single, pre-mixed vial, given by manual SC injection qw in Cycles 1-2, q2w in Cycles 3-6, and q4w thereafter ≤2 y. Cy 300 mg/m^2 PO or IV and Bor 1.3 mg/m^2 SC were given on Days 1, 8, 15, 22 of each 28-day cycle for ≤6 cycles and D 40 mg was given qw. Dosing was staggered ≥48 hours between pts to assess infusion related reactions (IRRs). Safety was evaluated after ≥10 pts received ≥1 treatment cycle. **Results:** Pts (n = 15) had a median (range) age of 63 (35-77) y and a median of 58 (15-157) d from diagnosis. Pts had a median of 1 (1-3) involved organ, with kidney involvement affecting 67% of pts and 40% of pts with ≥2 organs involved. At baseline, 73% and 27% of pts were grouped into New York Heart Association class I and II, respectively, and 93% of pts had an ECOG score of ≤1. Pts received a median of 2 (1-4) treatment cycles and a median of 5 (1-10) DARA injections. Most common (> 2 pts) treatment emergent adverse events (TEAEs) were nausea (47%), diarrhea (33%), fatigue (33%), injection site erythema (20%), anemia (20%), and rash (20%). Dyspnea and peripheral edema were reported in 1 (7%) pt each. One grade 3/4 TEAE (hypertension; unrelated to treatment) and no serious TEAEs occurred. IRRs occurred in 2 (13.3%) pts (all grade 1). Additional data will be presented. **Conclusions:** DARA-CyBorD is tolerable in pts with AL amyloidosis with a low IRR rate and no new safety signals. The limited incidence of dyspnea and peripheral edema indicate a low risk for volume overload. Randomization into ANDROMEDA has begun. Clinical trial information: NCT03201965.

8012 Poster Discussion Session; Displayed in Poster Session (Board #21), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 3:00 PM-4:15 PM

A phase II study of elotuzumab in combination with pomalidomide, bortezomib, and dexamethasone in relapsed and refractory multiple myeloma. *First Author: Andrew Jenho Yee, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Elotuzumab is an approved monoclonal antibody targeting SLAMF7 on NK cells and plasma cells that enhances the activity of lenalidomide and bortezomib in multiple myeloma (MM). We studied elotuzumab with pomalidomide, bortezomib, and dexamethasone (elo-PVD) in relapsed and refractory MM. **Methods:** The primary objective was to determine the overall response rate (ORR). Patients with refractory disease and ≥1 prior lines of treatment (including lenalidomide and a proteasome inhibitor) were eligible to participate. Elotuzumab was weekly for the first 2 cycles and then every other week. Pomalidomide was on days 1-21; bortezomib was on days 1, 8, 15; and dexamethasone was weekly. Each cycle was 28 days. **Results:** At time of data cutoff, 33 patients (pts) who started treatment were evaluable. The median age was 64 (range 52-79), and the median number of prior regimens was 3 (range 1-9); 27% had high risk FISH. All pts had prior lenalidomide and proteasome inhibitors (bortezomib 94%, 76% carfilzomib) and were refractory to their last line of therapy. Prior therapies also included: auto SCT (45%), pomalidomide (36%), daratumumab (21%), and isatuximab (3%). 31 pts were assessable for response (2 patients did not complete cycle 1 due to rapid disease progression or stroke and were not evaluable). The median length of follow up was 3.3 months (range 0.5-18.2): 23 pts continue on study; 7 pts discontinued for progressive disease and 3 pts discontinued for adverse events (AEs) (sepsis, pneumonia, or stroke). Best ORR was 52% (PR = 11, VGPR = 4, CR = 1); ORR for pts with prior anti-CD38 antibody, 43%; carfilzomib, 43%; pomalidomide, 40%. Median PFS was 9.7 months (95% CI 7.5-Inf). Grade 3-4 hematologic AEs included anemia (7%), neutropenia (34%), and thrombocytopenia (17%). Common non-hematologic AEs all grades included fatigue (38%), upper respiratory infection (38%), constipation (38%), hyperglycemia (38%), and neuropathy (38%, Gr 1-2 only), with 2 possibly related deaths (sepsis, pneumonia). **Conclusions:** Elo-PVD shows encouraging responses in patients with refractory MM. Treatment was well-tolerated with manageable toxicity and attention to infectious AEs. Clinical trial information: NCT02718833.

8013 Poster Discussion Session; Displayed in Poster Session (Board #22), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 3:00 PM-4:15 PM

Subcutaneous daratumumab (DARA) in patients (Pts) with relapsed or refractory multiple myeloma (RRMM): Part 2 update of the open-label, multicenter, dose escalation phase 1b study (PAVO). *First Author: Ajai Chari, Tisch Cancer Institute, Mount Sinai School of Medicine, New York, NY*

Background: Intravenous (IV) administration of DARA 16 mg/kg is approved as monotherapy and in combination with standard of care regimens for RRMM. The phase 1b PAVO study (NCT02519452) demonstrated that delivery of DARA with recombinant human hyaluronidase enzyme (rHuPH20) by subcutaneous (SC) infusion through a syringe pump (Part 1) or by manual SC injection (Part 2) was well tolerated with an efficacy profile consistent with IV DARA (Chari A, et al. ASH 2017; abstract 838). We present updated data from Part 2. **Methods:** Eligible pts received ≥2 prior lines of therapy (LOTs) including a proteasome inhibitor and an immunomodulatory drug. In Part 2, pts received a concentrated co-formulation of DARA (DARA SC; 1,800 mg in 15 mL) and rHuPH20 (30,000 U) dose in a single, pre-mixed vial, which was administered in 3 to 5 minutes by manual SC injection. Primary endpoints were C_{trough} of DARA at the end of weekly dosing on Cycle 3 Day 1 (C3D1) and safety. Secondary endpoints included overall response rate (ORR), rate of complete response, time to response, and duration of response. **Results:** Pts in Part 2 (n = 25) had a median age of 68 years and received a median of 3 prior LOTs. At a median follow-up of 4.6 months, none discontinued due to treatment-emergent adverse events (TEAEs). Pharmacokinetic analyses indicated that DARA SC had a T_{max} of approximately 72 h and achieved similar or greater C_{trough} on C3D1 compared to what has been observed with DARA IV. Most common Grade 3/4 TEAEs (> 1 pt) were lymphopenia (16%), thrombocytopenia (8%), and neutropenia (8%). IRRs were reported in 3 (12%) pts, all occurring ≤6 h of the first injection. No grade 4 IRRs or discontinuations due to IRRs occurred. DARA SC injections in the periumbilical area were well tolerated with reversible erythema observed in 20% of pts. DARA SC achieved an ORR of 44%, including 28% ≥very good partial response. **Conclusions:** DARA SC, which enables dosing in 3-5 minutes, was well tolerated with low IRR rates, had an acceptable PK profile, and demonstrated clinical response rates similar to DARA-IV. Updated data based on longer follow-up will be presented at the meeting. Clinical trial information: NCT02519452.

Phase I-b study of isatuximab + carfilzomib in relapsed and refractory multiple myeloma (RRMM). *First Author: Ajai Chari, Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Isatuximab (ISA) is an anti-CD38 mAb with potent anti-myeloma effects as monotherapy or together with lenalidomide (Len) + dexamethasone (d) in RRMM. Carfilzomib (K) is a proteasome inhibitor approved for use in RRMM as a single agent or in combination (Kd or LenKd). Objectives: The primary objective was to assess the maximum tolerated dose (MTD) of ISA + K in RRMM. Secondary objectives were assessment of safety, PK, immunogenicity, and efficacy (IMWG response criteria (ORR)). (NCT02332850) **Methods:** Eligible patients (pts) had disease progression after 2 prior lines, an ECOG < 3, and adequate organ function. A 3+3 dose escalation (DE) design was utilized. 3 dosing levels (DL) were tested: ISA 10 mg/kg Q2W, ISA 10 mg/kg QW x 4 then Q2W and ISA 20 mg/kg QW x 4 then Q2W in combination with K standard dose (27 mg/m2) and schedule. An expansion cohort (EC) of 18 pts was enrolled at DL2. **Results:** 15 pts were treated in DE and 18 in the EC. The median age (n = 33) was 61 yrs (range 39-79). Pts received a median of 3 (2-8) prior lines. All pts were IMid and PI exposed: 26/29 Len refractory (Refr), 21/29 Vel Refr, 13/29 Pom Refr and 8/11 K Refr. Median follow-up is 6.5m (0.5 – 24m). 29 pts are evaluable for response. ORR = 66% (1 sCR, 7 VGPR, 11 PR) and CBR is 86%. The median progression free survival has not been reached. Disposition: 15 pts have progressed (4 deaths from PD), 1 pt withdrew after 27 cycles and 17 remain on therapy. The median # of cycles given is 3 (range 1-27). No DLT or severe toxicity has been observed. Common adverse events (AEs-all grades, incidence ≥ 15%), were thrombocytopenia (66%), pain (60%), upper respiratory infection (56%), diarrhea (40%), fatigue (40%), anemia (33%), cough (33%), elevated creatinine (30%), nausea (30%), neutropenia (27%), headache (27%), dyspnea (16.7%) and fever (16.7%). Serious AEs occurred in 9pts and < 5% of AEs were Gr 3/4. Infusion reactions (IRs) were the most common ISA-related AE: 17 IRs in 16/32 pts (50%: Gr 1 (9) + Gr 2 (8)). **Conclusions:** Combining ISA and K appears safe; toxicity is c/w the AEs of the individual agents with few G3/4 AEs. Encouraging anti-MM activity (ORR 66%) was seen at all DLs. ISA 10 mg/Kg QW x 4 then Q2W dosing was selected for an ongoing Phase III trial of ISA + Kd versus Kd (IKEMA: NCT03275285). Clinical trial information: NCT-02332850.

Low vs high dose carfilzomib (Cfz) with dexamethasone (Dex) for relapsed/refractory multiple myeloma (RRMM): Results of SWOG S1304. *First Author: Sikander Ailawadhi, Mayo Clinic, Jacksonville, FL*

Background: Cfz has > 1 FDA approved doses in RRMM. Dose-response correlation is assumed without prospective data to compare efficacy of low-dose (27 mg/m^2; LDC) vs high-dose Cfz (56 mg/m^2; HDC). **Methods:** S1304 (NCT01903811), a randomized phase 2 trial compared LDC + dex vs HDC + dex, in Cfz nave RRMM pts with ²6 prior lines of treatment (Tt). Cycle 1 was 20 mg/m^2 with total planned Tt 1 year on each arm. Those progressing on LDC could cross to HDC. **Results:** 143 pts were enrolled, with 121 eligible + evaluable (LDC: 64, HDC: 57). Median follow up was 32 months (mo). There were no significant differences in pt characteristics or ORR between study arms (Table). Median PFS on HDC was 8 mo vs 6 mo on LDC (intent to treat); not statistically significant (HR 0.996 95% CI 0.785, 1.265). OS on 2 arms was also not significantly different (HR 1.069 95% CI 0.797, 1.434). PFS or OS were not significantly different between 2 arms in 1-3 vs 4-6 prior lines of Tt, bortezomib (btz) refractoriness or among pts who received ³2 or 12 cycles (2- and 12-month landmarks). There was a trend that HDC benefitted pts with any number of prior lines and not btz refractory, while LDC benefitted more 1-3 prior lines. Significantly different grade 3-5 AEs on the 2 arms are shown (Table). Cardiac AEs were not significantly different. **Conclusions:** In this only randomized comparison of different Cfz doses we did not find a PFS or OS benefit with HDC despite improved VGPR rates. Certain AEs were significantly higher with HDC. Ongoing weekly Cfz trials will further help define its utilization in RRMM.Clinical trial information: NCT01903811.

Selected patient characteristics, responses and grade 3-5 AEs at least possibly attributable to study treatment.

Characteristic	HDC (n = 57)	LDC (n = 64)	P-value
Age ³65	56%	48%	0.467
B2M ³3.5 mg/L	54%	56%	0.857
Cr ³2 mg/dL	0%	2%	1.000
Hb < 10 g/dL	11%	23%	0.091
4-6 Prior lines	26%	22%	0.671
Bortezomib refractory	49%	50%	1.000
Response Category	(n = 53)	(n = 59)	
VGPR	26%	8%	0.113
PR	21%	31%	
SD	40%	41%	
Increasing Disease	13%	20%	
AE Category	(n = 57)	(n = 64)	
General (most common: fatigue)	19%	3%	0.006
Nervous system (most common: peripheral neuropathy)	7%	0%	0.047
Investigations (most common: thrombocytopenia)	35%	16%	0.020
Cardiac	5%	8%	0.721
Maximum grade any AE	65%	39%	0.006

8016 Poster Discussion Session; Displayed in Poster Session (Board #25), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 3:00 PM-4:15 PM

Maintenance therapy (MT) with 25 versus 5 mg lenalidomide (Len) after prolonged Len consolidation therapy (CT) in newly-diagnosed, transplant-eligible patients (pts) with multiple myeloma (MM). *First Author: Roland Fenk, University Hospital Duesseldorf, Dept. of Hematology, Oncology and clinical Immunology, Duesseldorf, Germany*

Background: While Len MT after high-dose therapy (HDT) and autologous blood stem cell transplantation (aBSCT) is standard of care in pts with MM, optimal dosage has not been established. **Methods:** In this prospective, randomized, open label, multicenter phase III trial 188 pts (ITT population) were included 3 months after first-line HDT and aBSCT and were equally randomized to receive either 25 (n = 94, arm A) or 5 mg (n = 94, arm B) Len (21 of 28 days cycle) MT until disease progression following a uniform 6 months 25mg Len CT. **Results:** Patients characteristics were equally distributed with a median age of 58 years (range: 30-72). Len CT could be completed in 86 % pts and Len MT was applied for one year in 72 % and 61 % pts in arm A and B (2 years: 44 % vs. 34 %; 3 years: 27 % vs. 15 %). In arm A 51 %, 22 %, 10 % and 3 % pts continued 25 mg Len without dose reductions / discontinuations after CT, 1, 2 and 3 years MT. Dose reductions were mainly due to hematologic AEs (68 %), especially grade 3 neutropenia (56 %). Overall toxicity was higher in the 25 mg arm and infections (≥ grade 2) were the major AE during MT (1st year: 62 % vs. 42 %, 2nd year: 44 % vs. 36 %, 3rd year: 44 % vs. 28 %). The incidence of second primary malignancies was similar in both arms. Response rates improved during CT with an increase of sCR from 8 % to 21 % (p = 0.0001). During MT, 36 % and 23 % of pts. in arm A and B achieved sCR as best response (p = 0.08). After a median follow-up of 46.7 months the primary endpoint event-free survival (EFS) from randomization was significantly different with a median EFS of 44.8 and 33.0 months for arm A and B (HR 0.65, range: 0.44-0.97; p = 0.032). This was confirmed by Landmark analysis including only patients who entered MT (HR 0.63; p = 0.042). Overall survival (OS) was not different with a median 4-year-OS of 79 % and 67 % for arm A and B (p = 0.16). **Conclusions:** Low-dose Len is associated with significantly shorter EFS compared to the concept of upholding high-dose Len. Still, the rate of toxicity observed and the need for dose reductions in most patients requires reconsideration of the high-dose schedule and awaiting of long-term OS. Support: Celgene. Clinical trial information: NCT 00891384.

Carfilzomib weekly 20/56mg/m², lenalidomide and dexamethasone for early relapsed refractory multiple myeloma. *First Author: Valentine Richez, Nice Sophia Antipolis University, Nice, France*

Background: Triplet-based lenalidomide plus dexamethasone (Rd) combinations have become the new standard of care for early relapse and refractory multiple myeloma (RRMM), including carfilzomib plus lenalidomide/dexamethasone (KRd) based on ASPIRE phase 3 data. In ASPIRE, K is given twice a week at 20/27mg/m² on days 1, 2, 8, 9, 15, 16 of a 28 days based cycle. In ENDEAVOR, a second Kd phase 3 study validated that K 20/56mg/m² twice weekly was safe in early RRMM. We hypothesized that KRd on a weekly basis was far less inconvenient to patients (pts). The aim of this study was to evaluate efficacy and toxicity of KRd weekly regimen in pts treated for early RRMM. **Methods:** 28 pts received KRd in 28-day cycles until disease progression or until occurrence of unacceptable toxic effects. K was administered as a 30-minute infusion on days 1,8,15 (starting dose, 20mg/m^2 on day 1 of cycle 1; target dose, 56mg/m^2). R (25mg) was given on days 1 to 21. D (40mg) was administered weekly. **Results:** The median age was 64 years (45 - 80) with 14% older than 70 years, sex ratio M/F 1.3 and ISS disease stage 2 or 3 in 39%. Pts had received a median of 1 (1 - 3) previous lines of therapy including proteasome inhibitors (100%) and immunomodulatory drugs (43%). With a median follow up of 8 months, 3 pts (11%) relapsed, and one patient died. The median number of KRd cycles administered was 6.5 (1 – 12). Overall response rate was 93%, with 89% ≥VGPR and 61% ≥CR. The mean time to a response was 1.6 months. The median TTP and OS at 12 months were 89% and 95%, respectively. 29% of pts have discontinued treatment, with solely 50% due to adverse events (AEs). Hematologic AEs ≥ grade 3 were reported in 57% and non hematologic AEs ≥ grade 3 in 36%. No pts died related to AEs. Overall AEs ≥ grade 3 seen in ≥10% of pts was neutropenia, thrombocytopenia, vomiting and pyrexia. No pts experienced any severe cardiovascular AEs, including cardiac failure or any severe cardiac issues or thromboembolic events. **Conclusions:** KRd weekly at 20/56mg/m^2 is effective and safe to early RRMM pts. Further studies are warranted to confirm this data on a larger MM population. Furthermore, analysis of long-term outcome is needed on our studied population.

8018 Poster Discussion Session; Displayed in Poster Session (Board #27), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 3:00 PM-4:15 PM

Overall survival (OS) results of randomized phase III study (ADMYRE trial) of plitidepsin and dexamethasone (DXM) vs. DXM alone in patients with relapsed/refractory multiple myeloma (RRMM): Evaluation of the crossover impact. *First Author: Javier Gomez, PharmaMar, Madrid, Spain*

Background: Plitidepsin is a synthetic cyclic depsipeptide isolated from the marine tunicate *Aplidium albicans* targeting the proto-oncogene eEF1A2, which is over-expressed in multiple myeloma cells. In ADMYRE trial, Plitidepsin plus dexamethasone (DXM) (Arm A) met the primary endpoint (progression-free survival) and showed a survival improvement *versus* DXM alone (Arm B) (ASH 2017). **Methods:** RRMM patients with at least three but not more than six prior regimens, including at least bortezomib and lenalidomide/thalidomide, were randomized at 2:1 ratio to receive plitidepsin 5 mg/m^2 D1 and 15 plus DXM 40 mg D1,8,15 and 22 (Arm A), or DXM 40 mg D1,8,15 and 22 (Arm B) every four weeks. The rank preserving structural failure time (RPSFT) and the two-stage methods were used to present overall survival (OS) results after mitigating the crossover effect. **Results:** Two-hundred fifty-five patients were enrolled: (Arm A: 171/Arm B: 84). Thirty-seven patients in Arm B (44%) switched to Arm A after progression. Intention-to-treat (ITT) analysis not discounting the crossover effect showed a 20.3% risk reduction in favor of Arm A (median OS: A 11.6 mo. B: 8.9 mo.; HR = 0.797; log-rank p = 0.1261). Risk reduction improved to 32.4% with the RPSFT method (median OS: A 11.6 mo. B: 7.2 mo.; HR = 0.676; log-rank p = 0.0103) and to 37.8% with the two-stage method (median OS: A 11.6 mo. B: 6.4 mo.; HR = 0.622; log-rank p = 0.0015). Although assumptions for RPFST and two-stage analyses were plausibly met, statistically significant risk reductions were still maintained when severe penalizations were applied, with median OS differences around four months. **Conclusions:** Plitidepsin in combination with DXM demonstrated a clinically significant benefit in terms of overall survival in heavily pretreated RRMM, a disease where new therapeutic alternatives are still needed. Clinical trial information: NCT01102426.

Carfilzomib, bendamustine, and dexamethasone (KBd) in advanced multiple myeloma: The EMN09-trial. *First Author: Martin Gramatzki, Division of Stem Cell Transplantation and Immunotherapy, University of Kiel, Kiel, Germany*

Background: Various new agents have been introduced recently to treat relapsed/refractory multiple myeloma (RRMM), yet the chronification of the disease requires additional options for patients (pts) in advanced stages. Here, effectiveness and tolerability are important. Many advanced pts have received little chemotherapy but may suffer from peripheral neuropathy (PN). Carfilzomib (K) is a potent novel proteasome inhibitor not inducing significant PN. K was combined with bendamustine (B) to achieve synergistic effects. KB with low-dose dexamethasone (d) was tested in RRMM pts in a phase 1/2 trial (NCT02056756). **Methods:** 63 RRMM pts with ≥2 lines of prior therapy received KBd. Therapy consisted of 8 28-day courses of B at 70 mg/m^2 day 1,8; K at 27 mg/m^2 (initially 20 mg/m^2) day 1,2,8,9,15,16; d at 20 mg on every treatment day plus day 22,23. Responding pts received Kd maintenance every 14 days until PD. In the phase 1, a dose escalation in 6 pts to K at 36 mg/m^2 was attempted but led to 2 dose limiting toxicities. Thus, the phase 2 was conducted with K at 27 mg/m^2. **Results:** Pts had a median age of 66 years (range 37-79) and presented with RRMM in a median of 5.2 years after diagnosis. They were extensively pretreated, with a median of 4 prior lines (range 2-9) and 75% had previously received autologous stem cell transplantation, 87% bortezomib and 86% immunomodulatory drugs. At least VGPR rate was 32%, including 18% CR/sCR/nCR; 19% of pts achieved PR, 41% SD, 8% PD. Median PFS was 11.6 months, median OS 24.0 months. 1-year PFS was 72% in standard-risk and 35% in high-risk cytogenetics pts. Infections, particularly pneumonia, cardiac and thromboembolic adverse events (AEs) were the most frequent non-hematological AEs of grade ≥3; 51% of pts experienced ≥1 severe AE. Also the hematological toxicity was manageable. **Conclusions:** KBd was effective and well-tolerated in advanced RRMM pts requiring treatment rather late in the course of their disease. This cost-effective combination therapy with K at the 20/27 mg/m^2 and B at 70 mg/m^2 can be applied in an outpatient setting, with no significant nausea, hair loss or PN. Yet, cardiopulmonary and vascular signs need attention and infection prophylaxis is mandatory in these immunosuppressed pts. Clinical trial information: NCT02056756.

8020 Poster Discussion Session; Displayed in Poster Session (Board #29), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 3:00 PM-4:15 PM

Remission observed from a phase 1 clinical study of CAR-T therapy with safety switch targeting BCMA for patients with relapsed/refractory multiple myeloma. *First Author: Yarong Liu, HRAIN Biotechnology, Shanghai, China*

Background: Encouraging results are seen from several early phase clinical trials on the cellular immunotherapy based on chimeric antigen receptor (CAR)-engineered T (CAR-T) targeting B cell maturation antigen (BCMA) for the treatment of relapsed/refractory (RR) multiple myeloma (MM). We developed an anti-BCMA CAR-T cell product manufactured via gamma-retrovirus-mediated transduction of activated T cells to express a second-generation CAR with the 4-1BB costimulatory domain along with a truncated epidermal growth factor receptor (tEGFR) as a safety switch. The preclinical study confirmed its high reactivity against MM cells. **Methods:** A phase 1 clinical trial (NCT03093168) has been launched to evaluate the safety and feasibility of this BCMA CAR-T cell product for treating RRMM. The enrolled RRMM patients had received at least 3 prior treatment regimens, including a proteasome inhibitor and an immunomodulatory agent, or are double-refractory, and have over 20% BCMA expression on plasma cells. Patients were subjected to a lymphodepleting regimen with Cy once (300 mg/m^2, d-3) and Flu daily for 3 days (25 mg/m^2, d-5 to d-3) prior to the CAR-T infusion (d0) at a dose of 9×10^5 CAR$^+$ cells/kg. The efficacy was assessed by the International Uniform Response Criteria for Multiple Myeloma, and the toxicity iss graded by CTCAE 4.02. **Results:** As of December 31, 2017, 10 patients had been infused with this intended dose of the autologous BCMA CAR-T cells, and 7 patients had reached at least 1 month of follow-up. As of this data cut-off, no greater than Grade 1 neurotoxicities or cytokine release syndrome (CRS) had been observed. The overall response rate (ORR) for the 7 evaluable patients was 86%, including 2 sCRs and 2 MRD-negative responses (2 VGPR). The CAR-T cell expansion and persistence were consistently observed throughout these patients. **Conclusions:** Our result demonstrates the promising efficacy with the infused dose, including 2 sCRs and ongoing clinical responses for more than 12 months, with only mild and manageable CRS to date. These initial data provide strong evidence to support the further development of this anti-myeloma cellular immunotherapy. Clinical trial information: NCT03093168.

8021 Poster Session (Board #30), Mon, 8:00 AM-11:30 AM

A phase 3 randomized study of pembrolizumab (Pembro) plus pomalidomide (Pom) and dexamethasone (Dex) for relapsed/refractory multiple myeloma (RRMM): KEYNOTE-183. *First Author: Maria-Victoria Mateos, University of Salamanca Hospital, Salamanca, Spain*

Background: KEYNOTE-183 (NCT02576977) evaluated pom + low-dose dex (SOC) ± pembro in patients (pts) with RRMM. **Methods:** Pts were randomized 1:1 to pembro (200 mg Q3W) + SOC (4 mg pom [d 1-21] + 40 mg dex [d 1, 8, 15, 22]) every 28 d vs SOC until progression (PD), unacceptable toxicity, withdrawal. Coprimary endpoints: PFS (2011 IMWG criteria), OS; secondary endpoints: safety, ORR. On July 3, 2017 based on interim data presented to the DMC, the FDA halted KEYNOTE-183. **Results:** 249/300 pts enrolled (125, pembro + SOC; 124, SOC) with median (range) age: 65 y (45-94) vs 67 y (22-90); 28 (22%) vs 17 (14%) pts had high-risk cytogenetics. Median (range) drug exposure was 123.5 d (2-477) vs 127 d (2-463); median 4.4 cycles. AEs with ≥5% difference between arms: neutropenia (38% vs 27%), nausea (17% vs 12%), pneumonia (23% vs 15%), ALT increase (10% vs 3%), headache (13% vs 4%). No SAEs had ≥5% difference between arms. In pembro + SOC arm, 21 (18%) pts had immune-mediated AEs: skin reaction (5%), pneumonitis (4%), hyperthyroidism (3%), infusion reaction (2%), myopathy (2%), myocarditis, iridocyclitis, hepatitis, Steven-Johnson syndrome (SJS; 1% each). 29 (23%) pts vs 21 (17%) died (16 from PD, 13 from AEs vs 18 from PD, 3 from AEs). 4 (3%) treatment related deaths occurred; 2 (1.5% [1 myocarditis, 1 SJS]) related to pembro. Median follow-up was 7.8 mo vs 8.6 mo. Median PFS: 5.6 mo vs 8.4 mo; HR, 1.53 (95% CI, 1.05-2.22); P= 0.98. Median TTP: 8.1 vs 8.7 mo. Median OS: not reached vs 15.2 mo; HR, 1.61 (95% CI, 0.91-2.85); P= 0.95. In a retrospective random forest analysis age, ECOG PS, disease stage, presence of plasmacytoma, double refractory status were more relevant contributors to death than treatment. A subsequent multivariable COX regression analysis showed age, ECOG, presence of plasmacytoma significantly contributed to risk of death. Age and presence of plasmacytoma were prognostic, while ECOG was prognostic and predictive of outcome with OS HR = 0.85 (ECOG 0) and OS HR = 2.3 (ECOG 1). **Conclusions:** The benefit-risk profile for combination of pembro, pom and dex is unfavorable for RRMM. Evaluation of T-cell subsets and cytokines along with long-term safety and survival follow-up is ongoing. Clinical trial information: NCT02576977.

8022 Poster Session (Board #31), Mon, 8:00 AM-11:30 AM

Weekly carfilzomib, lenalidomide, and dexamethasone (KRd) in relapsed or refractory multiple myeloma (RRMM): A phase 1b study. *First Author: Noa Biran, John Theurer Cancer Center at Hackensack University Medical Center, Hackensack, NJ*

Background: KRd is approved for treatment of RRMM patients (pts). Under the approved KRd regimen, carfilzomib is given twice weekly (20/27 mg/m^2; 10-min IV infusion). Here we present updated results from a dose-finding study assessing weekly KRd. **Methods:** This study consisted of a dose-evaluation component and a dose-expansion component in both RRMM and newly diagnosed MM. Results for RRMM pts are presented here. Two dose levels were evaluated: carfilzomib 56 mg/m^2 and carfilzomib 70 mg/m^2. All pts received carfilzomib (30-min IV infusion on days [D] 1, 8, and 15; 20 mg/m^2 on C1D1), lenalidomide 25 mg (D1–21), and dexamethasone 40 mg (D1, 8, 15, and 22) on a 28-day cycle (dexamethasone was not given on D22 for cycles 9+). Pts in the expansion arm received the selected KRd regimen on the same schedule used for dose evaluation. Response was assessed by investigators. **Results:** Twenty-two RRMM pts were enrolled in the dose-evaluation part and received study drug (56 mg/m^2, n = 10; 70 mg/m^2, n = 12). The maximum tolerated dose of carfilzomib was not reached; the 70 mg/m^2 dose was selected for dose expansion and 34 additional RRMM pts received this dose. Results are presented for pts who received carfilzomib 56 mg/m^2 during dose evaluation (n = 10; median 2 prior regimens [range 1-3]) and for pts who received carfilzomib 70 mg/m^2 during dose evaluation or expansion (n = 46; median 1 prior regimen [range 1-5]). Median (mean) average carfilzomib dose was 53.2 (52.8) mg/m^2 in the 56 mg/m^2 group and 62.4 (61.3) mg/m^2 in the 70 mg/m^2 group. Pt incidence of grade ≥3 adverse events was 70.0% (56 mg/m^2) and 71.7% (70 mg/m^2). Pt incidence of carfilzomib discontinuation due to adverse events was 20.0% (56 mg/m^2) and 17.4% (70 mg/m^2). There were three total deaths in the 70 mg/m^2 group (one each due to cardiac arrest, cardiac disorder, and progressive disease). Overall response rates were 90.0% (56 mg/m^2) and 89.1% (70 mg/m^2); 20.0% (56 mg/m^2) and 30.4% (70 mg/m^2) of pts achieved a complete response (CR) or stringent CR. **Conclusions:** Once weekly KRd was effective and had manageable toxicity in pts with RRMM. As a weekly carfilzomib dosing regimen could offer pts greater convenience, these results support further clinical evaluation. Clinical trial information: NCT02335983.

8023 Poster Session (Board #32), Mon, 8:00 AM-11:30 AM

Utility and prognostic value of ^{18}F-FDG PET/CT scan in patients with newly diagnosed multiple myeloma. *First Author: Mohammed A. Aljama, Mayo Clinic, Division of hematology, Rochester, MN*

Background: Positron emission tomography–Computed tomography (PET/CT) can identify bony lesions, assess disease burden and detect extra-medullary disease in patients with newly diagnosed multiple myeloma (MM). **Methods:** We conducted a retrospective review of patients who had a PET/CT performed within sixty days of diagnosis and prior to commencement of therapy to identify the nature and prognostic impact of PET/CT abnormalities in newly diagnosed MM. **Results:** Between April 2005 and June 2017, 314 patients were identified and included in the analysis. 235 (75%) patients had focal lesions (FL), 183 (58%) had ≥3 FL, 38 (12%) had extra medullary disease (EMD) and 194 (62%) had documented lytic lesions. Median maximum standardized uptake value (SUVmax) in the entire cohort was 5.9 (range 0-48.3). Presence of ≥3 FL and EMD predicted overall survival (OS); median OS of 58 months for ≥3 FL vs 89 months for < 3 FL (P= 0.009) and median OS 45 months for EMD present vs 71 months for EMD absent (P= 0.025). Compared to those with SUVmax of less than 8.5, those with SUVmax of more than 8.5 had a shorter overall survival, 89.6 versus 57.8 months, respectively (P= 0.022). **Conclusions:** PET/CT is a valuable tool in assessing disease burden and provides prognostic information in patients with newly diagnosed MM treated with novel agents.

Early MRD negativity to predict deepening myeloma response in relapsed/refractory multiple myeloma (RRMM) patients treated with bb2121 anti-BCMA CAR T cells. *First Author: Nikhil C. Munshi, Dana-Farber Cancer Institute, Boston, MA*

Background: A high frequency of rapid minimal residual disease-negative (MRD-neg) responses has been seen in CRB-401, a phase I trial of bb2121 CAR T cell therapy for RRMM (Kochenderfer, ASH 2017). We report IMWG responses in MRD-neg patients (pts) and associated factors. **Methods:** Pts treated with $\geq 150 \times 10^6$ BCMA CAR+ T cells in the dose-escalation phase of CRB-401 and evaluable for MRD by Adaptive NGS-based MRD Assay (Adaptive Biotechnologies) were included in this analysis (n = 10 as of 02 Oct 2017; median follow-up: 34 wks; min, max: 7, 67). **Results:** Nine of 10 evaluable pts were MRD-neg with a sensitivity of 1 in 10^{-4} nucleated cells (1 pt), 1 in 10^{-5} (6 pts), and 1 in 10^{-6} (2 pts). Achievement of MRD negativity was independent of depth of response at first MRD-neg assessment; 2 pts had stable disease, 3 had PR, 2 had VGPR, and 2 had CR / stringent CR. Of 8 evaluable MRD-neg pts, all showed $\geq$ 85% and $\geq$ 97% decline in serum BCMA and involved free light-chain levels, respectively, at month (M) 1. Two of 9 MRD-evaluable pts were in CR at MRD-neg assessment and the remaining 7 achieved deeper response over time, 4 with CR or stringent CR, 2 with VGPR and 1 with PR between M1 and M15. One MRD-neg pt became MRD-positive at M12, and 1 MRD-neg pt had progressed as of data cut-off. Achievement of MRD negativity was independent of occurrence of cytokine release syndrome. MRD-neg was observed across all active bb2121 doses (150 [n = 3], 450 [n = 5], and 800 x 10^6 [n = 1] CAR+ T cells). Of 9 MRD-neg pts, 7 had at least 6M follow-up and 1 had IMWG progression (at M6); 3 had at least 12M follow-up, 1 had become MRD-positive and none had IMWG progression. Attainment of MRD-neg was independent of peak CAR T expansion (vector copy min, max: 93,744, 1,457,070 copies/μg gDNA; n = 9) and was observed in high ($>$ 50%) bone marrow plasma cells (BMPC; n = 6) and low BMPC (n = 3) tumor burden pts. Eight of 9 MRD-neg pts had cytogenetic abnormalities including del(17), del(13), amp(1q21), or t(11;14). **Conclusions:** bb2121 induced a high frequency of rapid MRD-neg response, independent of IMWG MM responses. These early MRD-neg responses starting at M1 offer insights into bb2121 kinetics and may portend achievement of deeper responses over time. Clinical trial information: NCT02658929.

8025 Poster Session (Board #34), Mon, 8:00 AM-11:30 AM

Autologous stem cell transplantation in multiple myeloma patients over age 75. *First Author: Ning Dong, Rutgers NJMS, Newark, NJ*

Background: Autologous stem cell transplantation (ASCT) has improved the outcome of patients with Multiple Myeloma (MM) substantially and is now the standard of care. Patients over the age of 75 years are often denied this procedure due to toxicity concern. Since 35% of patients with MM fall into this age category, the safety and effectiveness of ASCT in this patient population needs to be studied. **Methods:** 604 patients with MM who received an ASCT at John Theurer Cancer Center of HUMC between 2005-2014 were evaluated. A total of 44 patients $\geq$ 75 years of age (range 75-84) and 560 patients younger than 75 at time of ASCT were included. The Kaplan–Meier method was used to compare survival between those two age groups. **Results:** Features of patients older than 75 were summarized in table 1. Melphalan 200mg/ m^2 was our primary conditioning regiment (75% of all patients). MM patients who received ASCT at age 75 or older had similar PFS and OS when compared with younger patients; the 3-year PFS was 52% and 46%, respectively; median PFS was 36.1 months vs 33.7 months, respectively, p = 0.76; the 3-year OS was 84% vs 82%, respectively; median OS was 93.3 months vs 127.8 months, respectively, p = 0.27. Two patients died within 100 days after ASCT. One died from subdural hematoma on day +11 and the other from Staphylococcus aureus sepsis on day +25. **Conclusions:** MM patients over the age of 75 can have similar outcomes from ASCT compared to the younger population. Elderly patients with MM should not be denied ASCT merely based on age.

Patient features of MM patients who received ASCT at age 75 or older.

8026 Poster Session (Board #35), Mon, 8:00 AM-11:30 AM

Single cell analysis of multiple myeloma. *First Author: Guy Ledergor, Weizmann Institute of Science, Rehovot, Israel*

Background: Multiple myeloma (MM) remains mostly incurable despite advances in treatments in the last decade. Major clinical challenges include: capturing inter- and intra- patient heterogeneity, stratification of asymptomatic patients, sensitive and functional identification of residual disease to tailor therapeutic strategies, as well as performing accurate liquid biopsies to mitigate the need for recurrent bone marrow (BM) sampling. **Methods:** To capture BM and circulating plasma cells (PC), we performed single cell RNA-seq (scRNA-seq). Index sorting enabled to link cell surface markers intensity on each cell with its expression profile. Analysis of the transcriptome together with the specific B cell receptor (BCR) using k-nearest-neighbor graphs characterizes the inter and intra tumor heterogeneity of myeloma patients in both the BM and blood at single cell resolution. **Results:** Analysis of more than 30,000 PC sorted from 35 patients and 12 control subjects, created a detailed map of 43 transcriptionally homogeneous subpopulations. These were based on cluster-specific expression patterns of more than 1500 genes. PC from healthy donors clustered together and displayed 4 states representing either long-lived PC or cycling short-lived PC. In contrast, each patient presented a unique PC transcriptional state, with a specific BCR clonotype. We uncover novel overexpressed genes, previously unimplicated in MM, such as *LAMP5*. We identify intra-tumor heterogeneity in 10/35 patients, for example, a patient with a *FRZB* and *SMAD1* gene signature in 68% of PCs and an antimicrobial gene *DEFB1* in the rest of the PC, which share the same BCR clonotype. We define new markers to differentiate normal circulating PC from tumor cells (CTC) in the blood and show that CTC mirror the BM state. Further, we accurately characterize the heterogeneity within MGUS patients into PC with a normal transcriptional state in contrast to small clones with a defined malignant program. Finally, we identify small cancer clones in the setting of minimal residual disease (MRD) following high-dose therapy. **Conclusions:** We show the power of scRNA-seq as a new, high resolution tool, to identify new pathways and potential targets in myeloma, stratify patients based on unique molecular programs, and identify residual disease in both the BM and blood.

8027 Poster Session (Board #36), Mon, 8:00 AM-11:30 AM

Pomalidomide (POM) + low-dose dexamethasone (LoDEX) + daratumumab (DARA) in relapsed and/or refractory multiple myeloma (RRMM) after lenalidomide (LEN)-based treatment (Tx) failure. *First Author: David Samuel DiCapua Siegel, John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, NJ*

Background: POM + LoDEX + DARA in RRMM was approved in the US based on a phase 1b trial in heavily pretreated patients (pts; $\geq$ 2 prior lines [median, 4]; ORR, 60%). Data on the use of this regimen in earlier lines of Tx and immediately after LEN-based Tx are limited. Thus, MM-014 (NCT01946477) cohort B was initiated in pts with first- or second-line LEN-based Tx failures immediately before study entry to assess outcomes with POM + LoDEX + DARA sequenced earlier in Tx. **Methods:** Pts with RRMM after 1 or 2 prior lines who received a LEN-based Tx immediately before study and had progressive disease (PD) were eligible. In 28-d cycles (c), pts received POM 4 mg/d on d 1-21 + LoDEX 40 mg/d (20 mg/d if aged $>$ 75 yrs) on d 1, 8, 15, and 22, and DARA 16 mg/kg IV on DEX dosing days of c 1 and 2, then d 1 and 15 of c 3-6, then d 1 of c 7+. Thromboprophylaxis was mandatory. The primary objective was ORR by modified IMWG criteria. **Results:** A total of 46 pts were in the ITT population (median follow-up, 7.8 mos). 13 pts discontinued Tx (PD, 7; AEs, 2; other reasons, 4). Pts were refractory to (n = 36; 78%) or had relapsed after (n = 10; 22%) LEN-based Tx. Median duration of prior LEN-based Tx was 23.6 mos; 20 pts (43%) received LEN 25 mg/d in their last LEN-based Tx. ORR was 76.7% in efficacy-evaluable pts (n = 43), 72.2% in LEN-refractory pts, and 75.0% in pts who received LEN 25 mg/d in their last LEN-based Tx. Efficacy and safety are shown in the Table. At baseline, 10 pts (21.7%) had grade $\geq$ 2 neutropenia. There was 1 each of grade 3/4 pulmonary embolism and peripheral neuropathy. Any-grade infusion-related reactions occurred in 13 pts. Neutropenia (POM and DARA) and infusion-related reactions (DARA only) were primary reasons for dose interruptions. **Conclusions:** These results underscore the importance of POM-based Tx in RRMM after LEN. POM + LoDEX + DARA was safe, with promising activity when sequenced in earlier lines immediately after LEN-based Tx failure. Clinical trial information: NCT01946477.

Graft-versus-host disease (GVHD) risk with daratumumab (Dara) therapy post allogeneic transplantation (alloHCT) for multiple myeloma (MM). *First Author: Liana Nikolaenko, City of Hope Medical Center, Duarte, CA*

Background: Daratumumab (Dara) is an antibody targeting CD38+ MM cells that also affects CD38+ non-myeloma cells, including T cells, which mediate GVHD. Regulatory T cells (Tregs) are reduced while helper and cytotoxic T cells are increased in Dara-treated patients. Decreases in Tregs are associated with the development of GVHD. The association between Dara therapy post alloHCT and GVHD was evaluated. **Methods:** Multicenter, retrospective study. All patients who received alloHCT for MM were cross referenced with patients receiving Dara. Demographic data, details of prior MM therapy, conditioning regimen, time from transplant to Dara and time to GVHD were collected. **Results:** AlloHCT were performed between 2001 to 2016. Median time from alloHCT to first dose of Dara was 1.8 years (3.5 months to 15.3 years). Patient demographics are shown in Table 1. Median number of Dara infusions was 12 (range 1-19). A total of 14 patients (41%) developed GVHD post alloHCT: 9 patients had GVHD prior to Dara without relapse of GVHD after Dara, 5 patients developed GVHD after Dara (15%) with 4 of these 5 patients having no prior history of GVHD before Dara. One patient developed acute GVHD during Dara therapy while having history of chronic GVHD. Median time to onset of GVHD from first dose of Dara was 149 days (36 to 149 days). Overall response to Dara-based therapies was 38% (13/34), including 12 SD, 3 MR, 9PR, 2VGPR, 2CR, 4PD and 2 unavailable. Median follow up was 33.2 months (6.4 months to 16.5 years). **Conclusions:** Dara therapy post-alloHCT was well tolerated and did not increase risk of GVHD. These data suggest that Dara is an effective and safe option for use after alloHCT and could be considered in studies of salvage and maintenance post alloHCT.

A phase 1/2 study of carfilzomib, bendamustine, and dexamethasone (CBD) in newly diagnosed multiple myeloma patients. *First Author: Siyang Leng, Home, Sunnyside, NY*

Background: Carfilzomib and bendamustine have demonstrated efficacy in relapsed refractory myeloma. In this phase 1/2 study, we evaluated the combination of carfilzomib, bendamustine and dexamethasone in newly diagnosed patients. **Methods:** This is an ongoing, open label, single center study. Phase 1 dose escalation followed an up-and-down dosing scheme (Storer's Design D). Carfilzomib was administered at dose levels of 27, 36, 45 and 56 mg/m^2 on days 1,2,8,9,15,16, bendamustine at 70 and 90 mg/m^2 on days 1,2, and dexamethasone at 20 mg on days of carfilzomib and on day 22 of a 28 day cycle. Autologous stem cell transplant (ASCT) eligible patients received 4 cycles of CBD, underwent stem cell harvest, and then received an additional 4 cycles followed by ASCT. ASCT ineligible patients received 8 cycles of CBD. Both groups received maintenance with carfilzomib 36 mg/m^2 on days 1,2,15,16 every 28 days for up to 2 years. **Results:** To date, 18 patients have been treated. Median age was 65 (range 51-74); 12 were male, 7 Hispanic, 2 African American and 2 Asian. One patient was treated at each dose level from 1-4, without DLTs; 14 patients were treated at the maximum dose level. The overall response rate was 100% – 16 (89%) had complete response (CR) / very good partial response (VGPR), with 3 being MRD-negative CR by flow, 3 stringent CR, 1 CR, and 9 VGPR; 2 had partial response (PR). 2 patients with VGPR and 1 with PR are still receiving induction. All patients showed response after 1 cycle. Of the 13 patients who have completed 8 cycles of CBD, 7 underwent ASCT. The 12-month PFS rate was 100%, and median follow-up was 14.8 months. G3/4 hematologic toxicities include neutropenia (28%), thrombocytopenia (22%), anemia (17%), lymphopenia (17%). Notable non-hematologic toxicities (all grades) include infection (44%), creatinine increase (33%), weight loss (28%), and thromboembolic event (22%). Stem cell collection was not impacted. **Conclusions:** CBD appears to be a safe and highly effective induction regimen for myeloma, with an 89% rate of CR/VGPR in our cohort. Clinical trial information: NCT02002598.

8030 Poster Session (Board #39), Mon, 8:00 AM-11:30 AM

Prognostic value of minimal residual disease and polyclonal plasma cells in myeloma patients achieving a complete response to therapy. *First Author: Marcella Tschautscher, Mayo Clinic, Rochester, MN*

Background: Achievement of a complete response (CR) to therapy has been associated with improved outcomes in patients with multiple myeloma (MM). More recently, increasing application of minimal residual disease (MRD) assessment following therapy has shown that MRD negativity is a powerful prognostic factor for survival outcomes. The presence of MRD, even among patients who have achieved a conventional CR, predicts inferior outcomes. Given this, we wanted to examine the impact of the polyclonal plasma cell (pPC) compartment among patients who achieved CR but still have MRD. **Methods:** This is a retrospective cohort study where 460 myeloma patients were identified who met criteria for CR per IMWG criteria and had application of multicolor flow cytometry to the bone marrow (BM) for the purpose of confirming CR. Mono and pPCs were estimated during MRD testing. A Kaplan-Meier model was used to determine OS and the 2-sided log-rank test to compare MRD+ and MRD- groups. TTNT was calculated as the difference from date of confirmed CR and date of next therapy. **Results:** The median duration from diagnosis to CR was 11.7 months. The median follow-up for the entire cohort was 33.5 months (95% CI; 31, 36) from CR; and the median OS was not reached (95% CI; 63 mos, NR). Median TTNT was 31 months (95% CI; 27,36). Among the 460 patients, 70% were MRD-, with a median TTNT of 37.6 months vs 23 months for MRD+ patients ($p < 0.001$); the median OS was not reached for either group, but there was a trend towards better survival for MRD- patients. The improved TTNT with MRD negativity was seen irrespective of prior treatment and SCT status. Among the 139 patients with residual disease, median percentage of pPCs was 65% (2.5 to 98.5), and those with > 95% pPCs had a significantly better TTNT (NR vs 23 months; $p = 0.02$) and a trend towards better OS. **Conclusions:** Achievement of MRD negativity predicts for better response durability and trend toward improved OS among patients in conventional CR treated with modern therapies. The impact seems independent of the type of therapy that results in achievement of CR and MRD negative status. Finally, an increased proportion of pPC predicts for better outcomes within those who have residual tumor cells.

8031 Poster Session (Board #40), Mon, 8:00 AM-11:30 AM

Daratumumab plus bortezomib-melphalan-prednisone (VMP) in elderly (≥75 y) patients (Pts) with newly diagnosed multiple myeloma (NDMM) ineligible for transplantation (ALCYONE). *First Author: Michele Cavo, "Seràgnoli" Institute of Hematology, Department of Experimental, Diagnostic and Specialty Medicine, University of Bologna, Bologna, Italy*

Background: Daratumumab (D) plus VMP (D-VMP) prolonged progression-free survival (PFS) compared with VMP and was well-tolerated in the phase 3 ALCYONE study (NCT02195479). We examined the efficacy and safety profiles of D-VMP vs VMP in elderly (≥75 y) and non-elderly (< 75 y) NDMM pts in ALCYONE. **Methods:** Pts were ineligible for high-dose chemotherapy with ASCT. Pts received up to nine 6-week VMP cycles (V: 1.3 mg/m^2 SC Days 1, 4, 8, 11, 22, 25, 29, 32 [Cycle 1] and Days 1, 8, 22, 29 [Cycles 2-9]; M: 9 mg/m^2 PO and P: 60 mg/m^2 PO Days 1-4 [Cycles 1-9]) ± D (16 mg/kg IV QW for Cycle 1, Q3W for Cycles 2-9, and Q4W for Cycles 10+ [post VMP-treatment phase] until progression). Minimal residual disease (MRD) was assessed by clonoSEQ assay (Adaptive Biotechnologies). **Results:** 706 (350 D-VMP; 356 VMP) pts were randomized, including 211 ≥75 y (104 D-VMP; 107 VMP) and 495 < 75 y (246 D-VMP; 249 VMP) pts. For D-VMP vs VMP, the median duration of study treatment was 14.5 mo vs 12.0 mo for ≥75 y pts and 15.0 mo vs 12.0 mo for < 75 y pts, respectively. After median follow-up of 16.5 months, PFS was prolonged with D-VMP vs VMP in both the ≥75 y (median not reached [NR] vs 20.4 mo; HR 0.53; 95% CI 0.32-0.85) and < 75 y (median NR vs 17.9 mo; HR 0.49; 95% CI 0.36-0.68) pts. ORR and ≥complete response (CR) rates were consistently higher for D-VMP vs VMP in ≥75 y (ORR: 88% vs 70%; ≥CR: 41% vs 24%) and < 75 y (ORR: 92% vs 76%; ≥CR: 43% vs 25%) pts. MRD-negative rates (10^{-5} threshold) also increased with D-VMP vs VMP in ≥75 y (24% vs 8%) and < 75 y (22% vs 6%) pts. Rates of most common grade 3/4 (≥10%) treatment-emergent adverse events, peripheral sensory neuropathy, and infections are in Table. D-associated infusion-related reactions were 36% (9% grade 3/4) in ≥75 y and 24% (3% grade 3/4) in < 75 y pts. **Conclusions:** Efficacy and safety of D-VMP vs VMP in pts ≥75 y of age were consistent with the overall study population. Clinical trial information: NCT02195479.

Carfilzomib and dexamethasone (Kd56) vs bortezomib and dexamethasone (Vd) in relapsed or refractory multiple myeloma (RRMM): Updated overall survival (OS), safety, and subgroup analysis of ENDEAVOR. *First Author: Robert Z. Orlowski, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The phase 3 ENDEAVOR trial demonstrated significantly improved PFS and OS with Kd56 vs Vd in RRMM patients (pts; Dimopoulos *Lancet Oncol* 2016 and 2017). We report updated data after additional follow-up. **Methods:** Hazard ratios (HRs) and 95% CIs were estimated using stratified or unstratified Cox proportional hazards models for primary and subgroup OS analyses, respectively. **Results:** 929 pts were randomized (Kd56, n = 464; Vd, n = 465). As of 19-Jul-17, median OS was 47.8 (Kd56) vs 38.8 (Vd) months (mos; HR, 0.76 [95% CI, 0.633–0.915]; median follow-up, 44.3 vs 43.7 mos). OS was longer with Kd56 vs Vd within age subgroups (< 65 years [yrs]: median, 47.8 vs 42.2 mos; HR, 0.79 [95% CI, 0.598–1.031]; 65–74 yrs: median, 49.0 vs 36.2 mos; HR, 0.71 [95% CI, 0.520–0.958]; ≥75 yrs: median, 36.1 vs 23.9 mos; HR, 0.78 [95% CI, 0.506–1.199]). OS was longer with Kd56 vs Vd by prior lines of therapy (1 line: median, 51.3 vs 43.7 mos; HR, 0.77 [95% CI, 0.583–1.018]; 2–3 lines: median, 39.5 vs 28.4 mos; HR, 0.75 [95% CI, 0.589–0.959]) and prior bortezomib (btz) exposure (prior btz: median, 41.8 vs 32.7 mos; HR, 0.85 [95% CI, 0.669–1.082; no prior btz: median, not estimable [NE] vs 42.2 mos; HR, 0.66 [95% CI, 0.496–0.875]). OS was longer with Kd56 vs Vd for high-risk (median, 28.0 vs 22.7 mos; HR, 0.81 [95% CI, 0.580–1.136]) and standard-risk (median, NE vs 43.5 mos; HR, 0.79 [95% CI, 0.618–1.009]) cytogenetics pts. 457 (98.7%, Kd56) and 451 (98.9%, Vd) pts had an adverse event (AE); 379 (81.9%, Kd56) and 324 (71.1%, Vd) had a grade ≥3 AE. Exposure-adjusted pt incidences per 100 pt-yrs (95% CI) of AEs were 1352.07 (1233.62–1481.89) for Kd56 and 1754.86 (1600.15–1924.53) for Vd; for grade ≥3 AEs, these values were 162.31 (146.77–179.50) and 175.90 (157.75–196.13). The most common AEs in the Kd arm (≥ 30% of subjects) were anemia (43.6%), diarrhea (36.7%), pyrexia (32.6%), hypertension (32.4%), fatigue (32.2%) and dyspnea (32.2%). **Conclusions:** With median follow-up of ~44 mos, clinically meaningful OS improvements were observed with Kd56 vs Vd, including in all subgroups examined. The Kd56 safety profile was consistent with previous analyses. Clinical trial information: NCT01568866.

8033 Poster Session (Board #42), Mon, 8:00 AM-11:30 AM

Lack of racial disparity in outcome of African American (AA) and Caucasian patients with symptomatic multiple myeloma (MM) at the Veterans Affairs (VA) hospitals. *First Author: Nathanael Fillmore, VA Boston Healthcare System, Boston, MA*

Background: Recent studies have identified a significant and increasing disparity in survival amongst AA and Caucasian patients diagnosed with MM in the United States, and a concomitant disparity in access to novel chemotherapy and stem-cell transplant. We sought to investigate whether this disparity holds at the VA, which does not use a fee-for-service model. **Methods:** We used the VA's nationwide Corporate Data Warehouse to identify patients diagnosed with MM from 1999 to 2017, as well as their age, race, therapy at induction, and stem-cell transplant status. We compared overall survival between AA and Caucasian using Cox models. We assessed differences in treatment patterns using chi-squared tests. **Results:** We identified 15,717 patients diagnosed with MM, including 3,254 AA and 8,845 Caucasian patients. The median age at diagnosis was 65.6 years for AA and 70.1 for Caucasian (P<1e-15). As age has a substantial effect on overall survival, we adjusted our survival analysis for age at diagnosis. We found no difference in age-adjusted overall survival between AA and Caucasian, measured by hazard ratio of risk of death among AA relative to Caucasian (HR 0.99, 95% CI 0.94-1.05, P=0.69). However, among patients younger than 65 at diagnosis, we observed a significant decrease in age-adjusted risk of death for AA compared to Caucasian patients (HR 0.86, 95% CI 0.79-0.94, P=0.001). In patients >65 years, survival was similar between the 2 groups. The difference in younger population was not explained by access or utilization of the novel agents. We observed no racial disparity at the VA in the use of novel agents at induction (IMiD or PI), with 82.5% of AA patients and 81.5% of Caucasian patients receiving novel therapy (P=0.21); or in use of stem-cell transplant (10.1% of AA and 9.1% of Caucasian patients; P=0.09). **Conclusions:** No racial disparity was observed in overall survival or treatment patterns at the VA. Taken with previous research that does show these disparities in other US healthcare systems, this suggests that these disparities may be due primarily to economic factors, including cost of therapy, rather than factors related to disease biology.

8034 Poster Session (Board #43), Mon, 8:00 AM-11:30 AM

Pre-clinical development of TNB-383B, a fully human T-cell engaging bispecific antibody targeting BCMA for the treatment of multiple myeloma. *First Author: Ben Buelow, TeneoBio, Inc., Menlo Park, CA*

Background: T-cell redirecting therapies such as CAR-T cells and T-cell engaging bispecific antibodies (T-BsAb) targeting B Cell Maturation Antigen (BCMA) have been highly efficacious against relapsed/refractory myeloma (MM) in early phase clinical studies. However, strongly pan-T cell activating T-BsAbs have also been shown to overstimulate T cells, inducing toxicity and possibly decreasing efficacy. We have developed TNB-383B, a fully human BCMA-specific T-BsAb incorporating a low-activating αCD3 that preferentially activates effector over regulatory T cells. TNB-383B mediates T-cell killing of MM *in vitro, ex vivo* and *in vivo* but stimulates minimal cytokine release. **Methods:** *In vitro* and *ex vivo* efficacy studies included T-cell activation by cytokine- and tumor cell kill by calcein-release assays and/or flow cytometry. *In vivo* efficacy of the molecules was evaluated in NSG mice harboring myeloma cells and human PBMCs. Pharmacokinetics and tolerability were assessed in *Cynomolgus*. **Results:** TNB-383B showed T-cell activation and tumor-cell cytotoxicity *in vitro* and *ex vivo*, with markedly reduced cytokine production even at doses that showed maximum tumor cell lysis as compared to a positive control T-BsAb. *In vivo,* TNB-383B reduced tumor load and increased survival. TNB-383B had a T1/2 of ~13-16 days in *Cyno*, consistent with an IgG4 Ab. **Conclusions:** Our results suggest that TNB-383B may have a favorable toxicity profile with comparable or possibly improved efficacy compared to T-BsAbs that incorporate strong, pan T-cell activating anti-CD3 moieties in the treatment of MM.

8036 Poster Session (Board #45), Mon, 8:00 AM-11:30 AM

Molecular underpinnings of clinical disparity patterns in African American (AA) versus Caucasian American (CA) multiple myeloma (MM) patients. *First Author: Elizabeth M. Hill, NCI/NHLBI, Bethesda, MD*

Background: Due to unclear reasons, the AA population, compared to the CA population, has a 2-fold increased incidence of MM, has an earlier average age of diagnosis by 10 years, and has gained less benefit from novel treatments. To better understand underlying biological mechanisms of these disparities, we characterized genetic alterations using a first-in-kind targeted next generation sequencing (NGS) assay called myTYPE, allowing capture of both somatic mutations as well as gene translocations and gains/losses. **Methods:** Bone marrow clot sections were obtained from the NIH Plasma Cell Dyscrasia Racial Disparity Cohort. A total of 91 samples underwent DNA extraction, 81 met minimal quality control (QC) criteria and underwent NGS library preparation. Of these, 74 (51CA, 23 AA) passed all QC and sequenced using the Illumina platform with 100 bp paired end reads and a coverage of 600x. An additional 16 unmatched normal controls were sequenced for somatic analysis. Mutations were manually curated to select somatic based on COMSIC, MMRF, Bolli or truncating databases. myTYPE captures 120 genes including driver mutations, signaling pathways, therapeutic targets, IGH translocations, and copy number variations.**Results:** Of the 74 samples sequenced, 27 patients (37%) had at least one mutation. 12 genes with somatic mutations were identified. KRAS was most common, identified in 16% of patients (14% CA, 22% AA), followed by NRAS (4% CA, 9% AA) and BRAF (2% of CA, 13% AA). Mutations were also observed in FAM46C, DIS3, FGFR3, TP53, RASA2, KLHL6, KDM6A and SP140. Well-defined poor prognosis TP53 somatic mutations were more common in CA (6%) than AA (4%). Conversely, we found higher frequency of poor prognosis chromosomal alterations (1p deletions and 1q gains) in AA (23%) than in CA (13%) patients.**Conclusions:** This proof-of-principle analysis confirms the presence of varying underlying tumor biology between racial groups which likely contributes to the variance in CA and AA clinical outcomes. Our results support the need of future prospective interventional trials designed to capture these molecular characteristics in relation to specific therapies.

8037 Poster Session (Board #46), Mon, 8:00 AM-11:30 AM

Predictors of long-term survival in newly diagnosed multiple myeloma (NDMM) patients (pts) enrolled in the Connect MM registry. *First Author: Cristina Gasparetto, Duke University Medical Center, Durham, NC*

Background: There are limited longitudinal data on disease management & outcomes for long-term survivors of MM. The Connect MM Registry is a US, multicenter, prospective observational cohort study designed to examine diagnostic & treatment (tx) patterns, clinical outcomes & QoL in pts with NDMM. Data from Connect MM were used to identify pt- & disease-specific baseline (BL) characteristics associated with ≥ 6 y overall survival (OS) vs death at < 6 y in pts with NDMM. **Methods:** Adult pts in Cohort 1 (enrolled ≤ 60 days from diagnosis from Sep 2009 - Dec 2011) had sufficient follow-up for evaluation; those censored at < 6 y (study discontinuation, ongoing but survival < 6 y) were excluded. BL characteristics were compared via logistic regression to identify those associated with ≥ 6 y OS ($P < 0.05$). **Results:** As of Feb 2017, median follow-up for Cohort 1 (N = 1493) was 65.4 mo. Median age was 67 y (range 24-94), 57% were male, & 59% were standard/low risk per IMWG criteria. Most pts (91%) had ≥ 1 novel agent in their first drug regimen (1L; Table). BL characteristics associated with ≥ 6 y OS by multivariate analyses were: age (≤ 70 vs > 70), ECOG PS (0-1 vs 2-5), lower ISS stage, platelet count (≤ 150 vs > 150 x 10^9/L), & lack of history of diabetes, del(17p), extramedullary plasmacytoma, or serum-free light chain abnormality. Matrix for predicting OS ≥ 6 y will be included in the presentation. **Conclusions:** This analysis identified pt- & disease-specific BL characteristics associated with ≥ 6 y OS in pts with NDMM. Higher rates of triplet tx, SCT, maintenance (with/without SCT), & higher response rates were observed in pts with ≥ 6 y OS. Clinical trial information: NCT01081028.

	≥ 6 y OS (n = 246)	Death < 6 y[a] (n = 662)
First induction regimen in 1L, n (%)		
Triplet	111 (45)	260 (39)
1 novel tx	160 (65)	452 (68)
2 novel tx	69 (28)	142 (21)
SCT in 1L, n (%)	125 (51)	157 (24)
+ maintenance	89 (36)	89 (13)
no maintenance	36 (15)	68 (10)
No SCT in 1L, n (%)	121 (49)	505 (76)
+ maintenance	62 (25)	123 (19)
no maintenance	59 (24)	382 (58)
Best response to first induction regimen in 1L, n (%)		
Stringent CR	2 (< 1)	2 (< 1)
≥ CR	19 (8)	19 (3)
≥ very good PR	42 (18)	75 (12)
Overall response (≥ PR)	72 (31)	147 (24)
≥ minor response	167 (71)	371 (59)

[a]585 pts were censored at < 6 y and excluded. CR, complete response; PR, partial response

8038 Poster Session (Board #47), Mon, 8:00 AM-11:30 AM

Final results of a phase Ib study of isatuximab (ISA) plus pomalidomide (Pom) and dexamethasone (dex) in relapsed/refractory multiple myeloma (RRMM). *First Author: Joseph Mikhael, Mayo Clinic, Phoenix, AZ*

Background: ISA is a monoclonal antibody targeting CD38-expressing tumor cells. We report final data from a Ph Ib dose-escalation/expansion study of ISA + Pom/dex in pts with RRMM (NCT02283775). **Methods:** Pts with RRMM (≥2 prior MM therapies; includes lenalidomide + a proteasome inhibitor [PI]) received 5, 10, or 20 mg/kg ISA (4 weekly [QW] doses, then every 2 wks until progression/intolerable toxicity), Pom 4 mg (Days 1–21), and dex 40 mg (QW; 20 mg if ≥75 yrs old) in 28-day cycles. Primary objective: recommended dose of ISA + Pom/dex. Secondary objectives included efficacy (IMWG criteria), safety, pharmacokinetics (PK). **Results:** 45 pts received ISA at 5 (n = 8), 10 (n = 31), or 20 (n = 6) mg/kg. Median age 67 (42–82) yrs. Median 3 (2–10) prior lines; 41 (91%), 37 (82%), and 38 (84%) pts refractory to their last regimen, immunomodulatory drugs (IMiDs), or PIs, respectively. 6 pts had high-risk (HR) cytogenetics. Median treatment time: 9.6 mos; 19 (42%) pts remain on treatment. 2 pts (10 mg/kg) discontinued due to AEs (grade [Gr] 5 intestinal perforation [due to underlying MM]; Gr 3 infusion-associated reaction [IAR]). 1 pt at each dose reported a DLT; MTD not reached. Expansion cohort initiated at 10 mg/kg based on efficacy, safety, and PK data. Most common TEAEs, besides IARs/hematologic AEs: fatigue (62%), upper respiratory tract infection (42%), and dyspnea (40%). Gr ≥3 neutropenia occurred in 83% of pts (Gr 4, 56%); all cases reported as AEs resolved with dose modification/growth factor support. IARs occurred in 19 (42%) pts (Gr ≥3, 1 pt): 18 (40%) pts during 1st infusion, 3 (7%) pts at later infusions. Overall response rate (ORR) was 62%; ORR in HR cytogenetics: 33%; IMiD refractory: 57%; PI refractory: 63%. 12 (27%) pts achieved ≥ VGPR (1 CR; 1 sCR). Median time to 1st response, 0.95 mos; median duration of response, 18.7 mos (95% CI 12.5–NC). Median progression-free survival, 17.6 mos (95% CI 6.8–20.5). ISA PK is unaffected by Pom/dex co-administration. **Conclusions:** These final results confirm the promising clinical activity and manageable safety profile of ISA + Pom/dex in heavily pretreated RRMM. A Ph III confirmatory trial is ongoing with results expected later in 2018. Funding: Sanofi Clinical trial information: NCT02283775.

8039 Poster Session (Board #48), Mon, 8:00 AM-11:30 AM

Lenalidomide (LEN) pharmacokinetics (PKs) in multiple myeloma (MM) patients (pts) with various renal functions. *First Author: Yanshuo Cao, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: LEN is a backbone drug used in the treatment of MM. Because over 80% LEN is excreted unchanged in urine, dose modifications for RD are recommended, based on PK evaluation following single dose LEN in non-malignant renal failure. In this analysis, MM pts with varying degrees of RD after single and multiple dosing of LEN were evaluated for PK to validate these dosing recommendations. **Methods:** Previously untreated MM pts received LEN in combination with dexamethasone according to creatinine clearance (CrCL) as recommended by the current LEN label. CrCL was calculated based on 24-hour urine collection. Serial venous blood samples were obtained on Days 1 and 17 and analyzed for LEN. PK parameters were calculated using non-compartmental methods. **Results:** A total of 25 pts were enrolled, 9 pts with normal renal function (CrCl ≥ 60 ml/min), 8 with moderate RD (30 ≤ CrCl < 60 ml/min), and 8 with severe RD (CrCL < 30 ml/min or on dialysis). Median age: 59 years (range: 39-69); male/female: 16/9. After a single dose, LEN half-life increased with RD (4.1 vs 6.7 vs 11.1 hours, $p < 0.01$). Plasma LEN concentrations were lowest in moderate RD, resulting in significantly lower maximum concentration (Cmax) and area under concentration-time curve (AUC). LEN clearance decreased with more advanced RD, and correlated with calculated CrCL, with the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) formula providing the best correlation compared to the Modification of Diet in Renal Disease (MDRD) formula and the Cockcroft-Gault formula. There was no LEN accumulation between Day 1 and Day 17 in pts with normal renal function or moderate RD. Cmax and AUC were significantly lower on Day 17 for pts with severe RD (413.8 ng/ml vs 71.1 ng/ml, $p < 0.0001$, and 4946 ng×hr/ml vs 538 ng×hr/ml, $p = 0.002$). **Conclusions:** MM pts with moderate RD are significantly under-dosed with the current LEN dosing recommendation. LEN PKs after multiple doses are similar for pts with normal or moderate RD, but those with severe RD may benefit from therapeutic drug monitoring and dose adjustment. The CKD-EPI formula should be used to calculate CrCL and LEN dose determination. The current LEN dose recommendation should be revised for pts with moderate RD. Clinical trial information: NCT01270932.

8040 Poster Session (Board #49), Mon, 8:00 AM-11:30 AM

Extended 5-y follow-up (FU) of phase 3 ELOQUENT-2 study of elotuzumab + lenalidomide/dexamethasone (ELd) vs Ld in relapsed/refractory multiple myeloma (RRMM). *First Author: Sagar Lonial, Emory University, Winship Cancer Institute, Atlanta, GA*

Background: The immunostimulatory monoclonal antibody elotuzumab exhibits a dual mechanism of action, directly activating natural killer cells and mediating myeloma cell death via antibody-dependent cell-mediated cytotoxicity. In ELOQUENT-2 (NCT01239797), ELd showed sustained reduction in risk of disease progression or death at 2- (30%), 3- (27%), and 4-y (29%) FU vs Ld, and a favorable trend in overall survival (final analysis at 427 deaths). Here we present progression-free survival (PFS) data at 5 y, a milestone timepoint in cancer survival analyses. **Methods:** RRMM patients (pts) randomized 1:1 to ELd or Ld in 28-d cycles until disease progression/unacceptable toxicity. Coprimary endpoints: PFS and overall response rate (ORR) per independent review committee. **Results:** In all, 646 pts were randomized to ELd (n = 321) and Ld (n = 325). At database lock (Nov 29, 2017), 13% (ELd) vs 7% (Ld) of pts remained on treatment; discontinuation was mostly due to disease progression (55 vs 56%). At 5-y FU (minimum 60 mo), ELd showed 27% reduction in risk of progression or death vs Ld (HR 0.73, 95% CI 0.60–0.87) and relative improvement of 50% in PFS rate at 5 y (18 vs 12%). Pts with ≥very good partial response (ELd 36% vs Ld 30%) had the greatest reduction in risk of progression/death (HR 0.63, 95% CI 0.44–0.89). ORR was 79% (ELd) vs 66% (Ld). G3–4 AEs included blood and lymphatic system disorders (ELd vs Ld: 46 vs 46%), infections (35 vs 27%), vascular diseases (11 vs 8%), second primary malignancies (SPMs; 10 vs 6%), and cardiac disorders (5 vs 8%). Higher rate of any-grade infection (84 vs 75%) and SPMs (17 vs 11%) may reflect longer median duration of treatment with each agent of the ELd vs Ld regimens (E/L/d vs L/d: 17/17/17 vs 12/12 mo). Fewer deaths occurred with ELd than Ld (193 vs 208), mostly due to disease progression. **Conclusions:** Elotuzumab (+ Ld) has the longest median FU of an immuno-oncology agent in MM. At the milestone timepoint of 5 y, ELd showed sustained, durable clinically relevant improvement in PFS, a 27% reduction in the risk of progression or death, and a safety profile with minimal incremental AEs with ELd vs Ld. Study funding: BMS. Writing support: L Yee, Caudex, funded by BMS. Clinical trial information: NCT01239797.

8041 Poster Session (Board #50), Mon, 8:00 AM-11:30 AM

Treatment (tx) journeys in newly diagnosed multiple myeloma (NDMM) patients (pts): Results from the Connect MM Registry. *First Author: Sundar Jagannath, Mount Sinai Hospital, New York, NY*

Background: Real-world longitudinal data on tx sequencing & outcomes are limited. The Connect MM Registry is a US, multicenter, prospective observational cohort study designed to examine diagnostic & tx patterns, clinical outcomes & QoL in pts with NDMM. Using visual tools (Sankey Plots), tx sequences & transitions were longitudinally assessed in pts with NDMM from Connect MM who did or did not receive stem cell transplant (SCT, NSCT). **Methods:** Adult pts were enrolled ≤ 60 days from diagnosis in Cohorts 1 (n = 1493; 2009-2011) & 2 (n = 1518; 2012-2016). Tx were classified as containing: 1) immunomodulatory agents, 2) proteasome inhibitors (PI), 3) IMiD® agent + PI, 4) non-IMiD/PI agents (other), 5) tx gaps. Data is presented within Sankey plots, a type of flow diagram in which the proportional flow between variables (or nodes) is visualized. Flows between tx from first to last lines of tx, discontinuation, or death, were visually depicted & median progression-free survival (PFS) for lines 1, 2 & 3 of tx were examined. **Results:** As of Feb 2017, 966 SCT & 1941 NSCT pts have been treated (Table). Points of tx transitions were represented by nodes on the plots corresponding to a change in regimen, such as maintenance (or not), line 2 tx, line 3 tx, discontinuation or death. Substantial heterogeneity of treatment was observed. The most frequent treatment flow among SCT pts was IMiD agent + PI → IMiD agent → Ongoing (O) → Line Not Yet Reached (LNR) (16%); & for NSCT pts was PI → PI → O → LNR (8%). Outcomes per line of therapy were assessed. Median 1st PFS was nearly twice as long in all SCT pts compared to all NSCT pts. In SCT pts, median 1st, 2nd, & 3rd PFS measured from line start were 44.0, 8.3, & 4.5 mo; in NSCT pts, median 1st, 2nd, & 3rd PFS were 21.5, 7.3, & 5.8 mo, respectively. **Conclusions:** These real-world registry data depict the therapeutic journeys of pts with MM. The PFS by line data are similar to clinical trials of pts with MM. Clinical trial information: NCT01081028.

8042 Poster Session (Board #51), Mon, 8:00 AM-11:30 AM

Health-related quality of life in patients with newly diagnosed multiple myeloma who are ineligible for stem cell transplantation: Results from the ALCYONE trial. *First Author: Katharine Gries, Janssen Research & Development, LLC, Raritan, NJ*

Background: ALCYONE, an ongoing multicenter, open-label, Phase 3 trial of subjects with newly diagnosed multiple myeloma not eligible for high-dose chemotherapy with stem cell transplantation due to coexisting conditions or age ≥ 65 years, demonstrated significant progression-free survival (PFS) with daratumumab, bortezomib, melphalan, and prednisone (D-VMP) treatment compared with VMP alone. Measuring patient-reported outcomes (PROs) alongside disease progression provides the patient perspective on quality of survival and the value of health-related quality of life (HRQoL) for treatment decisions. **Methods:** The European Organization for Research and Treatment of Cancer Questionnaire (EORTC QLQ-C30) and EuroQol Questionnaire (EQ-5D-5L) visual analog scale (VAS) were completed using an electronic device (ePRO) at baseline and every 3 months during treatment; interim results presented for first 12 months. Key secondary endpoints included EORTC QLQ-C30 Global Health Status (GHS) and VAS scores. Treatment differences were assessed using repeated measures, mixed-effects model. Percent subjects achieving meaningful improvement based on established clinically important differences was summarized. **Results:** Study population included D-VMP (n = 350) and VMP (n = 356) subjects. Compliance rates > 90% at baseline and > 70% through month 12. Significantly better HRQoL in the D-VMP arm was observed at month 3 for GHS (p = 0.026) [Table]. Meaningful improvement in GHS was reported in 59.7% of D-VMP subjects compared to 52.0% VMP subjects (OR: 1.37; 95% CI: 1.02, 1.85). Similar HRQoL improvements were observed with the VAS. **Conclusions:** Patients experienced meaningful improvement in HRQoL over the course of therapy with more achieving meaningful change when treated with D-VMP. Improvements in HRQoL were consistent with the clinical benefit showing superior PFS of D-VMP over VMP alone. Clinical trial information: NCT02195479.

GHS Change from baseline.

8043 Poster Session (Board #52), Mon, 8:00 AM-11:30 AM

Real-world evidence of cardiac hospitalizations in carfilzomib- and non-carfilzomib-treated multiple myeloma patients in the United States. *First Author: Joseph Mikhael, International Myeloma Foundation, North Hollywood, CA*

Background: Approximately 30% of multiple myeloma (MM) patients (pts) are hospitalized for cardiac events after MM diagnosis. Carfilzomib (K), a 2nd generation proteasome inhibitor, was approved to treat MM in 2012. **Methods:** We conducted a matched retrospective claims-based cohort study of MM pts who initiated K or non-K treatment (tmt) between 2012-2015 using Truven MarketScan. Pts were > 18 yrs and had ≥1 yr baseline (BL) data before MM diagnosis. Line of therapy (LOT) and regimens were identified using drug prescription claims. Index LOT was defined as first K-containing LOT. Pts who received non-K regimens were matched 2:1 to K pts on age, sex, and index LOT. Hospitalizations were identified using diagnosis codes in claims during index LOT. Any cardiac hospitalizations (CH) included new and existing cardiac conditions defined as having a cardiac code (arrhythmia, heart failure, ischemic heart disease, cardiomyopathy, hypertension) as primary/secondary diagnoses on the claim; primary CH (PCH) had a cardiac code as primary diagnosis. Odds ratios (OR) and 95% confidence intervals (CI) were calculated, adjusting for tmt duration and BL conditions. **Results:** 498 K and 996 non-K pts were identified (median age 61 and 62 yrs, respectively). In both cohorts, 59% were male; 6%, 30%, and 64% were treated in LOT 1, 2, and 3+. Overall, there was no difference in BL cardiac history (84.9% and 84.1%, respectively). Median tmt duration was 105 and 158 days for K- and non-K pts, respectively. 34% of pts in each cohort were hospitalized. Any CH occurred in 16% and 12% of K- and non-K pts. Unadjusted OR (95% CI) for CH in K pts vs non-K pts was 1.47 (1.1–2.0). When adjusted for tmt duration, OR (95% CI) of CH in K pts vs non-K pts was 1.1 (0.8–1.5). Similar hospitalization risks were seen when additionally adjusting for BL conditions. PCH occurred in 2% and 3% of K and non-K pts, respectively (unadjusted OR [95% CI] 0.7 [0.4–1.4]; adjusted OR [95% CI] 0.55 [0.3–1.1]). **Conclusions:** In real world pts, the risk of cardiac-related hospitalizations during tmt was similar for K- and matched non-K treated pts when adjusted for tmt duration and BL conditions. Selection bias may impact the risk estimates.

8044 Poster Session (Board #53), Mon, 8:00 AM-11:30 AM

The MD Anderson modified cyclophosphamide, bortezomib, doxorubicin, and dexamethasone (mCBAD) for the treatment of newly diagnosed (NDMM) and relapsed/refractory multiple myeloma (RRMM). *First Author: Samer Tabchi, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: MM follows a clinical course leading to refractoriness and limited treatment options in RRMM. Aggressive NDMM needs rapid cytoreduction for disease control, which may not be possible with standard novel therapies. We report on a highly effective therapy that offers a salvage option for these patients. **Methods:** We searched our medical database for MM patients who received mCBAD from 2010-2016 – 28 day cycle of cyclophosphamide 350 mg/m^2 IV twice daily + mesna 400mg/m^2 IV daily (days 1-4), bortezomib 1.3 mg/m^2 SQ (days 1, 4, 8, 11), doxorubicin 9 mg/m^2 IV (days 1-4) , dexamethasone 40 mg PO daily (days 1-4, 9-12, 17-20). IMWG criteria were used for response assessment. Descriptive statistics, Fisher's exact test, Chi-square, Wilcoxon rank sum, and Kaplan-Meier were used for statistical purposes. **Results:** 80 patients met the inclusion criteria. Baseline characteristics, response, adverse events, PFS/OS are summarized in Table 1. Median follow-up for the censored observations was 21.3 months (1.35 – 69.22). **Conclusions:** mCBAD offers excellent response rates (ORR > 90%) and favorable PFS/OS in highly refractory high risk MM. It is also an excellent salvage regimen with about half of patients undergoing subsequent transplant. Patient selection is required due high treatment related mortality.

Duration of complete response (DurCR) impacts overall survival (OS) in multiple myeloma (MM). *First Author: Surbhi Sidana, Mayo Clinic, Rochester, MN*

Background: DurCR has a direct impact on progression free survival in MM, but its impact on OS is not well described. **Methods:** We retrospectively analyzed 351 patients with MM from 2004-16 who achieved CR (IMWG criteria) with first line therapy to assess impact of DurCR (time from achievement to loss of CR) on OS. **Results:** The table lists baseline characteristics. Loss of CR was experienced by 68% (239) patients, with (1) symptomatic progression in 25% (59); (2) biochemical progression in 24% (58); (3) two consecutive positive immunofixation or rise in monoclonal protein not meeting progression criteria in 37% (88); (4) two abnormal FLC ratios in light chain MM in 14% (34). In group 3, progression was seen in 73/88 (85%) patients (13 symptomatic, 60 biochemical) with median time from loss of CR to progression of 7 months and in 21/34 (62%) patients in group 4 (3 symptomatic, 18 biochemical) with median time of 4 months. After median follow-up of 72 months, median OS from start of therapy with DurCR $\geq$ 24 (n = 179, 51%) vs. $<$ 24 months (n = 172, 49%) was 150 vs. 80 months, $p < 0.001$. Estimated 5 and 10 year OS in DurCR $\geq$ 24 was 95% and 70% and in DurCR $<$ 24 was 66% and 25%, respectively. Landmark analysis for patients alive at 24 months from start of treatment showed similar results (DurCR $\geq$ 24 vs. $<$ 24, median OS: 150 vs. 83 months, $p < 0.001$). Among patients who experience loss of CR, OS from loss of CR was higher in patients with DurCR $\geq$ 24; 82 vs 56 months, p = 0.005. On multivariate Cox Proportional hazards model, DurCR remained a significant predictor of OS from start of treatment (CR $<$ 24 months vs. $\geq$ 24 months, HR: 4.0 (2.4-7.0), $p <$ 0.001), after adjusting for revised ISS, age $\geq$ 65 years, ASCT and maintenance therapy. **Conclusions:** DurCR is an important independent predictor of OS in MM, with estimated 5 and 10 year OS with DurCR $\geq$ 24 months being 95% and 70%, respectively. Importantly, majority of patients who experience loss of CR meet criteria of progression within median of 4-7 months.

8046 Poster Session (Board #55), Mon, 8:00 AM-11:30 AM

Impact of obesity on response in 751 myeloma patients receiving lenalidomide, bortezomib, and dexamethasone (RVd) induction. *First Author: R Donald Harvey, Winship Cancer Institute of Emory University, Atlanta, GA*

Background: Obesity is a putative risk factor for the development of monoclonal gammopathy of undetermined significance (MGUS) and multiple myeloma (MM). Induction regimens for MM have evolved; and lenalidomide, bortezomib, and dexamethasone (RVd) produces an overall response rate of 82%. Response, tolerability and therapy duration are related to agent dose, dose intensity, and comorbidities, which may be higher in the obese. We analyzed the effect of anthropometric measures on response and therapy duration in patients (pts) receiving RVd induction. **Methods:** Height (cm), weight (kg), body surface area (BSA), and body mass index (BMI) were obtained from a database of 751 pts receiving RVd. Demographics including sex, self-reported race, ISS stage at diagnosis, and cytogenetic risk category were analyzed with anthropometric data in a multivariate model with response per IMWG criteria, progression-free survival (PFS) and overall survival (OS). **Results:** Anthropometric measures were available in 746/751 (99%) pts. Of 746 pts analyzed, 54% were male, 57% white, and 30% black. Median BMI (kg/m^2) was 28 (range 17-53); BMI per category was underweight ($\leq$ 18.5) 0.9%, normal (18.5- $<$ 25) 25.7%, overweight (25- $<$ 30) 35.7%, obese (30-40) 32.3%, and morbidly obese ($>$ 40) 5.3%. Median BSA (m^2) was 1.94 (range 1.29-2.70). Median BMI and BSA were significantly higher in men ($p < 0.05$). Morbid obesity was more common in black versus white pts (8.4 vs 3.8%, p = 0.017) and women versus men (7.9 vs 3%, p = 0.03). Pts with BMI $\geq$ 40 had an estimated OS of 81 vs 98 months compared to pts with BMI $<$ 40 (p = 0.071); unadjusted hazard ratio (HR) 1.47 (95% CI: 0.56-3.49). Response of VGPR or better did not show a significant association with higher BSA ($>$ 2.25) (80.3 vs 70.3%, p = NS). On multivariate analysis, PFS and OS showed no association with BMI or BSA. ISS stage 3 disease (HR 2.1; 95% CI 1.4-3.4) and high risk cytogenetics (HR 2.2; 95% CI 1.5-3.7) were significantly associated with shorter OS ($p < 0.001$). **Conclusions:** Obesity does not significantly impact depth or duration of response with RVd induction. We advocate use of full dose RVd regardless of BSA or BMI in pts with acceptable performance status and managed comorbid conditions.

8047 Poster Session (Board #56), Mon, 8:00 AM-11:30 AM

Relationship of acquired resistance of myeloma cells to bortezomib with Lyn and Src induced inhibition of PP2A and effect of treatment with the tyrosine kinase inhibitor dasatinib. *First Author: Barry Paul, Duke University, Chapel Hill, NC*

Background: Multiple Myeloma (MM) is the second most common hematologic malignancy in the United States. Proteasome inhibitors—especially bortezomib (BTZ)—are a mainstay of treatment in MM, but nearly all patients eventually develop resistance to these agents. We hypothesize that resistant cells are escaping BTZ induced cell killing via dedifferentiation to a more primitive state resulting in inhibition of the tumor suppressive activity of PP2A. **Methods:** MM cell lines (RPMI-Dox, MM1R, and OPM1) were grown in media with increasing concentrations of BTZ over time to select for resistance, and then treated with dasatinib. MTT assays were conducted to confirm BTZ resistance. Sensitive and resistant cells were harvested for protein and RNA and evaluated through standard qRT-PCR, flow cytometry, and immunoblotting methods to determine levels of PP2A-C, Src, and Lyn, as well as the differentiation markers CD138 and IRF4. **Results:** MTT assays verified significant resistance in cells grown with BTZ (mean IC_{50} 225.80 $\pm$ 49.76 nM) compared to parental cells (mean IC_{50} 7.02 $\pm$3.97 nM). Immunoblotting confirmed differential phosphorylation of the Y307 inhibitory site of PP2A-C in the resistant cells. Levels of Src and Lyn RNA and protein were increased in the resistant cells, and treatment with the multikinase inhibitor dasatinib selectively increased cell death in the resistant cells (IC_{50} 1.31 $\pm$0.11 nM). Additionally, expression of the differentiation markers CD138 and IRF4 was absent in the BTZ resistant cells while being appropriately expressed in the parental cells. **Conclusions:** Our experiments show that inhibition of PP2A plays a significant role in acquired resistance to BTZ and that this process is primarily driven by increased expression of Src and Lyn. Inhibition of Src and Lyn activity with dasatinib was able to overcome this effect and selectively resensitize the resistant cells. Our data also imply that the resistant cells may be dedifferentiating to a more primitive state as evidenced by absent IFR4 and CD138 expression. These data suggest a role for kinase inhibitors in myeloma patients with acquired resistance to BTZ.

8049 Poster Session (Board #58), Mon, 8:00 AM-11:30 AM

Quality of life and cancer worry in a follow-up cohort of patients with asymptomatic monoclonal gammopathies. *First Author: Michelle Ann Theobald Hildebrandt, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Monoclonal gammopathy of unknown significance (MGUS) and smoldering multiple myeloma (SMM) are monoclonal gammopathies that precede multiple myeloma (MM). Although considered asymptomatic, patients diagnosed with these conditions are at greatly increased risk of developing MM. There is currently limited to no information on quality of life (QOL) or cancer worry/anxiety burden for patients with MGUS and SMM. **Methods:** We implemented a longitudinal QOL and cancer-related worry assessment in an observational cohort study of MGUS and SMM patients at MD Anderson Cancer Center (expected total enrollment of N = 200). Questionnaires included the QLQ-C30 cancer QOL tool and the MY20 myeloma-specific module, as well as questions to measure cancer worry. In this preliminary data analysis, a total of 46 patients completed the baseline questionnaires (MGUS = 17; SMM = 29). **Results:** Overall, individuals with MGUS have a worse QOL compared to SMM patients with MGUS patients reporting a $>$ 12 point lower Global QOL score (71.6 vs 83.9; P = 0.035). Significant differences were also observed for Physical Functioning (P = 0.012), Nausea/Vomiting (P = 0.045), and Pain (P = 0.027). For myeloma-specific QOL and symptoms, MGUS patients again reported higher levels of Back Pain (P = 0.017), Burning/Sore Eyes (P = 0.021), Restlessness/Agitation (P = 0.026), and Tingling in Hands/Feet (P = 0.031) compared to SMM patients. This increase in reported QOL burden corresponded to MGUS patients less feeling in control of their MM risk compared to SMM patients (P = 0.0038). **Conclusions:** Patients with MGUS self-reported a high QOL burden that was often greater than SMM patients and more closely in line with MM-specific or overall cancer reference values. Further, a sense of loss of control of their MM risk is heightened in MGUS patients. Together, even though MGUS is considered clinically asymptomatic, patients diagnosed with this condition are experiencing reduced QOL is impacting their overall well-being. These results suggest potential opportunities for interventional strategies to improve the lives of patients with monoclonal gammopathies. This work was supported in part by MD Anderson's Cancer Center Support Grant P30 CA016672.

8050 Poster Session (Board #59), Mon, 8:00 AM-11:30 AM

Comparative analysis of outcomes in African American (AA) and white (W) patients (pts) with multiple myeloma (MM) treated with lenalidomide (LEN) or pomalidomide (POM). *First Author: Sikander Ailawadhi, Mayo Clinic, Jacksonville, FL*

Background: AA are ≈2-fold more likely to develop MM, and racial and ethnic minorities may not have similar access to novel MM treatment (Tx). Outcomes are often worse in AA vs W pts with cancer, but data are mixed in MM. Thus, we compared outcomes in AA and W pts treated with LEN or POM. **Methods:** We performed a subgroup analysis with data from 4 clinical trials. E4A03 (Rajkumar et al. *Lancet Oncol* 2010) used LEN + high- or low-dose dexamethasone (LEN-D or LEN-d) as a first-line MM Tx. CALGB 100104 (McCarthy et al. *NEJM* 2012) studied LEN or placebo (PBO) maintenance after transplant. MM-009 (Weber et al. *NEJM* 2007) and MM-002 (Richardson et al. *Blood* 2014) used LEN-D or PBO-D and POM or POM-d, respectively, for relapsed/refractory MM. We compared baseline characteristics and Tx outcomes in AA vs W pts from the LEN-d arm of E4A03, all arms of CALGB and MM-009, and the combined POM and POM-d arms of MM-002. **Results:** Detailed results are in the Table. Baseline characteristics were generally similar in each trial. PFS/OS was similar in AA and W pts treated with LEN or POM except in the MM-002 trial, where PFS was longer in AA pts. Neutropenia was the most common hematologic Tx-emergent adverse event across the studies. **Conclusions:** Tx with LEN or POM resulted in similar or better outcomes in AA vs W pts in multiple Tx settings, emphasizing the importance of equitable access to Tx.

Association of venous thromboembolism with increased mortality in patients with multiple myeloma. *First Author: Martin W. Schoen, Saint Louis University School of Medicine, St. Louis, MO*

Background: Previous studies have demonstrated conflicting results regarding the effect of venous thromboembolism (VTE) on survival in patients with multiple myeloma (MM). In order to understand the impact of VTE on survival in MM, we studied outcomes in a nationwide population of United States Veterans with MM. **Methods:** Patients with newly diagnosed MM treated within the Veterans Health Administration (VHA) system between September 1, 1999 and 2013 were identified within the VHA Central Cancer Registry. Patients who did not receive treatment within 6 months of diagnosis were excluded. Age, sex, race, body mass index (BMI), comorbidities, treatment (including transplant status), hemoglobin (HGB), albumin, and renal function were included. VTE was identified using an algorithm consisting of a combination of ICD-9 codes and VTE treatment. Cox proportional hazards regression modeling was used to assess the association between VTE as a time-varying exposure and overall survival while controlling for known prognostic factors. **Results:** The analytic cohort consisted of 4797 patients, of which 641 developed VTE after MM diagnosis (15.4%). After controlling for age, race, BMI, medical comorbidities, baseline lab characteristics, year of diagnosis, and initial treatment with a novel agent (thalidomide, lenalidomide, or bortezomib), patients with MM and VTE had an increased risk of death at 2 years (Hazard Ratio [HR] 1.28, 95% CI 1.09-1.52) and 5 years (HR 1.17, 95% CI 1.04-1.31) but not at one year (HR 1.15, 95% CI 0.90-1.49). Landmark analyses of patients surviving at least 6 months showed VTE continued to be a risk factor for death at 2 years (HR 1.23, 95% CI 1.05-1.45) and 5 years (HR 1.17, 95% CI 1.04-1.32). **Conclusions:** After controlling for known MM prognostic factors, VTE was significantly associated with increased mortality in the 2-years following MM diagnosis. Whether the observed increase in mortality is a direct result of VTE could not be determined in this study. Further study of MM patients with a high-risk for VTE, including studies of thromboprophylaxis, could clarify the significance of this association.

8053 Poster Session (Board #62), Mon, 8:00 AM-11:30 AM

Daratumumab-based therapies in patients with AL amyloidosis. *First Author: Jithma P. Abeykoon, Department of Internal Medicine, Mayo Clinic, Rochester, MN*

Background: Treatment options for patients (pts) with relapsed/refractory (RR) AL amyloidosis are limited. Daratumumab (dara) has been approved as monotherapy (DMT) or combination therapy (DCT) for multiple myeloma (MM). Data for dara-based therapy (DBT) in AL are sparse. **Methods:** We studied pts with RR AL without coexisting MM seen at Mayo Clinic from 11/2015 to 02/2018 & treated with DBT. Hematologic response (HR) & organ response (OR) were defined per Consensus criteria. All time to event analyses were done from the time of DBT initiation. Pts with dFLC < 4 mg/dL at the time of start of DBT were considered non evaluable (NE) for HR other than disease progression. DCT included dara, pomalidomide & dexamethasone (dex) (35%), dara, lenalidomide & dex (26%), dara, bortezomib & dex (22%) & other DBT regimens (17%). **Results:** 45 pts (DMT, n = 22; DCT, n = 23) received DBT; median age at DBT initiation was 64 years (range: 46-82). Data for HR assessment were available in 44 pts & 31 were evaluable for HR. HR & end points are outlined in Table 1. Among 13 NE pts, response improved to CR in 5 (38%) while remaining 8 continued to be NE. Of these 13 pts, 77% reached dFLC < 1 mg/dL at last follow up (FU). Cardiac, renal & liver involvement was observed in 59%, 43% & 7% of pts. Cardiac, renal and liver OR was 46%, 32%, 0%, respectively. At last FU, 31 pts were on DBT. Three (7%) pts had disease progression. Hematologic toxicity (HT) from DBT included anemia ≤2 grade (Gr =) 69%, 3 Gr 3%; thrombocytopenia 1 Gr 38%; neutropenia ≤2 Gr21% & > 2 Gr 7%. Non-HTs included fatigue (23%), infusion reactions (21%), & treatment-emergent neuropathy (14%). **Conclusions:** DBT is safe & effective in heavily pretreated pts with AL. HR is achieved rapidly with DBT, particularly with DCT.

Characteristics and outcomes of primary plasma cell leukemia in the era of novel agents: Single center experience. *First Author: Iman Aboudalle, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Plasma cell leukemia (PCL) is a rare and aggressive disease characterized by a clonal proliferation of plasma cells in bone marrow and blood. PCL can present as *de novo* disease without underlying multiple myeloma. The purpose of this study is to describe the clinical characteristics and outcomes of primary (p) PCL in the era of novel agents. **Methods:** This is a retrospective study of patients (pts) with pPCL treated at The University of Texas MDACC from 01/1998-12/2017. The Kaplan Meier method was used to estimate progression free survival (PFS) and overall survival (OS). Univariate and multivariate Cox proportional hazards models were used to evaluate the associations between a continuous variable and important prognostic covariates, respectively, with time to event endpoints. **Results:** We identified 77 pts with pPCL as defined by International Myeloma Working Group (IMWG) criteria. 64 (83%) pts were treated with immunomodulatory drugs (IMiD) and/or proteasome inhibitors (PI) during induction. Overall response rate was 70% (45 pts) by IMWG response criteria in pts treated with novel agents. 30 pts received consolidation with autologous stem cell transplantation (ASCT). For all pts, median PFS was 11.1 months (mos) (95% CI: 8.6-14.8), with 8 pts presenting with leptomeningeal disease at the time of relapse. Median OS (mOS) from the time of diagnosis was 19.1 mos (95% CI: 15.3-26.1) with a median follow-up of 20 mos. The mOS for pts receiving ASCT was 33.6 mos (95% CI: 22.6-40.2). Pts who underwent ASCT had significantly prolonged mOS (HR=0.2, 95% CI: 0.11-0.45; p<0.0001) on multivariate analysis. The main cause of death was disease progression in 84% of pts. **Conclusions:** pPCL prognosis can be improved with the incorporation of novel agents and early consolidation with ASCT.

TPS8055 Poster Session (Board #64a), Mon, 8:00 AM-11:30 AM

Phase III (IMROZ) study design: Isatuximab plus bortezomib (V), lenalidomide (R), and dexamethasone (d) vs VRd in transplant-ineligible patients (pts) with newly diagnosed multiple myeloma (NDMM). *First Author: Robert Z. Orlowski, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Pts with transplant-ineligible NDMM require therapies which prolong survival and improve quality of life. The combination of VRd significantly improves progression-free (PFS) and overall survival compared with Rd in NDMM, and has an acceptable safety profile. Combining VRd with a monoclonal antibody (mAb) may further improve efficacy. Isatuximab (ISA) is an anti-CD38 mAb that demonstrates antitumor and immunomodulatory activities with strong potentiation when combined with V and R in MM xenograft models. Here we describe a Phase III, randomized, open-label, multicenter study (NCT03319667; IMROZ), evaluating clinical benefit of ISA plus VRd vs VRd in pts with transplant-ineligible NDMM. **Methods:** Approximately 440 adult pts with symptomatic MM (International Myeloma Working Group [IMWG] criteria) will be randomly assigned, according to Revised International Staging System criteria (I or II vs III vs unknown) and age ($<$ 70 vs $\geq$70 years), in a 3:2 ratio to ISA (10 mg/kg on Days 1, 8, 15, 22, 29 in Cycle 1; every 2 weeks [Q2W] thereafter), plus V (1.3 mg/m^2 on Days 1, 4, 8, 11, 22, 25, 29, 32), R (25 mg on Days 114, Days 2235), and d (20 mg on Days 1, 2, 4, 5, 8, 9, 11, 12, 15, 22, 23, 25, 26, 29, 30, 32, 33), or VRd alone for 4 6-week cycles (induction phase). After Cycle 4, pts will receive Rd with or without ISA in 4-week cycles (R on Days 121; d weekly; ISA Q2W) until disease progression, unacceptable adverse events (AEs), or pt decision to discontinue (continuous phase). ISA will be reduced to monthly dosing from Cycle 18. Pts who progress on Rd can cross-over to ISA plus Rd. Primary endpoint is PFS (IMWG criteria) assessed by a blinded independent review committee, and analyzed with a 1-sided stratified log-rank test. Key secondary endpoints include rate of very good partial response or better, minimal residual disease negativity rate, and complete response rate. Safety evaluations include AEs, laboratory parameters, vital signs, and physical examination. The IMROZ study is currently enrolling pts; recruitment is planned in approximately 100 countries worldwide, including Japan and China. Study funding: Sanofi. Clinical trial information: NCT03319667.

TPS8056 Poster Session (Board #64b), Mon, 8:00 AM-11:30 AM

A phase 3 randomized, controlled, open-label study of selinexor, bortezomib, and dexamethasone (SVd) versus bortezomib and dexamethasone (Vd) in patients with relapsed or refractory multiple myeloma (RRMM). *First Author: Sosana Delimpasi, General Hospital of Athens, Athens, Greece*

Background: Selinexor is an oral, selective inhibitor of nuclear export that specifically blocks exportin 1, leading to the nuclear accumulation & reactivation of tumor suppressor proteins. Twice weekly (BIW) bortezomib in combination with dexamethasone (Vd) is an established therapy in relapsed and refractory multiple myeloma (RRMM). While the activity of bortezomib (bort) BIW in combination with other agents is efficacious, prolonged use is limited due to peripheral neuropathy (PN) (50-60%) as well as acquired resistance to bort. Preclinical studies have shown that selinexor, when combined with bort, can restore sensitivity of bort-resistant MM, inhibiting tumor growth and increasing survival in murine MM xenografts. In a Ph 1b/2 study, the combination of weekly selinexor with weekly bort and dex (SVd) was well tolerated and highly active with an ORR of 83% in patients (pts) with PI non-refractory MM, furthermore PN was limited to 14%. In addition, in pts with PI refractory MM, an ORR of 43% was observed, supporting selinexor can resensitize myeloma to PI based therapies. **Methods:** The BOSTON trial (NCT03110562) is a global Ph III study of selinexor in combination with weekly bort and dex (QW SVd) vs BIW bort in combination with dex (BIW Vd), in pts with RRMM who have received 1 to 3 prior anti-MM regimens. The QW regimen of SVd may provide for a higher ORR and improved duration of response as well as provide for a considerable reduction (~40%) in overall bort dose vs BIW Vd arm, which may be associated with better tolerability (e.g., PN) compared with second-line Vd-based regimens. After progressive disease is confirmed by an Independent Review Committee, pts in the Vd arm may crossover to SVd. Crossover to Sd is allowed as compassionate use for pts who are not able to tolerate continued treatment with bort. Progression Free Survival (PFS) and ORR are primary endpoints. Secondary endpoints include overall survival and duration of response. An ORR primary analysis is planned after the last pt randomized has had the opportunity to complete at least 2 MM evaluations. Clinical trial information: NCT03110562.

TPS8057 Poster Session (Board #65a), Mon, 8:00 AM-11:30 AM

Randomized, open-label, phase 2/3 study of daratumumab (DARA) with or without JNJ-63723283, an anti-PD-1 monoclonal antibody, in relapsed/refractory multiple myeloma (RRMM). *First Author: Jan Van Droogenbroeck, Department of Hematology, AZ St.-Jan Brugge-Oostende AV, Brugge, Belgium*

Background: DARA, a human CD38 monoclonal antibody, is approved for treatment of RRMM. DARA produces deep clinical responses in RRMM and induces T-cell expansion through reduction of immune suppressive cell populations (CD38$^+$ myeloid-derived suppressor cells and regulatory T and B cells). JNJ-63723283 (JNJ-283) is a fully human monoclonal antibody that binds to PD-1 and enhances the induction of T cell-mediated pro-inflammatory cytokines and reduces tumor volume in preclinical models. JNJ-283 in combination with DARA may improve clinical responses in RRMM by enhancing the anti-tumor and immunomodulatory effects of DARA through PD-1 blockade. This study will assess the efficacy, safety, and pharmacokinetics of DARA $\pm$ JNJ-283 in patients (pts) with RRMM. **Methods:** This is an ongoing, multiphase, multicenter study of DARA (16 mg/kg intravenous [IV] QW for Cycles 1-2, Q2W for Cycles 3-6, and Q4W thereafter; 28-d cycles) $\pm$ JNJ-283 (240 mg IV Day 2 and 15 of Cycle 1 and then Q2W thereafter). Eligible pts ($\geq$18 years of age) must have received $\geq$3 prior lines of therapy, including a proteasome inhibitor (PI) and an immunomodulatory drug (IMiD), or have disease that is double refractory to both a PI and an IMiD. Pts must have demonstrated evidence of response to $\geq$1 prior treatment regimen. Pts previously treated with anti-CD38 therapy, including DARA, or anti-PD-1 and anti-PD-L1 antibodies are excluded. Approximately 6 pts will be enrolled in Part 1 (safety run-in cohort of DARA + JNJ-283). If $<$ 2 pts experience a dose-limiting toxicity, the study will proceed to Part 2 (Phase 2) in which 80 pts will be randomized 1:1 to the 2 treatment arms. The primary endpoint is overall response rate, and secondary endpoints include safety, $\geq$complete response and $\geq$very good partial response rates, duration of response, time to response, progression-free survival, overall survival, minimal residual disease, and pharmacokinetics/immunogenicity of DARA and JNJ-283. Enrollment of an additional 300 pts into Part 3 (Phase 3) will be considered if the primary efficacy endpoint is met and DARA plus JNJ-283 is deemed safe in Part 2. Clinical trial information: NCT03357952.

TPS8058 Poster Session (Board #65b), Mon, 8:00 AM-11:30 AM

Randomized, open-label, non-inferiority, phase 3 study of subcutaneous (SC) versus intravenous (IV) daratumumab (DARA) administration in patients with relapsed or refractory multiple myeloma (RRMM): COLUMBA. *First Author: Saad Zafar Usmani, Department of Hematologic Oncology & Blood Disorders, Levine Cancer Institute/Carolinas Healthcare System, Charlotte, NC*

Background: DARA, a human IgG1κ monoclonal antibody that targets CD38, induces deep and durable responses in patients with RRMM. In a phase 1b RRMM study, a SC co-formulation of DARA with recombinant human hyaluronidase (rHuPH20; DARA SC) was found to be well tolerated with low infusion-related reaction (IRR) rates. Moreover, response rates were similar to those observed historically with DARA IV. The phase 3 COLUMBA study will compare the efficacy, pharmacokinetics, and IRRs of DARA SC versus DARA IV in patients with RRMM. **Methods:** This is an ongoing phase 3, randomized, open-label, multicenter, non-inferiority study of DARA SC (1,800 mg DARA in combination with rHuPH20 [2,000 U/mL] administered by manual push [15 mL] over 3-5 minutes at alternating left/right abdominal sites) versus DARA IV (16 mg/kg IV infusion) weekly for Cycles 1-2 (28-day cycles), every 2 weeks for Cycles 3-6, and every 4 weeks thereafter until disease progression or unacceptable toxicity. Pre- and/or post-infusion medications include paracetamol, diphenhydramine, methylprednisolone, and an optional leukotriene inhibitor. Eligible patients ($\geq$18 years) with RRMM must have received $\geq$3 prior lines of therapy, including a proteasome inhibitor (PI; $\geq$2 cycles or 2 months of treatment) and an immunomodulatory drug (IMiD; $\geq$2 cycles or 2 months of treatment), or must be double refractory to both a PI and an IMiD. The co-primary endpoints are overall response rate and maximum C_{trough} concentration of DARA on Cycle 3 Day 1. Secondary endpoints include IRR rates, progression-free survival, $\geq$very good partial response and $\geq$complete response rates, time to next therapy, overall survival, time to response, and duration of response. Approximately 480 patients will be enrolled and randomly assigned (1:1) to the 2 treatment groups. Randomization will be stratified by body weight at baseline ($\leq$65 kg, 66 kg to 85 kg, $>$ 85 kg), number of prior lines of therapy ($\leq$4 prior lines versus $>$ 4 prior lines), and type of myeloma (IgG versus non-IgG). Clinical trial information: NCT03277105.

TPS8059 Poster Session (Board #66a), Mon, 8:00 AM-11:30 AM

Pomalidomide and dexamethasone (pom-dex) with or without daratumumab (DARA) in patients (pts) with relapsed or refractory multiple myeloma (RRMM): A multicenter, randomized, phase 3 study (APOLLO). *First Author: Pieter Sonneveld, Department of Hematology, Erasmus MC Cancer Institute, Rotterdam, Netherlands*

Background: DARA, a human IgGκ monoclonal antibody targeting CD38, is approved in the United States and Europe for use as a monotherapy and in combination with bortezomib/dexamethasone or lenalidomide/dexamethasone in pts with RRMM. In a phase 1b study, DARA + pom-dex demonstrated efficacy and tolerability in pts with RRMM, leading to the approval of this regimen for pts with RRMM in the United States. This phase 3 study will evaluate the efficacy and safety of DARA + pom-dex versus pom-dex alone in RRMM. **Methods:** This is an ongoing multicenter, open-label, phase 3 study of DARA + pom-dex versus pom-dex alone. RRMM pts who have received prior antimyeloma therapy, including a proteasome inhibitor and a lenalidomide-containing regimen, have responded to prior therapy, and have progressed on or after their last regimen, are eligible. Pts who have received only 1 prior line of therapy must have progressed ≤60 days of completing the lenalidomide-containing regimen. All pts will receive pom 4 mg orally on Days 1-21 of a 28-day cycle + dex 40 mg QW (20 mg for pts ≥75 year of age). Following a protocol amendment, pts in the DARA group will receive subcutaneous DARA (1,800 mg co-formulated with recombinant human hyaluronidase [rHuPH20]) QW in Cycles 1-2, Q2W in Cycles 3-6, and Q4W thereafter. All pts will receive preinfusion medications (including diphenhydramine, paracetamol, dexamethasone, and an optional leukotriene inhibitor), and postinfusion medications (diphenhydramine, lung disease control medications, and a short-acting β2 adrenergic receptor agonist) will be recommended for pts with a higher risk of respiratory complications. Progression-free survival is the primary endpoint. Secondary endpoints include safety, overall survival, overall response rate, duration of response, and minimal-residual-disease-negative rate. Approximately 302 pts will be enrolled across 11 countries. Clinical trial information: NCT03180736.

TPS8060 Poster Session (Board #66b), Mon, 8:00 AM-11:30 AM

Phase III (IKEMA) study design: Isatuximab plus carfilzomib and dexamethasone (Kd) vs Kd in patients with relapsed/refractory multiple myeloma (RRMM). *First Author: Thomas G. Martin, University of California at San Francisco, San Francisco, CA*

Background: Multiple myeloma (MM) remains an incurable disease requiring multiple lines of therapy, in which carfilzomib-based treatments are a standard of care. Isatuximab (ISA), an anti-CD38-targeted monoclonal antibody with antitumor and immunomodulatory activities in preclinical models of MM, has shown clinical activity as monotherapy and in combination with current standard of care in patients (pts) with RRMM. **Methods:** This Phase III, prospective, randomized, open-label study (NCT03275285; IKEMA) will evaluate the clinical benefit of ISA in combination with Kd versus Kd alone in pts with RRMM, who have received 13 prior lines of therapy. Pts who have received prior carfilzomib therapy, have primary refractory disease, or have free light chain measurable disease only will be excluded. Approximately 300 pts will be randomized according to 2 stratification factors (prior lines of therapy: 1 vs > 1; revised international staging system at baseline: I or II vs III vs unknown) in a 3:2 ratio to receive either ISA (10 mg/kg weekly in Cycle 1 then once every 2 weeks thereafter) in combination with carfilzomib (56 mg/m^2 on Days [d] 1, 2, 8, 9, 15, and 16, 20 mg/m^2 on d 1 and 2 of Cycle 1) and dexamethasone (20 mg on d 1, 2, 8, 9, 15, 16, 22, and 23) or Kd in 28-d cycles until disease progression, pt choice, or unacceptable toxicity. The primary endpoint is progression-free survival (PFS) according to International Myeloma Working Group Criteria. Key secondary endpoints include overall response rate, rate of very good partial response or greater, minimal residual disease negativity rate, complete response rate, and overall survival. Other secondary endpoints include safety, duration of response, time to progression, PFS2, pharmacokinetics, and quality of life. Safety evaluations will include adverse events and laboratory parameters, vital signs, and physical examination. The IKEMA study is currently enrolling pts; recruitment is planned in 16 countries worldwide. Study funding: Sanofi. Clinical trial information: NCT03275285.

TPS8061 Poster Session (Board #67a), Mon, 8:00 AM-11:30 AM

A phase 1/2, multicenter, dose-escalation and expansion study of combination therapy with venetoclax, daratumumab, and dexamethasone (with and without bortezomib) in subjects with relapsed or refractory multiple myeloma. *First Author: Orlando Bueno, AbbVie Inc., North Chicago, IL*

Background: Despite the introduction of new compounds to manage relapsed/refractory (R/R) multiple myeloma (MM) over the last decade, none are curative. Trials investigating novel agents or combinations are critical to advancing therapy. Overexpression of BCL-2 may contribute to the pathogenesis of t(11;14)-positive MM. Venetoclax (Ven) is a selective, potent, orally bioavailable BCL-2 inhibitor with activity in R/R t(11;14)-positive MM. Daratumumab, bortezomib, and dexamethasone is an FDA-approved triplet for MM. The addition of Ven to this regimen (± bortezomib) may result in additive antitumor effects via complementary mechanisms. **Methods:** This phase 1/2, multicenter study of Ven, daratumumab, and dexamethasone, with or without bortezomib, in R/R MM (NCT03314181) will have 2 parts, each with a dose-escalation and dose-expansion phase. Part 1 will evaluate Ven, daratumumab, dexamethasone (VenDd) in t(11;14)-positive patients who have had ≥ 3 prior therapies including a proteasome inhibitor (PI) and an immunomodulatory agent or who are double refractory to both. The dose escalation phase will evaluate safety and tolerability; the randomized, blinded, expansion phase will assess the objective response rate of VenDd versus placebo-Dd. Part 2 will examine VenDd and bortezomib (VenDVd) in patients who have received 1 to 3 prior therapies and are not PI-refractory. The dose escalation phase will evaluate safety and tolerability; the single-arm, open-label expansion phase will assess efficacy per the International Myeloma Working Group (IMWG) criteria. A Bayesian Optimal Interval (BOIN) design will be used to guide dose escalation/de-escalation decisions in Parts 1 and 2. Secondary objectives will include progression free survival, duration of response, time-to-progression, minimal residual disease negativity, and pharmacokinetics and immunogenicity profiles of the Ven/daratumumab combinations. Exploratory objectives include evaluation of pharmacodynamic and predictive biomarkers associated with outcomes. Clinical trial information: NCT03314181.

TPS8062 Poster Session (Board #68b), Mon, 8:00 AM-11:30 AM

Randomized, open-label, phase 3 study of subcutaneous daratumumab (DARA SC) versus active monitoring in patients (Pts) with high-risk smoldering multiple myeloma (SMM): AQUILA. *First Author: S.Vincent Rajkumar, Division of Hematology, Mayo Clinic, Rochester, MN*

Background: Current guidelines for SMM recommend active monitoring for progression to symptomatic MM before initiating treatment as standard of care. Earlier treatment may benefit pts with SMM at high risk of progression. DARA, a CD38-targeted monoclonal antibody, is approved as monotherapy and in combination with standard of care for relapsed/refractory MM (RRMM). In a phase 1b RRMM study, a SC co-formulation of DARA with recombinant human hyaluronidase (rHuPH20; DARA SC) showed low infusion reaction rates and similar response rates to those seen with intravenous (IV) DARA in RRMM. Given the encouraging single-agent activity of IV DARA observed in a phase 2 SMM study (12-month PFS rate: 95%), we hypothesized that DARA SC may delay progression of high-risk SMM to MM compared with active monitoring. **Methods:** AQUILA is an ongoing, phase 3, randomized, open-label, multicenter study of DARA SC (1,800 mg DARA + rHuPH20 [2,000 U/mL] administered by manual injection (15 mL) over approximately 5 minutes at alternating abdominal locations QW for Cycles 1 and 2, Q2W for Cycles 3-6, and Q4W thereafter for up to 39 cycles or 36 months; 28-d cycles) versus active monitoring (no study medication). Eligible pts (≥18 y) have had a confirmed diagnosis of SMM for ≤5 y, have factors indicating a high risk of progression (clonal bone marrow plasma cells [BMPCs] ≥10% + ≥1 of the following: serum M protein ≥30 g/L, IgA SMM, immunoparesis with reduction of 2 uninvolved Ig isotypes, serum involved: uninvolved free light chain ratio ≥8- < 100, or clonal BMPCs > 50%- < 60% with measurable disease), and have an ECOG performance status of ≤1. The primary endpoint is PFS as assessed by an independent review committee. Secondary endpoints include time to biochemical or diagnostic (SLiM-CRAB) progression, ORR, complete response rate, duration of and time to response, time to first-line treatment for MM, progression-free survival on first-line treatment for MM (PFS2), incidence of MM with adverse prognostic features, and OS. Disease will be evaluated per International Myeloma Working Group response criteria. Approximately 360 pts will be randomized (1:1) to the 2 arms. Clinical trial information: NCT03301220.

8500 **Oral Abstract Session, Mon, 8:00 AM-11:00 AM**

Phase II trial of concurrent chemoradiation with consolidation pembrolizumab in patients with unresectable stage III non-small cell lung cancer: Hoosier Cancer Research Network LUN 14-179. *First Author: Greg Andrew Durm, Indiana University Melvin and Bren Simon Cancer Center, Indianapolis, IN*

Background: Concurrent chemoradiation (CRT) has been the standard Rx for pts with unresectable stage III NSCLC. A recent phase III trial (PACIFIC) of consolidation durvalumab [PDL-1 inhibitor] demonstrated improved median PFS vs. placebo (16.8 vs. 5.6 mo, HR 0.52, $p < 0.001$). 12-mo (55.9% vs. 35.3%) and 18-mo (44.2% vs. 27%) PFS were also improved. Toxicity was manageable with a grade 3-4 pneumonitis rate of 3.4%, and 4 patients experienced grade 5 pneumonitis. We report the results of a phase 2 trial of consolidation pembrolizumab [PD-1 inhibitor] following concurrent CRT in patients with unresectable stage III NSCLC. **Methods:** After completion of CRT with carbo/pac, cis/etop, or cis/pemetrexed + 59-66.6 Gy XRT, those pts w/o PD after 4-8 weeks off CRT received pembro 200 mg IV q3wk for up to 1 yr. The primary endpoint was time to metastatic disease or death [TMDD]. Key secondary endpoints included PFS, OS, and toxicity. **Results:** 93 pts enrolled [92 eligible for efficacy analysis]. Median f/u was 16.4 mo and median age 66 (45-84). 64.1% male and 35.9% female. Stages were 59.8% IIIA and 40.2% IIIB. 55.4% non-SqCC and 43.5% SqCC with 1 mixed histology. 94.6% were current/former smokers. Chemo regimens included carbo/pac (71.7%), cis/etop (26.1%), cis/pemetrexed (2.2%). Median number of cycles of pembro was 13.5 [1-19]. 16% received < 4 cycles; 84% received ≥ 4 cycles; 37% completed 1 yr pembro. Median TMDD was not reached (95% CI 18.7-NR), but the estimates of 1-yr and 2-yr OS were 80.5% and 68.7% respectively. Median PFS was 15.4 months (95% CI 10.4-NR). 12, 18, and 24-month PFS were 59.9%, 49.5%, and 45.4% respectively. 16 (17.2%) pts developed G$\geq$2 pneumonitis, 5 (5.4%) had G3-4 pneumonitis. There was 1 pneumonitis-related death. In those developing pneumonitis, the median time was 8.4 wks [1.1-48.2]. No other G 3/4 toxicities exceeded 5% except dyspnea (5.4%). **Conclusions:** Consolidation pembrolizumab following CRT substantially improves TMDD and PFS compared with historical controls. Prelim OS data is promising and suggests a substantial gain in outcomes of patients with stage III NSCLC is possible with consolidation pembrolizumab. Clinical trial information: NCT02343952.

LBA8501 **Oral Abstract Session, Mon, 8:00 AM-11:00 AM**

Genome-wide sequencing for early stage lung cancer detection from plasma cell-free DNA (cfDNA): The Circulating Cancer Genome Atlas (CCGA) study. *First Author: Geoffrey R. Oxnard, Dana-Farber Cancer Institute, Boston, MA*

The full, final text of this abstract will be available at abstracts.asco.org at 7:30 a.m. ET on Saturday, June 2, 2018, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2018, issue of the *Journal of Clinical Oncology*. On site at the Meeting, this abstract will be printed in the Monday edition of *ASCO Daily News*.

8502 **Oral Abstract Session, Mon, 8:00 AM-11:00 AM**

Pragmatic study of a lymph node (LN) collection kit for non-small cell lung cancer (NSCLC) resection. *First Author: Raymond U. Osarogiagbon, Baptist Cancer Center, Memphis, TN*

Background: Surgical resection is the best curative modality for NSCLC, but overall survival (OS) rates vary with quality of pathologic (p) LN staging. We studied the impact of a pre-labeled LN collection kit on pLN staging quality, operative (OP) complications and OS. **Methods:** Prospective, population-based multiple baseline, staggered implementation study involving all patients undergoing curative-intent NSCLC resection in all 11 eligible hospitals (with $\geq$5 resections/yr) in 4 contiguous Hospital Referral Regions in E. Arkansas, N. Mississippi, W. Tennessee. After 12 months of prospective baseline observation, institutions sequentially implemented the kit in 3 balanced cohorts 3 months apart. We examined OS with Kaplan-Meier method, logrank test. Crude (HR) and adjusted Hazard Ratios (aHR) with 95% CI from Cox Models are adjusted for surgeon clustering, controlled for: age, sex, histology, tumor grade, extent of resection, pT, pM, number of comorbidities. **Results:** Of 1,171 OPs by 32 surgeons from 2014-2017, LN kit used in 650 (56%) OPs by 20 surgeons. Kit cases were older v non-kit cases (mean 68 v 67 years, $p = .026$). Race ($p = .12$), sex ($p = .089$), insurance ($p = .52$), clinical stage distribution ($p = .18$) were similar between groups. Comparing kit v non-kit cases, median OP time was 124 v 144 min ($p < .0001$), transfusion 9 v 5% ($p = .02$), all other periOP complication rates were similar, incomplete (non-R0) resection rates 3 v 4% ($p = .39$). LN staging quality: pNX rate 0 v 7%; no mediastinal LN 2 v 18%; attainment of NCCN quality criteria (R0 + anatomic resection + $\geq$1 N1 + $\geq$3 mediastinal LN stations) 77 v 31% ($p < .0001$ for all); 60-day readmission 15 v 13% ($p = .35$); 60 day mortality 3% v 5% ($p = .02$). With 20 months median follow up, 3-year OS was 80% in kit v 73% in non-kit cases ($p = .005$). Kit cases had $>$ 30% reduction in both HR (.67 [.50 - .89], $p = .005$) and aHR (.57 [.42 - .77], $p < .001$). In sensitivity analyses excluding sub-lobar resections, 60-day mortality, and non-adopting surgeons (to evaluate the possible impact of higher performing surgeons using the kit), aHR ranged from .54 to .61 (all $p < .013$). **Conclusions:** A LN collection kit improves staging quality and OS without adding to morbidity of curative NSCLC resection.

8503 **Oral Abstract Session, Mon, 8:00 AM-11:00 AM**

DREAM: A phase II study of durvalumab with first line chemotherapy in mesothelioma—First results. *First Author: Anna K. Nowak, School of Medicine, Faculty of Health and Medical Sciences, University of Western Australia, Crawley, Australia*

Background: DREAM is an open-label, single arm, multi-centre, phase II trial with a safety run in designed to determine the activity, safety and tolerability of durvalumab combined with cisplatin and pemetrexed as first line therapy in malignant pleural mesothelioma (MPM). ANZ Clinical trial registry number: ACTRN12616001170415. **Methods:** Chemotherapy-naïve patients with MPM of all histological subtypes, planned for first-line cisplatin and pemetrexed who had not received prior radiotherapy and had an Eastern Cooperative Oncology Group (ECOG) performance status of 0-1 were eligible. Patients received durvalumab (1125mg), cisplatin (75mg/m^2) and pemetrexed (500mg/m^2) 3-weekly for a maximum of 6 cycles, followed by durvalumab alone (1125 mg 3-weekly) until progression or to 12 months total therapy. Primary endpoint was progression-free survival at 6 months (PFS6). The design provides $>$90% power if the true PFS6 rate is 65%, with 5% type I error using an expected PFS6 from standard treatment of 45%. Matching tissue and bloods were collected for translational research. **Results:** Between Dec 2016 to Sep 2017 54 participants were recruited. The median age was 68 (42-82) with 82% male and 60% ECOG 0. They received a median of 6 cycles of chemotherapy (range 1-6) and 7 of durvalumab (given with and without chemotherapy) (range 1-18). The 6-patient safety run in confirmed the tolerability of chemoimmunotherapy. In the first 31 evaluable patients (pre-specified primary interim analysis), PFS6 based on modified RECIST (mRECIST) for MPM was 71%. The objective response rate (ORR) was 61% using mRECIST and 53% using iRECIST. Thirty-one patients (57%) experienced adverse events (AEs) that were grade $\geq$3. Nineteen patients (35%) had immune-related (ir) AEs including 2 grade 3 irAEs. **Conclusions:** In MPM, adding durvalumab to first line treatment with cisplatin and pemetrexed had higher rates of PFS6 and ORR than expected for chemotherapy alone, with acceptable tolerability. The final result of PFS6 for all 54 patients will be reported in late 2018. Clinical trial information: ACTRN12616001170415.

8504 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Inherited predisposition to malignant mesothelioma (MM) due to mutations in DNA repair genes. *First Author: Raffit Hassan, Thoracic and Gastrointestinal Oncology Branch, National Cancer Institute, Bethesda, MD*

Background: Identifying the profile of DNA repair genes predisposing to MM will enable treatment options for patients (pts) and risk assessment for their families. **Methods:** In this prospective study of the natural history of MM (NCT01950572) we enrolled 239 consecutive pts independent of site of disease, family history of cancer, age at diagnosis, ethnicity, or asbestos exposure. Germline DNA was sequenced for all 239 pts, identifying mutations of all classes in 73 DNA repair genes. Tumor DNA from 12 pts with germline *BAP1* mutations was evaluated by whole exome sequencing. **Results:** Of the 239 pts, 29 (12%) carried a pathogenic germline mutation in a DNA repair gene: *BAP1* (N = 17 pts), *CHEK2* (N = 5), *PALB2* (N = 2), and *BRCA2*, *MLH1*, *POT1*, *TP53,* and *MRE11A* (N = 1 each). Pts with mutations were more likely to be female (P = 0.02) and to have been diagnosed with another cancer (P = 0.009). Pts with germline mutations were more likely to have a 1° relative with a diagnosis of MM (P < 0.0001), melanoma (P = 0.003), or breast cancer (P = 0.022). Pleural MM pts with germline mutations had better overall survival than pts without mutations (median 7.9 vs 2.1 years, P = 0.003). There was no difference in history of asbestos exposure between pts with or without mutations (P = 0.64). Tumors from all 12 pts with germline *BAP1* mutations carried a second somatic event likely to lead to complete loss of BAP1 function. Five tumors had somatic stop mutations, 2 somatic missense mutations, 4 somatic loss of part or all of the *BAP1* locus and 1 copy neutral loss of the wildtype *BAP1* allele (LOH). **Conclusions:** Among unselected MM pts, 7% carried a pathogenic mutation in *BAP1* and 5% carried a pathogenic mutation in another DNA repair gene, which have not been previously described in MM. Analysis of more pts is important to evaluate if increased MM risk is conferred by any of these genes. Mutation carriers and their 1° relatives were at increased risk of developing MM, melanoma, or breast cancer. Genetic testing for germline mutations in DNA repair genes should be considered for MM pts since it has implications for both pts and their relatives. Finally, we suggest that, pts with *BAP1*-null tumors due to both germline and somatic mutations could be sensitive to PARP inhibitors. Clinical trial information: NCT01950572.

8505 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Impact on health-related quality of life of the addition of bevacizumab to cisplatin-pemetrexed in malignant pleural mesothelioma in the MAPS phase III trial. *First Author: Virginie Westeel, University of Franche-Comté, Besancon, France*

Background: The IFCT-GFPC-0701 MAPS phase III trial highlighted a significant improvement in overall survival with the addition of bevacizumab to the standard first-line chemotherapy regimen, cisplatin plus pemetrexed, in advanced malignant pleural mesothelioma. We present the results of health-related quality of life (HRQoL), a secondary endpoint of MAPS. **Methods:** HRQoL was assessed using the European Organisation for Research and Treatment of Cancer (EORTC) Quality of Life Questionnaire QLQ-C30 and the Lung Cancer specific module QLQ-LC13 at randomization and then every 9 weeks until progression. HRQoL deterioration-free survival (QFS), used to analyze longitudinal HRQoL data, was defined as the interval between randomization and the occurrence of the first clinically important deterioration of at least 5 points or death. Univariate and multivariate cox regression models were done to analyze variables associated with the QFS, including treatment arm. **Results:** A total of 448 patients were included in the MAPS trial between 2008 and 2014. At baseline, 428 patients (95.5%) completed the HRQoL questionnaire. We showed that the addition of bevacizumab to cisplatin and pemetrexed significantly improved QFS for two HRQoL dimensions: pain (Hazard Ratio (HR) = 0.81, 95% CI 0.67–0.99; p = 0.041) and peripheral neuropathy (HR 0.73, 95% CI 0.6–0.89, p = 0.002). A performance status 0-1, a hemoglobin level > 14g/dl and epithelioid histology were also associated with a longer QFS. **Conclusions:** This study shows that adding bevacizumab to standard chemotherapy in patients with advanced malignant pleural mesothelioma not only enhanced progression-free survival and overall survival, but resulted in a significant improvement in HRQoL. Clinical trial information: NCT00651456.

8506 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Phase 2 study of pembrolizumab in advanced small-cell lung cancer (SCLC): KEYNOTE-158. *First Author: Hyun Cheol Chung, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, Korea, Republic of (South)*

Background: The antitumor activity of pembrolizumab, an IgG4 anti-PD-1 monoclonal antibody, was evaluated in patients (pts) with SCLC in KEYNOTE-158 (NCT02628067), a phase 2 basket study of 11 cancer types. **Methods:** Enrolled pts were aged ≥18 y with advanced SCLC; had measurable disease per RECIST v1.1; ECOG PS ≤1; incurable disease with prior failure of, progression on, or intolerance to standard therapy; and evaluable tumor samples for PD-L1 (PD-L1 IHC 22C3 pharmDx assay [Agilent Technologies]) and other biomarkers. Pembrolizumab 200 mg Q3W was administered for 2 y or until disease progression or intolerable toxicity. The primary endpoint was ORR. DOR, PFS, and OS were secondary endpoints and were estimated by the Kaplan-Meier method. Tumor imaging was performed every 9 wks for the first year, then every 12 wks. Response was assessed per RECIST v1.1 by independent central radiologic review. PD-L1–positive was defined as PD-L1 combined positive score ≥1. **Results:** Among 107 SCLC pts, median age was 63 y (range, 24–84) and 85 (79%) had 1–2 prior therapies. At the data cutoff date (Aug 23, 2017), 36 pts (34%) were continuing on-study; median follow-up was 10.1 mo (range, 0.5–17.5). Tumors were PD-L1–positive in 42 pts (39%) and PD-L1–negative in 50 (47%); 0 had microsatellite instability-high (MSI-H) tumors and 83 (78%) had microsatellite-stable (MSS) tumors. ORR was 18.7% (20/107; 95% CI, 11.8–27.4) overall, 35.7% (15/42; 95% CI, 21.6–52.0) in pts with PD-L1–positive tumors, and 6.0% (3/50; 95% CI, 1.3–16.5) in pts with PD-L1–negative tumors. Overall, median DOR had not been reached (range, 2.1+ to 13.2+ mo); 12 pts (77%) had DOR ≥9 mo. Median PFS was 2.0 mo (95% CI, 1.9–2.1) in all pts, 2.1 mo (95% CI, 2.0–9.9) in pts with PD-L1–positive tumors, and 1.9 mo (95% CI, 1.6–2.0) in pts with PD-L1–negative tumors. Median OS was 9.1 mo (95% CI, 5.7–14.6) overall, 14.6 mo (5.6–not estimable) in pts with PD-L1–positive tumors, and 7.7 mo (95% CI, 3.9–10.4) in pts with PD-L1–negative tumors. Treatment-related AEs occurred in 63 pts (59%) and led to 4 discontinuations and 1 death (pneumonia). **Conclusions:** Pembrolizumab has shown promising antitumor activity and durable responses in advanced SCLC, especially in pts with PD-L1–positive tumors. Clinical trial information: NCT02628067.

8507 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Efficacy and safety of rovalpituzumab tesirine in patients With DLL3-expressing, ≥ 3rd line small cell lung cancer: Results from the phase 2 TRINITY study. *First Author: David Paul Carbone, Ohio State University, Columbus, OH*

Background: Small cell lung cancer (SCLC) accounts for ~15% of lung cancer with no approved therapies in ≥ 3rd line (3L) patients (pts). In 3L pts, historical data demonstrate a median overall survival (mOS) of 4.7 mo and a best overall response of 18%; no historical data exist for objective response rate (ORR). Rovalpituzumab tesirine (Rova-T™) is an antibody-drug conjugate targeting Delta-like 3 protein (DLL3), an atypical Notch ligand that is highly expressed in SCLC but not normal tissue. A Ph1 study showed that Rova-T has antitumor activity in pts with recurrent SCLC and high DLL3 expression, and a manageable safety profile. **Methods:** TRINITY was an open-label, single-arm, Ph2 study of Rova-T in adult pts with DLL3-expressing SCLC (NCT02674568). Eligibility: ≥ 2 prior systemic regimens including ≥ 1 platinum-based regimen; ECOG 0-1; stable CNS disease. Pts received 0.3 mg/kg Rova-T intravenously on Day 1 of a 6-week cycle for 2 cycles. DLL3-high (hi) pts had ≥ 75% tumor cells positive by immunohistochemistry; DLL3-positive (pos) pts had ≥ 25%. Primary endpoints: confirmed ORR, overall survival (OS). **Results:** Interim analysis (6 Oct 17) included 199 pts, of which 64% were 3L. Common drug-related adverse events (AEs) were fatigue (32%), photosensitivity (31%), pleural effusion (26%), peripheral edema (26%), thrombocytopenia (23%). Drug-related Grade 3/4 AEs were thrombocytopenia (15%), photosensitivity (7%), pleural effusion (7%), fatigue (5%). In DLL3-hi 3L pts, median progression-free survival (mPFS) = 4.1 mo, mOS = 6.7 mo. **Conclusions:** Rova-T demonstrated antitumor activity and a favorable benefit:risk profile in ≥ 3L SCLC pts, with clinically meaningful mOS and mPFS. Updated analysis will be shown at presentation. Clinical trial information: NCT02674568.

Final overall survival for CSLC 0501: Phase 3 study of adjuvant versus neoadjuvant chemotherapy with docetaxel combined carboplatin for resectable stageIB-IIIA non-small cell lung cancer. *First Author: Xue-ning Yang, Guangdong Lung Cancer Institute, Guangdong General Hospital (GGH) and Guangdong Academy of Medical Sciences, Guangzhou, China*

Background: Adjuvant or neoadjuvant chemotherapy increased 5% survival compared with surgery alone for completely resected stage II-IIIa NSCLC. No significant difference in overall survival among adjuvant vs neoadjuvant vs surgery was found in NATCH study. Clinical issue is how to select adjuvant or neoadjuvant therapy for resectable NSCLC. **Methods:** Patients with stage IB-IIIA NSCLC were eligible. Adjuvant or neoadjuvant chemo regimen was designed as 3 cycles DC (Docetaxel: 75mg/m2, Carboplatin:AUC = 5 on day 1 every 3wks). The primary end point was 3yrs disease Free Survival (DFS) rate; secondary end points were 3yrs and 5yrs Overall Survival (OS) and Safety. The trial was closed early due to stage IB was not eligible since 2008 and slow accrual. The preliminary results were reported at 2013 ASCO & 2016 ESMO. **Results:** 214 patients were screened from 13 sites from March 2006 to May 2011, 198 patients were randomized. 97 were assigned to neoadjuvant (N) arm and 101 to the adjuvant (A) arm. Stage Ib, II and IIIa were 32.5%, 40.6% and 26.9%, respectively. 100% cases received neoadjuvant chemo and 85.1% completed the planned adjuvant chemotherapy. ORR was 34% and 12.4% patients developed PD in N arm. The 3yrs DFS rate was 53.4% (A) vs 40.2% (N) with HR 0.52 (95% CI 0.30–0.91), p = 0.033. 5yrs DFS rate was 47.9% vs 29.9%, HR 0.42 (0.24–0.75), p = 0.005. Median DFS 4.8 vs 2.1 yrs with HR 0.69 (0.48–0.98), p = 0.036. 5yrs OS was 57.8% vs 42.1%, HR 0.48 (0.27–0.85), P = 0.0143. Median OS 7.1 vs 4.2 yrs, HR 0.73 (0.50–1.07), p = 0.104. For stage II and IIIa subgroup 3yrs DFS rate was 49.3% vs 33.3% with p = 0.031, HR 0.43 (0.21–0.87), p = 0.031. 5yrs OS was 49.7% vs 40.7%, HR 0.60 (0.30–1.19), p = 0.142. Median OS 5.2 vs 3.6 yrs, HR 0.83 (0.53–1.30) , p = 0.414. Recurrence model was similar between the two arms. 41.2% patients experienced grade 3-4 neutropenia. One chemotherapy related death in A arm.One patient died of perioperative pulmonary embolism in N arm. **Conclusions:** The 5-yrs DFS and OS of CSLC 0501 showed arm A was superior to arm N. Adjuvant chemotherapy or neoadjuvant with docetaxel plus carboplatin are feasible and safe in resectable clinical stage IB-IIIA NSCLC. Clinical trial information: NCT00321334.

Comparative efficacy and safety of pemetrexed or paclitaxel plus thoracic radiation therapy (TRT) in elderly patients with nonsquamous locally advanced NSCLC. *First Author: Ge Bai, Cancer Center, The First Affiliated Hospital of Xinjiang Medical University, Ürümqi, China*

Background: Concurrent chemoradiotherapy is the standard treatment of locally advanced NSCLC, which can significantly reduce the risk of death and prolong the survival of patients.As we focus on the tolerance and side effects of elderly patients with concurrent chemoradiotherapy.The purpose of this study is to compare the efficacy and safety of Pemetrexed versus Paclitaxel plus thoracic radiation therapy (TRT) in elderly patients with locally advanced nonsquamous NSCLC,to provide the basis for the choice of the best chemotherapy for elderly patients. **Methods:** Patients (66years-75years) with stage IIIA/B unresectable nonsquamous NSCLC in our single center , randomly received (1:1) pemetrexed 500 mg/m^2 d1 every 3 weeks plus concurrent TRT (arm PEM), or paclitaxel 45 mg/m^2 d1 every weeks plus concurrent TRT (arm PAC). TRT: 60~66 Gy/2 Gy/30~33f IMRT radiotherapy. **Results:** Eighty-two patients were eligible to enter the group and completed treatment (41 in arm PEM,41 in arm PAC).The objective remission rate (CR+PR) of PEM group was significantly higher than PAC group (72. 0% v 56. 0%;P = 0. 021);The 2 year overall survival rate of the PEM group was significantly higher than PAC group (49.6% v 30.7%;P = 0.037).The incidence of radioactive pneumonia PEM group was lower than PAC group (20.1% to 33.1%;P = 0.032);While, no statistically significant difference between bone marrow suppression and digestive tract reaction. **Conclusions:** Pemetrexed combined with TRT was superior to paclitaxel concurrent chemoradiotherapy for elderly nonsquamous LA-NSCLC.

Safety evaluation of nivolumab added concurrently to radiotherapy in a standard first line chemo-RT regimen in unresectable locally advanced NSCLC: The ETOP NICOLAS phase II trial. *First Author: Solange Peters, Oncology Department, Lausanne University Hospital, Lausanne, Switzerland*

Background: The feasibility of combined chemo-radiotherapy (chemo-RT) and concurrent PD-1 inhibition is of high scientific interest and has shown promising results in pre-clinical models. So far, concurrent immune-checkpoint inhibition and radical thoracic RT has never been assessed in a clinical trial. **Methods:** NICOLAS is a phase II trial evaluating the safety of the addition of nivolumab to first-line chemo-RT in stage III NSCLC. Efficacy will be evaluated if a safety conclusion has been achieved, based on a hierarchical design. Patients received 3 cycles of platinum-based chemotherapy (etoposide, vinorelbine or pemetrexed) and radical RT of 66 Gy. Nivolumab treatment (240 mg / Q4W) started concurrently to RT. The primary safety endpoint is defined as the rate of pneumonitis grade $\geq$3 at 6 months post RT. An interim analysis was scheduled when the first 21 patients reached 3 months follow-up after completion of RT, based on the assumption that 70% of the pneumonitis events occur within the first 3 months. An early positive safety conclusion is reached at interim analysis if there is no incidence of pneumonitis grade $\geq$3 in the initial 21 patients (exact group sequential design at one-sided significance level of 0.05 and power = 83%, testing a 6-month pneumonitis rate $\geq$33% versus $\leq$15%). **Results:** Up to December 14, 2017, 49 patients have been recruited with a median follow-up of 6.6 months [95% CI: 5.6, 7.8]. The median age is 63 years, with the majority of the patients being male (67.3%), former smokers (75.5%) and with tumor stage IIIb (65.3%). The most frequently observed adverse events (AEs) are fatigue and anemia. No unexpected AEs or increased safety risk were observed. For the first 21 patients, no pneumonitis grade $\geq$3 was observed by the end of the 3-month post RT follow-up period. The majority of these patients (18 patients) were on a concurrent chemo-RT schedule. **Conclusions:** This early interim safety analysis provides evidence that the addition of nivolumab to concurrent chemo-RT is safe and tolerable. In a next step, the 1-year progression-free survival will be evaluated according to the hierarchical design in an expanded patient cohort. Clinical trial information: NCT02434081.

Long-term survival comparison of stereotactic radiotherapy versus surgery for elderly patients with clinical stage T1-T2 non-small cell lung cancer. *First Author: Feng-Ming Spring Kong, Indiana University Department of Radiation Oncology, Indianapolis, IN*

Background: There are several matched-paired analysis reports of comparing the long-term outcome between Stereotactic Body Radiation Therapy (SBRT) and surgical resection. Most of them are small series. This study aimed to compare the long-term overall survival (OS) after SBRT and surgery from a single medical center with surgery performed with the same group of surgeons. **Methods:** We used our cancer registry of 2005-2015. Patients with clinical staged T1 and T2 N0 diseases treated with either primary surgery or SBRT . Only patients elder than 65 years. The log rank p-value was used for overall survival comparison between the groups. Cox regression was used for univariate test for age, gender, race, smoking history, alcohol use, primary site location, laterality, T stage, and histology grade. Variables with $p < 0.05$ from univariate analysis were then used for propensity score based matching to compare the effect of surgery or SBRT on overall survival. **Results:** A total 1244 patients with clinically staged T1-T2 N0 NSCLC, 774 patients were elder than 65 years and matched: 508 patients with surgery and 266 patients with SBRT. The median age was 73 years (range: 65-96 years), 50% were male, and 67% had T1 disease. Median follow-up was 60 months.Age ($p < 0.001$), gender (p = 0.007), primary lobar location, middle and lower lobe ($p < 0.001$), grade of 1, 2, 3, and 4 ($p < 0.001$) and treatment modality of surgery versus SBRT ($P < 0.001$) were all significantly associated with OS under univariate analysis. The median OS and survival rates at one-, three- and five years were 81 months (95%CI:66-92), 85%, 70% and 58% after surgery, and 37 months (95%CI:28-46), 83%, 50% and 29% after SBRT, respectively (log-rank $p < 0.001$). **Conclusions:** This matched analysis, representing the largest one in the literature, demonstrated that patients treated with surgery have significantly better long-term survival than that of SBRT in elderly patients. This result varies from some of previous reports showing similar survival between SBRT and surgery. Prospective randomized study is needed to determine whether SBRT can present as an alternative for operable patients.

8512 Poster Discussion Session; Displayed in Poster Session (Board #118), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 4:45 PM-6:00 PM

A phase II trial of stereotactic body radiation therapy for operable T1N0M0 non-small cell lung cancer: Japan Clinical Oncology Group (JCOG0403)—Long term follow-up results. *First Author: Yasushi Nagata, Hiroshima Univ Hosp, Hiroshima, Japan*

Background: The purpose was to evaluate the safety and efficacy of stereotactic body radiation therapy (SBRT) in patients (pts) with both operable and inoperable T1N0M0 non-small cell lung cancer (NSCLC) (UICC 6th ed., 2002). The 3 and 5 year follow-up results were published in 2015. This is the updated report with a 10-year follow-up for the operable population. **Methods:** The eligibility criteria included NSCLC, clinical T1N0M0, operable pts assessed by thoracic surgeons. Operability was recategorized by the study coordinator after registration and before the primary analysis. The prescription was 48 Gy at the isocenter in 4 fractions over 4-8 days. The primary endpoint was the 3-year overall survival (OS) and the secondary endpoints included progression-free survival (PFS), local-progression free survival (LPFS), event-free survival (EFS) and toxicity. **Results:** Between July 2004 and May 2007, 65 operable pts were registered and 64 eligible pts were included in efficacy analysis. The pts characteristics were: male 45, female 20; median age 79 (range 50-91). All pts completed the protocol treatment. At the last follow-up in February 2017 (median follow-up is 5.2 years), 20 died with disease, 24 died with other disease, 1 with treatment-related death, 2 died with unknown reason and 17 alive. The median survival was 5.6 year (95% CI: 4.1 – 7.1 year).The 3, 5, 10-year survival were 76.5% (95% CI: 64.0% - 85.1%), 54.0% (95% CI: 41.0% - 65.4%) and 23.8% (95% CI: 13.7% - 35.5%). The 10-year PFS, LPFS, and EFS were 19.1% (95% CI: 9.8% - 30.7%), 20.9% (95% CI: 11.1% - 32.8%), 13.7% (95% CI: 6.0% - 24.6%). A total of 27 failures were observed including 9 with local failure, 11 with regional nodal failure and 11 with distant metastases. Grade 3 toxicity occurred in 6 pts: chest pain 1 (1.5%), dyspnea 4 (6.2%), hypoxia 1 (1.5%), and pneumonitis 2 (3.1%). No grade 4 or 5 toxicity occurred. **Conclusions:** Long term results confirmed the efficacy and safety of the previous result. SBRT has a potential to be an alternative to surgery and deserves a further evaluation. To further improve the tumor control, a randomized phase III study investigating higher dose is underway (JCOG1408). Clinical trial information: NCT00238875.

Effect of radiation dose escalation on outcomes in patients with N2 stage IIIA NSCLC undergoing induction therapy prior to surgical resection. *First Author: Greg Andrew Durm, Indiana University Melvin and Bren Simon Cancer Center, Indianapolis, IN*

Background: For pts with resectable stage IIIA NSCLC, one accepted tx option is induction therapy with concurrent chemoradiation followed by surgical resection in selected pts. However, the appropriate dose of radiation (RT) has remained largely unanswered. Full dose RT has been reported to be safe and is often used in clinical practice. We conducted a National Cancer Database analysis to compare outcomes between dose escalation vs. conventional dose RT during induction therapy in patients with T1-T3, N2, M0 NSCLC tx with surgical resection. **Methods:** We queried the NCDB between 2006-2014 for pts with T1-T3, N2, M0 NSCLC undergoing curative surgery after induction therapy. We compared the short-term postoperative outcomes and long-term survival based on RT dose groups. Group 1: standard dose (45-50.4 Gy, 67%), Group 2: high dose ($>$ 50.4 Gy 33%). Statistical analysis was performed using SAS v9.4, and $p < 0.05$ was considered to be significant. **Results:** 2499 pts met inclusion criteria. High dose RT was significantly more common in academic centers, in later years, and left-sided tumors in the database, but not related to age, race, sex, Charlson Comorbidity Index (CCI) or type of surgery performed. Perioperative outcomes (length of stay, 30- and 90-day mortality) were not significantly affected by RT dose. Mediastinal sterilization ($<$ pN2 disease) increased significantly with dose escalation as did path CR rates, but median and 5-year survival did not (Table, with 95% CIs). In multivariate analysis, long-term OS was significantly higher in men, younger age, lower CCI and lobectomy, but not affected by RT dose (even if treated as a continuous variable). **Conclusions:** In pts with clinical stage IIIA NSCLC treated with induction concurrent chemoradiation, RT dose escalation resulted in increased mediastinal sterilization and pCR rates, but it did not change perioperative mortality or long-term OS.

2004-2014	N	5yr-OS (%)	Median OS (mo)	Mediastinal sterilization (%)	pCR (%)
45 to 50.4 Gy	1677	46.2 (43.4,49.1)	48.6 (42.6, 56.0)	51.1 (48.6,53.5)	13.3 (11.7,15.1)
Above 50.4 Gy	822	46.4 (41.7,50.9)	55.1 (42.8, 62.4)	61.0 (57.5,64.4)	18.5 (15.8,21.4)

SWOG S0905: A randomized phase II study of cediranib versus placebo in combination with cisplatin and pemetrexed in chemonaive patients with malignant pleural mesothelioma. *First Author: Anne S. Tsao, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Anti-angiogenic inhibitors combined with cisplatin-pemetrexed (CP) have shown efficacy in unresectable malignant pleural mesothelioma (MPM). Cediranib, a vascular endothelial growth factor receptor and platelet derived growth factor receptor inhibitor, showed preliminary efficacy in SWOG 0905 phase I. **Methods:** S0905 phase II randomized MPM patients to CP with cediranib/placebo followed by maintenance cediranib/placebo (CPC v CPP). Randomization was stratified by PS (0-1 vs 2) and histology [epithelioid (E) vs biphasic or sarcomatoid (B/S)].The primary endpoint was RECIST PFS. The trial was designed to detect a difference in PFS at the 1-sided 0.10 level, using a stratified log-rank test. **Results:** Ninety-two eligible patients were enrolled (2011-2016). Median age was 72, 85% men, 75% E and 25% B/S histology. The trial met its primary objective: PFS was significantly prolonged by CPC (HR 0.69, p = 0.096, median PFS 7.2 vs 5.6 months). CPC did not increase RECIST RR (26% vs 18%, p = 0.48), but did prolong the duration of response (median 6 vs 1.7 months). By modified RECIST, CPC increased RR (53% vs 20%, p = 0.01). CPC numerically improved OS (HR 0.84, p = 0.44; median OS 10 vs. 8.5 months). E patients had a markedly improved survival compared to B/S patients (median PFS 7.1 vs 3.4 months, HR 0.61, p = 0.047 and median OS 10.9 vs 6.4 months, HR 0.605, p = 0.045). B/S patients may derive less benefit from cediranib than E patients in terms of OS (HR 0.83 for E v HR 1.03 for B/S) despite a similar RECIST PFS (B/S HR 0.71 and E HR 0.72). Grade 3-4 toxicities were 64% versus 54% for CPC vs. CPP (p = 0.273). The most common toxicities (any grade) associated with CPC were diarrhea (46.7% vs. 17%) and hypertension (44% vs. 15%). **Conclusions:** The addition of cediranib to CP improves RECIST PFS in patients with MPM. E patients may benefit more with anti-angiogenic agents. Clinical trial information: NCT01064648.

Outcome	CPC (median in months)	CPP (median in months)	HR [95% CI], p-value
ITT PFS (RECIST)	7.2	5.6	0.69 [0.45-1.07], 0.096
ITT PFS (modified RECIST)	6.9	5.6	0.84 [0.55 – 1.23], 0.42
ITT OS	10	8.5	0.84 [0.54 – 1.32], 0.44
E PFS (RECIST)	7.4	6.1	0.72 [0.44-1.17], 0.18
B/S PFS (RECIST)	3.4	3	0.71 [0.29-1.7], 0.44

Phase 2, multicenter study of the EZH2 inhibitor tazemetostat as monotherapy in adults with relapsed or refractory (R/R) malignant mesothelioma (MM) with BAP1 inactivation. *First Author: Marjorie Glass Zauderer, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: MM often presents at an advanced stage with a median survival of ~1 year. Treatments are limited; none clearly improve survival in second-line. In 40–60% of MM patients (pts) BRCA1 associated protein 1 (BAP1) is inactive and linked to a dependency on EZH2 (enhancer of zeste-homolog 2). EZH2 regulates gene expression to prevent differentiation of stem and progenitor cells, and aberrant EZH2 activity is implicated as an oncogenic driver. Tazemetostat, a potent, selective, oral EZH2 inhibitor demonstrated clinical activity in other malignancies; here we report preliminary data in inactive BAP1 MM. **Methods:** This is a phase 2, multicenter, open-label, single-arm study of tazemetostat (800 mg po BID) in pts with measurable R/R MM. PK and safety were assessed in a cohort of 13 pts. Efficacy was assessed via a 2-stage Green Dahlberg design in 61 pts with inactive BAP1 with a primary endpoint of 12-week disease control rate [DCR; CR or PR + SD]. Response was evaluated every 6 weeks with modified RECIST and/or RECIST 1.1. Secondary endpoints included ORR, PFS, OS, safety, population PK and response biomarkers (RNAseq, immunomodulation, exploratory prognostic indices). **Results:** Enrollment is complete (N = 74). Disease characteristics were typical of MM with the exception of a bias towards epithelioid histology (88%) that has a higher incidence of BAP1 inactivation. All pts had $\geq$1 prior systemic therapy. No pts discontinued due to AEs; however, 5 pts had dose reductions due to AEs. Fatigue (32%), decreased appetite (28%), dyspnea (28%), and nausea (27%) were the most frequently reported AEs of any grade regardless of attribution. In the efficacy portion of the study, the Stage 2 DCR criterion of $\geq$35% was surpassed, with 31 pts (51%) achieving disease control at 12 weeks and 15 pts (25%) sustained disease control at 24 weeks, 5 of whom are ongoing. Two of 61 patients had a confirmed partial response. **Conclusions:** Tazemetostat monotherapy shows promising antitumor activity, including confirmed responses and long-term disease control, with favorable safety/tolerability in pts with MM. These results support further evaluation of tazemetostat in pts with MM. Clinical trial information: NCT02860286.

The TCGA malignant pleural mesothelioma (MPM) project: VISTA expression and delineation of a novel clinical-molecular subtype of MPM. *First Author: Marc Ladanyi, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: To expand the understanding of MPM biology and pave the way for novel therapeutic strategies, The Cancer Genome Atlas (TCGA) Research Network conducted a comprehensive integrated genomic study of MPM. **Methods:** We performed whole exome, mRNA, miRNA, and non-coding RNA sequencing, copy number analysis, DNA methylation and reverse-phase protein array profiling on 74 rigorously reviewed and annotated MPM cases with no prior radio- or chemotherapy, followed by integrated data analyses. Findings were extended or validated using additional external datasets. **Results:** Three key findings emerged from the analyses of this comprehensive integrated genomic dataset. First, we defined a novel subtype of MPM characterized by extensive loss of heterozygosity, (genomic near-haploidization), and inactivating mutations in TP53 and SETDB1, which encodes a histone methyltransferase involved in epigenetic gene silencing. SETDB1 mutations appear specific to this novel subset of MPM, which accounts for approximately 3% of MPM patients, is more frequently found in younger and female patients and shows little or no linkage to asbestos exposure. Secondly, we detected strong expression of the immune checkpoint molecule VISTA [a.k.a. PD1-H (PD1 homolog) or B7-H5] in MPM, particularly in the more differentiated epithelioid subtype, where it is higher than in any other cancer type studied by TCGA. Immunohistochemistry confirmed that VISTA is present in epithelioid MPM tumor cells and in normal and reactive mesothelium, suggesting that its expression in epithelioid MPM may reflect retention of mesothelial cell antigen presenting properties. Thirdly, through the most comprehensive analysis of BAP1 status in MPM to date, we found the overall prevalence of BAP1 alterations to be 57%, and defined their downstream effects in terms of gene expression, transcriptional networks, and immune cell reactivity. **Conclusions:** Our findings highlight new avenues for further investigation of MPM biology and novel therapeutic options. In particular, our findings provide both a rationale and a biomarker for clinical trials of emerging anti-VISTA immunotherapies in this highly lethal cancer.

Safety and clinical activity of durvalumab in combination with tremelimumab in extensive disease small-cell lung cancer (ED-SCLC). *First Author: Daniel C. Cho, Perlmutter Cancer Center at NYU Langone Medical Center, New York, NY*

Background: Treatment options for ED-SCLC are limited, with standard first-line platinum and etoposide and second-line topotecan having limited clinical activity. Beyond these agents, no approved therapy prolongs survival. Dual checkpoint inhibition with the anti-PD-L1 durvalumab in combination with the anti-CTLA-4 tremelimumab has demonstrated a manageable safety profile and clinical activity in several solid tumor types. Here we present safety and clinical activity data for the combination in pretreated patients with ED-SCLC. **Methods:** In this phase 1 dose-exploration and expansion study, patients with ECOG PS 0–1 received durvalumab 20 mg/kg every 4 wks in combination with tremelimumab 1 mg/kg every 4 wks for 7 doses, then every 12 wks for 2 doses, followed by durvalumab 10 mg/kg every 2 wks for up to 12 mos, with retreatment permitted for progression after 12 mos of therapy. Antitumor activity was evaluated by investigator-assessed RECIST v1.1. **Results:** As of 20 Oct 2017, 30 patients (median age 63.5 y, 57% male, 70% ECOG PS 1) received treatment in the expansion phase. All patients had prior systemic therapy (median 2 prior therapies); 19 patients were platinum resistant/refractory. 20 patients (67%) reported $\geq$1 treatment-related AE (TRAE); the most common were fatigue (n = 7 [23%]) and pruritus (n = 7 [23%]). 7 patients (23%) had grade 3/4 TRAEs. No patients discontinued due to TRAEs and there were no treatment-related deaths. Confirmed ORR was 13.3% (2 CR, 2 PR; 95% CI 3.8–30.7), including 3 platinum resistant/refractory patients (1 CR with 2 prior therapies, 2 PR each with 1 prior treatment); median duration of response was 18.9 mos (95% CI 16.3–18.9). Disease control rate at 16 wks was 20.0% (95% CI 7.7–38.6). Median PFS was 1.8 mos (95% CI 1.0–1.9), median OS was 7.9 mos (95% CI 3.2–15.8), and 12-mo OS rate was 41.7% (95% CI 23.3–59.2). In addition, one patient with a brain metastasis was continuing in follow-up $>$ 2 years after starting treatment. **Conclusions:** Durvalumab in combination with tremelimumab had a tolerable safety profile and promising activity in pretreated ED-SCLC. Responses were durable and seen in both platinum-sensitive and platinum resistant/refractory patients. Clinical trial information: NCT02261220.

Safety and antitumor activity of durvalumab monotherapy in patients with pretreated extensive disease small-cell lung cancer (ED-SCLC). *First Author: Jonathan Wade Goldman, UCLA Medical Center, Los Angeles, CA*

Background: SCLC is an aggressive lung cancer with high rate of relapse following initial treatment; immunotherapy holds potential as a novel treatment option for this disease. The anti-PD-L1 antibody durvalumab has demonstrated clinical activity with manageable toxicity in several tumor types, including NSCLC. Here we report on the SCLC expansion cohort of a phase 1/2 study of durvalumab monotherapy. **Methods:** Patients with pretreated ED-SCLC, ECOG PS 0-1, regardless of PD-L1 expression, received durvalumab 10 mg/kg every 2 weeks for up to 12 months. The primary objective was to determine the safety profile; antitumor activity was evaluated using investigator-assessed RECIST v1.1. **Results:** As of 16 October 2017, 21 patients with ED-SCLC (median age 65.0 y, 62% male, 91% ECOG PS 1, 90% current/former smokers) were treated with durvalumab, median 3 cycles, median duration of follow-up 36.4 months (range 1.4–37.9). 20 patients (95.2%) received prior anti-cancer therapy (median, 2 lines). 7 patients (33.3%) had treatment-related AEs, all were grade 1 or 2; the most common were nausea, fatigue, and rash maculo-papular (each 9.5%). There were no treatment-related AEs leading to discontinuation and no treatment-related deaths. Confirmed ORR was 9.5% (2 PR; 95% CI 1.2–30.4) and DCR24 was 14.3% (95% CI 3.0–36.3). Duration of response was 14.6 months for one patient (treatment-naïve), and 29.5+ months for the other patient (platinum refractory with 3 prior lines of therapy), who continued to maintain response 25.5 months after completing protocol-defined initial treatment with durvalumab. Median PFS was 1.5 months (95% CI 0.9–1.8), median OS was 4.8 months (95% CI 1.3–10.4), and 12-month OS rate was 27.6% (95% CI 10.2–48.4). **Conclusions:** Consistent with studies in other tumor types and with other anti-PD-1/PD-L1 therapies, durvalumab monotherapy demonstrates durable clinical activity in certain patients with pretreated ED-SCLC with no new safety signals. Clinical trial information: NCT01693562.

Efficacy of milciclib (PHA-848125AC), a pan-cyclin d-dependent kinase inhibitor, in two phase II studies with thymic carcinoma (TC) and B3 thymoma (B3T) patients. *First Author: Benjamin Besse, Gustave Roussy, Villejuif, France*

Background: Thymic carcinoma (TC) and B3 thymoma (B3T) are rare malignant tumors of the thymus. While TC, a highly aggressive and easily metastasizing cancer, has a very poor prognosis, B3T is a slow-growing cancer. Milciclib, a pan inhibitor of cyclin D-dependent kinases, Src and other kinases, exhibits antitumor activity against a number of solid tumors. Objectives of these studies were to evaluate efficacy and safety of oral treatment with milciclib in TC/B3T patients (pts). **Methods:** Two separate phase 2 multi-centered clinical trials (CDKO-125A-006: 72 pts, previously treated with one chemotherapy and CDKO-125A-007: 30 pts, previously treated with multiple chemotherapies) were conducted in the USA, France, and Italy. The proportion of patients with B3T and TC were 27.8% and 72.2% (CDKO-125a-006) and 56.7% and 43.3% (CDKO-125a-007), respectively. Milciclib was orally administered (150 mg daily; 1 cycle is 7d on/7d off) for multiple cycles. Progression-Free Survival rate at 3 months (PFS-3) was the primary endpoint. **Results:** Oral treatment with milciclib met PFS-3 as primary endpoint and OS as a secondary endpoint in both phase 2 trials. Five pts in CDKO-125A-006 and 2 in CDKO-125A-007 continued with treatment over 2 years and 2 of them over 5 years. 46.1% of pts in both studies experienced at least one AE. Common Grade 3-4 hematological and other toxicities were neutropenia (8.4%), creatinine, amylase, lipase increase (5.6%), nausea and asthenia (8.3%). The AEs leading to discontinuation were 12.7% for both studies. Clinical trial information: NCT01011439 and NCT01301391. **Conclusions:** Oral treatment with milciclib was safe and well-tolerated and met primary and secondary endpoints, achieving disease stabilization in a majority of TC/B3T patients.

The comparison of tumor mutational burden (TMB) in patients of early and late stage lung adenocarcinoma in China. *First Author: Kai Zhang, Cancer Center, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan 430022, China*

Background: Although PD-L1 positivity improves immunotherapy efficacy, PD-L1 testing alone is insufficient for patient selection in most malignancies. High tumor mutational burden (TMB) is an emerging positive biomarker of immunotherapy in a growing number of malignancies. In this study, a method for TMB by cancer-gene panel (CGP) was set up, by which TMB from Chinese lung adenocarcinoma samples was measured to analyze the association between TMB and genes alterations in the implications for immunotherapy. **Methods:** The accuracy of TMB detection by our CGP was confirmed from data of TCGA and whole exome sequencing (WES) in our clinical samples. TMB detection method by CGP was further validated from sequencing accuracy, coefficient of variation, and the limit of detection of tumor purity. The level of TMB in Chinese lung adenocarcinoma samples and its correlation with genes alterations were then analyzed. **Results:** In our study, TMB measured by CGP has a high correlation with that measured by WES in 31 clinical tumor samples (R^2= 0.9111). Immunotherapy from the Rizvi cohort confirmed the accuracy of TMB detection by CGP. The mean level of TMB measured by CGP from 599 Chinese lung adenocarcinoma samples was similar with that from 389 TCGA lung adenocarcinoma samples (7.29 vs 7.6 mutations/Mb). We found that high level of TMB was significantly correlated with several genes alterations including TP53, KRAS and genes in DNA damage response pathway as BRCA1/2, ATR, CHEK2, POLE and MMR genes. However, low level of TMB was correlated with EGFR and ALK alteration obviously. Of note, we first discovered that the level of TMB was lower in the early stage lung adenocarcinoma compared with that in the late stage lung adenocarcinoma from Chinese clinical samples. **Conclusions:** TMB calculated by CGP and WES was highly correlated via analyzing data both from TCGA and our tumor samples. We found that the level of TMB was effected by several genes alterations in the analysis of our samples. We also found that the low level of TMB might imply a poor effect of mono-immunotherapy in the treatment of early stage lung adenocarcinoma. Of note, combining immunotherapy with DNA damaging agents could be a good way to improve efficacy.

8521 Poster Session (Board #127), Sun, 8:00 AM-11:30 AM

Neoadjuvant chemo/immunotherapy for the treatment of stages IIIA resectable non-small cell lung cancer (NSCLC): A phase II multicenter exploratory study—NADIM study-SLCG. *First Author: Mariano Provencio-Pulla, Hospital Universitario Puerta de Hierro Majadahonda, Madrid, Spain*

Background: The combination of chemotherapy and immunotherapy (CT-IO) has a high response rate and longer survival in unselected patients (pts) with metastatic non-small cell lung cancer (NSCLC). There are no data about this combination in the neoadjuvant setting. **Methods:** A Phase II, single-arm, open-label multicenter study of resectable stage IIIA N2-NSCLC adult patients with CT plus IO (nivolumab (NV)) followed by adjuvant treatment for 1 year. Neoadjuvant treatment: Three cycles of NV 360mg IV Q3W + paclitaxel 200mg/m^2 + carboplatin AUC 6 IV Q3W. After completing neoadjuvant therapy, tumor assessment is performed in patients prior to surgery. Surgery is performed in the 3rd or 4th week after day 21 of the third cycle of neoadjuvant treatment. Adjuvant treatment: nivolumab 240mg IV Q2W for 4 months and nivolumab 480mg IV Q4W for 8 months (total one year) after surgical resection. The study aims to recruit 46 pts. The primary endpoint is Progression-Free Survival (PFS) at 24 months. Efficacy is explored using objective pathologic response criteria. We present preliminary data on patients that completed 3 cycles and underwent surgical assessment. **Results:** At the time of submission, 30 pts had been included and 13 underwent surgery. CT-IO was well-tolerated and surgery was not delayed in any patient. None of the pts withdrew from the study preoperatively due to progression or toxicity. Thirteen surgeries had been performed and all tumors were deemed resectable. 9 cases (69.2%) achieved complete pathologic response (CPR) (CI 95% 38.6-90.9%), and 2 had a major pathologic response (MPR),defined as $<$ 10% viable tumor cells in the resection specimen. Considering both CPR and MPR, the overall response rate was 84.6% (95% CI 54.6-98.1%). **Conclusions:** This is the first multicentric study testing CT-IO in the neoadjuvant setting with promising antitumor activity. Neoadjuvant CT-IO with nivolumab in resectable IIIA NSCLC yields a complete pathologic response rate that has never been seen previously. The data will be updated at the time of the congress. EudraCT Number: 2016-003732-20 Clinical trial information: NCT03081689.

8522 Poster Session (Board #128), Sun, 8:00 AM-11:30 AM

Post-operative radiation therapy (PORT) in resected non-small cell lung cancer (NSCLC): An updated population based analysis. *First Author: Stephen Shamp, University Hospitals, Cleveland, OH*

Background: Post-operative radiation therapy (PORT) in resected NSCLC remains controversial. A previous Surveillance, Epidemiology, and End Results (SEER) analysis showed improved overall survival (OS) in subset with N2 disease, and detriment in N0-N1 (JCO, 2006). Reanalysis of the ANITA trial demonstrated overall detriment of PORT on OS, but improved OS in subset with N2 disease or N1 disease who did not receive chemotherapy (CT). Since SEER recently introduced chemotherapy information, we aim to analyze outcomes of PORT in conjunction with CT in these patient populations **Methods:** Patients with AJCC 6th stage II-III NSCLC diagnosed between 2004-2014 who underwent lobectomy or pneumonectomy were identified using the SEER 18 database. Patients who survived less than 4 months were excluded to account for perioperative mortality. Neoadjuvant RT was excluded. 15,644 patients met the criteria and were included, with a median followup of 31 months (range 5-120). Survival outcome was calculated using Kaplan-Meier analysis, with log-rank comparison. Multivariable analysis (MVA) was calculated using cox proportional hazard ratio **Results:** On Kaplan-Meier survival analysis, PORT was associated with inferior OS ($p < 0.0001$, 5-yr OS 40% vs 50%) whereas CT was associated with improved OS ($p < 0.0001$, 5-yr OS 46% vs 41%). Subset analysis demonstrated that PORT was associated with worse OS for patient with N0 and N1 disease both with and without CT, as well as N2 disease without CT ($p < 0.001$ for all). OS was similar with or without PORT for patients with N2 disease who received CT ($p = 0.41$). On MVA, receipt of PORT was associated with younger age, not receiving CT, advanced T and N stage, male sex, and receiving lobectomy. On MVA, improved OS was associated with younger age, receipt of CT, less advanced T and N stage, female sex, not receiving PORT, Asian race, and receiving lobectomy **Conclusions:** In a population based cohort, PORT use is associated with reduced OS, and CT is associated with improved OS. Subset analysis shows OS was similar with or without PORT for patients with N2 disease who received CT, but was associated with reduced OS in N2 without CT, as well as N0 and N1. Pneumonectomy was associated with reduced OS

8523 Poster Session (Board #129), Sun, 8:00 AM-11:30 AM

The population-based impact of adjuvant chemotherapy (CTx) on outcomes in AJCC6 stage IB non-small cell lung cancer (NSCLC). *First Author: Rahul Krishan Arora, Tom Baker Cancer Centre, University of Calgary, Calgary, AB, Canada*

Background: Adjuvant CTx is the standard of care in stage II and IIIA NSCLC, but its value in AJCC6 stage IB NSCLC (T2N0M0) is unclear. Guidelines suggest consideration of adjuvant CTx for stage IB patients at high recurrence risk, but CTx use is variable. Prior population-based studies lacked NSCLC-specific survival (CSS) and key covariates such as health insurance status. Using a Canadian cohort with universal health care coverage and CSS data, we aimed to identify predictors of use and assess the real-world benefit of adjuvant CTx in stage IB NSCLC. **Methods:** We examined all patients who underwent surgery for T2N0M0 NSCLC in a large Canadian province between 2004 and 2015 and categorized cases based on receipt of adjuvant CTx within 6 months of curative resection. We identified predictors of CTx receipt with logistic regression. We also identified correlates of overall survival (OS) and CSS using Kaplan-Meier methods and Cox regression. **Results:** 967 patients met eligibility criteria. Median age was 68 (IQR 61-74) years at diagnosis, 455 (47%) were men, and 164 (17%) received adjuvant CTx. Sex, topology, and laterality were similar in patients treated with or without CTx. Lower age at diagnosis, lower Charlson Comorbidity Index, large cell histology, and tumor size $\geq$ 4 cm were associated with higher likelihood of CTx receipt (all $p <$ 0.05). In the entire cohort and in the subset with $\geq$ 4 cm tumors, CTx improved OS but not DSS on univariate analysis. In both groups, CTx did not correlate with OS or DSS on multivariate analysis (Table). **Conclusions:** Adjuvant CTx does not improve survival in this real-world cohort of T2N0M0 NSCLC patients, even for patients with $\geq$ 4cm tumors, suggesting that it has a limited role in real-world practice.

8524 Poster Session (Board #130), Sun, 8:00 AM-11:30 AM

Evaluation of different treatment strategies between right-sided and left-sided pneumonectomy for stage I-IIIA non-small cell lung cancer patients. *First Author: Ziping Wang, Department of Thoracic Medical Oncology, Peking University Cancer Hospital & Institute, Beijing, China*

Background: This study aimed to investigate the survival difference between right-sided and left-sided pneumonectomy in stage I-IIIA NSCLC patients, and to further develop the best treatment strategies. **Methods:** Data from the Surveillance, Epidemiology, and End Results (SEER) Program of the National Cancer Institute across 18 cancer registry sites in the United States were used for the present study. To avoid the bias between groups, we used an innovative propensity score matching analysis. **Results:** Stage I-IIIA NSCLC patients with pneumonectomy from 2004 to 2014 were included in this study. Of all 2,683 patients who received pneumonectomy, Overall survival (OS) (HR = 0.875, 95%CI: 0.793 to 0.967, P = 0.008) and cancer-specific survival (HR = 0.863, 95%CI: 0.771 to 0.965, P = 0.010) were significantly longer with left-sided pneumonectomy over right-sided pneumonectomy. After propensity score matching analysis for 2,050 patients, OS (HR = 0.858, 95%CI: 0.768 to 0.959, P = 0.007) and cancer-specific survival (HR = 0.847, 95%CI: 0.745 to 0.963, P = 0.011) were also significantly superior of left-sided compared with opposite-sided pneumonectomy. After matching procedure, among left-sided pneumonectomy patients, adjuvant therapy significantly prolonged OS (46 versus 30 months, HR = 1.458, 95%CI: 1.239 to 1.715, P < 0.001) and cancer-specific survival (67 versus 51 months, HR = 1.314, 95%CI: 1.093 to 1.579, P = 0.004) while among right-sided pneumonectomy patients, adjuvant therapy was not associated with cancer-specific survival benefit (46 versus 42 months, HR = 1.112, 95%CI: 0.933 to 1.325, P = 0.236). Subgroup analysis showed that adjuvant chemotherapy could significantly improve OS and cancer-specific survival for both sided pneumonectomy patients. But patients with right-sided pneumonectomy who received radiotherapy were associated with worse survival. **Conclusions:** Right-sided pneumonectomy was associated with worse survival compared with left-sided pneumonectomy. Adjuvant chemotherapy contribute significant benefit to patients who received both sided pneumonectomy, but radiotherapy worsened prognosis for right-sided pneumonectomy.

8525 Poster Session (Board #131), Sun, 8:00 AM-11:30 AM

Population-based study predicting the probability of death resulting from non-small cell lung cancer (NSCLC) and other causes among NSCLC patients with surgery. *First Author: Bo Jia, Department of Thoracic Medical Oncology, Peking University Cancer Hospital & Institute, Beijing, China*

Background: This study aimed to predict the probability of death for non-small cell lung cancer (NSCLC) patients who received surgery and construct a comprehensive nomogram prognostic model to predict cumulative incidence of death resulting from NSCLC, other cancers, and non–cancer-related causes. **Methods:** Data from the Surveillance, Epidemiology, and End Results (SEER) Program of the National Cancer Institute across 18 cancer registry sites in the United States were used for the present study. We estimated probabilities of death resulting from NSCLC, other cancers, and non-cancer causes for NSCLC patients who received surgery and analyzed relationships of patients' characteristics with probability of death. A nomogram prognostic model was used to predict the probability of death. **Results:** The entire cohort comprised 44,880 NSCLC patients who received surgery from 2004 to 2014. Male, race, tumor anatomic sites, histologic subtype, tumor differentiation, tumor size, tumor extent, lymph node involvement, examined lymph node, positive lymph node, type of surgery showed significant associations with probability of death ($P < 0.001$). Chemotherapy was associated with a significantly lower cumulative incidence of death ($P < 0.001$) while radiotherapy was associated with a significantly higher incidence of death ($P < 0.001$). The nomogram was constructed based on multivariate models with training data set. The probability of 5- or 10-year death can be calculated using this nomogram. In the validation cohort, the unadjusted C-index was 0.73 (95% CI, 0.72-0.74), 0.71 (95% CI, 0.66-0.75) and 0.69 (95% CI, 0.68-0.70) for lung cancer death, other cancer death and non-cancer death causes. **Conclusions:** A prognostic nomogram model was developed for predicting the probability of death for NSCLC patients who received surgery. This nomogram may be useful for clinicians to develop the best treatment strategies for NSCLC patients after surgery.

8526 Poster Session (Board #132), Sun, 8:00 AM-11:30 AM

Effects of comprehensive genomic testing in a large non-small cell cancer NSCLC cohort: Racial and survival impacts. *First Author: Fatemeh Ardeshir-Larijani, University Hospital Siedman Cancer Center, Case Western Reserve University, Cleveland, OH*

Background: The clinical outcome of Non-Small Cell Cancer (NSCLC) has been advanced with molecular targeted therapy. To our knowledge, there is no data addressing targeted therapy outcomes based on race. Here, we focus on racial differences in response to targeted therapy in NSCLC. **Methods:** From a total of 1396 NSCLC patient between 2013 and 2017, 330 of them underwent targeted-exome sequencing. We conducted a matched study by propensity score generated using logistic regression with, sex, race, age, smoking, surgical resection, Immunotherapy and tumor stage as covariates. We used 258 genomic sequenced matched to 774 non-sequenced patients (1:3 match) to evaluate the outcomes (OS, PFS) of seven targeted gene therapies (*EGFR*, *ALK/EML*, *MET, BRAF, ROS1, ERBB2, RET*) using Kaplan-Meier method. **Results:** Of the 258 matched patients with genomic sequencing, 123 had at least one of the seven targeted gene mutations and 80 patients received targeted therapy (66% Caucasians, 24% African American (AA) , 10% others). The percentage of patients receiving targeted therapy for their tumors was 94% with *EGFR* (60/77), 35% with *MET* (6/17), 100% with *ALK/EML* (6/6), 0.05% with *BRAF* (1/19), 20% with *RET* (1/5), 50% with *ROS1* (1/2), and 62% with *ERBB2* (5/8) mutations. Independently from treatment types,those ones with genomic sequencing had significantly better OS (P = 0.002, 25.3 Vs. 14.6 months) and PFS (P = 0.008, 21.8 Vs. 12.3 Months) compared to non-sequenced matched control subjects. Patients who underwent targeted genomic therapy had both better OS (35.2 Vs. 28.3 m, P = 0.03) and PFS (29 Vs. 16.3 m, P = 0.01). There was no significant racial difference in baseline characteristics and driver mutation frequency (p = 0.47) except that *ALK/EML* had a higher mutation rate in AA (P = 0.019). No racial disparity in receiving targeted therapy (P = 0.45) was observed. Notably, Caucasian patients with mutant *EGFR* or *ALK* had significantly better OS (P = 0.01, 34.2 Vs. 14.9 m) and PFS (P = 0.02, 24.4 Vs.13.5) compared with AA patients. **Conclusions:** Genomic sequencing and targeted therapy increased survival outcomes in advanced NSCLC patients. Caucasians harboring *EGFR* or *ALK/EML* mutations had better survival compared to AAs.

8527 Poster Session (Board #133), Sun, 8:00 AM-11:30 AM

Definitive local therapy for oligo-recurrence in patients with completely resected non-small cell lung cancer. *First Author: Haruhisa Matsuguma, Division of Thoracic Surgery, Utsunomiya, Japan*

Background: The aim of this study was to elucidate a curable subgroup among patients with non-small cell lung cancer (NSCLC) who experienced post-operative recurrence. **Methods:** Between 1986 and 2012, among the 1,408 patients who underwent complete resection for NSCLC with anatomical lung resection at our institution, 420 experienced recurrence. After excluding 14 patients with insufficient information about recurrence, 406 patients were included in this retrospective study. We investigated the association between several clinicopathological factors and post-recurrence survival (PRS) and post-recurrence progression-free survival (PR-PFS). **Results:** The 5y-PRS and PR-PFS rates were 13.8% and 5.5%, respectively. By multivariate analysis, sex, disease-free interval (DFI), specific targeted therapy, time of recurrence, number of recurrent foci, and definitive-local therapy (DLT) were found to be independent prognostic factors for both PRS and PR-PFS. These 6 prognostic factors were classified into two types according to the 5 year PR-PFS rate difference. Among the 6 prognostic factors, Sex, DFI, and Specific targeted therapy were not associated with long term improvement of PR-PFS. **Conclusions:** We found that recent medical practice, a small number of recurrent foci (oligo-recurrence), and DLT treatment, were associated with cure of post-operative recurrence.

		Univariate		Multivariate	
	Variable	5y PR-PFS rate(%)	MST (months)	HR	P-value
Sex	Female/Male	3.0 / 7.1	6.8 / 5.5	1.33	0.018
DFI (months)	< 12 / ≥12	5.7 / 4.7	4.4 / 8.3	0.69	0.001
Time of recurrence	1987-1996 / 1997-2005 / 2006-	4.5 / 2.0 / 11.2	5.0 / 5.3 / 8.9	- / 0.95 / 0.71	- / 0.737 / 0.016
DLT	No / Yes	1.2 / 14.0	4.7 / 8.4	0.51	< 0.001
Specific targeted therapy	No / Yes	5.3 / 5.4	5.7 / 22.4	0.50	0.005
Number of recurrences	≥4 / 2 - 3 / 1	1.6 / 4.4 / 12.7	5.1 / 6.1 / 7.9	- / 0.82 / 0.64	- / 0.177 / 0.005

8528 Poster Session (Board #134), Sun, 8:00 AM-11:30 AM

A deep-learning radiomics model for predicting survival in early-stage non-small cell lung cancer. *First Author: Tafadzwa Lawrence Chaunzwa, Computational Imaging and Bioinformatics Laboratory, Harvard Medical School, Boston, MA*

Background: There is a growing body of evidence suggesting radiomic phenotypes can augment prognostic power, when used in combination with clinical features and tumor genomic profiles in lung cancer. In this study we present a deep-learning model that can act as a non-invasive prognostic biomarker in patients with Stage-I Non-Small Cell Lung Cancer (NSCLC). Our model would be able to assign patients to short term or long term survival groups, based on CT characteristics. **Methods:** Pretreatment CT studies were retrieved for 299 patients who underwent surgery for Stage-I NSCLC at MGH between 2004-2010. Image pre-processing included manual tumor identification, and isotropic rescaling of CT data. Further data curation resulted in a final cohort of 186 patients. Median follow-up from time of diagnosis was 2.9 years and 9.7% of patients were deceased at 2 years. To mitigate bias against a low probability event (mortality), data augmentation was performed yielding 242 50x50 pixel patches to feed into our model. A pre-trained 16 layer deep neural network (VGG-16) was used to perform visual recognition and data analysis. Fine-tuning of the last two convolutional blocks and a fully-connected classifier was performed with a training set of 144 labeled CT scans, matched to one of two groups based on 2 year survival. 34 samples were used for initial cross-validation. Data containing variations of imaging scanners and protocols were used in training to create a model that is robust for the variations. **Results:** Our model learned to classify patients with long term vs short term survival in an independent validation set of 64 samples with 75% accuracy and AUC = 0.798. In comparison, a multivariate linear regression model of conventional clinical prognostic factors (age, gender, tumor stage, histology, and smoking status) had a lower predictive performance (AUC = 0.665). Event rates were balanced between training and independent-validation groups. **Conclusions:** These findings suggest that Artificial Intelligence-enhanced radiomic feature extraction and predictive modeling can aid the clinician in assessing the benefits of treatment for patients with early-stage NSCLC.

8530 Poster Session (Board #136), Sun, 8:00 AM-11:30 AM

Carboplatin (CBDCA), S-1 and concurrent thoracic radiotherapy (TRT) for elderly patients with locally advanced non-small cell lung cancer (NSCLC): A phase II study. *First Author: Seiji Niho, Department of Thoracic Oncology, National Cancer Center Hospital East, Kashiwa, Japan*

Background: S-1 is an oral anticancer agent containing a mixture of tegafur, 5-chloro-2, 4-dihydroxypyridine, and potassium oxonate, which has been shown to have a radiosensitizing effect in preclinical models. Recent phase II studies have shown that chemoradiotherapy using cisplatin and S-1 yields promising PFS durations of 15 to 20 months in non-elderly (less than 75 years old) patients with locally advanced NSCLC. We conducted a phase II study of CBDCA, S-1 and TRT for elderly patients with locally advanced NSCLC. **Methods:** The eligibility criteria included patients with unresectable stage III NSCLC, a chemotherapy-naïve status, PS 0 to 1, and age $\geq$ 71 years. Patients received CBDCA (AUC 3) on day 1 and S-1 (40mg/m^2 twice daily) on days 1 to 14, q4w, up to 4 cycles, plus concurrent TRT at a total dose of 60Gy. The primary endpoint was 1-year PFS rate. The sample size was set at 28 patients, with a one-sided alpha of 0.05, beta of 0.2, and expected and threshold values for primary endpoints of 50% and 30%. **Results:** Between Feb 2014 and Dec 2016, 28 patients were enrolled in this study. All 28 patients were eligible and assessable. Baseline characteristics as follows: median age (range) 77 (71-83) years; women, n = 3 (11%); ECOG PS of 0, n = 15 (54%); stage IIIB, n = 8 (29%); tumor histopathological type: adeno, n = 12 (43%), squamous, n = 13 (46%), and NSCLC-NOS, n = 3 (11%). All 4 cycles of CBDCA plus S-1 could be completed in 15 patients (54%). TRT at 60 Gy was completed in 26 patients (93%). Response rate was 71%. Grade 3-4 toxicities included neutropenia (7%), thrombocytopenia (21%), hypoalbuminemia (7%), hyponatremia (11%), anorexia (7%), fatigue (7%), and colitis (7%). Grade 3 radiation pneumonitis was observed in 5 patients (18%). No treatment-related death was observed. The 1-year PFS rate was 56% (90% CI, 40.0 to 71.7%), and the median PFS was 13.9 months (95%CI, 4.8 to 23.0 months) with a median follow-up period of 18.2 months in censored cases. **Conclusions:** Combination chemotherapy of CBDCA plus S-1 and concurrent TRT had promising efficacy in elderly patients with locally advanced NSCLC; however, radiation pneumonitis was frequently observed. Clinical trial information: UMIN000005794.

8531 Poster Session (Board #137), Sun, 8:00 AM-11:30 AM

Multimodal treatment in operable stage III non-small cell lung cancer using the new TNM staging classification version 8: Long term results of a pooled analysis of three SAKK trials. *First Author: Martin Frueh, Department of Oncology/Haematology, Cantonal Hospital St Gallen, St Gallen, Switzerland*

Background: The impact of the 8th edition of the TNM staging system on the optimal treatment choice and the best treatment strategy for stage III non-small cell lung cancer (NSCLC) is unclear. We applied the 8th version of the TNM classification to a pooled analysis of stage III NSCLC trials in order to test its validity and assess long term outcomes and prognostic factors. **Methods:** Individual patient data of 368 patients from three very similarly designed trials (SAKK 16/96, SAKK 16/00 and SAKK 16/01) were pooled. Patients with operable stage III NSCLC received preoperative radiotherapy following three cycles of induction cisplatin/docetaxel (tri-modal) or neoadjuvant cisplatin/docetaxel alone (bi-modal). Factors associated with improved 5-year overall survival (OS) were evaluated using a logistic regression model. **Results:** When applying the 8th TNM staging version*, 162 patients moved from stage IIIA to IIIB* and 5-and 10-year OS rates were 41% and 29% for stage IIIA and 35% and 27% for stage IIIB*. When using the 6th version 5- and 10-year OS rates were 38% and 28% for stage IIIA and 36% and 24% for stage IIIB. Factors associated with improved 5-year OS were age, R0 resection and pCR ($p = 0.043$, $p < 0.001$ and $p = 0.009$). There was no difference in the bi- vs. tri-modal group with regards to OS (median: 28 months [95% CI: 21-39 months] vs. 37 months [95% CI: 24-51 months], $p = 0.9$), event-free survival (median: 12 months [95% CI: 9-15 months] vs. 13 months [95% CI: 10-22 months], $p = 0.71$), local recurrence rate (48% vs 44%, $p = 0.61$), and pathologic complete remissions (pCR) rate (15% vs. 16% $p = 0.75$). R0 resection rates were lower in the bi-modal group (69% vs. 87%, $p < 0.001$). **Conclusions:** Similarly favourable long term outcomes were observed when the 8th vs. 6th TNM classification was applied. With the exception of the excluded patients with T4* due to multiple lesions in different lobes, multimodality treatment decisions in operable stage III NSCLC can be based on the 8th TNM version in upcoming trials. Tri-modal therapy resulted in higher R0 resection rates but did not improve OS. Younger age, R0 resection and pCR were associated with improved 5-year survival.

8532 Poster Session (Board #138), Sun, 8:00 AM-11:30 AM

Neoadjuvant atezolizumab + chemotherapy in resectable non-small cell lung cancer (NSCLC). *First Author: Catherine A. Shu, Columbia University Medical Center, New York, NY*

Background: Neoadjuvant chemotherapy is an accepted treatment approach for resectable NSCLC. Major pathologic response (mPR) defined as $\geq$ 90% tumor necrosis is seen in 20% of patients (pts) receiving neoadjuvant chemotherapy and portends a favorable survival. Combination anti-PD-(L)1 therapy and chemotherapy has demonstrated potential synergy in metastatic NSCLC. This ongoing phase II study explores the combination of neoadjuvant atezolizumab + chemotherapy. **Methods:** Pts with stage IB-IIIA resectable NSCLC receive 4 cycles of atezolizumab, nab-paclitaxel, and carboplatin prior to surgery. Never-smokers are excluded. Planned enrollment is 30 pts with a primary endpoint of mPR. Stage I trial evaluation after enrollment of 18 pts will be performed with pre-defined stoppage criteria for lack of efficacy (mPR in $\leq$ 4 pts). If $\geq$ 5/18 pts have mPR, an additional 12 pts will be treated in Stage II. The primary endpoint is met if $\geq$ 11/30 pts have mPR. **Results:** From 6/2016 to 1/2018, 14 evaluable pts were treated. Baseline characteristics: median age 71 years (range 49-83), 36% female, 57% adenocarcinoma, 85% stage IIIA, and 54% PD-L1 positive ($\geq$1%, 22C3). The most common toxicity was neutropenia (12/14 Grade 3-4), with 9/14 pts requiring chemotherapy dose reduction. 1 pt experienced G3 transaminase elevation, and another developed Type I diabetes (1 year after completion of treatment). 8/14 (57%) had radiologic PR, and the remainder had SD. 11/14 pts underwent resection successfully; 1 pt had post-operative complications unrelated to study drugs leading to death. The Stage I trial continuation criteria was met with 7/14 (50%) pts with mPR, including 3 with complete pathologic response (21%). mPR was seen in both PD-L1+ and PD-L1- pts. With a median follow-up of 8.6 months (95% CI 3.5, 17.8), there were 4 recurrent events: 2 were brain metastases. **Conclusions:** The combination of atezolizumab + chemotherapy demonstrated significant activity in the neoadjuvant setting. Treatment response was seen regardless of PD-L1 score. Correlative studies including multiplex IHC and tumor exome sequencing are ongoing. The data exceeded the futility boundary for mPR in Stage I and will proceed to Stage II. Clinical trial information: NCT02716038. Clinical trial information: NCT02716038.

8533 Poster Session (Board #139), Sun, 8:00 AM-11:30 AM

The effect of prior smoking history on the molecular profile of EGFR mutant (EGFRm) non-small cell lung cancer (NSCLC). *First Author: Hadas Sorotsky, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Although *EGFR*m NSCLC occurs mainly in non-smoking patients, most series report 20%-35% of cases in current or previous smokers. Broad molecular profiling of *EGFR*m NSCLC in smokers has not been reported. **Methods:** Surgically resected primary *EGFR* exon 19 or 21 mutated NSCLC tumors from 108 patients were molecularly profiled by whole exome sequencing using the IIlumina HiSeq2000 platform. Alignment and variant discovery analysis was performed according to GATK best practices workflow; 87 sequenced to a mean coverage of 65.1x. Demographics and outcomes were compared for smokers and non-smokers (non-S), and by mutation profile. **Results:** Of the 63 non-smokers and 24 smokers (7 current/recent within 10 years), 71% were female, 53% were non-Asian, 64.5 years was the median age and 57.5% were EGFR exon 19. Of the 87 patients, 52% were stage I, 20.5% were stage II and 27.5% were stage III+. Smoking was associated with male sex ($p = 0.0028$) and non-Asian ethnicity ($p = 0.0006$) but not with age, stage or *EGFR* exon 19/21 subtype. Multiple "driver" mutations occurred in tumors of 25% smokers and 23.8% non-S. *TP53/EGFR* co-mutation occurred in 57.9% smokers and 46.2% non-S. Total non-synonymous mutation burden (TMB) was higher in smokers: median TMB in smokers 175.35 (84.93-388.24) compared to 155.31 (56.52-414.84) in non-S ($p = 0.096$). The strongest prognostic factor for OS and DFS was stage (I, II, III+) ($p < 0.001$ for each). In univariate analysis, there was a trend to shorter OS in smokers: HR 1.9 (CI 0.98-3.67, $p = 0.05$). Smoking within 10 years of NSCLC diagnosis was associated with shorter DFS HR 0.37(0.13-1.09) ($p = 0.06$) but not OS ($p = 0.34$). Neither *EGFR*m subtype nor *TP53/EGFR* co-mutation was associated with DFS or OS. High TMB was associated with shorter DFS: HR above *vs* below the median 1.96 (CI 1.06-3.62, $p = 0.028$), and OS HR 2.04 (CI 1.01-4.11, $p = 0.043$). TMB was still significant for DFS after adjusting for smoking status ($p = 0.033$), but not for OS ($p = 0.1$). **Conclusions:** *EGFR*m NSCLC in smokers is associated with a trend to higher non-synonymous TMB. Stage remains the strongest prognostic factor, but TMB appears to have a greater effect on survival outcomes than smoking status.

8534 Poster Session (Board #140), Sun, 8:00 AM-11:30 AM

Comparative evaluation of effectiveness of neoadjuvant chemoimmunotherapy (nPCIT) for non-small cell lung cancer (NSCLC). *First Author: Yuri Lazutin, Rostov Research Institute of Oncology, Rostov on Don, Russian Federation*

Background: The purpose of the study was to compare the results of neoadjuvant polychemoimmunotherapy (nPCIT) and conventional neoadjuvant polychemotherapy (nPCT) in patients with NSCLC. **Methods:** 64 pts with NSCLC were divided into 2 groups: main group – 32 pts, 2 nPCIT cycles (cisplatin 80 mg/m2 on day 1, gemcitabine 1200 mg/m2 on days 1 and 8 with i.v. infusions of the recombinant hybrid protein of tumor necrosis factor-alpha-thymosin-alpha1 100 000 IU on days 0, 3 and 6); control group – 32 pts, nPCT with the same cytostatics. Central cancer in 17(53.1%) pts of the main group (cT1NX-6.2%, cT2NX-37.5%, cT3NX-3.1%) and 20 (62.5%) (cT1NX-9.4%, cT2NX-40.6%) controls, peripheral cancer in 15(46.9%) (cT2b NX-9.4%, cT3> 7 NX-21.8%, cT3NX-18.7%, cT4NX-3.1%) and 12 (37.5%) (cT2b NX-12.5%, cT3NX-34.3%, cT4NX-3.1%), respectively. Squamous cell carcinoma in 17(53.2%) and 14(43.8%), adenocarcinoma in 7(21.8%) and 5(15.6%), non-small cell carcinoma in 8(25%) and 13(40.6%) pts, respectively. **Results:** CR in 3 (9.4%) and 2 (6.2%), PR - 14 (43.7%) and 13 (40.6%), SD - 13 (40.6%) and 14 (43.7%), PD - 2 (6.2%) and 3 (9.4%). Objective overall response rate was 53.1% in nPCIT vs 46.8% in nPCT, CR+PR+SD was 93.7% and 90.6%, respectively. 29 (90.6%) pts in each group received surgery. Extended lobectomy/bilobectomy in 14 (48.2%) pts in each group, extended pneumonectomy in 7 (24.1%) in nPCIT and 8 (27.5%) in nPCT. N2 disease in 10 (34.5%) and 13 (44.8%) pts, respectively. Post-surgical restaging: st. 0 – 10.3% vs 6.9%, st. I - 34.5% vs 31%, st. II - 20.7% vs 17.2%, st. IIIA - 34.5% vs 44.7%. Median survival in the main group - not reached, in controls – 23 months. OS was studied in pts with st. 0-II and st. IIIAN2 NSCLC; 3-year OS in early stages was 72% in the main group vs 49% in controls ($p = 0.0735$). **Conclusions:** The direct results were similar in nPCIT and nPCT, but 2-year EFS was 72% and 44%, respectively, with a tendency to improvement ($p = 0.05421$). 2-year OS in pts with st. IIIAN2 NSCLC improved to 55% in the main group vs 32% in controls ($p = 0.031777$).

8535 Poster Session (Board #141), Sun, 8:00 AM-11:30 AM

NanoPac inhalation treatment of NSCLC in a nude rat orthotopic lung cancer model. *First Author: Gere Dizerega, US Biotest, San Luis Obispo, CA*

Background: NanoPac is sub micronized paclitaxel in stable powder form without coating or carrier agents. In a previous PK study, healthy male rats inhaled a single exposure of nebulized NanoPac (0.37 mg/kg or 1.0 mg/kg) or IV Abraxane (5.0 mg/kg) with a final necropsy time-point at 14 days. $T_{1/2}$ of NanoPac and Abraxane were 56hrs and 20hrs with drug present at 14 days and not after 3 days, respectively. Tissue examined from the last time point were microscopically indistinguishable from non-treated controls. **Methods:** 120 nude rats were assigned to 6 groups and intratracheally instilled with Calu-3 lung tumor cells ($2x10^6$). Target doses and treatment schedules; Group 1 (Control: untreated), Group 2 (Abraxane: IV 5 mg/kg q1wx3), Group 3 (NanoPac: Inhaled (IH) 0.5 mg/kg q1wx4), Group 4 (NanoPac: IH 1.0 mg/kg q1wx4), Group 5 (NanoPac: IH 0.5 mg/kg q2wx4), Group 6 (NanoPac: IH 1.0 mg/kg q2wx4). Nebulized NanoPac (2μm Mass Median Aerodynamic Diameter) was delivered via nebulization into a nose-only exposure chamber; necropsy occurred (Group 2: 14 days), (Groups 3-6: 1 - 4 days) post final treatment. Histology was performed on sections of left lung stained with H&E from 10 animals in each group and scored using a 4-point grading scale. **Results:** Average lung/brain weight ratios for Group 2 (2.3) and Groups 3-6 (2.7) indicated a therapeutic effect vs Group 1 (3.2). Lung tumor burden decreased in combined Groups 3-6 as compared to Groups 1 and 2; characterized by the histological measures of tumor mass, primitive tumor cell population and tumor regression. Average primitive tumor cell population was significantly less ($p < 0.05$) for Groups 3-6 (0.3) compared to Group 1 (0.9) or Group 2 (1.0). Combined NanoPac Groups 3-6 (22/40) exhibited a significant ($p < 0.05$) incidence of tumor regression compared to Group 1 (0/10) and Group 2 (1/10). **Conclusions:** NanoPac treatment groups compared to Control and Abraxane groups demonstrated a therapeutic effect as measured by lower lung/brain weight ratio and lower overall lung tumor burden without apparent adverse events. Histological analysis of lung tumor burden treated with NanoPac IH showed a decrease in tumor mass, a decrease in primitive tumor cell population, and an increase in tumor regression.

8536 Poster Session (Board #142), Sun, 8:00 AM-11:30 AM

Concurrent chemotherapy and radiation versus chemotherapy alone for N3 stage IIIb NSCLC in elderly patients. *First Author: Angel Qin, University of Michigan, Ann Arbor, MI*

Background: The NCCN guidelines recommend treating stage IIIB NSCLC (non-small cell lung cancer) with concurrent chemotherapy and radiation (chemo-RT). There is data to suggest that N3 stage IIIB disease conveys worse prognosis, but this has not been explicitly interrogated. There is also concern regarding the safety of chemo-RT in patients ≥70 years old as they are under-represented in clinical trials, have worse overall survival, and experience increased toxicities. We therefore sought to interrogate the survival of N3 Stage IIIB NSCLC using the NCDB (National Cancer Database) with a focus on patients ≥70 years old. **Methods:** We conducted a retrospective analysis on data from the 2014 NCDB PUF (participant user file) of patients diagnosed with N3 stage IIIB NSCLC between 2010 and 2013. Kaplan-Meier method was used for median overall survival (OS) with log-rank tests. Multivariable Cox models were used for multivariable and subgroup analyses. **Results:** 9,769 patients were included in our analysis, 7,770 who received chemo-RT and 1,999 who received chemotherapy alone. A higher proportion of patients in the chemotherapy group were ≥70 years old compared to the chemo-RT group (46.6% and 34.5% respectively, $p < 0.0001$). The median OS for the chemo-RT group was 16.4 months compared to 12.7 months for the chemotherapy group ($p < 0.0001$). For patients ≥70 years old, the median OS was 15.0 months for those who received chemo-RT compared to 12.4 months for chemotherapy alone ($p < 0.0001$). In multivariable analyses, the benefit of chemo-RT was similar regardless of age. For age < 70, the hazards ratio (HR) was 0.73 with a 95% confidence interval (CI) of 0.67-0.79 and for age ≥70, HR = 0.77, 95% CI = 0.71-0.83 ($p = 0.43$). Subgroup analyses in patients ≥70 indicated a benefit to chemo-RT (HR < 1.0) across all patient and disease strata, including Charlson Comorbidity Index ($p < 0.05$ irrespective of score). **Conclusions:** There is a survival benefit to chemo-RT versus chemotherapy alone in N3 stage IIIB NSCLC in patients ≥70 years old, who represented 37% of all patients. Our findings suggest that age and comorbidity index alone should not preclude clinicians from recommending aggressive therapy to these patients.

8537 Poster Session (Board #143), Sun, 8:00 AM-11:30 AM

NORA trial (GECP 15/02): First efficacy results of the Spanish Lung Cancer Group (SLCG) phase II trial of concurrent chemo-radiotherapy (CT-RT) with cisplatin (P) plus metronomic oral vinorelbine (mOV) for unresectable locally advanced non-small cell lung cancer (LA-NSCLC). *First Author: Dolores Isla, Hospital Clínico Lozano Blesa, Zaragoza, Spain*

Background: CT-RT is the standard treatment for unresectable LA-NSCLC. P plus vinorelbine is widely used. Metronomic CT is a frequent administration of low doses of CT. mOV has shown good efficacy and improved safety, and could improve the RT effect. Our goal is to evaluate the efficacy and safety of P-mOV with radical RT in patients (pts) with LA-NSCLC. **Methods:** Pts aged 18-75 years with histologically proven untreated and unresectable LA-NSCLC, adequate bone marrow, hepatic & renal function, ECOG PS0-1, received P 80mg/m^2 D1 every 3 weeks combined with mOV 50mg/day on days D1, 3 & 5/weekly, 2 cycles (cy) as induction; patients without progression received 2 more cy of P at the same dose with mOV 30mg/day on D1, 3 & 5/weekly, concurrently with RT (66Gy in 6.5weeks). Primary endpoint was progression-free survival (PFS) by RECIST v1.1; secondary endpoints were: overall response rate (ORR), disease control rate (DCR), overall survival and safety profile. To guarantee an overall type-1 α error no greater than 0.05 and a type II (β) error 0.1 for PFS, a sample size of 67 pts was planned. **Results:** Sixty-seven pts were recruited in 17 Spanish sites from 04/2016 to 06/2017. One of them didn't meet all the inclusion criteria. We analyzed the first 57 pts included. Pt characteristics: Male 77.3%; median age 62 (range 33-75); PS 0/1 50/50%; smokers 45.5%; adenocarcinoma/squamous 34.8/43.9%; stage IIIA/B 43.9/56.1%. Only 29.8% of pts presented any grade 3-4 adverse event, including: neutropenia 22.8%; anemia 3.5%; febrile neutropenia 7%; esophagitis 1.8%; pneumonitis 1.8%. There were two deaths non-related to the treatment, during this period. Forty-four pts have completed the treatment. ORR: 66.7%. DCR: 79%. With a median follow-up of 11.2 months (range 1.1-21.7), the median PFS is 11.9 months (CI95%; 10.1-NR). **Conclusions:** mOV-P with RT is as effective as the standard administration of vinorelbine, improving its safety profile. EudraCT 2015-003312-21. Clinical trial information: EudraCT 2015-003312-21.

8538 Poster Session (Board #144), Sun, 8:00 AM-11:30 AM

Insurance disparity in cause-specific mortalities: A SEER study on early stage, non-elderly NSCLC cancer survivors. *First Author: Changchuan Jiang, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Lung cancer is the leading cause of cancer-related death in the US. Non-elderly, early stage (stage I&II) non-small cell lung cancer (NSCLC) patients have the most promising prognosis with appropriate treatments. Studies have shown uninsured and elderly patients on Medicaid being less likely to receive guideline-concordant therapy and thus with higher mortality. However, it remains unknown how insurance status influences cause-specific survival in non-elderly NSCLC patients, and whether disparity of care is improved in this cohort after ACA. **Methods:** Surveillance, Epidemiology, and End Results Program from 2007-2014 was used to identify NSCLC patients on stage I and II on diagnosis. Elderly patients ($>$ 65 years) were excluded. Demographic and lung cancer characteristics including age, gender, race, education, income, insurance status, tumor grade/stage and treatment were analyzed. Competing risk analysis was conducted using SAS9.4. **Results:** A total of 13,898 patients were included. After adjusting for socio-demographic factors, tumor grade and treatment, Medicaid and non-insured were associated with higher lung cancer mortality (HR: Medicaid 1.30 (1.17-1.44), non-insured 1.26 (1.05-1.50)). Patients with any Medicaid sustain the highest mortality for cardiovascular diseases(CVD) and non-cancer respiratory diseases(NCR) across different insurance status (CVD HR: Medicaid 2.17 (1.57-2.99), non-insured 1.37 (0.74-2.56); NCR HR: Medicaid 2.46 (1.76-3.43), non-insured 0.73 (0.30-1.81)). Diagnosis after ACA was associated with lower lung cancer specific mortality but not related to CVD or NCR mortality. No effect modification was found for diagnosis after ACA on any specific cause mortality. **Conclusions:** Despite ACA and Medicaid expansion in 2010, Medicaid and non-insured patients have higher cancer mortality compared with insured in early-stage NSCLC patients. Furthermore, non-elderly, early-stage NSCLC cancer survivors with Medicaid have remarkably higher CVD mortality compared to private insured survivors even without any insurance, which may reflect the disparity in health literacy, primary care, and cancer survivorship care access.

8539 Poster Session (Board #145), Sun, 8:00 AM-11:30 AM

Progression-free survival (PFS) and cardiac-toxicity-adjusted-PFS (CTA-PFS) as predictors of overall survival (OS) in locally advanced non-small cell lung cancers (LA-NSCLC) treated with concurrent chemoradiation (CCRT): A secondary analysis of NRG Oncology RTOG 0617. *First Author: Chen Hu, Johns Hopkins University, Baltimore, MD*

Background: OS is the gold standard for LA-NSCLC with CCRT, with complex relationships among RT dosimetry, systemic therapies, cardiopulmonary toxicity, progression (PD) and OS of growing scientific and clinical interest. **Methods:** RTOG 0617 (NCT00533949) randomized standard (SD, 60 Gy) versus high-dose (HD, 74 Gy) CCRT +/- cetuximab from 11/07-06/11. This analysis includes 469 patients (pts) given $\geq$50 Gy. A PFS event was defined as the first occurrence of local, regional, distant PD or death w/o documented PD. A CTA-PFS event was the first occurrence of grade 2+ treatment-related cardiac toxicity event or a PFS event. Landmark analyses at 6mo and 12mo were used to minimize the immortal time bias. Cox model with PD or CT/PD as a time-dependent covariate was used to evaluate their predictive roles. Median f/u time for surviving pts was 5.1 years. **Results:** As reported, pts treated with HD had significantly lower OS rates (HR = 1.28, 95%CI: 1.04-1.58, p = 0.018) and CTA-PFS rates (HR = 1.24, 95%CI: 1.02-1.51, p = 0.035), and marginally lower PFS rates (HR = 1.21, 95%CI: 0.99-1.47, p = 0.06) than pts treated with SD. Median survival time (MST) among pts having PD within 6mo versus not were 13.4mo (95%CI: 10.0-19.0) and 30.7mo (95%CI: 28.0-37.0) ($p < 0.001$). MST for pts having PD within 12mo versus not were 20.6mo (95%CI: 18.8-25.0) and 60mo (95%CI: 47.6-74.5)($p < 0.001$). Results are similar when using CTA-PFS with 6mo or 12mo cutoff ($p < 0.001$). RT dose was no longer significantly associated with OS (p = 0.08 or p = 0.15) when PD or CT/PD was included in multivariable analysis ($p < 0.001$), suggesting OS differences in HD/SD may be partially captured by PFS or CTA-PFS. **Conclusions:** RTOG 0617 survival results suggest that PFS (or CTA-PFS) status at 6mo or 12mo predicts long-term OS, and may potentially be considered as a surrogate endpoint of OS in clinical trials. Pts who were progression-free at 12mo had a MST of 5 years. Further validation on external datasets and in the modern era of immunotherapy are needed.

8540 Poster Session (Board #146), Sun, 8:00 AM-11:30 AM

Routine use of a modest next generation sequencing panel provides additional clinically useful data beyond single gene testing in non-small cell lung cancer and is fit for purpose as a clinical assay: Collated data from a single molecular diagnostic laboratory. *First Author: David Allan Moore, Sarah Cannon Molecular Diagnostics, London, United Kingdom*

Background: Testing of the EGFR gene for sensitising mutations is a critical part of patient stratification in non-small cell lung cancer. Analysis of a modest panel of relevant genes using a targeted Next Generation Sequencing (tNGS) has the potential to identify an extended range of actionable or trialable alterations compared with more limited technologies. There are additional analytical and technological advantages to this approach. Sarah Cannon Molecular Diagnostics has been delivering somatic variant analysis through Oncomine solid tumour panel since 2014. This project involved the collation of data from 3 years' worth of molecular diagnostic tNGS testing performed on non-small cell lung cancer specimens. **Methods:** The laboratory database was interrogated to identify all cases of non-small cell lung cancer submitted for testing from a 3 year period. Rate of rejection due to insufficient tumor, assay failure rate and turnaround time was calculated. For all cases successfully tested data was manually extracted for the relevant driver mutations and incidental evidence of gene amplification. **Results:** A total of 2796 NSCLC cases were submitted for multigene panel analysis over 3 years. 217 samples (7.8%) were rejected outright due to either low tumor content (189). Of 2579 accepted for testing, 'analysis failed' was reported in 131 (5.1%). Median turnaround time was 7 working days. 17% of cases reported were positive for a recognised EGFR driver mutation and 11% of EGFR-driven cancers also had a T790M mutation detected. 35% of those reported had evidence of a driver mutation in KRAS, 5.4% had other recognised driver mutations in BRAF, ERBB2, PIK3CA or NRAS and 3.5% of cases had no driver mutation but incidental evidence of amplification. **Conclusions:** A tNGS panel can be delivered as a diagnostic test for mutation analysis with an acceptable success rate and turnaround. Over 60% of patients have a driver event identified, providing additional relevant information beyond single gene testing.

8541 Poster Session (Board #147), Sun, 8:00 AM-11:30 AM

Neoadjuvant atezolizumab in resectable non-small cell lung cancer (NSCLC): Initial results from a multicenter study (LCMC3). *First Author: Valerie W. Rusch, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Platinum-based chemotherapy, before or after surgery, provides only a 5% benefit in 5yr. OS in locally advanced NSCLC. A recent pilot study (JCO 2017 35:15suppl, 8508) showed that preoperative immune checkpoint inhibitor therapy was well tolerated and yielded a clinically meaningful major pathologic response rate (MPR ≤10% residual viable tumor cells). This large multicenter trial tests the MPR rate and novel biomarkers of benefit using this novel neoadjuvant approach with atezolizumab (atezo) [NCT02927301]. **Methods:** Pts with stages IB -selected IIIB resectable NSCLC were to receive 2 cycles of atezo (1200 mg, days 1, 22) then undergo resection (day 40 +/- 10). Chest CT, PET obtained pre- and post atezo to assess clinical response. Primary tumor +/- node biopsies and blood samples were obtained before atezo and at surgery for biomarker studies. The primary endpoint was MPR. Secondary endpoints included safety, response by PD-L1, OS, and DFS. **Results:** For the prespecified initial safety analysis, the first 21 of 180 planned pts (67 pts currently on study) are reported: 13 males, median age 65 y, all ECOG 0-1; 4 current, 16 former smokers; 13 non-squamous NSCLC; clinical stages Ib/IIa/IIb/IIIa/IIIb = 4/2/6/5/4. Two pts received one dose of atezo due to treatment related AE (Gr 1 pyrexia, Gr 2 dyspnea) but underwent uncomplicated resection with MPR assessment. There were no Gr 5 AE, 5 Gr 3-4 AE (1 treatment related). By RECIST, 20 pts had SD, and 1 had PD. There were no major delays to surgery. 19 pts had MPR assessment: 1 pt discontinued atezo preop due to CNS mets and 1 pt had unresectable disease. MPR rate was 4/19 (21%, 95% CI 6-46). Excluding 2 pts who had known driver mutations (1 EGFR+, 1 ALK+), MPR rate was 4/17 (24%, 95% CI 7-50). 11/19 patients had ≤50% viable tumor. **Conclusions:** This first report of atezo in the neoadjuvant setting shows that preoperative treatment is feasible and well tolerated. MPR rate is encouraging. Clinical and pathological responses are often discordant. Safety and efficacy results from additional pts will be presented. Correlative analyses on pre- and post atezo tissues are ongoing. Preliminary correlative analyses in blood samples are included in a separate abstract. Clinical trial information: NCT02927301.

8542 Poster Session (Board #148), Sun, 8:00 AM-11:30 AM

Association between certain NSCLC driver mutations and sensitivity markers for chemotherapy or PD-(L)1 inhibition: A large-sample analysis. *First Author: Wenhua Liang, Department of Thoracic Surgery/Oncology, the First Affiliated Hospital of Guangzhou Medical University, China State Key Laboratory and National Clinical Research Center for Respiratory Disease, Guangzhou, China*

Background: Driver gene alterations play a pivotal role in NSCLC and are predictive markers for specific targeted therapy. However, few evidence has correlated certain mutation types with the sensitivity markers for different chemo-agents or immune-checkpoint inhibitors which are inevitable during the whole course of treatment. **Methods:** Specimens and clinical data were obtained from a consecutive cohort of resectable NSCLC patients from 2016-03 to 2017-11. Hybridization-capture sequencing (Ion Proton) of 8 important NSCLC-related drivers was conducted. The slides were tested for PD-L1 (SP142), ERCC1, RRM1, TS and β-tubulin3 by immunohistochemical staining. **Results:** Among a total of 785 patients, 498 (63.4%) patients had at least 1 driver alterations. The prevalence of each driver agreed with previous reports and their association with sensitivity markers were summarized as The overall percentage was used as a cut-off for each marker. *, representing good sensitivity to corresponding drugs. According to the results, preferable regimens might be indicated; the sensitivity indication was consistent with previous observations. For Kras+ patients, PD-(L)1 inhibition is an optimal option and platinum should be included when using chemo; for BRAF mutation where limited data presented, anti PD-(L)1 is optionable and taxanes might be the most sensitive chemo-agents. **Conclusions:** These results may aid in selecting optimal salvage regimen after targeted therapy failure, or adjuvant chemo-regimen where targeted therapy has not been a routine option. Further validation using true response data was warranted.

Type	Prevalence %	ERCC1 low %	RRM1 low %	TS low %	β-tubulin3 low %	PD-L1(+) %

8543 Poster Session (Board #149), Sun, 8:00 AM-11:30 AM

Association between hospital volume, treatment patterns, and overall survival (OS) of patients with stage 3A non-small cell lung cancer (NSCLC). *First Author: Sri Harsha Tella, University of South Carolina, Columbia, SC*

Background: There is significant heterogeneity in the treatment of stage IIIA NSCLC. We evaluated the therapeutic and survival disparities in IIIA NSCLC patients based on the hospital volume using National Cancer Data Base (NCDB). **Methods:** IIIA NSCLC patients diagnosed between 2004-2015 were included. We classified facilities by tertiles (T; mean patients with IIIA NSCLC treated/yr): T1: < 67.07; T2: 67.01 to 123.68 and T3: ≥123.68. We used SPSS to account for clustering of patients within centers (based on the volumes: lower, middle & higher 1/3rd of the cases) and Cox regression to determine the volume-outcome relationship, adjusting for patient demographics (age, sex, race), tumor characteristics (size, nodes and grade), insurance & therapy. Kaplan Meier estimates of OS were compared with log-rank test. **Results:** This analysis includes 101,110 patients treated at 1329 facilities. The median age at diagnosis was 68 yrs. The median annual facility volume was 91 patients/yr (range, 1- 798). Multivariable analysis showed that facility volume were independently associated with all-cause mortality ($p < .0001$). The unadjusted median OS by facility volume was: T1: 15 months (m), T2: 16 m, and T3: 19 m ($P < .0001$). Compared with patients treated at T3 facilities, patients treated at lower-tertile facilities had significantly higher risk of death [T2 hazard ratio (HR), 1.09 (95% CI, 1.07-1.11); T1 HR, 1.11 (95% CI, 1.09 - 1.13)]. Patients treated at high volume centers were more likely to get surgery (27 vs 17%) and trimodality treatment (12% vs 9%) ($p = 0.01$). Chemo and radiation therapy patterns were similar among facilities. Receipt of surgical therapy was independently associated with prolonged OS. Compared to patients who received lobectomy, patients who received pneumonectomy had significantly higher risk of death HR, 1.32 (95% CI,1.3-1.4, $p < 0.0001$). **Conclusions:** Patients who were treated for stage IIIA NSCLC at T3 centers (> 123 cases/yr) had a significant improvement in survival and are more likely to receive trimodality therapy.

	Therapy (%)				Survival (%)		
	Surgery	Chemo	Radiation	Trimodality	1 yr	3yr	5 yr
T1 (33%)	17	69	68	9	57	26	17
T2 (34%)	20	70	68	10	59	28	19
T3 (33%)	27	70	65	12	64	33	23

8544 Poster Session (Board #150), Sun, 8:00 AM-11:30 AM

The ASCENT trial: A phase II study of neoadjuvant afatinib, chemoradiation and surgery for stage III EGFR mutation-positive NSCLC. *First Author: Lecia V. Sequist, Massachusetts General Hospital Cancer Center and Harvard Medical School, Boston, MA*

Background: The stage III NSCLC paradigm now includes immunotherapy (IO), but advanced EGFR-mutant (EGFR+) pts typically don't respond to IO. In 2011 we began a phase II trial of neoadjuvant afatinib (NeoAfat) and standard of care (SOC) curative intent treatment for EGFR+ stage III NSCLC, NCT01553942. We present an interim analysis given the evolving SOC landscape. **Methods:** EGFR+ stage III pts amenable to curative-intent chemoradiation (CRT) ± surgery were treated with NeoAfat 40mg po QD x2mo, then concurrent CRT: cisplatin 75mg/m2 + pemetrexed 500mg/m2 IV q3wk up to 4 cycles and 3D conformal RT or IMRT personalized to tumor size, site, operability. Surgery and adjuvant afatinib (AdjAfat) x2yr were optional. Primary outcome was objective response rate (ORR) to NeoAfat. **Results:** 13 pts were treated (10F/3M); med age 56 (range 34-75). EGFR mutations: del19 (n = 9); L858R (n = 4). Stage: operable IIIA (n = 7); inoperable IIIA/B (n = 6). NeoAfat ORR = 69% (95% CI 39-91); 5 (38%) pts dose reduced NeoAfat. All pts proceeded to CRT with pre-op med RT dose of 54 Gy (range 45-66; n = 7), definitive med dose of 65 Gy (range 63-72; n = 6). 5 (71%) of the 7 surgical pts had major (4) or complete (1) pathologic response. 7 (54%) pts started AdjAfat at med dose of 30mg QD; 4 completed 2yr, 2 aborted early, 1 ongoing . Key grade 3/4 toxicities: rash 5), diarrhea (5), esophagitis (3), nausea (3), pneumonitis (2 gr 3) and febrile neutropenia (1); no treatment-related deaths. With med follow-up of 24.1 mo (range 5.0-64.2), 6 (46%) pts have recurred; including 4/6 inoperable pts, 2/7 who had surgery, 1/5 with major path response (CNS-only recurrence). Med PFS is 34.6 mo (95% CI 12.6-NR). 2-yr OS is 85% (95% CI 33-98). **Conclusions:** Neoadjuvant afatinib achieves high ORR and major surgical path responses, and doesn't impair receipt of SOC, curative CRT ± surgery in EGFR+ stage III NSCLC. Feasibility of NeoAfat exceeds AdjAfat in stage III setting. The prolonged PFS compares favorably to PACIFIC IO arm; more data is needed about optimal strategy for stage III EGFR+ pts. ASCENT is still ongoing, but it and similar randomized RTOG 1306 have accrued slowly, highlighting the challenge of studying curative approaches in genotype-defined subgroups. Clinical trial information: NCT01553942.

8545 Poster Session (Board #151), Sun, 8:00 AM-11:30 AM

Using deep-learning radiomics to predict lung cancer histology. *First Author: Tafadzwa Lawrence Chaunzwa, Computational Imaging and Bioinformatics Laboratory, Harvard Medical School, Boston, MA*

Background: Histologic phenotype is an important predictor of clinical outcomes in lung cancer. Tissue diagnosis is the most definitive approach to categorization, however, this is often technically challenging for thoracic lesions. In this study, we explore Deep-Learning Radiomics methods for non-invasive histology classification in early-stage Non-Small Cell Lung Cancer (NSCLC). **Methods:** A cohort of 157 patients with Stage I NSCLC identified as either adenocarcinoma or squamous cell carcinoma on pathology was used. All patients were surgical candidates at Massachusetts General Hospital between 2004-2010. Deep feature extraction from pretreatment CT images was conducted using a pre-trained VGG-16 convolutional neural network (CNN). In addition to appending fully-connected classifying layers to the network, a transfer learning approach was also employed using different classifiers. Three machine-learning classification models were independently evaluated on the extracted features: K-Nearest Neighbors (kNN), Random Forest Classifier (RF), and Least Absolute Shrinkage and Selection Operator (LASSO). Principal component analysis was employed in selecting features corresponding to 90% cumulative explained variance. A LASSO method was then used to select the best features. Models were trained on 100 patients and cross-validated on an independent test-set of 57 patients. **Results:** All models were able to perform binary classification of tumor histology (adenocarcinoma vs squamous cell carcinoma). The fully-connected CNN had the highest performance (AUC = 0.751). Other classifiers also showed significant predictive power after dimension reduction of the feature space (from 512 to 46), with AUC = 0.712 for LASSO ($\alpha = 0.1$), and AUC = 0.689 for kNN (k = 5). RF had the lowest predictive performance (AUC = 0.533). 73% of the study group had adenocarcinoma vs 27% with squamous cell carcinoma, and ratios were balanced between training and validation sets. **Conclusions:** Deep-Learning Radiomics is a promising approach to non-invasive lung cancer histology classification. These methods can potentially augment other emerging techniques, such as liquid biopsy; offering complementary information to help in clinical decision making.

8547 Poster Session (Board #153), Sun, 8:00 AM-11:30 AM

Clinical relevance of intratumoural immune cell composition in non-small cell lung cancer. *First Author: Xuetao Li, Guangdong Lung Cancer Institute, Guangdong General Hospital affiliated to South China University of Technology & Guangdong Academy of Medical Sciences, Guangdong Key Laboratory of Lung Cancer Translational Medicine, Guangzhou 510080, China, Guangzhou, China*

Background: While the understanding of immune landscape of NSCLC has been greatly improved, it is largely unknown how local repertoire of tumor infiltrating leukocytes differs in context of tumor genomics and impacts on prognosis and response to immunotherapy. The aim of this study was to deconvolve immune cell fractions from bulk tissue gene expression profiles (GEPs), and to determine the distinct immune cell composition in molecular subgroups of NSCLC. **Methods:** Bulk GEPs of 1692 tumor samples of NSCLC patients with known clinical information were obtained from GEO. CIBERSORT algorithm was used to infer the relative proportions of 22 human leukocyte subsets in each tumor. The common and specific immune infiltrating patterns were established for histological and genomic subgroups of NSCLC defined by driver gene mutations. The correlation between intratumoural immune profiles and overall survival (OS) was assessed using multivariable Cox regression model. **Results:** An increased fraction of regulatory T cells ($p < 0.001$) and a decreased fraction of plasma cells (PCs) ($p < 0.003$) were found in advanced NSCLC. With respect to histology, macrophages (Ms) were significant differential cellular component between adenocarcinoma and squamous cell carcinoma. Nevertheless, the high fraction of PCs had longer median OS (8.4 vs 4.4 years, HR 0.59, p = 1e-05) than the low fraction of PCs. The median OS for the low fraction of neutrophils was 7.9 years vs 5.6 years for the high fraction of neutrophils (HR 1.64, p = 0.00072). We found that EGFR-mutant NSCLC was characterized by enriched CD4+ memory resting (CD4mr) ($p < 0.0001$) and dendritic resting ($p < 0.0001$) cells, as well as lacking of Ms ($p < 0.001$). Strikingly, ALK-mutant NSCLC showed a similar intratumoural immune profile with KRAS-mutant NSCLC, illustrated by a low fraction of CD4mr cells and enriched Ms in both molecular subgroups. **Conclusions:** Our results pointed out the complex relationship between the heterogeneity of intratumoural immune infiltrates, tumor genomics, and patient prognosis across subtypes of NSCLC. Further research is warranted to validate the relation in independent patient cohorts and to explore the impact of immune landscape on immunotherapeutic response.

8548 Poster Session (Board #154), Sun, 8:00 AM-11:30 AM

Evaluating PD-L1 status and its correlation with clinical features in surgically resected lung adenocarcinoma patients: Comparison of tissue microarrays and whole tissue section. *First Author: Hsu-Ching Huang, Chest Department, Taipei Veterans General Hospital, Taipei, Taiwan*

Background: PD-1/PD-L1 has been a novel therapeutic target in non-small-cell lung cancer (NSCLC). PD-L1 immunohistochemical staining is the most commonly used test for therapeutic guide. Although PD-L1 expression heterogeneity is well acknowledged, data are limited in PD-L1 staining results between small biopsied sample and whole tissue section (WTS) obtained from the same specimen. Current study aimed to compare PD-L1 staining between tissue microarray (TMA) and WTS and correlate it with clinical features. **Methods:** Two hundred and nineteen lung adenocarcinomas from patients who underwent surgical resection in Taipei Veterans General Hospital during Sep. 2002 and Aug. 2006 were used to construct TMA. Among them, the correspondent WTS was available in 173 specimens. Tumor PD-L1 staining on TMA and WTS were evaluated by SP142 (Spring Bioscience) on Leica autostainer. Positive PD-L1 expression was defined as membranous staining in $\geq$ 1% of tumor cells. Correlations between TMA and WTS PD-L1 expression were performed. Patients' demographic characteristics, survival and histology subtypes were investigated and correlated with PD-L1 expression on WTS. **Results:** 25 (14.5%) and 58 (33.5%) specimens were PD-L1 positive in TMA and WTS, respectively. Thirty-three (19.1%) specimens were PD-L1 negative in TMA but positive in WTS. The expression level was 1% in 8, 2-5% in 7; 6-49% in 14, and $\geq$ 50% in 4 specimens. Discordancy was more common in larger tumor size (p = 0.025), wild type EGFR (p = 0.044), and advanced stage (p = 0.01). Tumors with lepidic predominant histology ($p < 0.001$), EGFR wild-type (p = 0.002) and early disease stage (p = 0.006) were more likely to be PD-L1 negative. Kaplan-Meier survival analysis showed longer recurrence-free survival ($p < 0.001$) among patients with negative PD-L1 expression. **Conclusions:** PD-L1 IHC readout discordancy between small and large samples were not uncommon in NSCLC and it seemed related to tumor size and stage. Patients with negative PD-L1 expression tended to have longer recurrence-free survival.

8549 Poster Session (Board #155), Sun, 8:00 AM-11:30 AM

Impact of somatic mutations on recurrence free survival (RFS) and overall survival (OS) for resected non-small cell lung cancer (NSCLC): results from the Japan Molecular Epidemiology for lung cancer study (JME). *First Author: Akihiro Tamiya, National Hospital Organization Kinki-Chuo Chest Medical Center, Sakai, Japan*

Background: We previously reported molecular profiling as a primary endpoint in a prospective multicenter molecular epidemiology study, collecting 876 surgically resected NSCLC and examining 72-gene somatic mutation status using the next-generation sequencing (JME study; Kawaguchi T, J Clin Oncol 2016). The secondary endpoint was OS and RFS analysis (UMIN 000008177). Here, we report follow-up data and clinical outcomes in the JME study and the impact of somatic mutations on RFS and OS. **Methods:** All the patients were enrolled from July 2012 to December 2013, and clinical and prognostic data were obtained until the end of November 2017. Cox proportional hazards model were applied to assess the impact of the gene mutations on RFS and OS, considering gender, smoking history, age, stage, histology, history of adjuvant chemotherapy, EGFR, KRAS, TP53, and number of coexisting mutations. **Results:** Median follow up time was 48.4 months, and 876 patients were analyzed: 419 were men; 734 were non-squamous carcinoma; 441 had smoking history; 450 were $\geq$70 years; 618/131/127 were stage I/II/III-IV, 309 received the adjuvant chemotherapy. Among these, 141 had $\geq$ two somatic mutations. Multivariate analysis showed the number of coexisting mutations ($\geq$2 vs. 0 or 1, HR = 1.643, 95%CI: 1.126-2.373), age ($\geq$70 vs. $<$ 70, HR = 1.561, 95%CI: 1.201-2.035) and pathological stage (II vs. I, HR = 3.103, 95%CI: 2.217-4.304; $\geq$III vs. I, HR = 6.382, 95%CI: 4.641-8.758) were significantly associated with RFS, while in OS, *EGFR* mutations (yes vs. no, HR = 0.450, 95%CI: 0.277-0.715), adjuvant chemotherapy (yes vs. no, HR = 0.493, 95%CI: 1.406-2.967), age ($\geq$70 vs. $<$ 70, HR = 1.694, 95%CI: 1.201-2.415) and pathological stage (II vs. I, HR = 2.448, 95%CI: 1.581-3.723; $\geq$III vs. I, HR = 6.601, 95% CI: 4.498-9.665) were also significant prognostic factors. **Conclusions:** Our prospective study showed less number of coexisting mutations, earlier stage and younger age were associated with longer RFS, while in OS, *EGFR* mutation and adjuvant chemotherapy were significantly associated with improved OS as well as earlier stage and younger age in resected NSCLC.

8550 Poster Session (Board #156), Sun, 8:00 AM-11:30 AM

Circulating tumor DNA (ctDNA) as a marker of minimal residual disease (MRD) in localized non-small cell lung carcinoma (NSCLC). *First Author: Nicholas I. Simon, Northwestern University, Chicago, IL*

Background: ctDNA has been used to identify driver genomic alterations during treatment of metastatic NSCLC. Recent studies have also demonstrated ctDNA being used as a way to monitor response to therapy. Here we performed an analysis on a cohort of NSCLC patients (pts) with localized disease who underwent ctDNA testing after definitive treatments to determine whether ctDNA can be used as a marker of MRD. **Methods:** Between 2015-2018, 51 pts with localized NSCLC received ctDNA testing. ctDNA testing was done using the next generation sequencing (NGS) panel of 73 genes via digital sequencing technology (Guardant360). Statistical analysis was performed to determine which factors were associated with ctDNA levels and recurrence free survival (RFS). **Results:** Of the 51 pts analyzed, 23 pts had ctDNA testing performed after definitive treatment. Median duration of follow up was 10 months (range: 1 to 23). 30% (n = 7) had Stage I disease, 30% (n = 7) had Stage II disease, and 40% (n = 9) had stage III disease. 74% (n = 17) were adenocarcinoma while 26% (n = 6) were squamous cell carcinoma. 52% (n = 12) had no recurrence during our observation time, while 48% (n = 11) experienced progression. For definitive treatments, 35% (n = 8) underwent surgery alone, 43% (n = 10) underwent surgery with adjuvant chemotherapy, 4% (n = 1) underwent radiation alone, and 17% (n = 4) underwent chemoradiation therapy prior to their ctDNA levels [variant allele frequency (VAF)] being drawn. Of these, 13% (n = 3) tested negative for any ctDNA, while 87% (n = 20) were positive. None of the pts with undetectable levels of ctDNA experienced recurrence of cancer. Nine among 20 pts with detectable ctDNA had recurrence. Kaplan-Meir survival analysis revealed a trend toward significant association between the presence of detectable ctDNA and RFS (p = 0.055). Among pts with detectable ctDNA, there were no differences in RFS between pts with high vs. low ctDNA levels (cut off at 1% VAF). Presence of ctDNA was not associated with sex, smoking history, histology, stage, nor modality of definitive treatment. **Conclusions:** Our analysis demonstrates that ctDNA could potentially be used as a marker of MRD following definitive treatment for localized NSCLC.

8551 Poster Session (Board #157), Sun, 8:00 AM-11:30 AM

Microwave ablation plus recombinant human endostatin (endostar) versus microwave ablation alone in inoperable stage I non small cell lung cancer. *First Author: Min Meng, Shandong Provincial Hospital Affliated to Shandong University, Jinan, China*

Background: Previous studies showed that inoperable stage I non small cell lung cancer (NSCLC) benefited from microwave ablation (MWA) alone. This prospective, randomized, control, single-center clinical trial aimed to determining the survival benefit of MWA plus recombinant human endostatin (endostar) compared with MWA alone. **Methods:** Patients with untreated, inoperable, stage I NSCLC were recruited. They were divided into MWA/ endostar group and MWA group, the former received MWA in the primary tumor sites, followed by 2 to 4 cycles of endostar and the latter treated with MWA only. The primary endpoint was overall survival (OS), the second endpoint included disease-free survival (DFS) , and adverse events (AE). **Results:** A total of 183 patients were enrolled, involved 92 cases in the MWA/ endostar group and 91 cases in the MWA group. Up to the latest follow-up , there were 24 cases of disease progression and 6 deaths in the MWA/ endostar group, versus 49 cases of disease progression and 9 deaths in the MWA group. DFS in the MWA/ endostar group (30.0 months, 95% CI, 27.1-32.9) was significantly better than MWA group (21.3 months, 95% CI, 19.5-23.1, p = 0.000). But there was no significant difference (p = 0.471) in OS between the MWA/ endostar group (31.6 months ,95% CI, 28.3-35.0) and MWA group (30.0 months, 95% CI, 27.2-36.5). The 1, 2 and 3 year survival rates in the MWA/ endostar group were 94%, 82% and 82%, respectively, while those in the MWA group were 94%, 89% and 89%, respectively. There was no significant difference between the two groups (p = 0.982, p = 0.924, p = 0.924). AEs of MWA were observed in 63.7 % patients. Endostar -associated AEs were not observed in the MWA/ endostar group. **Conclusions:** MWA was a safe and effective alternative treatment for patients with inoperable stage I non small cell lung cancer. MWA combined with endostar significantly improved DFS compared to MWA alone, while not increased the MWA-related complications.

8552 Poster Session (Board #158), Sun, 8:00 AM-11:30 AM

Long-term results of a phase I/II trial of nelfinavir with concurrent chemoradiotherapy for locally advanced non-small cell lung cancer. *First Author: Ramesh Rengan, Department of Radiation Oncology, University of Washington, Seattle, WA*

Background: The objective of this Phase I/II trial was to determine the response rate and overall survival (OS) of concurrent chemoradiotherapy (CT-RT) in combination with the radiosensitizer Nelfinavir in locally advanced non-small cell lung cancer (LA-NSCLC) compared to historical controls. **Methods:** Nelfinavir (Dose Level (DL) 1: 625mg PO BID, DL2:1250mg PO BID) was administered for 7 to 14 days prior to and during concurrent CT-RT to patients (pts) with biopsy confirmed unresectable IIIA and IIIB NSCLC. 23 pts (65.7%) had stage IIIA disease; 11 pts (31.4%) had stage IIIB disease; 1 pt (2.9%) had N2 recurrence after surgery. Median age was 60 years for all pts. 19 pts (54.2%) were male, 16 (45.7%) were female. Patients were treated with concurrent CT-RT to a dose of 66.6/1.8Gy and cisplatinum and VP-16. DLTs were defined as any treatment related Grade 4 hematologic toxicity requiring a break in therapy or non-hematologic Grade $\geq$ 3 toxicity except esophagitis and pneumonitis. Protocol specified criteria for compliance included receiving greater than 80% of the prescribed RT treatments and 70% of the prescribed Nelfinavir doses. **Results:** Thirty-five pts were enrolled and met protocol-specified criteria for compliance, 5 at DL1 and 30 at DL2. No DLTs were observed. The recommended phase II dose of Nelfinavir was 1250 mg PO BID. Median follow-up for all pts was 6.8 years and minimum follow-up for survivors was 5 years. 33 of the 35 pts had evaluable post-treatment CT with RECIST response rate of 94% and (31/33) stable disease rate of 6% (2/33). The cumulative incidence of local failure as site of first failure was 20%, with the median time to failure not reached (NR). The cumulative incidence of distant failure as site of first failure was 51%, with the median time to distant failure of 15.8 months. The median progression-free survival was 12 months. The median OS for all pts was 40 months; 5 year OS was 37 %. **Conclusions:** Nelfinavir administered with concurrent CT-RT is associated with acceptable toxicity and very promising local control, overall response rate, and survival in unresectable LA-NSCLC. These data suggest that Nelfinavir may enhance the efficacy of chemo-RT in this disease. Clinical trial information: NCT00589056.

8553 Poster Session (Board #159), Sun, 8:00 AM-11:30 AM

Significance of aromatase-estrogen receptor axis in EGFR status of lung adenocarcinoma. *First Author: Kazumi Tanaka, Department of General Surgical Science, Gunma University Graduate School of Medicine, Maebashi, Japan*

Background: Aromatase alongside with estrogen receptor beta (ERβ) is a potential target for novel therapeutic strategy in lung adenocarcinoma (AC). The purpose of this study is to examine the correlations of expressions of aromatase and ERβ with other prognostic factors including epidermal growth factor receptor (*EGFR*) in lung AC. **Methods:** We analyzed 186 consecutive patients with lung AC who underwent surgical resection at Gunma University Hospital between Dec. 2003 and Feb. 2010. The clinicopathological characteristics and survivals of patients were subclassified based on the expressions of aromatase, ERα, ERβ, and progesterone receptor (PR) as determined by immunohistochemical staining. Gene alterations of *EGFR* and *KRAS* were evaluated with SmartAmp2. Multivariate analysis using Cox regression model was carried out to evaluate the effect of aromatase expression. In vitro experiment was performed with shRNA transduced aromatase-depleted lung AC cells. **Results:** Expressions of aromatase, ERα, ERβ, and PR were detected in 86.6%, 1.6%, 78.5%, 2.7% of all patients, respectively. In all patients, the expression of aromatase is an independent prognostic factor in OS (Hazard Ratio [HR] = 2.1; 95% confidential interval [CI], 1.2-3.6; *P*= .008) and RFS (HR = 1.8; 95%CI, 1.1-2.8; *P*= .022), while that of ERβ is not statistically significant. In patients with wild-type *EGFR*, high aromatase expression is also an independent prognostic factor in OS (HR = 2.4; 95%CI, 1.2-4.6; *P*= .009) and RFS (HR = 2.5; 95%CI, 1.3-4.7; *P*= .006). Interestingly, high aromatase expression is significantly correlated with poor survival only in women (OS, *P*= .019; RFS, *P*= 0.033) in patients with wild-type *EGFR*, while no prognostic significance is observed in patients with *EGFR* mutations. In line with this, depletion by shRNA of aromatase suppressed oncogenic activity in soft agar assays. **Conclusions:** Aromatase expression is independent negative prognostic factor in especially *EGFR* wild-type adenocarcinoma. We further showed that in patients with wild-type *EGFR*, high aromatase expression is a significant correlated with poor survival only in women. Aromatase-depleted lung AC cells transduced shRNA, demonstrate decreased tumorigenicity.

8554 Poster Session (Board #160), Sun, 8:00 AM-11:30 AM

Long-term outcomes after sublobar resection for clinical stage IA lung adenocarcinoma meeting node-negative criteria defined by HRCT and FDG-PET/CT. *First Author: Yasuhiro Tsutani, Hiroshima University, Hiroshima, Japan*

Background: The purpose of this study is to evaluate long-term outcomes after sublobar resection for patients with clinical stage IA lung adenocarcinoma meeting our proposed node-negative (N0) criteria: solid component size of less than 0.8 cm on HRCT or SUVmax of less than 1.5 on FDG-PET/CT. **Methods:** Between April 2006 and December 2010, 347 patients with clinical stage IA lung adenocarcinoma underwent complete resection after preoperative HRCT and FDG-PET/CT in Kanagawa Cancer Center and Hiroshima University. Long-term outcomes of patients who met the N0 criteria after sublobar resection were evaluated. **Results:** Two-hundred one (57.9%) patients met the N0 criteria. Patients who met the N0 criteria were significantly associated with low grade adenocarcinoma subtype (adenocarcinoma in situ, minimally invasive adenocarcinoma, or lepidic adenocarcinoma; $P < 0.001$), negative lymphatic invasion ($P < 0.001$), negative vascular invasion ($P < 0.001$), and negative pleural invasion ($P < 0.001$). One of 201 (0.5%) patients had lymph node metastasis. The median follow-up period was 86.1 months. There was significant difference in overall survival (OS) between patients who met the N0 criteria (5-year OS rate, 93.9%; 10-year OS rate, 90.3%) and those who did not meet the N0 criteria (5-year OS rate, 81.5%; 10-year OS rate, 64.3%; $P < 0.001$). In patients who met the N0 criteria, there was no significant difference in OS between patients who underwent lobectomy (5-year OS rate, 94.3%; 10-year OS rate, 92.6%) and those who underwent sublobar resection (5-year OS rate, 93.8%; 10-year OS rate, 89.3%; $P = 0.640$). **Conclusions:** Sublobar resection is feasible for clinical stage IA lung adenocarcinoma meeting N0 criteria defined by HRCT and FDG-PET/CT with excellent long-term survival.

8555 Poster Session (Board #161), Sun, 8:00 AM-11:30 AM

A phase I study of neoadjuvant cisplatin (C), docetaxel (D) and nintedanib (N) for resectable non-small cell lung cancer (NSCLC). *First Author: Tina Cascone, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Major pathologic response (mPR) in resected NSCLC following neoadjuvant chemotherapy correlates with long-term survival. This phase 1 study assessed the safety and efficacy of N added to neoadjuvant C and D, using mPR as primary surrogate of efficacy endpoint. **Methods:** Eligible patients (pts) had stage IB (≥4 cm) to IIIA (single station N2) resectable NSCLC (AJCC 7^{th}). The study included an expansion phase of N 200 mg p.o. bid priming monotherapy for 28 days, followed by 3 cycles of C 75 mg/m^2, D 75 mg/m^2 every 21 days, and N 200 mg p.o. bid, and surgery (after a run-in phase in 6 pts determined safety of escalating N doses). With 33 pts, the study had 90% power to detect an increase in mPR from 15% (historical controls) to 35%, with a 10% type I error rate. Based on the Simon's two-stage design, the protocol called for discontinuation of the trial if there were < 4 responders in the first 19 pts treated at N 200 dose level (NCT02225405). **Results:** From July 2015 to May 2017, 21 pts (15 female, 1/8/12 stages I/II/III) were treated (6 with N 150 mg bid, 15 with N 200 mg bid). Only 1/15 pts treated with N 200 mg bid achieved a mPR (6.7%, 95% CI 0.2% - 32.0%). An interim analysis demonstrated that the probability of observing ≥4 mPRs if accrual were to continue to 19 pts was only 5.4%, assuming the prior of p beta(0.35, 0.65). Hence, the study was discontinued for futility. The best objective response rate by RECIST 1.1 in all 21 pts was 33.3%. No patients responded to N priming monotherapy. With a median follow up time of 11 months, the 12-month RFS in the whole cohort was 71% (95% CI 49%, 100%). The most frequent treatment-related grade 3-4 toxicities in all pts were: transaminitis (14.3%); nausea (9.5%) and electrolyte abnormalities (14.3%). No unexpected perioperative complications were observed. **Conclusions:** Although tolerable, neoadjuvant N, C, and D did not increase the mPR rate compared to historical controls of induction chemotherapy alone. Additional studies of the combination in this setting are not recommended. Our trial design, utilizing mPR as an intermediary endpoint, may serve as a framework to rapidly screen novel compounds that should be investigated further as neoadjuvant therapies for resectable NSCLC. Clinical trial information: NCT02225405.

8556 Poster Session (Board #162), Sun, 8:00 AM-11:30 AM

A comparative safety analysis for durvalumab in patients with locally advanced, unresectable NSCLC: PACIFIC versus pooled durvalumab monotherapy studies. *First Author: Scott Joseph Antonia, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

Background: In PACIFIC, durvalumab significantly extended PFS compared with placebo (HR 0.52; P<0.0001) for pts with locally advanced, unresectable NSCLC who had previously received concurrent chemoradiotherapy (cCRT). The safety profile of durvalumab in this study was similar to placebo. Here we report a safety analysis of a descriptive comparison of PACIFIC with a pooled dataset of durvalumab monotherapy studies. **Methods:** Data were pooled for pts treated with durvalumab monotherapy (10 mg/kg IV Q2W) from three trials (N=1,889), the Phase III PACIFIC (n=475), Phase II ATLANTIC (n=444 advanced NSCLC pts), and Phase I/II 1108 (n=970 solid tumor pts, including 304 NSCLC pts) studies. The incidences of all-causality AEs (as of Feb 13, 2017, data cutoff for the PACIFIC analysis) were graded using CTCAE v4.03 and summarized descriptively for comparison between PACIFIC and the pooled dataset. **Results:** Compared with the pooled dataset (Table), PACIFIC had lower incidences of grade 3/4 AEs and SAEs, but a higher rate of AEs leading to discontinuation (15.4% [durvalumab] vs. 9.8% [placebo] compared with 9.4% [pooled dataset]). In a separate comparison excluding PACIFIC from the pooled dataset (N=1,414), any-grade (grade 3/4) pneumonitis/radiation pneumonitis occurred in 33.9% (3.4%) of pts on durvalumab and 24.8% (3.0%) on placebo in PACIFIC (with similar grade 3/4 incidences for both) and 2.3% (0.5%) of pts in the reduced pooled dataset. **Conclusions:** Durvalumab monotherapy has a well-defined and acceptable safety profile. Differences observed in the rates of AEs with durvalumab on the PACIFIC regimen may be attributable to the pt population or prior cCRT.

8557 Poster Session (Board #163), Sun, 8:00 AM-11:30 AM

Geriatric assessment to predict toxicity in elderly patients with unresectable locally advanced non-small-cell lung cancer treated with concurrent chemoradiotherapy. *First Author: Ernest Nadal, Department of Medical Oncology, Catalan Institute of Oncology, Hospitalet (Barcelona), Spain*

Background: There is no consensus on the treatment of elderly patients with unresectable locally advanced non-small-cell lung cancer (LA-NSCLC). We aimed to determine whether the comprehensive geriatric assessment (CGA) as well as other screening tools were able to predict toxicity in this clinical setting. **Methods:** Elderly patients (≥ 75y) with LA-NSCLC underwent CGA, the Vulnerable Elders Survey (VES-13) screening tool and the Cancer and Aging Research Group (CARG) toxicity predictive tool. Based on CGA, fit and medium-fit patients were deemed candidates for platinum-based chemotherapy concurrent with thoracic radiation therapy (cCRT) and unfit patients received best supportive care. The ability of CGA, CARG and VES-13 to predict grade 3–4 (G3-4) toxicity was assessed by logistic regression. **Results:** 85 elderly patients with LA-NSCLC were assessed by CGA and classified into fit 37%, medium fit 48% and unfit 15%. Based on VES-13, 56% were considered vulnerable. Fifty-four fit and medium-fit patients received cCRT and 42 (78%) patients completed the scheduled treatment. No differences in treatment completion were seen among both CGA groups. Reasons for not completing cCRT were toxicity (10%), cancer recurrence (4%), patient decision (4%) or aggravation of comorbidities (4%). The median OS (mOS) in fit and medium-fit patients receiving cCRT was 21.1 months (95% CI 16.2 – 26.0). Most common G3-4 adverse events were neutropenia (20%), febrile neutropenia (7.5%), asthenia/fatigue (11%), respiratory infection (13%) and radiation pneumonitis (13%). CARG toxicity tool classified fit and medium-fit patients into high 10%, medium 52% and low risk 38%. GGA groups were not predictive of G3-4 toxicity. Medium and high risk patients based on CARG were more likely to have G3-4 toxicity ($p = 0.086$).Vulnerable patients defined by VES-13 had significantly higher risk of grade 3-4 toxicity (OR = 3.99, 95% CI 1.28-12.37, $p = 0.017$). **Conclusions:** CGA is helpful in selecting elderly patients with unresectable LA-NSCLC that may benefit from cCRT. VES-13 was significantly associated with higher risk of G3-4 toxicity in this clinical setting.

8558 Poster Session (Board #164), Sun, 8:00 AM-11:30 AM

Long-term survival after salvage SBRT for recurrent or secondary non-small cell lung cancer after prior surgery or radiation therapy. *First Author: Chunyu He, Indiana University Department of Radiation Oncology, Department of Thoracic Radiation Oncology, Affiliated Cancer Hospital of Zhengzhou University, Zhengzhou, China*

Background: Patients with locally recurrent or newly diagnosed NSCLC after previous definitive radiotherapy (RT) or surgery pose a challenge in management. SBRT has been attempted as option of salvage treatment. The objective of this study is to report long-term outcome of SBRT in patients with recurrent or second primary NSCLC after previous local treatment. **Methods:** This single-institution retrospective study included patients with NSCLC who received thoracic SBRT for newly diagnosed or recurrent NSCLC. The primary and second endpoints were overall survival and radiation pneumonitis, respectively. Clinical factors analyzed included age, gender, race, tobacco history, respiratory/cardiovascular comorbidity, histology, modality of previous treatment, T stage, gross tumor volume (GTV), planning target volume (PTV), and prescription dose. Radiation pneumonitis was graded consistently per RTOG1106. **Results:** A total of 326 patients met the inclusion criteria, including 43, 40 and 243 patients with prior RT, surgery, and no prior treatment, respectively. The median follow-up was 59 (95% CI 48-68) months. The median survival were 23 (95% CI 15-31), 50 (95% CI 35-65), and 32 (95% CI 25-40) months, and the 5-year survival rates were 26.2%, 42.4%, and 24.7%, respectively (P= 0.077). In those treated with previous RT, there were no significant differences in overall survival between conventionally fractionated radiation therapy and SBRT (median survival 25.0 vs 13.4month, P= 0.280). In those treated with prior surgery, there was no significant difference in overall survival between pneumonectomy and lobectomy (56.0 vs 50.0 months, P= 0.576). The were significant differences in rates of grade 1+ (44.2%, 30.0%, 21.5%, P= 0.007), and 2+ RP (18.6%, 12.5%, 7.0%, P= 0.039), but no statistically significant differences in grade 3+ pneumonitis among these three groups. **Conclusions:** Salvage SBRT after previous radiation or surgery provides a chance of cure, with 5-year survival not significantly different from that of SBRT for newly diagnosed NSCLC, with significantly increased but acceptable risk of radiation pneumonitis.

8560 Poster Session (Board #166), Sun, 8:00 AM-11:30 AM

Long-term survival following trimodality therapy vs. medical management of malignant pleural mesothelioma. *First Author: Frédéric Larose, Institut Universitaire de Cardiologie et de Pneumologie de Québec, Quebec City, QC, Canada*

Background: Medical management based on palliative chemotherapy is currently the standard of care in malignant pleural mesothelioma (MPM). Median survival of 12-16 months has been reported with modern chemotherapy regimens. Multimodality therapy incorporating radical surgery, systemic chemotherapy and radiotherapy has recently evolved. The MARS feasibility study suggested that extrapleural pneumonectomy might be detrimental, but recent publications suggested that pleurectomy/decortication (P/D) may lead to better outcomes with overall median survival of 30-35 months in selected patients. Retrospective studies comparing trimodality therapy vs. medical management conducted in centers where surgery is offered are obviously limited by selection bias. Our objective was to compare overall survival in patients offered trimodality therapy at a single institution to the one of patients treated at another institution where the management of MPM is exclusively medical. **Methods:** Retrospective analysis of two databases: 106 consecutive patients (cohort 1) treated by a single team in London (UK) from 2009 to 2016 and 98 consecutive patients (cohort 2) exclusively treated medically at the Quebec Heart and Lung Institute (Canada) during the same period were included. **Results:** In cohort 1, all patients had P/D with hyperthermic pleural lavage with povidone-iodine, prophylactic chest wall radiotherapy and systemic chemotherapy. In cohort 2, 51% received palliative care only; 31% were treated with chemotherapy. Median survival was 32 months vs 10 months in cohort 1 and 2, respectively (hazard ratio with age, gender, pathology and TNM staging as covariates: 3.81; 95% CI: 2.66 – 5.45; $p < 0.0001$). **Conclusions:** Aggressive therapy of MPM using cancer-directed surgery, systemic chemotherapy and prophylactic radiotherapy may provide a significant survival benefit in selected patients.

	Trimodality therapy (n = 106)	Medical therapy (n = 98)	P
Age (mean ± SD)	64 ± 2	70 ± 5	< 0.0001
Gender (n, % male)	83 (78%)	73 (74%)	0.16
Pathology (n, %)			< 0.0001
Epithelioid	73 (69%)	57 (58%)	
Sarcomatoid	2 (2%)	15 (15%)	
Biphasic	31 (29%)	21 (21%)	
Unknown	0	5 (5%)

3 – 4	84 (79%)	55 (56%)	

8561 Poster Session (Board #167), Sun, 8:00 AM-11:30 AM

Uncommon ALK fusion partners in advanced ALK-positive non-small-cell lung cancer. *First Author: Jin Kang, Guangdong Lung Cancer Institute, Guangdong General Hospital (GGH) and Guangdong Academy of Medical Sciences, Guangzhou, China*

Background: The variants affect the efficacy of crizotinib in echinoderm microtubule protein-like-4 (*EML4*)- anaplastic lymphoma kinase (*ALK*) fusion-positive non–small-cell lung cancers (NSCLCs). Non–EML4-ALK fusions were detected and may have biologic and clinical implications differently. However, few studies focused on the effects of non–EML4-ALK fusions on the efficacy of crizotinib. **Methods:** Among 182 ALK-positive patients whose ALK rearrangement were confirmed by fluorescence in situ hybridization developing resistance to crizotinib as the initial ALK-TKI between October 2010 and December 2017, 41 patients with sufficient tumor specimens could be evaluated for *ALK* variants by next-generation sequencing (NGS). Uncommon *ALK* fusion partners include non-EML4 or EML4-based variants. We retrospectively investigated progression-free survival (PFS), objective response rate (ORR) and overall survival (OS) between the patients with uncommon *ALK* fusion partners and those with EML4-ALK variants. **Results:** The frequency of uncommon ALK fusion partners was 34.1% (14/41). Among the 14 patients , there are 9 patients only harboring with one kind of non-EML4 partners. The ALK fusion partners of the other 5 patients included non-EML4 and EML4. The median PFS was longer in patients with uncommon ALK fusion partners than in those with EML4 variants (10.5 months VS 3.7 months [95% CI, 0.85 to 3.06 months], respectively; P = 0.142). The ORR between two groups were 64.3% and 77.8% in the two groups respectively. The median OS was 34.2 months and 21.0 months in the two groups respectively (95% CI, 1.21 to 4.65 months ; P = 0.012) . Four patients harbored with uncommon *ALK* fusion partners developed primary resistance to crizotinib and these fusions included DTNB-ALK, NR_110271-ALK, ZC3H8-ALK and STED2-ALK. A emerging FSHR-ALK fusion was found in a patient who had dynamic plasma to be monitored during the treatment of crizotinib. **Conclusions:** The *ALK* fusion partners have a profound impact on the efficacy of ALK TKIs. Some partners led to primary resistance to crizotinib and some partners might produce better efficacy of ALK TKIs than *EML4* in advanced *ALK*-positive NSCLCs. The *ALK* fusion partners should be detected by NGS beforehand.

8562 Poster Session (Board #168), Sun, 8:00 AM-11:30 AM

***PBRM1* genomic alterations in mesothelioma: Potential predictor of immunotherapy efficacy.** *First Author: Jeffrey S. Ross, SUNY Upstate Medical University, Syracuse, NY*

Background: PBRM1, of the SWI/SNF family, modulates chromatin remodeling. *PBRM1* genomic alterations (GA) are enriched in renal cell carcinoma and mesothelioma (MS). Recent evidence suggests that *PBRM1* GA are strongly associated with neoantigen production and responsiveness to immune checkpoint inhibitors (ICPI). **Methods:** Comprehensive genomic profiling (CGP) was performed on 50 ng of DNA for 783 FFPE mesothelioma (MS) samples using a hybrid-capture, adaptor ligation-based next-generation sequencing assay to a median coverage depth of > 600X. The results were analyzed for all classes of GA and tumor mutational burden (TMB), determined on up to 1.2 Mb of DNA. Microsatellite instability (MSI) status was evaluated by principal component analysis of optimal homopolymer loci. GA were counted as relevant if known to disrupt *PBRM1* or homozygous in the tumor. **Results:** Of 783 relapsed/refractory MS, 8 (1%) were pericardial (PCDMS), 187 (24%) peritoneal (PERMS), and 588 (75%) pleural (PLRMS) tumors (Table). Median ages were similar, but specimens from males were more common (72%) in PLRMS and females (56%) in PERMS. The *PBRM1* GA frequency was 11% overall, from 7.7% (PLRMS) to 20.3% (PERMS). *BAP1* GA were found in 84.1% of *PBRM1*-altered MS and *NF2* GA in 28%. In *PBRM1* wild type MS, *BAP1* GA were in 43.7% and *NF2* GA in 31.2%. The median TMB was low and TMB > 20 mut/Mb were very uncommon. There were very few instances of MS with high MSI. MS patients with *PBRM1* GA responding to ICPI treatment will be presented. **Conclusions:** Immunotherapy strategies for the treatment of MS have recently emerged. *PBRM1* GA are seen in 11% of MS and represent a potential predictive biomarker for therapy selection in this typically devastating disease. Further study of PBRM1 status in the ICPI treatment of MS in the clinical trial setting appears warranted.

	Total MS	PCDMS	PERMS	PLRMS

8563 Poster Session (Board #169), Sun, 8:00 AM-11:30 AM

Phase 1b study of avelumab in advanced previously treated mesothelioma: long-term follow-up from JAVELIN Solid Tumor. *First Author: Raffit Hassan, Thoracic and Gastrointestinal Oncology Branch, National Cancer Institute, Bethesda, MD*

Background: Avelumab, a human anti-PD-L1 IgG1 antibody, is approved for treatment of metastatic Merkel cell carcinoma in various countries and advanced urothelial carcinoma progressed on platinum therapy in the US. We report updated results with avelumab in a phase 1b cohort of patients (pts) with mesothelioma. **Methods:** Pts with unresectable pleural or peritoneal mesothelioma progressed after platinum and pemetrexed therapy received avelumab 10 mg/kg IV Q2W until progression, unacceptable toxicity, or withdrawal. Endpoints included objective response rate (ORR), progression-free survival (PFS), overall survival (OS), and adverse events (AEs). A post-hoc landmark analysis was performed using a Cox regression model. **Results:** At data cutoff on Dec 31, 2016, 53 pts were treated and followed for a median of 24.8 mo (range 16.8–27.8). Pts had received a median of 2 prior lines of therapy (range 1–8). Confirmed ORR was 9.4% (95% CI 3.1–20.7) including complete response (CR) in 1.9% and partial response (PR) in 7.5%. Median duration of response was 15.2 mo (95% CI 11.1–not estimable). 26 pts (49.1%) had stable disease (SD) as best response and the disease control rate was 58.5%. Median PFS was 4.1 mo (95% CI 1.4–6.2) and the 6-mo PFS rate was 38.0% (95% CI 24.2–51.7). Median OS was 10.9 mo (95% CI 7.5–21.0) and the 12-mo OS rate was 45.9% (95% CI 31.9–58.8). In a landmark analysis of pts still on treatment at 3 mo, duration of OS beyond 3 mo was longer in patients who had achieved CR/PR (HR $<$ 0.01; 95% CI 0–inf.) or SD (HR 0.43; 95% CI 0.20–0.89) vs other pts. In evaluable pts with PD-L1+ (n = 16) or PD-L1− (n = 27) tumors ($\geq$5% tumor cell cutoff), ORR was 18.8% (95% CI 4.0–45.6) and 7.4% (95% CI 0.9–24.3), respectively. Treatment-related (TR)AEs occurred in 43 pts (81.1%), including infusion-related reaction (35.8%; all grade 1/2), chills (15.1%), fatigue (15.1%), and pyrexia (11.3%) in $>$ 10%. 5 pts (9.4%) had a grade $\geq$3 TRAE. 12 pts (22.6%) had an immune-related TRAE, which was grade $\geq$3 in 3 pts (5.7%; pneumonitis, colitis, and type 1 diabetes mellitus). No treatment-related deaths occurred. **Conclusions:** Updated data confirm the clinical activity and acceptable safety of avelumab in pts with previously treated mesothelioma. Clinical trial information: NCT01772004.

8564 Poster Session (Board #170), Sun, 8:00 AM-11:30 AM

Frequency of germline mutations in cancer susceptibility genes in malignant mesothelioma. *First Author: Vasiliki Panou, Department of Respiratory Diseases & Department of Clinical Medicine & Clinical Cancer Research Center & Research Unit of Anaesthesia and Intensive Care Medicine, Aalborg University Hospital, Aalborg, Denmark*

Background: Malignant mesothelioma (MM) is thought to be largely due to asbestos exposure, but the prevalence and the causative role of germline cancer susceptibility gene mutations in MM is unknown. **Methods:** Targeted genomic capture and next generation sequencing of 85 cancer susceptibility genes was performed on DNA extracted from peripheral blood or saliva from 198 patients with pleural, peritoneal, or tunica vaginalis MM presenting to The University of Chicago Mesothelioma Clinic. **Results:** The patient population fit usual MM demographics: the majority were male (n = 136, 69%), had pleural disease (n = 148, 75%), epithelioid histology (n = 157, 79%), and a history of occupational asbestos exposure (n = 129, 65%). The median age at MM diagnosis was 67 years (range 24-88). We identified 24 pathogenic germline mutations in 13 genes in 23/198 (12%) MM patients. *BAP1* mutations were the most common (n = 6, 25%). The remaining were in genes involved in cell cycle and DNA repair (n = 14), oxygen sensing (n = 2), endosome trafficking (n = 1), and cell growth (n = 1). Pleural site (OR 0.23; 95% CI 0.10-0.58), asbestos exposure (OR 0.28; 95% CI 0.11-0.72), and older age (OR 0.95, 95% CI 0.92-0.99) were associated with decreased odds of carrying a germline mutation while having a second cancer diagnosis (OR 3.33; 95% CI 1.22-9.07) significantly increased the odds. The odds of carrying a mutation in *BAP1* (OR 1658; 95% CI 199-76224), *BRCA2* (OR 5; 95% CI 1.0-14.7), *CDKN2A* (OR 53; 95% CI 6-249), *TMEM127* (OR 88; 95% CI 1.7-1105), and *VHL* (OR 50; 95% CI 1.1-453) were significantly higher in MM cases than in a non-cancer control population. Tumor sequencing identified mutations in a homologous recombination (HR) DNA repair pathway gene in 52% (n = 29/54), including *BAP1* (n = 27), *FANCA* (n = 2), *ATM* (n = 1), *ATR* (n = 1), *BRCA2* (n = 1), and *CHEK2* (n = 1). **Conclusions:** A significant proportion of MM patients carry germline pathogenic mutations in cancer susceptibility genes, especially those with peritoneal MM, minimal asbestos exposure, young age, and a second cancer diagnosis. These data support clinical germline genetic testing for MM patients and provide rationale for a further investigation of the HR pathway in MM.

8565 Poster Session (Board #171), Sun, 8:00 AM-11:30 AM

Phase II trial of pembrolizumab (P) in patients (pts) with previously-treated mesothelioma (MM). *First Author: Arpita Desai, University of Chicago, Chicago, IL*

Background: We conducted a phase II trial (NCT02399371) of P in previously treated MM to characterize activity in a non-selected population and determine a PD-L1 expression threshold **Methods:** Eligible pts had histologically confirmed MM, PS 0-1, disease progression, 1-2 prior regimens. P 200 mg was given Q21 days; CT scans Q9 weeks. 1^0 endpoints determine 1) objective response rate (RR) in an unselected and a PD-L1 positive population 2) optimal threshold for PD-L1 expression (22C3 IHC tumor cell/tumor proportion score (TPS) assay). Part A required $\geq$3 responses in 35 PD-L1 unselected pts. Part B PD-L1 preselects if a threshold is found in Part A. We previously reported (WCLC 2016) 7 responses in Part A; as no PD-L1 threshold was found (ROC 0.62), Part B enrolled 30 pts with no biomarker enrichment. **Results:** 65 pts enrolled 5/15-2/18; 1 withdrew. Median age: 68 (range 26-85); PS 0: 53%; male: 77%; epithelioid/biphasic/sarcomatoid: 76.6%/15.6%/7.8%; pleural/peritoneal: 87.5%/12.5%; 1 prior regimen: 61%. Mean cycles: 9 (range 1-34). Partial response: 12 (19%), stable disease: 29 (47%). Median progression-free survival (PFS): 4.5 months (mo) (95% CI: 2.3, 6.2). Median overall survival: 11.5 mo (95% CI: 7.6, 14). Grade $^3/_4$ toxicity: adrenal insufficiency 3%, pneumonitis 3%, rash 3%, colitis 1.6%, confusion 1.6%, hepatitis 1.6%, hyperglycemia 1.6%. Grade 5: hepatitis 1.6%, unknown 1.6%. PD-L1 expression by TPS (N = 62): none ($<$ 1%) 45%; low (1-49%) 32%; high ($\geq$50%) 23%. RR by TPS: none 7%, low 26%, high 31%. RR by histology: epithelioid 16%, biphasic 10%, sarcomatoid 40%. RR by site: pleural 20%, peritoneal 12.5%. PD-L1 did not correlate with RR as a continuous metric (ROC area 0.65; 95% CI: 0.48, 0.82); there was a trend to higher RR in PD-L1 $\geq$1% (28%) vs. PD-L1 $<$ 1% (7%). Median/1-year PFS by TPS: none 3.1 mo/7%; low 6.2 mo/7%; high 6.1 mo/31%. **Conclusions:** P has clinically meaningful single-agent activity in PD-L1 unselected, previously treated MM, yielding a 19% RR, a 66% disease control rate, and manageable toxicity. Though an optimal PD-L1 threshold could not be established, there was a trend to higher RR and more durable PFS with increasing PD-L1 expression. Responses were more frequent in pleural and sarcomatoid MM. Funded by MARF. Clinical trial information: NCT02399371.

8566 Poster Session (Board #172), Sun, 8:00 AM-11:30 AM

Tumor burden (TB) and treatment exposure (TE) in patients (pts) with malignant pleural mesothelioma (MPM) receiving nintedanib (N)/placebo (P) in combination with first-line pemetrexed/cisplatin (PEM/CIS) in phase II of the LUME-Meso study. *First Author: Sanjay Popat, Royal Marsden Hospital NHS Foundation Trust, London, United Kingdom*

Background: In the double-blind, placebo-controlled phase II/III LUME-Meso trial, N was combined with up to 6 cycles of PEM/CIS, followed by N monotherapy until progression or toxicity. The primary analysis of phase II showed improved progression-free survival (primary endpoint) with N vs P (hazard ratio (HR) = 0.56; 95% confidence interval (CI): 0.34–0.91; p = 0.017); for overall survival HR = 0.77; 95% CI 0.46–1.29. We evaluated outcomes in the combination and monotherapy phases to understand better the overall study results. **Methods:** Pts with unresectable MPM (ECOG PS 0–1), stratified by histology, were randomized 1:1 to receive $\leq$6 cycles PEM (500 mg/m^2)/CIS (75 mg/m^2) Day 1 + N or P; 200 mg bid, Days 2–21), followed by N or P monotherapy maintenance. TE was analyzed for PEM/CIS, N and P. TB, measured using sum of diameter by modified RECIST 1.0, was analyzed over time, using a mixed-effects model in pts with at least two imaging datapoints. **Results:** 87 pts were randomized: 85 pts (N: 44, P: 41) were treated; 61 pts (N: 34, P: 27) received maintenance; median follow-up was 29 months. Both groups received a median of 6 cycles of PEM/CIS. In the combination phase, greater and longer reduction in TB was seen with N. Average TB reduction from baseline to nadir was 46% greater for N vs P (33.1 vs 22.6 mm). The nadir occurred at 4.1 vs 2.3 months for N vs P. In the monotherapy phase, treatment with N vs P showed markedly slower tumor regrowth from nadir (e.g. +46% vs +112% at 12 months). Median TE (N vs P) was 7.8 vs 5.3 months over the full treatment period. In the monotherapy phase, TE was 5.3 vs 2.8 months. The proportion of pts with serious AEs (N vs P) was similar between treatment groups during combination (34% vs 32%); during monotherapy the rate was 15% vs 26%. **Conclusions:** Pts receiving N had greater, more sustained reduction in TB than those receiving P and remained on active therapy for longer. AEs were manageable in both phases of the trial. Together with the primary study results, these analyses show that combination of N + PEM/CIS followed by N maintenance delivers clinical benefit to pts with MPM. Clinical trial information: NCT01907100.

8567 Poster Session (Board #173), Sun, 8:00 AM-11:30 AM

Long-term survival outcomes of a placebo-controlled phase 3 trial with NGR-hTNF in combination with best investigator choice in relapsed malignant pleural mesothelioma (MPM). *First Author: Vanesa Gregorc, Department of Oncology, San Raffaele Scientific Institute, Milan, Italy*

Background: NGR-hTNF is a vascular-targeting agent able to increase intratumoral chemotherapy penetration and T-cell infiltration by modifying tumor microenvironment. MPM patients failing first-line therapy have limited treatment options. **Methods:** In the phase 3 trial NGR015 (ASCO 2015; abs 7501), 400 patients received single-agent gemcitabine, vinorelbine or doxorubicin ± NGR-hTNF as second-line therapy. By ITT analysis, overall survival (OS) did not differ between arms (median follow-up 18.7 months; data maturity 75%). In subgroup analyses, there was a significant interaction only between treatment and treatment-free interval (TFI) after first-line therapy. NGR-hTNF improved OS and PFS in the short TFI subset (< median: 4.8 months; n = 198). We assessed long-term outcomes in patients with short TFI and prognostic TFI value after adjusting for baseline covariates (age, sex, PS, histology, EORTC score, NLR, response to prior therapy and selected chemotherapy). **Results:** At a median follow-up of 33.8 months (data maturity 86%), a treatment-by-TFI interaction for OS persisted in univariate (p = 0.004) and multivariable models (p = 0.002). In the short TFI subset, median OS was 9.2 months (95% CI 6.6-11.8) for NGR-hTNF vs 6.3 months (5.7-7.0) for placebo (HR 0.67; 0.48-0.93; p = 0.02; adjusted HR 0.64; 0.45-0.89; p = 0.008). Survival rates were 39% (29-50) vs 24% (16-32) at 1 year and 18% (9-26) vs 9% (3-15) at 2 years. The 25% survival rate occurred 7 months later with NGR-hTNF than with placebo (17.3 months vs 10.2 months). NGR-hTNF treatment was associated also with improved PFS (median 3.4 vs 1.9 months; HR 0.66; 0.48-0.91; p = 0.01; adjusted HR 0.65; 0.47-0.90; p = 0.009). In sensitivity analyses, consistent results were found using a 6-month TFI cutoff. The prognostic TFI value was assessed in the control group to avoid confounding effects of experimental treatment. A short TFI independently correlated with worse OS (HR 1.79; 1.29-2.50; p = 0.0006). **Conclusions:** Benefit with NGR-hTNF treatment in the short TFI subgroup was maintained after a 3-year follow-up, deserving a confirmatory randomized trial as these MPM patients have a poor prognosis. Clinical trial information: NCT01098266.

8568 Poster Session (Board #174), Sun, 8:00 AM-11:30 AM

Association between progression-free survival (PFS) rate (PFSR) and overall survival (OS) in LUME-Meso, a study of nintedanib (N) vs. placebo (P) in combination with first-line pemetrexed/cisplatin (PEM/CIS) in patients (pts) with malignant pleural mesothelioma (MPM). *First Author: Nick Pavlakis, Northern Cancer Institute, St Leonards, Sydney, Australia*

Background: We evaluated the relationship between PFSR and OS in the Phase II part of LUME-Meso, a double-blind, placebo-controlled study that showed improved PFS (primary endpoint; hazard ratio [HR] = 0.56; 95% confidence interval [CI]: 0.34–0.91; p = 0.017), for N vs P; for OS HR = 0.77; 95% CI 0.46–1.29. **Methods:** Pts with unresectable MPM (ECOG PS 0–1), stratified by histology (epithelioid/biphasic), were randomized 1:1 to receive ≤6 cycles PEM (500 mg/m^2)/CIS (75 mg/m^2) on Day 1 + N or P (200 mg bid on Days 2–21), followed by N or P monotherapy maintenance. PFSR was defined as the proportion of pts who did not meet criteria for progressive disease (PD) at the specified time point (a 'landmark analysis'). PFSR was assessed at 6 (PFSR6) and 8 (PFSR8) months. The association with OS was then evaluated based on the progression status at the landmark. Pts who died prior to the landmark were excluded from analysis. **Results:** 87 pts were randomized (N: 44; P: 43). The PFSR6 analysis included 71 pts (28 with PD and 43 without PD); subsequently there were 52 deaths. The PFSR8 analysis included 63 pts (32 with PD and 31 without PD); subsequently there were 45 deaths. There were more pts treated with N vs P who had not progressed at 6 (63% vs 37%) and 8 (71% vs 29%) months. Both PFSR6 and PFSR8 predicted OS (HR for PFSR6: 0.19; 95% CI: 0.11–0.35; HR for PFSR8: 0.18; 95% CI: 0.09–0.37). In the PFSR6 analysis, median OS was 22.8 months (95% CI: 15.6–28.4) in pts without PD prior to the landmark vs 6.1 months (95% CI: 3.3–7.0) in pts with PD prior to the landmark. In the PFSR8 analysis, median OS was 23.9 months (95% CI: 15.6–28.4) in pts without PD prior to the landmark vs 5.0 months (95% CI: 3.9–11.6) in pts with PD prior to the landmark. PFSR also predicted OS in pts with epithelioid histology at 6 months (n = 63; HR = 0.19; 95% CI: 0.10–0.36) and at 8 months (n = 57; HR = 0.20; 95% CI: 0.09–0.40). **Conclusions:** In our study in pts with MPM, landmark PFSR at 6 and 8 months predicts OS. These data are consistent with previously published findings. Phase III of LUME-Meso is ongoing (NCT01907100). Clinical trial information: NCT01907100.

8569 Poster Session (Board #175), Sun, 8:00 AM-11:30 AM

A real-world experience of nivolumab in advanced malignant mesothelioma (MM). *First Author: Hussein Hamad, Baylor College of medicine, Houston, TX*

Background: Nivolumab showed promising results in phase II clinical trials for advanced MM patients with good performance status (PS). Limited data exists for poor PS patients treated outside of clinical trial. We report the efficacy and safety in patients enrolled in a Nivolumab expanded-access program (EAP). **Methods:** 27 advanced MM patients were enrolled in EAP and treated from 12/2015 - 12/2017 at Mesothelioma Treatment Center at Baylor College of Medicine. Nivolumab 3 mg/kg was administered every 2 weeks until disease progression. Blinded radiologist assessed responses using RECIST 1.1 criteria. Baseline tumor volumes (BTV) were measured. PD-L-1 expression on tumor samples was quantified by PD-L1 IHC 28-8 pharmDx assay. **Results:** 25 patients were evaluable (2 patients expired before evaluation for response). Median age was 67 years (range 38-89). 72% were male, 56% had PS ≥ 2; epithelioid/ biphasic histologies: 76%/ 24%. Median follow up time was 6 months (range 2-23). 72% received Nivolumab as second line or later therapy. Median progression free survival was 5 months. Response rate was 24% (3 CR, 3 PR); 9 stable disease (SD), disease control rate (DCR) was 60% (CR+PR+SD). Median duration of response 6 months (range 2-24). For patients with PS ≥ 2, DCR was 50%. For patients treated as first line, DCR was 42%. 20 patients had PDL-1 expression evaluated; DCR was 55% in patients (45%) with PDL1 < 1%, and 63% in those with PD L 1 > 1%. Median BTV was 251 cm^3, DCR was 50% for patients with BTV > median and 75% for patients with BTV < median. At 6 months, 52% of patients were alive. Grade 1/2 adverse events (AE) include skin rash (1), body aches/arthritis (2) and enteritis/diarrhea (2). No grade 3/4 AE or treatment related death occurred. **Conclusions:** Nivolumab is effective and safe for MM patients with poor PS. Durable responses were achieved in a subset of patients. Our limited data showed responses regardless of tumor PD-L1 expression. Smaller BTV may predict response but validation of this observation is warranted.

8570 Poster Session (Board #176), Sun, 8:00 AM-11:30 AM

Efficacy and safety of lurbinectedin (PM1183) in small cell lung cancer (SCLC): Results from a phase 2 study. *First Author: Jose Manuel Trigo Perez, Hospital Virgen de la Victoria, Malaga, Spain*

Background: SCLC is a deadly cancer and despite initial 80% response, almost all patients (pts) will relapse and die of this disease. Limited options exist after failure of first line, with a median time to progression (TTP) of around 3.5 months. New therapeutic agents are needed. Lurbinectedin (L) is a new anticancer drug that blocks transcription and induces DNA double-strand breaks, leading to apoptosis. **Methods:** A multicenter phase 2 basket trial to assess the efficacy and safety of L in several types of advanced solid tumors, including SCLC, is ongoing. In the SCLC cohort, 15 adult patients without brain metastases, who had received one prior chemotherapy line, were recruited. If at least one confirmed response was observed, recruitment would be increased to 100 patients. The study intervention comprised L 3.2 mg/m^2 in a 1-hour infusion every 3 weeks. **Results:** 50 pts were treated and evaluable for efficacy. Median age was 60 years (range, 40-83) and 29 (58%) were males. 45 (80%) had an ECOG of 0/1. 34 pts (68%) had metastatic disease at study entry. 25 (50%) pts had a chemotherapy free interval (CTFI) ≥ 90 days and 22 (44%) had a CTFI < 90 days (unknown in 3). Pts received a median of 5 cycles of therapy (range, 1-18) and a median total dose of 15.9 mg/m^2 (range, 2.9-58.2). Nineteen pts (38%) had a partial response (PR); among pts with CTFI ≥ 90 days, 52% (13/25) had a PR. Twenty pts (40%) had disease stabilization, 6 of them for > 4 months. Median response duration was (K-M) 5.3 (CI 95% 2.8-8.8) and median progression free survival (PFS) was 4.2 months (CI 95% 2.8-6.3). Median PFS for pts with CTFI ≥ 90 days was 4.7 months 95% CI (3.1-7.4). Myelosuppression was the most common adverse event: 44% neutropenia grade (G) 3/4, 12% febrile neutropenia, and 8% thrombocytopenia G 3/4; 8 pts had dose delay due to neutropenia G2-4, and 10 pts had dose reduced because of neutropenia G4. G-CSF was given to 9 pts. There was one protocol-defined withdrawal due to neutropenia. **Conclusions:** Lurbinectedin as a single agent shows compelling activity as second line treatment in SCLC, with an acceptable tolerability and manageable safety profile. No unexpected or grade 5 toxicity occurred. Updated results will be presented. Clinical trial information: NCT02454972.

8571 Poster Session (Board #177), Sun, 8:00 AM-11:30 AM

Safety and efficacy of combination olaparib (O) and temozolomide (T) in small cell lung cancer (SCLC). *First Author: Anna F. Farago, Massachusetts General Hospital, Boston, MA*

Background: SCLC is a high-grade neuroendocrine malignancy with overall response rates (ORR) to second-line chemotherapy generally ranging from 10-30%. The poly(ADP-ribose) polymerase (PARP) inhibitor O has activity in SCLC in preclinical studies and may synergize with the alkylating agent T. **Methods:** We performed a single-arm phase 1/2 study of combination O/T in adults with SCLC. Eligibility criteria included histologically/cytologically confirmed incurable SCLC which had progressed following ≥ 1 platinum-based chemotherapy. O (tablet formulation) and T were administered orally on days 1-7 of 21-day cycles at escalating doses using a 3+3 design in the phase 1 portion, followed by a phase 2 expansion at the recommended phase 2 dose (RP2D). Response assessments were performed every 6 weeks. The primary endpoint of the phase 2 portion was ORR. We present data at a planned interim analysis after enrollment of 20 patients at the RP2D. Patient-derived xenografts (PDXs) were generated from a subset of patients prior to O/T and at progression. O/T activity was assessed *in vivo* in PDXs in a co-clinical trial. **Results:** 13 patients were enrolled to 4 escalating dose levels in the phase 1 portion, and 17 additional patients were enrolled at the RP2D, O 200 mg BID and T 75 mg/m2 QD. The median (m) age was 62.0 years (range 39.2-85.2) and m prior lines of therapy was 2 (range 1-7). The most common treatment emergent adverse events (AEs) related to study drugs across dose levels were thrombocytopenia (67%; 23% grade (g) 3-4), anemia (63%; 23% g 3-4), and neutropenia (50%; 47% g 3-4). There was one related g 5 AE due to pneumonia and neutropenia. Among 29 evaluable patients at all dose levels, ORR was 41.4% (95% CI 23.5-59.3), with responses seen in 10/19 and 2/9 platinum-sensitive and -resistant patients, respectively. The mPFS was 87 days (95% CI 48-159), the mOS was 220 days (95% CI 140-308), and the mDOR was 103 days. In PDX models, responses to O/T mirrored those in donor patients, and basal total PARylation was a strong predictive biomarker for sensitivity. **Conclusions:** O/T shows promising clinical activity in SCLC. Further exploration of dosing strategies and biomarkers in patients and PDXs is underway. Clinical trial information: NCT02446704.

8572 Poster Session (Board #178), Sun, 8:00 AM-11:30 AM

Large-scale nationwide genomic screening system for small cell lung cancer in Japan (LC-SCRUM-Japan). *First Author: Yukari Ogawa, Kyorin University Hospital, Mitaka, Japan*

Background: Recent genomic analyses of small-cell lung cancer (SCLC) have provided insights into novel therapeutic targets such as the PI3K pathway. Thus, we prospectively analyzed clinical samples of SCLC using a large-scale nationwide genomic screening project in Japan (LC-SCRUM-Japan) to identify the patients harboring targetable genomic alterations. **Methods:** Submitted tumor samples were subjected to a next-generation sequencing (NGS) system, Oncomine™ Comprehensive Assay, enabling the simultaneous analysis of 143 (ver.1) or 161 (ver.3) cancer-related genes. **Results:** From July 2015 to January 2018, 544 patients had been enrolled. The median age was 68 years. 76% were male and 95% were smokers. Among 468 samples completed analysis, we identified high prevalence of inactivating TP53/RB1 mutations in 341 (73%) /148 (32%) of cases, respectively. MYC/MYCL1/MYCN amplifications were detected in 18 (4%) /23 (5%) /7 (2%) of cases, respectively. The NGS analysis also showed that 30 (6%) of cases had activating alterations in receptor tyrosine kinase genes: 7 EGFR mutations, 8 KRAS mutations and 15 FGFR1 copy number gains. Mutations in the PI3K pathway were detected in 35 (7%) of the tumors: 13 PIK3CA mutations, 17 PTEN inactivating mutations, 1 AKT mutation and 4 TSC2 inactivating mutations. Among them, 6 cases harboring mutations in the PI3K pathway enrolled in the investigator-initiated phase II study of gedatolisib (UMIN 000020585). Survival data was available in 244 patients receiving platinum-based chemotherapy. Multivariate analysis revealed that the presence of MYC/MYCN amplification or KRAS mutation were significantly associated with poor progression free survival of the first-line chemotherapy (HR, 3.07; 95% CI 1.81 – 5.20; $p < 0.001$) and unfavorable survival (HR; 2.31; 95% CI 1.26 – 4.22; p = 0.007). **Conclusions:** To our knowledge, this is the world's largest prospective genomic screening project for SCLC. This nationwide screening system is helpful for identifying biologically relevant genomic alterations and prognostic prediction in SCLC. This screening program is currently ongoing to screen 800 SCLCs as a final goal. Updated screening results will be presented at the 2018 ASCO Annual Meeting.

8573 Poster Session (Board #179), Sun, 8:00 AM-11:30 AM

Outcomes of EGFR-mutant lung adenocarcinomas (AC) that transform to small cell lung cancer (SCLC). *First Author: Nicolas Marcoux, Massachusetts General Hospital, Boston, MA*

Background: 5-10% of EGFR-mutant ACs undergo SCLC/neuroendocrine transformation (SCLC-T) but the clinical course of such pts is poorly characterized. **Methods:** We identified 50 pts with EGFR-mutant SCLC-T seen at our institutions. Medical records were reviewed retrospectively after IRB approval. Demographics, disease features and outcomes were analyzed. **Results:** Among 50 pts (27F/23M), median (med) age was 55. At diagnosis, 44 had AC histology; 5 had *de novo* SCLC or mixed AC/SCLC. All but the 5 cases with baseline SCLC received ≥1 EGFR TKI prior to SCLC-T; 93% were on a TKI at the time of SCLC-T (24 erlotinib/gefitinib, 5 afatinib, 9 osimertinib, 4 other). Med time from original diagnosis to SCLC-T was 17.8 mo (95% CI 13.0-25.9). 44/50 cases had tissue genotyping at first evidence of SCLC (albeit with varied assays); all maintained their founder EGFR mutation; among 16 with prior T790M-positivity, 13 lost T790M at SCLC-T, 3 were T790M-pos at SCLC-T. Other recurrent mutations included TP53 (24/33, 73%), Rb1 (13/21, 62%) and PIK3CA (10/36, 28%). The most common therapy given upon SCLC-T was platinum-etoposide (n = 35); this regimen had a clinical response rate (cRR) of 51% and med PFS of 2.8 mo (95% CI 2.1-4.8). 20 pts received taxane-based therapy at some point after SCLC-T: cRR = 50%, med PFS = 3.1 mo (95% CI 0.9-3.2). None of 15 pts receiving immunotherapy (including 6 ipi/nivo) for SCLC-T responded. Med OS from stage IV cancer diagnosis was 36.8 mo (95% CI 25.0-41.5) and med OS from time of SCLC diagnosis was 10.9 mo (95% CI 7.3-13.8). **Conclusions:** EGFR-mutant AC with SCLC-T is a rare but recurrent phenomenon, often characterized by Rb1, TP53 and PIK3CA mutations. The SCLC-T subclone is typically distinct from the T790M subclone in pts with serial biopsies. The med OS of 10.9 mo after SCLC-T is similar to newly diagnosed, EGFR wild-type advanced SCLC. Responses to platinum-etoposide and taxanes were frequent but transient, while no responses were seen with immunotherapy. Interestingly, med OS from initial diagnosis was similar to that of pts that never transform to SCLC at 36.8 mo. Further investigation is needed to better elucidate optimal strategies for this group.

8574 Poster Session (Board #180), Sun, 8:00 AM-11:30 AM

Identifying treatment options for SCLC patients with multiplexed clinical proteomic testing. *First Author: Eunkyung An, NantOmics, LLC, Rockville, MD*

Background: Even with standard platinum doublet therapy, most patients with small-cell lung cancer (SCLC) survive < 1 year. For those with refractory or relapsed disease, second-line, single-agent chemotherapy is recommended. Pre-treated SCLC patients can opt for clinical trials of agents such as temozolomide, fluorouracil (5FU), and antibody-drug conjugates (ADC) targeting the proteins DLL3, CD56, or TROP2. Some of these therapies have produced responses in untreated SCLC. To assess the proportions of patients who would be likely to respond to these therapies, we profiled protein targets in clinical tumor biopsies of SCLC using quantitative mass spectrometry. **Methods:** Archived tumor samples from 88 SCLC patients were microdissected and solubilized for proteomic quantification of 58 therapeutically relevant biomarkers. In each sample, quantities of tumor protein were compared with pre-defined thresholds based on evidence from clinical studies or on quantification limits of proteomic assays. Prevalences and protein expression levels in SCLC were compared with those of other cancer indications analyzed in the same clinical laboratory. **Results:** 15 of 83 (18%) SCLC tumors had low or absent MGMT protein expression (< 200 attomoles per microgram [amol/ug]), indicating likely response to temozolomide. 14 of 88 (15%) overexpressed TYMP protein (> 1335 amol/ug), suggesting likely response to 5FU. Except for one patient, likely responders to temozolomide or 5FU were mutually exclusive. Prevalences of quantifiable levels of the ADC markers DLL3, TROP2, and CD56 were 43%, 49% and 97%, respectively. The SCLC tumors expressed a wide range of DLL3 protein (range: 101 – 1201 amol/ug); median expression in SCLC was 2 times higher than in pediatric neurological cancers, while median expression of TROP2 was lower in SCLC than in other indications. CD56 protein levels in SCLC were similar to other indications, but with higher prevalences in SCLC. **Conclusions:** In patients with SCLC, clinical proteomics identified protein targets of multiple approved and investigational therapies.

8575 Poster Session (Board #181), Sun, 8:00 AM-11:30 AM

A phase II study of pembrolizumab and paclitaxel in refractory extensive disease small cell lung cancer. *First Author: YuJung Kim, Seoul National University, Seongnam-si, Korea South*

Background: Patients with platinum refractory extensive disease (ED) small cell lung cancer (SCLC) have a poor prognosis and a little progress have been made. We aimed to investigate the efficacy and safety of pembrolizumab and paclitaxel in these patients. **Methods:** In this phase II, open-label, multicenter study, 26 patients who progressed after etoposide/platinum chemotherapy were enrolled. The patients received paclitaxel 175mg/m2 every 3 weeks for up to 6 cycles. Pembrolizumab 200mg was added from the second cycle and continued until disease progression or unacceptable toxicity. The primary endpoint was objective response rate (ORR) and secondary endpoints were progression-free survival (PFS), overall survival (OS), safety, and biomarker analysis including programmed death-ligand 1 (PD-L1) expression, next-generation sequencing (NGS), and flow cytometric analysis of peripheral blood immune cells. **Results:** The median age was 68.5 years, and 88% were male. Of the 26 evaluable patients, the ORR was 23.1% (complete response: 3.8%, confirmed partial response [PR]: 19.2%, stable disease: 57.7%, progressive disease 7.7%, not evaluable 11.5%). Including unconfirmed PR, 38.4% responded, and disease control rate was 80.7%. The median PFS and OS were 5.0 months (95% CI, 2.7-6.7) and 9.2 months (95% CI, 6.6-15.1), respectively. Grade 3 or 4 adverse events included febrile neutropenia (8%), neutropenia (8%), asthenia (8%), hyponatremia (8%) and type I diabetes (4%). Four patients showed PD-L1 positivity and no significant difference in PFS was observed according to PD-L1 positivity (5.0 *vs.* 3.9 months, $P = 0.897$). NGS was performed in 12 tumor samples, and we could not find significant differences in mutational load or specific genetic alteration, except for the *MET* copy number gain (PFS 10.5 *vs.* 3.4 months, $P = 0.019$). According to flow cytometric analysis, NK cell activity was significantly lower in responders after 2 cycles of treatment ($P = 0.022$). **Conclusions:** Pembrolizumab and paclitaxel combination therapy showed a moderate activity with an acceptable toxicity in refractory ED SCLC. Further studies are warranted to define a subset of patients who may benefit from the addition of pembrolizumab. Clinical trial information: NCT02551432.

8576 Poster Session (Board #182), Sun, 8:00 AM-11:30 AM

Genomic evolutions in the progression from lung preneoplasia to adenocarcinoma. *First Author: Xin Hu, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Carcinogenesis may result from accumulation of genomic and epigenomic aberrations. It has been postulated that atypical adenomatous hyperplasia (AAH), the only recognized pre-neoplasia to lung adenocarcinoma (ADC) may progress to adenocarcinoma in situ (AIS), minimally invasive adenocarcinoma (MIA) and further to frankly invasive ADC. Yet the pathological definition and management of these lesions remain controversial due to lack of sufficient molecular evidences. This aim of this study is to delineate the temporal molecular carcinogenetic events and evolutionary process during the evolution from pre-neoplastic lesions to early-stage adenocarcinoma. **Methods:** We performed multi-regional (2-5 spatially separated regions per lesion) whole exome sequencing and reduced representation bisulfite sequencing to AAH (N = 22), AIS (N = 27), MIA (N = 54) and ADC (N = 13) from 53 patients including 39 patients presenting with multifocal disease and 23 patients carrying more than two different types of lesions. **Results:** Mutation burden progressively increases from AAH to AIS, then to MIA and ADC, with evidence of positive selection of non-silent mutations. APOBEC signature also progressively increases with APOBEC enrichment scores of 0.94 in AAH, 0.99 in AIS, 1.04 in MIA and 1.28 in ADC, ($p = 0.011$). In addition, genomic heterogeneity becomes more complex with neoplastic evolution with tumor allelic frequency-derived median Shannon index. Interestingly, aneuploidy was a common phenomenon in AIS, MIA and ADC, but not in AAH, while allelic imbalance (AI) only became prevalent in MIA and ADC, followed by structural rearrangements in ADC. Phylogenetic analysis revealed varying evolutional processes in different lesions highlighting the substantial heterogeneity even at the preneoplastic states. **Conclusions:** We provide molecular evidence supporting the pathological model of early lung carcinogenesis from AAH, to AIS, MIA and ADC, suggesting progressive genomic evolution at the single nucleotide level during carcinogenesis of lung ADC with macro-evolution at the transition from AAH to AIS and AIS to MIA, possibly driven by ploidy change and allelic imbalance (AI), respectively.

8577 Poster Session (Board #183), Sun, 8:00 AM-11:30 AM

Early assessment of therapy response in small cell lung cancer via longitudinal ctDNA analysis. *First Author: John F. Palma, Roche, Pleasanton, CA*

Background: From the prospective, observational German Lung Cancer Multi-Marker Study we selected the first 72 consecutive small-cell lung cancer (SCLC) patients, UICC-stage IIIB/IV, where plasma samples were available prior to start of therapy, and prior to the second cycle of chemotherapy, and prior to third cycle. We hypothesized that assessment of the level of ctDNA after starting therapy relates to treatment effect and prognosis. **Methods:** We employed AVENIO ctDNA Surveillance Kit, a 197-gene NGS assay, which allowed us to perform longitudinal ctDNA analysis and measure the mutant molecules per milliliter-of-plasma (MMPM), which quantifies ctDNA over all variants of all sequenced genomic regions. All extracted cfDNA samples were processed and sequenced in order of date of blood draw. **Results:** At baseline (b0), we identified variants in all (72/72) subjects to enable ctDNA monitoring. Using serial liquid biopsies from each subject, the mean MMPM at post-first treatment cycle (p1) and the mean MMPM at post-second treatment cycle (p2) were analyzed. We tested a Continuous Responder algorithm, defined by a continuous drop in ctDNA levels represented by mean MMPM reduction over time ($p2 < p1 < b0$), to a mean MMPM below 20 at p2. As a result, continuous responders 26/72 were associated with a better therapy response OS HR = 1.9 (95% CI 1.1 – 3.2, log-rank P = 0.015). The continuous responders demonstrated a median survival benefit of 4.4 months over the poor responders. Neither gender, nor age, nor ECOG, nor stage were predictors of response in the models. **Conclusions:** An early assessment of treatment effect can be measured by mutant molecule counts in the plasma. A decrease in post-treatment ctDNA levels was associated with better prognosis in advanced SCLC.

8578 Poster Session (Board #184), Sun, 8:00 AM-11:30 AM

Association of the high expressions of SOX2 and IGF-1R signaling molecules in thymic epithelial tumors with shorter overall survival. *First Author: Guk Jin Lee, Catholic University of Korea, Bucheon, Korea, Republic of (South)*

Background: Thymic epithelial tumors (TET) are consisted of thymoma(TM) and thymic carcinoma(TC). They are rare heterogeneous tumors with a broad spectrum of clinical characteristics. Although the investigations for potential markers provided some insights into the molecular biology of TET, still there is no established target and biomarker. **Methods:** We performed the gene microarray related to Insulin-like growth factor-1 receptor (IGF-1R) pathway in the fresh tissues (6 TMs and 5 TCs), and validated the analyzed data of expression profile with quantitative measurement of IGF1, IGF2, IGF1R, INSR, SOX2, and OCT-4 mRNA transcripts using RT-PCR. With the tumor tissues collected from 140 TET patients, we constructed the tissue microarray and did immunohistochemistry (IHC) for IGF-1R signaling-related molecules including SOX2, IGF1R, IGF-1, and pAKT. **Results:** The mRNA expressions of SOX2 (216 folds) and IGF-1 (5.2 folds) were notably higher in fresh tumor tissue from TC patients than TM, but no significant differences of IGF-1R, Oct-4, and INSR were found between two tumors. Among 140 TET cases, 111 cases were TM, and 29 cases were TC. The expression level of SOX2 (HR 7.57, $P = 0.001$) and IGF-1 (HR = 9.43, $P = 0.001$) were significantly higher in TC than TM. With analyzing intermolecular correlation between each molecule, there was statistically significant implications between SOX2 and IGF-1, SOX2 and pAKT ($P = 0.021$, $P = 0.026$). In univariate analysis, LDH, clinical TNM staging, WHO classification, SOX2, IGF-1R, IGF-1, and pAKT expression were significantly correlated with overall survival (OS). By multivariate analysis using forward-selection procedure, not only clinical N staging and M staging, but also positive expression of SOX2 and IGF-1 (HR 4.48, $P = 0.001$) were strongly correlated with OS. **Conclusions:** Taken together, our study shows that there are great differences between SOX2 and IGF-1 expressions between thymoma and thymic carcinoma. In thymic epithelial tumors, the expression of SOX2 has a strong relation to IGF-1 expression and their higher expressions are significantly associated with shorter overall survival and more aggressive tumor behavior.

8579 Poster Session (Board #185), Sun, 8:00 AM-11:30 AM

A phase II study of regorafenib in patients with thymic epithelial tumours previously treated with chemotherapy. *First Author: Matteo Perrino, Department of Oncology, Humanitas Research Hospital - Humanitas Cancer Center, Rozzano, Italy*

Background: Angiogenesis has an important role in thymic epithelial tumours (TETs); VEGF, PDGF and PDGFRα are overexpressed in TETs, and VEGF expression and microvessel density are associated with invasiveness and stage. Regorafenib potently inhibits VEGFR1, 2, and 3, TIE2, FGFR and PDGFR-β. The aim of this study is to determine the activity of Regorafenib as monotherapy in patients (pts) with advanced/metatstatic Thymoma (type B2 – B3) (T) and Thymic Carcinoma (TC) previously treated with cisplatin-based chemotherapy. **Methods:** Pts with progressive disease were prospectively enrolled in single arm, phase II trial to receive oral Regorafenib 160 mg once daily 3 weeks on/1 week off until documented disease progression, unacceptable toxicity, or pt refusal. Tumour assessment and safety were asessed every six and three weeks, respectively. This Fleming phase II trial was designed to reject the null hypothesis of a progression free survival (PFS) rate ≤25% with a type I error of 0.10 and a statistical power of 80% at the alternative hypothesis of a PFS rate of ≥50%. The drug should be recommended for further study if 8 or more of the 19 total evaluable pts would be progression free at 2 months. Clinical trial information: NCT02307500. **Results:** Results of the 19 enrolled pts are presented. Pt characteristics are as follow: median age 54 years (range 40;75), male/female 11/8 (58%/42%); T/TC 7/12 (37%/63%), and number of previous lines (1line/≥2lines) of chemotherapy 9/10 (47%/53%). Two pts were not evaluable for response (10.6%). According to RECIST criteria, we observed partial response (PR) in 1 pt (T) (5.3%), stable disease (SD) in 14 pts (9T/5TC) (73.5%), and progressive disease (PD) in 2 pts (1T/1TC) (10.6%), with a disease control rate of 78.8%. Response evaluation with Choi criteria is planned. With a median follow up of 6.4 months (0.9-39.3 months), median PFS was 8.9 months, while median OS was not reached. Thirteen patients were progression free at 2 months. The 1-year PFS rate and 1-year OS rate were 17.9% and 94.4%, respectively. **Conclusions:** The primary end-point of this study was reached. On the basis of PFS and OS results, the efficacy of Regorafenib should be better evaluated in subsequent larger trials. Clinical trial information: NCT02307500.

TPS8580 Poster Session (Board #186a), Sun, 8:00 AM-11:30 AM

Phase II randomized clinical trial comparing immunotherapy plus stereotactic ablative radiotherapy (I-SABR) versus SABR alone for stage I, selected stage IIa or isolated lung parenchymal recurrent non-small cell lung cancer: I-SABR. *First Author: Joe Y. Chang, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Stereotactic ablative radiotherapy (SABR), which delivers high biologically effective radiation doses, can kill cancer cells, release tumor-associated antigens, and activate tumor-specific T cells, thereby functioning as a cancer-specific vaccine in situ. The combination of the immune-triggering effects of ionizing radiation with immune check point PD-1inhibitor may leverage the effects of radiotherapy, transforming what was once considered a local therapy to a novel systemic treatment. Further, the combined effects of local control plus systemic control may improve cure rate in early stage NSCLC. **Methods:** This is a randomized phase II trial (NCT03110978) designed to study SABR (biological effective dose > 100 Gy) with or without concurrent and adjuvant Nivolumab for total of 7 doses in early stage or isolated recurrent NSCLC. Inclusion criteria: stage I disease (tumor≤5cm, N0M0) OR selected cases of stage IIa disease (tumor > 5cm but≤7cm, N0M0), including multiple primary tumors, OR isolated lung-parenchymal recurrent or persistent NSCLC suitable for SABR. Tumor tissue / blood/stool samples will be collected before/during/after treatment and at the time of recurrence. Primary endpoints: Event-free survival , secondary malignancy and death; Secondary endpoints: overall survival; toxicity; exploratory analyses of potential predictive markers and immunologic mechanisms of action. Statistical design: It is considered significant with a decrease of the 4-year cumulative event rate from 46% to 23%. Assuming a one-sided type I error rate of 0.05, an accrual rate of 3.5 patients per month, and an additional 20 months of follow-up, a study with 70 patients in each arm will have 85% power to detect an improvement of 23% in 4-year EFS rate. One interim analysis will be done to allow early termination of the trial should evidence at that time reveal that I-SABR is superior to SABR-only or that no difference is found between the two treatment arms. Up to January 2018, 20 of planned 140 patients have been enrolled, met with anticipated enrollment rate. Clinical trial information: NCT03110978.

TPS8581 Poster Session (Board #186b), Sun, 8:00 AM-11:30 AM

EA5142 adjuvant nivolumab in resected lung cancers (ANVIL). *First Author: Jamie E. Chaft, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: There have been no advances in the systemic treatment of resected lung cancers in the last decade. In contrast, targeted therapies and immunotherapies have demonstrated benefit in advanced disease. Furthermore, adjuvant immunotherapy after concurrent chemoradiation in locally advanced non-small cell lung cancer (NSCLC) has demonstrated improvement in progression free survival. The role of adjuvant immunotherapy after surgery remains unknown. The Adjuvant Lung Cancer Enrichment Marker Identification and Sequencing Trial (ALCHEMIST) is a National Cancer Institute sponsored National Clinical Trials Network initiative to address the role of genomic testing and personalized therapies in the adjuvant treatment of NSCLC. EA5142 is the arm of the ALCHEMIST investigating adjuvant nivolumab in patients not eligible for the *EGFR* or *ALK* directed trials. **Methods:** ALCHEMIST is a clinical trial platform that consists of integrated protocols: ALCHEMIST Screening (A151216; NCT02194738), ALCHEMIST-EGFR (A081105; NCT02193282), ALCHEMIST-ALK (E4512; NCT02201992), and ALCHEMIST-nivo (EA5142; NCT02595944; ANVIL). In ALCHEMIST-Screening, up to 8,000 patients with pathologically confirmed stage IB (≥ 4 cm)-IIIA NSCLC will be enrolled after surgical resection. Tumors that are non-squamous histology will be centrally genotyped for *EGFR* mutations and *ALK* rearrangements. Patients with *EGFR* or *ALK*-positive tumors are offered enrollment in trials evaluating adjuvant erlotinib or crizotinib, respectively. In the ~80% of patients enrolled with tumors that have wildtype *EGFR* and *ALK* or those with squamous histology, central testing will be performed for PD-L1 by immunohistochemistry (DAKO 28-8). Adjuvant chemotherapy and/or radiotherapy is allowed but not required. Patients are randomized to nivolumab versus standard of care observation, stratified by stage, histology, prior adjuvant treatment, and PD-L1 status (≥1% or < 1%). ANVIL is active at over 600 US sites and is actively enrolling. The study statistical plan is to detect co-primary endpoints of a 30% improvement in overall survival and/or a 33% improvement in disease free survival favoring nivolumab. EA5142 design changes under review at CTEP will be presented. Clinical trial information: NCT02595944.

TPS8582 Poster Session (Board #187a), Sun, 8:00 AM-11:30 AM

Nivolumab plus cisplatin/pemetrexed or cisplatin/gemcitabine as induction in resectable NSCLC. *First Author: Nathaniel R. Evans, Thomas Jefferson University, Philadelphia, PA*

Background: For patients (pts) with stage IB (≥4cm)-IIIA Non-small-cell lung cancer (NSCLC), multi-modality therapy yields a modest improvement in 5 year post-surgical overall survival (OS), with comparable benefit for induction and postoperative adjuvant chemotherapy (chemo). Induction can speed the discovery of promising regimens by using pathologic response as a surrogate for OS. About 20% of pts treated with induction chemo have major pathologic response (MPR) (< 10% viable tumor) at primary and lymph nodes while pathologic complete responses (pCR) average 4%. MPR was strongly associated with improved OS (Hellmann MD, Lancet, 2014). PD-1 checkpoint inhibitors (CI), nivolumab (nivo), pembrolizumab (pembro), and the PD-L1 CI, atezolizumab, are established in advanced NSCLC as 2nd line therapy, and pembro is approved as a single agent as 1st line treatment of pts with PD-L1 high expressing tumors. In a phase III 1st line NSCLC study, pts with high mutational burden tumors had superior OS with nivo plus ipilimumab compared to doublet chemo. Pembro plus carboplatin with pemetrexed (P) was approved as 1st line therapy based on a randomized phase II study in advanced NSQ NSCLC showing improved clinical response and PFS compared to chemo alone with no increase in grade III toxicity. We therefore hypothesize that the addition of nivo to induction cisplatin (C) P or C gemcitabine (G) will increase the MPR rate over induction chemo alone compared to historical controls. **Methods:** This is an investigator initiated trial for pts with newly diagnosed clinical stage I-IIIA (stage I ≥ 4cm) SQ and NSQ NSCLC. Induction is C 75mg/m2 IV q 3w x 3 plus either P 500 mg/m2 IV q 3wks x 3 or G 1250mg/m2 IV d1, d8 q 3 wks x 3 plus nivo 360mg IV q 3w x 3. Surgery is planned 3 wks after the last dose. The primary outcome is MPR. Secondary outcomes include safety, pCR, overall clinical response rate, clinical CR, 1 year PFS, OS and exploratory outcomes assessing markers of immune bias. Enrollment will be 34 pts. Clinical trial information: NCT03366766.

TPS8583 Poster Session (Board #187b), Sun, 8:00 AM-11:30 AM

Randomized, double-blind phase 3 study evaluating neoadjuvant platinum-based chemotherapy with perioperative pembrolizumab or placebo in resectable stage IIB or IIIA NSCLC: KEYNOTE-671. *First Author: Hiran C. Fernando, Department of Surgery and Department of Thoracic Oncology, INOVA Fairfax Medical Campus, Falls Church, VA*

Background: Robust and durable antitumor activity was previously demonstrated with pembrolizumab in patients with advanced NSCLC, both as a monotherapy in the first- and second-line settings (in patients with PD-L1 tumor proportion score [TPS] ≥50% and ≥1%, respectively) and when combined with pemetrexed-carboplatin (in patients with nonsquamous histology). KEYNOTE-671 (NCT03425643) is a phase 3 study that evaluates standard neoadjuvant chemotherapy with perioperative pembrolizumab or placebo in early-stage NSCLC. **Methods:** This international double-blind phase 3 trial enrolls patients aged ≥18 years with previously untreated, resectable stage IIB/IIIA NSCLC, ECOG PS 0–1, and tumor samples for evaluation of PD-L1 expression. Patients are randomized 1:1 to neoadjuvant chemotherapy (cisplatin 75 mg/m^2 with gemcitabine 1000 mg/m^2 [days 1 and 8; squamous histology] or pemetrexed 500 mg/m^2 [nonsquamous histology]) combined with either pembrolizumab 200 mg or placebo Q3W for 4 cycles, followed by surgery, then adjuvant pembrolizumab 200 mg or placebo Q3W for 13 cycles. Randomization is stratified by disease stage, PD-L1 TPS < 50% vs ≥50%, squamous vs nonsquamous, and East Asia vs non-East Asia. Radiographic response is assessed 3 weeks after cycles 2 and 4, and every 12 weeks from adjuvant cycle 1 (RECIST v1.1, blinded independent central review). Disease recurrence/progression is confirmed by biopsy. Adverse events are graded per CTCAE v4.0 or later. Primary endpoints are event-free survival (time from randomization to first of disease/local progression, unresectable tumor, local/distant recurrence, or death) and overall survival (time from randomization to all-cause death). Secondary endpoints are major pathological response (≤10% viable tumor cells in resected primary tumor/lymph nodes), pathological complete response (no residual invasive cancer on H&E stained slides of resected lung specimen/lymph nodes post–neoadjuvant therapy), safety, and patient-reported outcomes. An estimated 786 patients will be enrolled, beginning March 9, 2018. Clinical trial information: NCT03425643.

TPS8584 Poster Session (Board #188a), Sun, 8:00 AM-11:30 AM

SAKK 16/14: Anti-PD-L1 antibody durvalumab (MEDI4736) in addition to neoadjuvant chemotherapy in patients with stage IIIA(N2) non-small cell lung cancer (NSCLC)—A multicenter single-arm phase II trial. *First Author: Sacha Rothschild, University Hospital Basel, Basel, Switzerland*

Background: Improving the outcome of locally advanced non-small cell lung cancer (NSCLC) is one of the major challenges in thoracic oncology. Based on previous trials from the Swiss Group for Clinical Cancer Research (SAKK) neoadjuvant chemotherapy with 3 cycles of cisplatin/docetaxel is an accepted standard of care. Recently, the PACIFIC trial showed significantly improved progression-free survival (PFS) for durvalumab as consolidation therapy after definitive chemoradiotherapy in unresectable stage III NSCLC. Here, we give an update on the ongoing trial and present results from a predefined safety evaluation focusing on 30-day post-operative mortality rate. **Methods:** This is a single-arm phase II clinical trial evaluating the addition of perioperative immunotherapy with durvalumab to the previously established standard of care for stage IIIA(N2) patients. Eligible patients must have pathologically proven NSCLC stage IIIA(N2) (T1-3 N2 M0) according to the 7th edition of the TNM classification, irrespective of histological subtype, genomic aberrations or PD-L1 expression status. Tumor tissue has to be available for the mandatory translational research. Patients whose tumor is deemed resectable at diagnosis receive 3 cycles of chemotherapy with cisplatin 100 mg/m^2 and docetaxel 85 mg/m^2 every three weeks followed by two cycles of durvalumab 750 mg every two weeks. Following surgery, patients will be treated with durvalumab 750 mg every two weeks for 12 months. The primary endpoint of the trial is event-free survival at 12 months. Secondary endpoints include OS, objective response, nodal down-staging, complete resection, pattern of recurrence and toxicity. Additionally, a large translation research program accompanies the trial investigating potential predictive biomarkers of anti-PD-L1 therapy. Based on the protocol, a first safety evaluation has been done after the first 25 operated patients. This analysis demonstrated a 30-day post-operative mortality of less than 10%. According to the decision rule described in the protocol the trial thus shall continue as per protocol. Clinical trial information: NCT02572843.

TPS8585 Poster Session (Board #188b), Sun, 8:00 AM-11:30 AM

Phase II trial of atezolizumab before and after definitive chemoradiation for unresectable stage III NSCLC. *First Author: Helen J. Ross, Mayo Clinic, Scottsdale, AZ*

Background: Over 40,000 patients in the US/year are diagnosed with stage III NSCLC, but only ~25% will be cured by standard chemoradiation (CRT). Combining checkpoint inhibition through PD-L1 blockade with CRT may attenuate tumor related immunosuppression via depletion of Tregs and clonal expansion of effector T-cells, thereby improving tumor immunogenicity. Responses to immunotherapy seem to be higher in patients with significant cytoreduction, such as with radiation (RT). Further, CRT may reveal otherwise hidden antigens that can present additional targets to the reconstituting immune system. Whether anti-PD-L1 therapy before CRT will further improve outcomes in this setting is unknown. **Methods:** This phase II single arm Alliance Foundation Trials study (AFT-16, NCT03102242) will evaluate safety and efficacy of atezolizumab before and after definitive CRT. 63 patients with stage III NSCLC, PS 0-1, no active autoimmune disease and no underlying organ dysfunction will be enrolled at 15 US Alliance sites. Treatment consists of 4 cycles of neoadjuvant atezolizumab 1200 mg IV q 21 days with restaging after cycles 2 and 4. Non-progressing patients undergo carboplatin and paclitaxel (C/P) weekly with 60 Gy RT followed by 2 cycles of C/P consolidation followed by atezolizumab to complete one year of therapy. The primary endpoint of this pilot study is disease control rate (CR +PR+SD) after neoadjuvant atezolizumab. Secondary endpoints include ORR, PFS and OS, safety and QoL assessed by the EORTC QLQ-30. Correlatives include the role of PD-L1 and tumor mutation burden as predictive biomarkers. Tumor tissue will be obtained at study entry, and plasma and immune cells will be isolated at study entry, post neoadjuvant atezolizumab, post CRT, during adjuvant atezolizumab and at study end. Additional potential predictive biomarkers will be to define how atezolizumab affects the proportions of immunologic subtypes and immune activation using flow cytometry and T cell receptor immunophenotyping, multiplex immunohistochemistry and cytokine analysis. The trial was activated on 11/1/17. As of 2/13/18, the trial has been opened at 4 centers and 8 patients have been enrolled. Clinical trial information: NCT03102242.

TPS8586 Poster Session (Board #189a), Sun, 8:00 AM-11:30 AM

CONFIRM: A phase III randomized trial to evaluate the efficacy of nivolumab versus placebo in relapsed mesothelioma. *First Author: Dean Anthony Fennell, University Hospitals of Leicester, Leicester, United Kingdom*

Background: Mesothelioma, an incurable, apoptosis-resistant cancer, represents a growing health burden but remains under-researched, with limited treatment options. Despite a significant number of clinical studies in the second line setting, no randomized study has been positive. Early promising signals of activity relating to both PD-L1 and PD-1 targeted treatment in mesothelioma warrant a randomized phase III trial to evaluate the efficacy of nivolumab. **Methods:** CONFIRM is the first ever placebo controlled, randomized phase III trial of a PD-1/PD-L1 immune checkpoint inhibitor in mesothelioma. The primary objective is to determine if nivolumab increases overall survival (OS). Secondary endpoints include progression-free survival; response rate; safety/tolerability; quality of life and cost per QALY. A translational study will determine if sensitivity to nivolumab differs according to PD-L1 expression (subgroups < 1%, 1-49%, ≥50%); and the correlation between OS and mutational burden, estimated by genome-wide analysis of CNAs, and immunotranscriptomic profile. The trial is coordinated by the CRUK Southampton Clinical Trials Unit, within the Centre for Cancer Immunotherapy, UK. The trial aims to recruit 336 patients with pleural or peritoneal mesothelioma who have received at least two prior lines of therapy, from UK sites between March 2017-2021. Current enrolment at 01 Feb 2018 was 63. Patients will be randomized 2:1 (treatment: control), stratified according to epithelioid vs. non-epithelioid, to receive 240mg nivolumab (anti PD-1 antibody) monotherapy or saline placebo as a 30 minute intravenous infusion. Allocation will be double blind. Treatment will be every 14 days until disease progression for max. 12 months. Trial follow up will continue for 6 months after the last participant has progressed, or completed or discontinued treatment. The trial is powered (80% with 2-sided 4% significance level) to detect a hazard ratio of 0.7 using an adjusted Cox regression model (time to event) and will be analyzed using intention-to-treat. This trial is funded by Cancer Research UK (C16728/A21400) and Bristol Myers Squibb (CA 209-841). Trial registrations: NCT03063450, ISRCTN79814141. Clinical trial information: NCT03063450.

TPS8587 Poster Session (Board #189b), Sun, 8:00 AM-11:30 AM

ATLANTIS: Global, randomized phase III study of lurbinectedin (L) with doxorubicin (DOX) vs. CAV or topotecan (T) in small-cell lung cancer after platinum therapy. *First Author: Anna F. Farago, Massachusetts General Hospital, Boston, MA*

Background: Lurbinectedin (L), a synthetic analog of marine-based tetrahydroisoquinolone, blocks active transcription, produces DNA breaks and apoptosis, and affects the inflammatory microenvironment. L showed promising activity in combination with DOX in a phase I cohort of relapsed small cell lung cancer (SCLC) patients (pts) (overall response rate (ORR) = 67%, n = 21, ASCO 2015, abstract 7509). Most common toxicities were hematologic. Lower dose improved safety and confirmed activity in an expanded cohort (ORR = 37%, n = 27 SCLC pts). **Methods:** We present an ongoing multinational (20 countries), multicenter (154 sites), open-label, randomized phase III study of L/DOX *vs.* control arm (investigator choice of either cyclophosphamide, DOX and vincristine (CAV) or topotecan (T)). 600 pts will be randomized (1:1) and stratified according to ECOG performance status (PS), central nervous system (CNS) involvement, previous treatment with antiPD1/antiPD-L1, chemotherapy-free interval, and investigator´s choice of control arm. Interim safety analysis by an independent data monitoring committee (IDMC) is planned when the first 150 pts are randomized. The most relevant inclusion criteria are: age $\geq$18 years; confirmed SCLC diagnosis (if primary site unknown, Ki-67 expression $>$ 50%); previous platinum-containing line (additional immunotherapy allowed); ECOG PS 0-2; adequate major organ function (including LVEF $>$ 50%). Main exclusion criteria include chemotherapy-free interval $<$ 30 days; prior treatment with L DOX or T; symptomatic or steroids-requiring CNS involvement. The primary objective is to determine a difference in progression-free survival (RECIST v.1.1) by independent review committee. Secondary endpoints include overall survival, survival rates at 12/18/24 months, antitumor response, duration of response, quality of life, safety, and pharmacokinetics. The first patient was randomized in August 2016. The pre-planned interim safety analysis was done on November 2017 and the IDMC recommended to continue the trial unmodified. Trial recruitment is expected to be completed in Q2 2018. Clinical trial information: NCT02566993.

TPS8588 Poster Session (Board #190a), Sun, 8:00 AM-11:30 AM

A two-part, open-label, randomized, phase 2/3 study of dinutuximab and irinotecan versus irinotecan for second-line treatment of subjects with relapsed or refractory small cell lung cancer. *First Author: Martin J. Edelman, Fox Chase Cancer Center, Philadelphia, PA*

Background: Small cell lung cancer (SCLC) is characterized by rapid growth and early dissemination to distant sites. Although highly responsive to initial chemotherapy and radiotherapy, most patients relapse within one year of starting treatment (Tx). The outcome for patients with SCLC who relapse or are refractory (RR) to first-line Tx is poor. Topotecan (T) is the only FDA-approved agent for second-line (SL) Tx of platinum-sensitive patients with SCLC. Irinotecan (I) is listed by the National Comprehensive Cancer Network as an alternative agent for second and subsequent lines of therapy. Dinutuximab (D) is a chimeric monoclonal antibody that binds cell surface glycolipid disialoganglioside GD2 and induces tumor cell lysis through antibody-dependent cell-mediated and complement-dependent cytotoxicity. GD2 is expressed in a variety of neuroectoderm-derived tumors, including SCLCs. The potential for combination D and I to improve upon outcomes currently seen with single-agent SL Tx (I or T) in RR SCLC warrants exploration. **Methods:** A two-part, multicenter, open-label, randomized study of D and I versus I alone in subjects with RR SCLC is underway (NCT03098030). Inclusion criteria include documented progressive disease during or RR disease after first-line platinum-based Tx and an Eastern Cooperative Oncology Group performance status of 0 or 1. Subjects who are candidates for re-Tx with original platinum-based regimen as SL Tx will be excluded. Part 1 of the study involved intrasubject (n = 12) dose escalation to evaluate the safety and tolerability of D in combination with I. Part 1 results are to be presented (Edelman et al., European Lung Cancer Congress, 11-14 April 2018). Part 2 of the study is currently enrolling and is designed to determine whether combination D and I prolongs overall survival compared with I alone. Subjects will be randomized 2:2:1 to: I, D and I, or T. Randomization will be stratified by duration of response to prior platinum Tx (relapse-free period $<$ 3 or $\geq$3 months). It is anticipated first data monitoring committee review will occur in April 2018. Clinical trial information: NCT03098030.

TPS8589 Poster Session (Board #190b), Sun, 8:00 AM-11:30 AM

Phase I/II trial of anti-PD-1 checkpoint inhibitor nivolumab and ^{177}Lu-DOTA^{0}-Tyr^{3}-Octreotate for patients with extensive-stage small cell lung cancer. *First Author: Chul Kim, Georgetown University, Washington, DC*

Background: Small cell lung cancer (SCLC) accounts up to 15% of all new cases of lung cancer. 60% of patients with SCLC present with extensive-stage SCLC (ES-SCLC). Despite initial sensitivity to chemotherapy, patients with ES-SCLC relapse quickly. Studies have shown that somatostatin receptors are expressed in SCLC. ^{177}Lu-DOTA^{0}-Tyr^{3}-Octreotate (Lutathera) is a ^{177}Lutetium-labeled somatostatin analog that can target somatostatin receptor positive cancer cells. Mounting evidence suggests that radiation therapy can augment the immunogenic response. Based on these findings, we hypothesize that Lutathera and nivolumab, an anti-PD-1 therapy, may have synergistic effects on the generation of anticancer immunity and this combination given as maintenance treatment may delay progression in patients with ES-SCLC. **Methods:** This is a multicenter phase I/II trial of Lutathera and nivolumab in patients with ES-SCLC (NCT03325816). Patients with tracer uptake on gallium-68 dotatate PET scan (NETSPOT) will be eligible. In the phase I part, we aim to determine the recommended phase II dose of Lutathera and nivolumab in patients with relapsed or refractory ES-SCLC, non-progressing ES-SCLC after first-line chemotherapy, or advanced grade I-II pulmonary neuroendocrine tumors. In the phase II part, patients with ES-SCLC are randomly assigned to either maintenance treatment with Lutathera and nivolumab or observation, after completion of front-line chemotherapy. The primary endpoint for the phase II part is progression-free survival (PFS). Crossover is allowed at progression for those in the observation group. Assuming a median PFS of 2 months following first-line platinum-based chemotherapy for ES-SCLC in the observation group, and an expected median PFS of 5 months for the maintenance therapy group (hazard ratio 0.4), a total of 52 patients are required to have 80% power at a two-tailed alpha of 0.05. Seven cancer centers will participate in the trial: Georgetown University, Hackensack University Medical Center, Walter Reed National Military Medical Center, Memorial Sloan Kettering Cancer Center, Vanderbilt University, UCLA, and UCSF. Clinical trial information: NCT03325816.

IMpower131: Primary PFS and safety analysis of a randomized phase III study of atezolizumab + carboplatin + paclitaxel or nab-paclitaxel vs carboplatin + nab-paclitaxel as 1L therapy in advanced squamous NSCLC. *First Author: Robert M. Jotte, Rocky Mountain Cancer Centers, Denver, CO*

The full, final text of this abstract will be available at abstracts.asco.org at 7:30 a.m. ET on Saturday, June 2, 2018, and in the Annual Meeting Proceedings online supplement to the June 20, 2018, issue of the *Journal of Clinical Oncology*. On site at the Meeting, this abstract will be printed in the Monday edition of *ASCO Daily News*.

9001 **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

Nivolumab (Nivo) + platinum-doublet chemotherapy (Chemo) vs chemo as first-line (1L) treatment (Tx) for advanced non-small cell lung cancer (NSCLC) with <1% tumor PD-L1 expression: Results from CheckMate 227. *First Author: Hossein Borghaei, Fox Chase Cancer Center, Philadelphia, PA*

Background: CheckMate 227 (NCT02477826), a phase 3 study of 1L nivo + ipilimumab (ipi), nivo, or nivo + chemo vs chemo in advanced NSCLC, met its co-primary endpoint of prolonged progression-free survival (PFS) with nivo + ipi vs chemo in patients (pts) with tumor mutational burden ≥10 mutations/Mb. Identifying effective tx for pts without known predictive biomarkers remains an unmet need. Prior studies suggest addition of chemo to anti–PD-(L)1 tx can improve outcomes in an unselected pt population, although benefit is most pronounced in pts with higher tumor PD-L1 expression. We report results for nivo + chemo vs chemo in pts with < 1% tumor PD-L1 expression. **Methods:** Pts (n = 550) with chemo-naive, stage IV/recurrent NSCLC, no known sensitizing *EGFR/ALK* mutations, and < 1% tumor PD-L1 expression were stratified by tumor histology and randomized 1:1:1 to nivo 3 mg/kg Q2W + ipi 1 mg/kg Q6W, nivo 360 mg Q3W + chemo, or chemo (optional pemetrexed maintenance after chemo for nonsquamous [non-SQ] NSCLC). Pts were treated up to 2 yr. A descriptive analysis was performed for the secondary endpoint of PFS for nivo + chemo vs chemo in pts with < 1% tumor PD-L1 expression. No alpha was allocated for this analysis. **Results:** Baseline characteristics were balanced between nivo + chemo (n = 177) and chemo (n = 186) arms. PFS was improved with nivo + chemo vs chemo (HR = 0.74 [95% CI: 0.58, 0.94]; minimum follow-up 11.2 mo; descriptive comparison). PFS benefit with nivo + chemo was observed across most subgroups. Among histologic subgroups, benefit was more pronounced in non-SQ (HR = 0.68) relative to SQ NSCLC (HR = 0.92). Rates of any grade tx-related adverse events leading to discontinuation were 13% with nivo + chemo and 14% with chemo. **Conclusions:** 1L nivo + chemo improved PFS vs chemo in pts with advanced NSCLC and < 1% tumor PD-L1 expression, and was well tolerated. Results are encouraging in this analysis, which includes only pts with < 1% PD-L1. CheckMate 227 Part 2 (ongoing) is evaluating nivo + chemo vs chemo irrespective of PD-L1 expression and will further inform benefit from this combination across different subgroups of NSCLC. Clinical trial information: NCT02477826.

9002 **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

Overall survival (OS) analysis of IMpower150, a randomized Ph 3 study of atezolizumab (atezo) + chemotherapy (chemo) ± bevacizumab (bev) vs chemo + bev in 1L nonsquamous (NSQ) NSCLC. *First Author: Mark A. Socinski, Florida Hospital Cancer Institute, Orlando, FL*

Background: Atezo (anti–PD-L1) inhibits PD-L1 to restore anticancer immunity; bev may enhance atezo efficacy by inhibiting VEGF immunosuppression and promoting T-cell tumor infiltration. IMpower150 is the first randomized Ph 3 trial evaluating atezo + chemo (carboplatin [C] + paclitaxel [P]) ± bev vs CP + bev in 1L NSQ NSCLC. PFS benefit was observed with atezo + CP + bev vs CP + bev regardless of PD-L1 expression. Here we present the IMpower150 interim OS results. **Methods:** 1202 patients (pts) received atezo 1200 mg + C AUC 6 + P 200 mg/m^2 (Arm A) or atezo + CP + bev 15 mg/kg (Arm B) vs CP + bev (Arm C) IV q3w for 4 or 6 cycles per investigator (INV); then maintenance atezo, atezo + bev, or bev, respectively. Co-primary endpoints were INV-assessed PFS in the ITT-WT (*EGFR/ALK* WT) and in WT pts with expression of a tumor T-effector gene signature (Teff-high WT) and OS in the ITT-WT. Data cutoff: 1/22/2018. **Results:** 349, 359, and 337 ITT-WT pts were enrolled in Arms A, B, and C, respectively, with median age 63 y, 62% male, 85% current/previous smokers, and 42% ECOG PS 0. With 13.5 mo min FU, OS was improved in Arm B vs C (HR, 0.78 [95% CI: 0.64, 0.96]; $P = 0.016$) in the ITT-WT; populations of interest are shown in the Table. Arm A vs C OS HR was 0.88 (95% CI: 0.72, 1.08; $P = 0.204$). In all treated patients, Gr 3-4 treatment-related AEs occurred in 43%, 57%, and 49% of pts in Arms A, B, and C, respectively. **Conclusions:** IMpower150 showed a significant OS benefit with atezo + CP + bev vs CP + bev in 1L NSQ NSCLC, and no new safety signals were seen. Clinical trial information: NCT02366143. IC, tumor-infiltrating immune cells; NE, not estimable; TC, tumor cells. [a] WT excludes pts with *EGFR* or *ALK* genomic alterations. [b] Present at baseline. TC1/2/3 or IC1/2/3 = PD-L1+ ≥ 1% of TC or IC; TC0 and IC0 = PD-L1+ < 1% of TC and IC

9003 **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

Deleterious effect of baseline steroids on efficacy of PD-(L)1 blockade in patients with NSCLC. *First Author: Kathryn Cecilia Arbour, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Treatment with PD-(L)1 inhibitors is now standard therapy for patients with lung cancer. The immunosuppressive effect of steroids may reduce efficacy of PD-(L)1 blockade. On-treatment steroids for treatment of irAEs do not appear to affect efficacy, but the potential impact of baseline steroids at time of treatment initiation is unknown. Clinical trials typically excluded patients receiving baseline corticosteroids leading us to use real-world data to examine the effect of steroids at treatment initiation. **Methods:** We identified 640 PD-(L)1 naïve patients with advanced NSCLC from two institutions (Memorial Sloan Kettering Cancer Center [MSKCC] and Gustave Roussy Cancer Center [GRCC]) treated with single agent PD-(L)1 blockade. Clinical and pharmacy records were reviewed to identify IV or PO steroid use at the time of beginning PD-(L)1 and stratified into two groups: ≥10mg qd prednisone equivalents vs < 10mg/no steroids on Day 1 of PD-(L)1 therapy. Response was evaluated according to RECIST 1.1. Progression free survival (PFS) and overall survival (OS) comparisons were made using log-rank test. Multivariate analyses were performed using Cox proportional hazards model and logistic regression. **Results:** 14% (90/640) received ≥10mg/qd steroids at the start of PD-(L)1 blockade. Common indications for steroids were dyspnea (33%), fatigue (21%), and brain metastases (19%). In both independent cohorts (MSKCC and GRCC), baseline steroids were associated with decreased ORR, PFS, and OS with PD-(L)1 blockade (Table). In the pooled population, after adjusting for smoking history, performance status, and history of brain metastases, baseline steroids remained significantly associated with decreased ORR ($p = 0.05$), PFS ($p = 0.03$), and OS ($p < 0.001$). **Conclusions:** Baseline steroid use of ≥10mg of prednisone was associated with poorer outcome in NSCLC patients treated with PD-(L)1 blockade. Prudent use of steroids at the time of initiating PD-(L)1 blockade is recommended.

9004 **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

Dacomitinib (daco) versus gefitinib (gef) for first-line treatment of advanced NSCLC (ARCHER 1050): Final overall survival (OS) analysis. *First Author: Tony Mok, State Key Laboratory of South China, Department of Clinical Oncology, Chinese University of Hong Kong, Hong Kong, China*

Background: In the ongoing phase 3 ARCHER 1050 study, first-line treatment with daco significantly improved the primary endpoint of progression-free survival, duration of response, and time to treatment failure vs gef in patients (pts) with epidermal growth factor receptor (*EGFR*) mutation-positive advanced non-small cell lung cancer (NSCLC) (Wu et al, *Lancet Oncol*, 2017). Here, we present the OS results. **Methods:** Pts with newly diagnosed stage IIIB/IV or recurrent NSCLC harboring an *EGFR* mutation (exon 19 del or exon 21 L858R ± exon 20 T790M) and without central nervous system metastasis were randomized 1:1 to oral daco 45 mg/day or oral gef 250 mg/day. Pts were stratified by race and *EGFR* mutation type. **Results:** As of 17 February 2017, a total of 220 deaths (48.7%) occurred over a median follow-up of 31.3 months (mo): 103 (45.4%) in the daco arm (n = 227) and 117 (52.0%) in the gef arm (n = 225). Daco showed a significant improvement in OS compared to gef (hazard ratio [HR], 0.76; 95% confidence interval [CI], 0.582–0.993; 2-sided $P = 0.044$ based on stratified analysis). Median OS (95% CI) was 34.1 mo (29.5–37.7) with daco vs 26.8 mo (23.7–32.1) with gef. Survival rates at 30 mo were 56.2% with daco and 46.3% with gef. The table shows preliminary OS subgroup analyses by race and *EGFR* mutation type, with >55% of pts being censored in some subsets. OS subgroup analyses were consistent with the primary OS analysis across most baseline characteristics. **Conclusions:** In pts with advanced *EGFR* mutation-positive NSCLC, daco is the first to show a significant improvement in OS in a phase 3 trial compared with a standard-of-care tyrosine kinase inhibitor. Daco should be considered as one of the standard treatment options for these pts. Clinical trial information: NCT01774721.

9005 **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

Phase III study comparing gefitinib monotherapy (G) to combination therapy with gefitinib, carboplatin, and pemetrexed (GCP) for untreated patients (pts) with advanced non-small cell lung cancer (NSCLC) with EGFR mutations (NEJ009). *First Author: Atsushi Nakamura, Sendai Kousei Hospital, Sendai, Japan*

Background: Although EGFR-TKI alone has been a standard first-line treatment for pts with advanced NSCLC with EGFR mutations, our phase II study (NEJ005) showed promising efficacy of GCP. NEJ009, an open-label, randomized phase III study, was conducted to evaluate the superiority of GCP vs G in progression-free survival (PFS), PFS2, and overall survival (OS). **Methods:** Pts with newly diagnosed stage III/IV/ recurrent NSCLC harboring an EGFR activating mutations (exon 19 deletion or exon 21 L858R) were randomized 1:1 to G 250 mg PO QD or GCP (G 250mg PO QD combined with carboplatin AUC 5 + pemetrexed 500mg/m2, every 3 weeks). The primary endpoints consisting of PFS, PFS2, and OS were sequentially analyzed according to a preplanned gate-keeping method. Secondary endpoints included objective response rate, safety, and quality of life. **Results:** In September 2017, a preplanned required number of events of PFS2 was observed. The ITT population included 344 pts with baseline characteristics fairly well balanced between the arms. Although GCP demonstrated significantly better PFS compared to G, there was no difference in PFS2 between the arms as below. Additional OS analysis (G:101 events vs GCP:83 events) revealed that median survival time of GCP was much longer than that of G (52.2 months vs 38.8 months, HR:0.695, p = 0.013). **Conclusions:** NEJ009 was the first phase III study which evaluated the efficacy of a combination of EGFR-TKI and platinum doublet chemotherapy in untreated advanced NSCLC pts with EGFR mutations. Although GCP regimen failed to demonstrate its superiority in PFS2, it may increase long survivors. ITT Population GCP (N = 169) G (N = 172) Median (months) Median (months) HR PFS 20.9 11.2 0.493 [95%CI: 18.0, 24.2] [95%CI: 9.0, 13.4] [95%CI: 0.390, 0.623] P < 0.001 PFS2 20.9 21.1 0.891 [95% CI: 18.0, 24.2] [95%CI: 17.9, 24.9] [95%CI: 0.708, 1.122] P = 0.806.

9006 **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

Phase III study comparing bevacizumab plus erlotinib to erlotinib in patients with untreated NSCLC harboring activating EGFR mutations: NEJ026. *First Author: Naoki Furuya, Division of Respiratory Medicine, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan*

Background: Development of treatment for EGFR-mutated non-small-cell lung cancer (NSCLC) had been focused on monotherapy of gefitinib, erlotinib, or afatinib. Combinations of EGFR-TKIs and VEGF inhibitors are one of candidates for next strategy for EGFR-mutated tumor. We conducted a phase III study comparing BE to E. **Methods:** Chemotherapy-naïve pts with advanced non-squamous NSCLC harbouring EGFR-mutation were randomly assigned to receive either combination with erlotinib (150 mg daily) plus bevacizumab (15 mg/kg iv q3w) or erlotinib (150 mg daily). Status of EGFR mutations in plasma samples were monitored routinely during the study treatment and a second-line treatment. The primary endpoint was PFS. Secondary endpoints were OS, RR, safety, and QoL. We hypothesized that hazard ratio of PFS was 0.63. It was estimated that 147 events would be needed for the study to have a power of 80% and a two-sided significance level of 5%. Accordingly, this study was planned to enroll 214 pts in total. **Results:** Between Jun 3, 2015, and Aug 31, 2016, 228 pts with EGFR mutations were enrolled. There were one cessation prior to the study treatment and one withdrawal of consent; the remaining 226 pts were assigned to BE (n = 112) and E (n = 114). The interim analysis preplanned was performed at 117 PFS events using full analysis set of 224 pts except for both an ineligible case and a case lost to follow-up in E. Pts were followed up for a median of 12.4 months. The interim analysis showed that the study met its primary endpoint. At data cutoff (Sept 21, 2017), median PFS was 16.9 months (95% CI 14.2-21.0) in BE and 13.3 months (11.1-15.3) in E (p = 0.0157) (HR 0.605, 95% CI 0.417-0.877). Though hemorrhage, proteinuria, and hypertension as toxicities significantly increased in BE compared to in E, there was no significant difference among other toxicities between BE and E. Five cases had low-grade pneumonitis in E but no pneumonitis in BE. There was no treatment-related death. **Conclusions:** In this study, BE as a combination of EGFR-TKIs and VEGF inhibitors achieved durable response and good tolerability. This regimen is considered as a new standard treatment in EGFR-mutated NSCLC. Clinical trial information: UMIN000017069.

9007 **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

Erlotinib plus bevacizumab (EB) versus erlotinib alone (E) as first-line treatment for advanced EGFR mutation–positive non-squamous non–small-cell lung cancer (NSCLC): Survival follow-up results of JO25567. *First Author: Noboru Yamamoto, Department of Thoracic Oncology, National Cancer Center Hospital, Tokyo, Japan*

Background: In JO25567 (Clinical trials registry number. JapicCTI-111390), EB significantly prolonged progression-free survival (PFS) in patients with NSCLC with activating EGFR mutation compared with E alone. Overall survival (OS) data were immature at the cutoff date for the primary analysis (Seto T et al. Lancet Oncol. 2014;15:1236-44.). We conducted survival follow-up of the patients in JO25567. **Methods:** JO25567 was open-label randomized trial. Patients with stage 3b/4 or recurrent non-squamous EGFR mutation–positive NSCLC and no previous chemotherapy were randomly allocated to receive EB (E, 150 mg/day; B, 15 mg/kg every 3 weeks) or E (150 mg/day) until disease progression or unacceptable toxicity. Primary endpoint was PFS. To conduct this follow-up, written informed consents were obtained from alive patients. JO25567 data of the patients who were not enrolled into this follow-up due to death or lost to follow-up were also included into this analysis. **Results:** From 152 patients in JO25567 (EB, n = 75, E, n = 77), 52 patients had died and 25 patients were lost to follow-up at the start of this follow-up. Seventy-five patients (EB, n = 35; E, n = 40) were enrolled between June and October 2014. As of the data cut-off date of 31 October 2017, median OS from random assignment was 47.0 months for EB and 47.4 months for E (HR, 0.81; 95% CI, 0.53-1.23; log-rank $p = 0.3267$). Forty OS events (53.3%) had occurred in EB and 49 events (63.6%) in E. Five-year survival rate was 41% in EB and 35% in E. There were no major difference of OS between patient characteristics. Sixty-four patients (85.3%) in EB and 65 patients (84.4%) in E received post-study treatments. **Conclusions:** The median OS around 4 years were observed in both arms. There was a slight trend of survival improvement in EB than E alone, however, the significant difference of PFS was not directly translated into the difference of OS between these treatments. Clinical trial information: JapicCTI-142569.

9008 Clinical Science Symposium, Fri, 4:30 PM-6:00 PM

Avelumab (anti–PD-L1) in combination with crizotinib or lorlatinib in patients with previously treated advanced NSCLC: Phase 1b results from JAVELIN Lung 101. *First Author: Alice Tsang Shaw, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: ALK tyrosine kinase inhibitors (TKIs) are standard of care for patients (pts) with advanced ALK+ NSCLC, and preclinical data suggest potential synergistic activity with checkpoint inhibitors in NSCLC irrespective of ALK status. Avelumab is a human anti–PD-L1 IgG1 monoclonal antibody approved in various countries for treatment of metastatic Merkel cell carcinoma, and in the US for advanced urothelial carcinoma that has progressed following platinum therapy. We report initial results from JAVELIN Lung 101 (NCT02584634), a phase 1b/2 dose-finding trial of avelumab + crizotinib (A+C) or the next-generation ALK TKI lorlatinib (A+L) in pts with advanced/metastatic ALK-negative/wildtype (ALK−) or ALK+ NSCLC, respectively. **Methods:** In phase 1b, pts with previously treated ALK− NSCLC received A (10 mg/kg Q2W) + C (250 mg BID) while pts with ALK+ NSCLC received A (10 mg/kg Q2W) + L (100 mg QD) (starting dose levels in each group). The primary endpoint was dose-limiting toxicities (DLTs); secondary endpoints included adverse events (AEs) and objective responses. **Results:** At data cutoff on Oct 27, 2017, 12 ALK− pts had received A+C and 28 ALK+ pts had received A+L. All ALK− pts had received prior anticancer therapy; ALK+ pts had received a median 2 prior ALK TKIs (range 1-3; data not reported for 1 ALK+ pt). DLTs occurred with A+C in 5 ALK− pts (41.7%): ALT and AST increase (2 pts each), febrile neutropenia, hepatitis, QT prolongation, and rash (1 pt each). No DLTs occurred with A+L in ALK+ pts. Grade ≥3 AEs of any causality occurred with A+C in 7 ALK− pts (58.3%; most common [≥10%] was ALT increase [16.7%, n = 2]), and with A+L in 15 ALK+ pts (53.6%; most common were hypertriglyceridemia [14.3%, n = 4] and GGT increase [10.7%, n = 3]). The confirmed objective response rate with A+C in ALK− pts was 16.7% (95% CI, 2.1-48.4; partial response [PR] in 2 pts), and with A+L in ALK+ pts was 46.4% (95% CI, 27.5-66.1; PR in 12 pts; complete response in 1 pt). **Conclusions:** A+L showed an acceptable safety profile, distinct from A+C, and promising antitumor activity in pts with ALK+ NSCLC, and will be evaluated in treatment-naive pts in phase 2. Clinical trial information: NCT02584634.

9009 Clinical Science Symposium, Fri, 4:30 PM-6:00 PM

Safety and clinical activity results from a phase Ib study of alectinib plus atezolizumab in *ALK*+ advanced NSCLC (aNSCLC). *First Author: Dong-Wan Kim, Seoul National University Hospital, Seoul, Korea, Republic of (South)*

Background: Alectinib has proven systemic and CNS efficacy in patients (pts) with *ALK*+ aNSCLC (ALEX study). Tumor cell death caused by alectinib may release antigens broadening the potential anti-tumor T cell response. The monoclonal antibody atezolizumab (atezo) releases T cell suppression by inhibiting PD-L1 binding and improves OS in second-line NSCLC treatment. We hypothesized atezo in combination with alectinib would lead to enhanced efficacy. **Methods:** This phase Ib enrolled treatment-naïve pts with *ALK*+ aNSCLC regardless of PD-L1 status, including pts with untreated asymptomatic brain metastases. Pts received alectinib 600 mg PO BID for 7 days (safety evaluation), followed by alectinib 600 mg PO BID with atezo 1200 mg IV q3w (expansion stage) until progression or unacceptable toxicity. The primary objective was to evaluate the safety and tolerability of the combination. Secondary objectives included evaluation of tumor response (ORR) per RECIST v1.1. **Results:** At cut-off (18 August 2017) 21 pts (safety stage n = 7; expansion stage n = 14) who received ≥1 dose of alectinib or atezo were considered safety evaluable. Median age was 53 years. Incidence of grade 3 and serious adverse events (AEs) were 62% (52.4% treatment-related) and 33%, respectively. No grade 4–5 AEs were reported. Four pts (19%) discontinued atezo and 2 pts (10%) discontinued alectinib due to AEs. 14 pts (67%) had alectinib dose interruptions/modifications. No dose-limiting toxicities were observed. At a median follow up of 13 months, (1–22), ORR was 81% (95% CI 58.1–94.6); median progression-free survival was 21.7 months (95% CI 10.3–21.7), median duration of response was 20.3 months (95% CI 11.5–20.3), however, only 6 pts had progressed at the time of data cut-off. On-treatment CD8+ T-cell increase was observed post-alectinib run-in. **Conclusions:** Combination of full dose alectinib and atezo appears to have an acceptable safety profile with no new safety findings for either agent. Early efficacy results are encouraging but further follow-up is needed to define the role of this combination in pts with treatment-naïve *ALK*+ NSCLC.

9010 Clinical Science Symposium, Fri, 4:30 PM-6:00 PM

Efficacy of immune-checkpoint inhibitors (ICI) in non-small cell lung cancer (NSCLC) patients harboring activating molecular alterations (ImmunoTarget). *First Author: Julien Mazieres, Hôpital Larrey, Centre Hospitalier Universitaire Toulouse, Toulouse, France*

Background: Data on ICI activity in patients with oncogenic driver are limited. The aim of this study was to collect further data across various molecular subgroups. **Methods:** We conducted a retrospective multicenter study of patients receiving ICI for stage IV NSCLC with genomic alterations. Anonymized data were evaluated for clinicopathologic characteristics and outcomes: best response (RECIST v1.1), progression-free survival (PFS) and overall survival (OS) from ICI initiation. **Results:** We included 527 patients treated in 25 centers The. Molecular alterations involved *KRAS* (n = 252), *EGFR* (n = 110), *BRAF* (n = 38), *MET* (n = 36), *HER2* (n = 23), *ALK* (n = 18), *RET* (n = 14), *ROS1* (n = 5), and multiple drivers (n = 31). Median age was 60 years, sex-ratio was 1:1, never/former/current smokers were 27/51/22%, and the majority of tumors were adenocarcinoma. ICIs were mainly anti-PD1 (92%) given in the first (5%), second (42%), third (26%), or later line (27%) settings. The best response rate was 19% [15-22%]. The median PFS and OS were 2.8 [2.5-3.1] and 13.3 [9.8-14.8] months, respectively. Outcomes by molecular subtypes are reported below (table 1). *EGFR*-mutant had shorter PFS compared to *KRAS*-mutant ($p < 0.001$). T790M mutation was associated with a shorter PFS than other *EGFR* mutations ($p = 0.0001$) whereas the benefit was the same across all *KRAS* mutation subtypes. Among MET alterations, exon 14 mutations were the most sensitive to ICI. PFS was positively influenced by smoking ($p = 0.003$) and PDL1 expression ($p = 0.02$) in the overall population but not for EGFR-mutant. **Conclusions:** ICI has inconstant efficacy in NSCLC harboring activating mutation. KRAS, BRAF and MET-exon 14 patients derive a greater benefit than EGFR, ALK and RET patients.

		Best response (%)			PFS			OS
Driver	n	CR/PR	SD	PD	Median (months*)	6 m PFS (%)	1 y PFS (%)	Median (months*)
BRAF	38	28.1	28.1	43.8	3.0	35	19	13.6
KRAS	252	27.2	23.1	49.8	3.2	39	26	13.5
ROS1	5	20	0	80	NA	NA	NA	NA
MET	36	15.6	34.4	50.0	3.4	33	23	18.4
EGFR	110	11.0	18.0	71.0	2.0	16	6	8.8

Response and durability of anti-PD-(L)1 therapy in never- or light-smokers with non-small cell lung cancer (NSCLC) and high PD-L1 expression. *First Author: Justin F. Gainor, Massachusetts General Hospital, Boston, MA*

Background: PD-1 blockade is now standard first-line therapy for patients (pts) with advanced NSCLC and a PD-L1 tumor proportion score (TPS) ≥50%. Tumor mutation burden (TMB) is also a biomarker of response to PD-1 blockade and correlates with smoking status in patients with NSCLC. Never/minimal smokers usually have low TMB and diminished response to PD-1 blockade. The impact of high PD-L1 expression on response to PD-1 blockade among never- or light-smokers has not been well studied. **Methods:** We retrospectively identified pts with NSCLC at 3 centers who were never- or light-smokers (≤10 pack years) and had received PD-(L)1 blockade. High PD-L1 expression was determined using commercially-available (22C3 or 28-8) or institutional laboratory developed tests (E1L3N) and defined as TPS ≥50%. A subset of pts underwent hybrid-capture NGS of 341-468 genes (MSK-IMPACT) to determine TMB. **Results:** We identified 52 light- (56%) or never-smokers (44%) with TPS ≥50% who received PD-(L)1 blockade in the first- (63%), second- (21%) or ≥third-line (15%) setting. Oncogenic driver mutations included KRAS (21%), EGFR (12%), BRAF (7%), RET/HER2/MET (4% each). Among 21 pts with MSK-IMPACT testing, median TMB was expectedly low (4.1 mutations/Mb). Objective responses were observed in 16 (ORR 31%) pts, including 6 (ORR 26%) never-smokers. The median duration of response (DOR) was 5.6 months (range 1-23+). Median progression-free survival and overall survival were 3.0 months (95% CI 2.2-5.1 months) and 16.4 months (95% CI 10.7-18.7 months), respectively. **Conclusions:** In never- or light-smokers with advanced NSCLC and high PD-L1 expression, PD-(L)1 blockade is associated with a moderate objective response rate; however, the durability of this activity appears diminished compared to historical controls. The immunobiologic features determining initial response versus durability of benefit to PD-(L)1 blockade may be distinct.

9012 Poster Discussion Session; Displayed in Poster Session (Board #335), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 11:30 AM-12:45 PM

Combination of gefitinib and olaparib versus gefitinib alone in EGFR mutant non-small-cell lung cancer (NSCLC): A randomized phase 2 study (GOAL, Spanish Lung Cancer Group). *First Author: Rosario Garcia Campelo, Medical Oncology Service, University Hospital A Coruña (XXIAC-SERGAS), A Coruña, Spain*

Background: Low BRCA1 mRNA levels correlate with longer progression free survival (PFS) in erlotinib treated EGFR mutant NSCLC patients (p), while risk of shortened PFS was associated with intermediate/high BRCA1 levels (HR, 8.46; P<0.0001). We explored the combination of the poly (ADP-ribose) polymerase (PARP) inhibitor, olaparib with gefitinib in EGFR mutant NSCLC p. In a previous phase 1 trial, the safety of the combination was confirmed. Recommended phase 2 dose (RP2D) is gefitinib, 250 mg daily, and olaparib, 200 mg thrice daily. **Methods:** Stage IV treatment naïve NSCLC p with centrally confirmed EGFR mutations and measurable disease were recruited in the study (NCT01513174). We randomly allocated p (1:1) to receive gefitinib 250 mg daily or the combination at the RP2D. The primary endpoint was PFS. PFS related to BRCA1 mRNA was a secondary endpoint, and 53BP1 and enhancer of zeste homolog 2 (EZH2) were analyzed as modulators of BRCA1, overall survival (OS), response rate (RR), safety and tolerability. Target accrual was 186 p. This sample provided 80% power to detect HR of 0.63 after 116 PFS events. The first PFS analysis, side effect profile and RR had a February 28th, 2018 cut-off, minimum follow-up of 18 months (mo). **Results:** Of the 182 p who underwent randomization, 91 received gefitinib and 91 received gefitinib+olaparib, with no differences in gender, age, never smoker, performance status, bone or brain metastases or EGFR mutation. Median PFS for exon 19 deletions and exon 21 L858R EGFR mutations was 10.4 mo for gefitinib group and 12.8 mo for gefitinib + olaparib group (HR for disease progression or death, 0.83; P=0.329). RR was 68% in gefitinib group and 78% in gefitinib + olaparib group. **Conclusions:** The gefitinib+olaparib combination did not provide significant benefit over gefitinib alone. Median PFS was 2.4 mo longer for the combination and risk of disease progression or death was 17% lower with gefitinib+olaparib than gefitinib alone. The pre-specified assessment of BRCA1, 53BP1 and EZH2 could determine if a subgroup of p might obtain major benefit from the combination. Clinical trial information: NCT01513174.

Combination of metformin plus TKI vs. TKI alone in EGFR(+) LUNG adenocarcinoma: A randomized phase II study. *First Author: Oscar Gerardo Arrieta Rodriguez, Instituto Nacional de Cancerologia (INCan), Mexico City, Mexico*

Background: Metformin has been shown to have antitumor activity by increasing AMPK through different mechanisms involving tumor suppressor gene, LKB1. LKB1 inactivation is common in Non-small cell lung cancer (NSCLC) and is associated with a more aggressive clinical phenotype. Retrospective studies have shown that metformin could effectively increase the sensitivity to TKIs in NSCLC, thus improving Progression Free Survival (PFS) and potentially impacting Overall Survival (OS) in these patients. We compared the effect of metformin in combination with EGFR-TKI versus TKIs alone on the clinical prognosis of adenocarcinoma patients with *EGFR* mutations. **Methods:** In this phase 2 clinical trial (NCT03071705) we randomly assigned 116 patients with stage IV *EGFR*-mutated lung adenocarcinoma to receive therapy with metformin + EGFR-TKI (M+TKI) (n = 49) or EGFR-TKI (TKI) alone (n = 67). TKI was chosen upon clinician´s discretion. Patients were excluded if they had a history of diabetes or had received therapy with metformin or TKIs (> 2 cycles) previous to enrollment. The primary endpoint was PFS, secondary endpoints included objective response rate (ORR), disease control rate (DCR) and OS. **Results:** Baseline characteristics were well balanced between treatment arms. Mean patient follow up was 12.9 (±10.9) months. Median PFS was significantly longer for patients receiving M+TKI compared to those who received TKI (14.0 months vs. 10.0 months; p = 0.017) . ORR was higher in the experimental arm of the trial, compared to the control group (67.4% vs. 47.5%; p = 0.044), although, the DCR was similar in the two groups (97% vs. 88.5%; p = 0.085). Median OS was 24.8 months. Patients receiving M+TKI had a longer OS compared to those receiving TKI (27.2 months vs. 19.0 months, p = 0.015). Multivariate analysis showed that, among others, the therapeutic arm (M+TKI vs. TKI) is an independently associated factor for both PFS and OS. **Conclusions:** Our study strongly suggests that the addition of Metformin to standard EGFR-TKI therapy has a significant effect in PFS, ORR and OS of patients with *EGFR*-mutated NSCLC. Metformin use is a safe and efficacious addition to the therapeutic scheme of *EGFR*+ NSCLC. Clinical trial information: NCT03071705.

9014 Poster Discussion Session; Displayed in Poster Session (Board #337), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 11:30 AM-12:45 PM

A phase II study of pembrolizumab in EGFR-mutant, PD-L1+, tyrosine kinase inhibitor (TKI) naïve patients with advanced NSCLC. *First Author: Aaron Elliott Lisberg, UCLA, Los Angeles, CA*

Background: Despite the significant antitumor activity of pembrolizumab in non-small cell lung cancer (NSCLC), clinical benefit has been less frequently observed in patients whose tumors harbor epidermal growth factor receptor (*EGFR*) mutations compared to *EGFR* wild-type patients. Our single center experience on the KEYNOTE-001 trial suggested that pembrolizumab-treated EGFR-mutant patients, who were tyrosine kinase inhibitor (TKI) naïve, had superior clinical outcomes to those previously treated with a TKI. As TKI naïve EGFR-mutants have generally been excluded from pembrolizumab studies, data to guide treatment decisions in this patient population is lacking, particularly in patients with PD-L1 expression ≥50%. **Methods:** We conducted a phase II trial (NCT02879994) of pembrolizumab in TKI naive patients with *EGFR* mutation positive, advanced NSCLC and PD-L1 positive (≥1%, 22C3 antibody) tumors. Pembrolizumab was administered 200mg q3wks. The primary endpoint was objective response rate. Secondary endpoints included safety of pembrolizumab, additional pembrolizumab efficacy endpoints, and efficacy and safety of an *EGFR* TKI after pembrolizumab. **Results:** Enrollment was ceased due to lack of efficacy after 11 of 25 planned patients were treated. 82% of trial patients were treatment naïve, 64% had sensitizing *EGFR* mutations, and 73% had PD-L1 expression ≥50%. Only 1 patient had an objective response (ORR: 9%), but repeat analysis of this patient's tumor definitively showed the original report of an *EGFR* mutation to be erroneous. Observed treatment related adverse events were similar to prior experience with pembrolizumab, but two deaths within 6 months of enrollment, including one attributed to pneumonitis, were of concern. **Conclusions:** Pembrolizumab's lack of efficacy in TKI naïve, PD-L1+, EGFR-mutant patients with advanced NSCLC, including those with PD-L1 expression ≥50%, suggests that it is not an appropriate therapeutic choice in this setting. Clinical trial information: NCT02879994.

9015 Poster Discussion Session; Displayed in Poster Session (Board #338), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 11:30 AM-12:45 PM

First report of safety, PK, and preliminary antitumor activity of the oral EGFR/HER2 exon 20 inhibitor TAK-788 (AP32788) in non–small cell lung cancer (NSCLC). *First Author: Robert Charles Doebele, University of Colorado Cancer Center, Aurora, CO*

Background: TAK-788 is an investigational TKI with potent, selective preclinical activity against activating EGFR and HER2 mutations, including exon 20 insertions. We report the first results of a phase 1/2 first-in-human, open-label, multicenter study of TAK-788 (NCT02716116). **Methods:** Pts with advanced NSCLC refractory to standard therapy received daily oral doses (5–120 mg) of TAK-788 in the ongoing dose-escalation phase (3+3 design). Preliminary antitumor activity (by RECIST v1.1), safety, and PK are reported for pts receiving ≥1 dose. **Results:** As of 8 September 2017, 34 pts (median age, 60 y; female, 65%; ≥2 prior anticancer therapies, 88%; Table) were treated and 10 remain on TAK-788 at data cutoff. $AUC_{0\text{-}24,ss}$ increased in a dose-proportional manner over the dose range with effective $t_{1/2}$ of ~16 (range 6–28) h. Most common treatment-emergent AEs (TEAEs; ≥20% of pts): diarrhea (47%), nausea (26%), fatigue (21%). Grade ≥3 TEAEs in ≥2 pts (excluding disease progression): dyspnea (n = 3, 9%); anemia, asthenia, dehydration, lung infection, pleural effusion, pneumonia, pneumonitis (n = 2 each, 6%). Two DLTs, both pneumonitis, were reported (80 mg, grade 3; 120 mg, grade 5). Of 14 evaluable pts, 3 had PR (80 mg, n = 2, both confirmed; 120 mg, single PR awaiting confirmation), 6 had SD (40 mg, n = 3; 80 mg, n = 2; 120 mg, n = 1), and 5 had PD as best response (40 mg, n = 3; 80 mg, n = 1; 120 mg, n = 1); all pts with PR or SD had EGFR exon 20 insertions. **Conclusions:** TAK-788 exhibits antitumor activity in pts with EGFR exon 20 insertions with an AE profile consistent with other EGFR TKIs. Phase 2 will begin after determination of the RP2D, with 4 molecularly defined cohorts in NSCLC.Clinical trial information: NCT02716116.

Baseline characteristics.

	5 mg (n = 4)	10 mg (n = 5)	20 mg (n = 5)	40 mg (n = 6)	80 mg (n = 7)	120 mg (n = 7)	Total (n = 34)
Mutation type,[a] %							
Common EGFR mutations (exon 19 deletion / L8585R)	25	20	0	0	0	0	6
EGFR-T790M+	0	0	0	0	14	0	3
EGFR exon 20 insertion	50	40	60	83	71	57	62
HER2	0	20	40	17	14	29	21

[a]One pt (20 mg) had both EGFR and HER2 mutations; 1 pt (80 mg) had EGFR exon 20 insertion + T790M.

Tepotinib in patients with advanced non-small cell lung cancer (NSCLC) harboring *MET* exon 14-skipping mutations: Phase II trial. *First Author: Enriqueta Felip, Hospital Universitari de la Vall d'Hebron, Barcelona, Spain*

Background: *MET* mutations causing exon 14 skipping (*METΔex14*) produce c-Met receptors lacking a negative regulatory site, with the result that *METΔex14* mutations are oncogenic drivers. 3-4% of NSCLCs harbor *METΔex14* mutations; these tumors appear to be sensitive to c-Met inhibition. Selective c-Met inhibitors have the potential to be effective and well tolerated in patients (pts) with NSCLC. This single-arm phase II trial (NCT02864992) is investigating the efficacy and safety of the potent, selective c-Met inhibitor tepotinib in pts with *METΔex14*+ NSCLC. **Methods:** Adults with stage IIIB/IV *METΔex14*+ NSCLC without EGFR-activating mutations or *ALK* rearrangements who have received 0–2 lines of prior therapy are eligible. *METΔex14* mutations are identified in tumor and/or circulating tumor DNA (ctDNA) in plasma by a central laboratory. Pts receive tepotinib 500 mg QD until disease progression, intolerable toxicity, or withdrawal for other reasons. Primary endpoint: objective response. Secondary endpoints include safety. Recruitment of approx. 90 pts (60 tumor + 60 ctDNA *METΔex14*+, overlap anticipated) in Europe, USA, and Japan is planned. **Results:** 34 pts have been treated to date; data are available for 22 (male, n=16; Caucasian/Asian, n=17/5; median age 73.5 years; prior lines of therapy: 0, n=8, 1, n=8; 2, n=5; 3, n=1; *METΔex14*+ tumor and ctDNA, n=11, *METΔex14*+ tumor only, n=10, *METΔex14*+ ctDNA only, n=1); 19 remain on treatment. Based on investigator assessment, 9/15 (60.0%) evaluable pts had a confirmed PR and 3 (20.0%) had SD. All responders remain in response. 13 pts were evaluable for response by independent review: confirmed PR, n=6 (46.2%); SD, n=1 (7.7%). 13/22 pts with data available had tepotinib-related treatment-emergent adverse events (TRTEAEs; G1/2 peripheral edema = 9, G1/2 diarrhea = 7), with 3 having G3 TRTEAEs (asymptomatic amylase increase = 2; GGT increase = 1) and one a serious TRTEAE (interstitial pneumonia). 2 deaths not related to therapy have occurred (disease progression and bronchopulmonary hemorrhage). **Conclusions:** Tepotinib 500 mg QD has promising activity in *METΔex14*+ NSCLC. Its safety profile is as expected based on prior studies. Recruitment is ongoing. Clinical trial information: NCT02864992.

Results from a second-line (2L) NSCLC cohort treated with M7824 (MSB0011359C), a bifunctional fusion protein targeting TGF-β and PD-L1. *First Author: Luis G. Paz-Ares, University Hospital 12 de October, Madrid, Spain*

Background: Inhibiting the transforming growth factor β (TGF-β) pathway, which promotes tumor immunosuppression, may enhance the response to PD-(L)1 monoclonal antibodies (mAbs). 2L+ overall response rates (ORRs) with PD-(L)1 inhibitors in patients (pts) with advanced NSCLC range from 12% to 19% (PD-L1 unselected), highlighting the need for better treatments. M7824 is an innovative first-in-class bifunctional fusion protein composed of a human anti–PD-L1 IgG1 mAb fused with 2 extracellular domains of TGF-β receptor II (a TGF-β "trap"). **Methods:** In this expansion cohort of the ongoing, phase 1 trial NCT02517398, pts with advanced NSCLC unselected for PD-L1 who progressed following 1L standard treatment (no prior immunotherapy) were randomized to receive M7824 500 mg (n = 40) or 1200 mg (n = 40) q2w until disease progression, unacceptable toxicity, or trial withdrawal. The primary objective is to assess BOR per RECIST v1.1; other objectives include dose exploration and safety/tolerability assessment. Tumor cell PD-L1 expression was evaluable in 75 pts (Ab clone 73-10 [$>$ 80% = $>$ 50% with 22C3]). **Results:** As of October 25, 2017, 80 pts received M7824 for a median of 11.9 (range, 2-48) wk, with a median follow-up of 35.2 wk; 17 pts remain on treatment. Investigator-assessed unconfirmed ORR was 25.0% (500 mg ORR, 22.5%; 1200 mg ORR, 27.5%). Clinical activity was observed across PD-L1 expression levels (Table); ORR was 40.7% in PD-L1+ and 71.4% in PD-L1–high pts at 1200 mg. The most common treatment-related adverse events (TRAEs) were pruritus (18.8%), maculopapular rash (17.5%), and decreased appetite (12.5%). Grade ≥3 TRAEs occurred in 20 pts (25.0%). 6 pts (500 mg, n = 2; 1200 mg, n = 4) discontinued treatment due to TRAEs. No treatment-related deaths occurred. Clinical trial information: NCT02517398. **Conclusions:** M7824 monotherapy had promising efficacy across PD-L1 subgroups, with an ORR at the RP2D of 1200 mg of 40.7% and 71.4% in PD-L1+ and –high pts, respectively. Treatment was well tolerated.

ORR	500 mg	1200 mg	Total
All	9/40, 22.5	11/40, 27.5	20/80, 25.0
PD-L1+ (≥1%) pts, n, %	7/31, 22.6	11/27, 40.7	18/58, 31.0
PD-L1 high (≥80%) pts, n, %	2/6,33.3	5/7,71.4	7/13,53.8

Responses and durability in NSCLC treated with pegilodecakin and anti-PD-1. *First Author: Edward B. Garon, David Geffen School of Medicine at University of California, Los Angeles, Los Angeles, CA*

Background: Responses in NSCLC to agents targeting the PD-1/PD-L1 axis are correlated with PD-L1 expression by immunohistochemistry (IHC), tumor mutational burden (TMB), interferon associated mRNA Expression Profile (GEP) and the absence of liver metastases. Anti-PD-1 impedes the inhibition of T cells while pegilodecakin (AM0010) stimulates the survival, and expansion of intra-tumoral, antigen activated CD8+ T cells (Mumm et al., 2010). This provides a rationale for combining anti-PD-1 agents with pegilodecakin. **Methods:** Pretreated NSCLC subjects (n = 34), received pegilodecakin (10-20μg/kg QD, SC) with pembrolizumab (2mg/kg, q3wk IV; n = 5) or nivolumab (3mg/kg, q2wk IV; n = 29). Median follow-up is 31.2 months (range 28.3 to 33+) and 17.5 months (range 8.3 to 25.9+), respectively. Responses were assessed by irRC. Twenty subjects had sufficient tissue for PD-L1 testing with the 22C3 IHC assay (CLIA) and 10 subjects had sufficient tissue for TMB evaluation by whole exome sequencing (WES) and pre-treatment GEP by Nanostring. **Results:** In 26 subjects evaluable for response, the ORR was 41% (11 PRs). Another 12 subjects (46%) had SD as best response. As investigators were asked to preferentially enroll PD-L1 negative patients, PD-L1 expression was $<$ 1% in 12 of 20 PD-L1 evaluable subjects with 4 achieving a PR. Ten subjects had sufficient tissue for TMB and GEP, including 6 PRs. Five of the 8 who tested low to intermediate for TMB (≤ 243 mut) had a PR as did 2 of 6 GEP negative subjects. In addition, 5 of 8 subjects with liver metastasis had a PR. The mPFS and mOS of the five NSCLC subjects (4/4 tested PD-L1 $<$ 1%) treated with pegilodecakin + pembrolizumab was 10.9 and 32.2 months, respectively. The mPFS and mOS for the pegilodecakin + nivolumab cohort (8/16 PD-L1 $<$ 1%) has not been reached. **Conclusions:** Pegilodecakin when added to anti-PD-1 therapy in advanced NSCLC patients was associated with response rates and durability of benefit greater than has been seen with anti-PD-1 alone. Responses were seen in settings in which anti-PD-1 therapy has demonstrated limited benefit, such as absent PD-L1 expression, low TMB and/or the presence of liver metastasis. These preliminary findings support further studies of pegilodecakin with anti-PD-1 therapies. Clinical trial information: NCT02009449.

9019 Poster Discussion Session; Displayed in Poster Session (Board #342), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 11:30 AM-12:45 PM

First comprehensive report of impact of genomic alterations, chemotherapy, targeted therapy and immunotherapy on outcomes in the genomics driven squamous master protocol LungMAP. *First Author: Vassiliki Papadimitrakopoulou, Department of Thoracic/Head and Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Lung-MAP (S1400) is an umbrella protocol for genomic screening of previously treated squamous cell lung cancer patients and evaluation of targeted therapies in biomarker-matched groups and immunotherapy in patients without putative drivers. The protocol opened on June 16, 2014. Nine sub-studies have activated; the original 5 are closed, 4 are currently accruing. **Methods:** Tumor samples are analyzed by FoundationOne NGS assay. Completed studies evaluated taselisib (T) for PI3K mutations, palbociclib(P) for cell cycle gene alterations (CCGA), AZD4547(A) for FGFR alterations, rilotumumab and erlotinib(RE) for c-MET positive tumors, and durvalumab(Dur) . Originally including randomization to docetaxel(Doc), the studies were amended to single-arm phase 2 . Outcomes by treatment and biomarkers were assessed using a Cox model adjusting for performance status, lines of therapy, age, and gender. Prognosis of biomarkers was evaluated from time of study assignment. **Results:** As of January 5, 2018, 1407 patients registered to screening, 1244 with biomarker results and 529 patients have registered to a sub-study. Fifty-six eligible patients registered to Doc, 66 to Dur, and 90 to a targeted therapy arm (25 to A, 31 to P, 26 to T, 5 to E, 3 to RE). Relative to the Doc (median = 7.6 months(m)), overall survival was better for Dur (HR [95%CI]: 0.63 [0.42-0.96], median = 11.6 m). There was no significant difference with targeted therapy versus Doc (HR [95%CI]:1.05 [0.68-1.65], median = 7.0 m). FGFR alterations may be associated with worse prognosis (p = 0.06). Clinical trial information: NCT02154490. **Conclusions:** The outcomes with targeted therapies in these genomically complex tumors suggest limited efficacy and support the efficacy of immunotherapy. FGFR alterations are associated with poor survival. Continued evaluation of novel targets and therapeutics including immunotherapy within LungMAP are planned.

Biomarker	Prevalence	Biomarker + (Median in months)	Biomarker - (Median in months)	HR [95% CI], p-value
PI3K	8%	6.7	6.8	1.0 [0.78-1.29], 0.88
CCGA	19%	6.6	6.9	1.03 [0.85-1.24], 0.81
FGFR	16%	5.4	7.0	1.20 [0.99-1.46], 0.06

Nivolumab (Nivo) + Ipilimumab (Ipi) vs Platinum-Doublet Chemotherapy (Chemo) as First-line (1L) Treatment (Tx) for Advanced Non-Small Cell Lung Cancer (NSCLC): Safety Analysis and Patient-Reported Outcomes (PROs) From CheckMate 227. *First Author: Martin Reck, LungenClinic Grosshansdorf, German Center for Lung Research, Grosshansdorf, Germany*

Background: CheckMate 227 (NCT02477826) is a large phase 3 study of 1L nivo + ipi, nivo, or nivo + chemo vs chemo in advanced NSCLC. The study met its co-primary endpoint demonstrating significantly prolonged progression-free survival with nivo + ipi vs chemo in patients (pts) with tumor mutational burden ≥10 mutations/Mb. The safety profile of 1L nivo + low-dose ipi was consistent with previous reports. Additional detailed analyses may inform the management of immune-related adverse events. **Methods:** Pts (N = 1739) with chemo-naive, stage IV/recurrent NSCLC without known sensitizing *EGFR*/*ALK* mutations were randomized 1:1:1 to nivo (3 mg/kg Q2W) + ipi (1 mg/kg Q6W), nivo monotherapy (240 mg Q2W), or chemo for pts with ≥1% tumor PD-L1 expression and to nivo + ipi, nivo (360 mg Q3W) + chemo, or chemo for pts with < 1% tumor PD-L1 expression. Tx continued until disease progression or unacceptable toxicity for up to 2 yr. Safety and PROs were exploratory endpoints. Safety analyses included time to onset and resolution of select treatment-related adverse events (select TRAEs; those with a potential immunologic cause) and corticosteroid use. PROs were assessed using the Lung Cancer Symptom Scale and EQ-5D instruments. **Results:** Minimum follow-up was 11.2 mo. Median duration of therapy was 4.2 mo with nivo + ipi and 2.6 mo with chemo. Rates of any grade and grade 3–4 TRAEs were 75% and 31% with nivo + ipi, and 81% and 36% with chemo, respectively. TRAEs led to discontinuation in 17% of pts receiving nivo + ipi and in 9% of pts receiving chemo. Most frequent grade 3–4 select TRAEs in pts receiving nivo + ipi were hepatic (8%), endocrine (4%), skin (4%), pulmonary (3%), and gastrointestinal (2%). Median time to onset of select TRAEs ranged from 2–15 wk, and the majority resolved with corticosteroid use (median time to resolution was ≤10 wk). PRO results will be reported in the final presentation. **Conclusions:** In CheckMate 227, nivo + low-dose ipi was well tolerated in NSCLC. Toxicities were manageable with previously established tx algorithms, including corticosteroids. Clinical trial information: NCT02477826.

Health-related quality of life (HRQoL) in the KEYNOTE-189 study of pembrolizumab (pembro) or placebo (pbo) + pemetrexed (pem) + platinum (plt) for metastatic NSCLC. *First Author: Marina Chiara Garassino, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: In the double-blind, phase 3 KEYNOTE-189 study (NCT02578680), pembro + pem + plt significantly improved OS and PFS over pbo + pem + plt as first-line therapy for nonsquamous NSCLC. Grade 3-5 drug-related AE rates were higher with pembro. We report the prespecified patient-reported outcome (PRO) analyses from KEYNOTE-189. **Methods:** 616 patients (pts) were randomized to pembro 200 mg Q3W or pbo for 2 y; all pts received pem + 4 cycles of carboplatin or cisplatin. The EORTC QLQ-C30 and QLQ-LC13 were administered at cycles 1-5, then every 3 cycles during yr 1 and every 4 cycles during yrs 2 and 3. Key PRO outcomes were change from baseline to wks 12 and 21 in the QLQ-C30 global health status/QoL score and time to deterioration in the composite of cough, chest pain, or dyspnea. PROs were analyzed in all treated pts who completed ≥1 PRO instrument (n = 602). *P* values are nominal and 2-sided. **Results:** QLQ-C30 and QLQ-LC13 compliance was ~90% at baseline and wk 12 in both arms and was ~75% with pembro and ~63% with pbo at wk 21. Mean baseline scores were 61.98 and 60.56 in the pembro and pbo arms. At wks 12 and 21, global health status/QoL scores were stable with pembro and decreased with pbo, with significantly greater decrement with pbo at wk 21 (Table). The proportion of improved global health status/QoL was similar at wk 12 (28.9% with pembro vs 26.5% with pbo; $P = .5450$) but was greater with pembro at wk 21 (30.1% vs 22.5%; $P = .0496$). Median time to deterioration in the composite of cough, chest pain, or dyspnea was NR with pembro (95% CI 10.2 mo-NR) vs 7.0 mo (95% CI, 4.8-NR) with pbo (HR 0.81; 95% CI 0.60-1.09; nominal 2-sided $P = .081$). **Conclusions:** In this double-blind trial, pembro + pem + plt maintained or improved HRQoL over pem + plt alone despite a higher grade 3-5 treatment-related AE rate. Along with superior efficacy, these data support the use of pembro + pem + plt as first-line therapy for metastatic nonsquamous NSCLC. Clinical trial information: NCT02578680.

Clinical and molecular features predicting long-term response (LTR) to anti-PD-(L)1 based therapy in patients with NSCLC. *First Author: Hira Rizvi, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The transcendent feature of response to anti-PD-(L)1 therapy is durable, long-term responses, which can last up to years. Much effort in biomarkers has focused exclusively on initial response, but not all responses remain durable. The features predicting which patients will derive long-term response (LTR) may be even more important to identifying with precision those patients who most profoundly benefit from PD-1 blockade. **Methods:** Patients with advanced NSCLC who were treated with anti-PD-(L)1 based therapy from April 2011 through November 2016 were identified. LTR was defined as patients with progression-free survival lasting longer than 18 months. Efficacy was assessed by RECIST v1.1. Tumor mutation burden (TMB) was determined using MSK-IMPACT and PD-L1 expression by IHC. Fisher's exact test was used to compare proportions between two groups and Mann-Whitney *U* to compare continuous variables. **Results:** Of 766 patients with NSCLC treated with anti-PD-(L)1 based therapy, 62 (8%) had LTR. Among those with LTR, 77% had complete/partial response as best response and 68% remain progression-free (median follow up 2.5 years). The median TMB was 12.24 mutations/Mb (n = 32), which represents the 82th percentile of all NSCLC cases profiled by MSK-IMPACT (n = 3000, median 5.66 mutations/Mb). No patient with LTR harbored an EGFR mutation. Of 36 patients with PD-L1 testing, 75% had PD-L1 expression ≥ 1% and 44% had PD-L1 expression ≥ 50%. When compared to patients without LTR, those with LTR were more likely to be smokers (81% vs 92%, p = 0.026), PD-L1 expression > 0% (44% vs 75%, p < 0.001) and ≥ 50% (35% vs 44%, p = 0.01), and TMB > median (54% vs 78%, p = 0.009). When compared to those with transient response (< 18 months), those with LTR had significantly higher TMB (p = 0.002), but not PD-L1 expression (p = 0.44). **Conclusions:** Smoking status, PD-L1 expression, and TMB correlate with long-term response in NSCLC patients treated with anti-PD-(L)1 based therapy. TMB, but not PD-L1 expression, is distinctly increased in those with LTR compared to those with transient response. The features predicting initial response compared to durable response may be distinct.

9023 Poster Discussion Session; Displayed in Poster Session (Board #346), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 11:30 AM-12:45 PM

Randomized phase II study of pembrolizumab after stereotactic body radiotherapy (SBRT) versus pembrolizumab alone in patients with advanced non-small cell lung cancer: The PEMBRO-RT study. *First Author: Willemijn Theelen, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: High dose radiation can lead to increased tumor antigen release, improved antigen presentation and T-cell infiltration. It may therefore enhance the effects of checkpoint inhibition. We evaluated if stereotactic body radiation therapy (SBRT) on a single metastasis preceding pembrolizumab treatment in patients with NSCLC is well tolerated and leads to an increased tumor response. **Methods:** Patients (n = 74) with advanced NSCLC (≥2^{nd} line) regardless of PD-L1 status were randomized (1:1) between pembrolizumab (200mg q3w) alone (control arm) or pembrolizumab preceded by SBRT (3x8Gy within 7 days prior to the first cycle) on a single metastasis (experimental arm). Sequential biopsies were obtained from the same, non-irradiated tumor site at baseline and after two cycles of pembrolizumab. The primary endpoint was improvement in overall response rate (ORR) at 12 weeks from 20% in the control arm to 50% in the experimental arm according to RECIST 1.1. **Results:** From July 2015 until the time of writing, 72 patients had been randomized and 64 patients who received at least one cycle of pembrolizumab could be evaluated for the primary endpoint. ORR at 12 weeks was 19% in the control arm (n = 32) vs 41% in the experimental arm (n = 32); the number of patients with a CR, PR, SD and PD were 0/6/7/19 and 1/12/6/13, respectively. Median PFS was 1.8 months in the control arm vs 6.4 months in the experimental arm; HR 0.55 (CI 0.31 – 0.98, p = 0.04). Grade ≥3 toxicity was experienced in 22% of patients in the control arm vs 17% in the experimental arm. The most common AEs were fatigue, nausea, fever and hypothyroidism. No increase in treatment related toxicity was observed in the experimental arm. **Conclusions:** With 86% of patients evaluable, we conclude that pembrolizumab preceded by SBRT resulted in a doubling of the ORR without increase in toxicity. The primary endpoint of 50% DCR was not (yet) met. This is a well-tolerated and promising treatment strategy to augment the anti-tumor immune response with checkpoint blockade. Definitive results as well as correlations with PD-L1 expression will be available and discussed at ASCO. Clinical trial information: NCT02492568.

9024 Poster Session (Board #347), Sun, 8:00 AM-11:30 AM

Quality of life analysis of Pemetrexed versus Erlotinib maintenance in EGFR mutation negative advanced non small cell lung cancer. *First Author: Vivek Agarwala, Tata Memorial Centre, Mumbai, India*

Background: Both Pemetrexed and Erlotinib have shown survival benefit when used as maintenance therapy in advanced non small cell lung cancer (NSCLC) after platinum doublet chemotherapy. Hence this study was planned to compare the outcomes between the 2 drugs. The current abstract is focused on quality of life (QOL) results. **Methods:** This was a open label, randomized, phase 3 study done in adult palliatively treated EGFR-negative, NSCLC patients who had non progressive disease post administration of first line chemotherapy Pemetrexed-Carboplatin. Patients were 1:1 randomized between tablet Erlotinib 150 mg orally administered once daily versus injection Pemetrexed 500 mg/m2 administered intravenously every 3 weeks. The therapy was continued either till disease progression or development of intolerable side effects. The primary endpoint was to compare the QOL between the 2 arms at 3 months. Other secondary endpoints were to study and compare the progression free survival (PFS), overall survival (OS) and adverse event rate. We had 200 patients in this study and the sample size had 80% power, with type 1 error of 5% to detect a difference of 0.3 in effect size. **Results:** Total 200 patients were recruited in the study. The median follow up was 25.37 months (95%CI 21.4-29.3 months). There was no difference in global QOL between the 2 arms at 3 months (p=0.384). There was no difference in any domain of QOL except a higher score for diarrhea was seen in the Erlotinib arm (p=0.001). The PFS (HR 0.99; 95% CI 0.73-1.34, p=0.939) and OS (HR 0.88; 95%CI 0.62-1.27, p=0.493) were similar between both the arms. **Conclusion:** Maintenance Pemetrexed post Pemetrexed-Platinum chemotherapy fails to improve QOL or time to event outcomes (OS & PFS) over maintenance Erlotinib in EGFR mutation negative advanced NSCLC. Clinical trial information: CTRI/2014/08/004847.

9025 Poster Session (Board #348), Sun, 8:00 AM-11:30 AM

A randomized phase 3 study of abemaciclib versus erlotinib in previously treated patients with stage IV NSCLC with *KRAS* mutation: JUNIPER. *First Author: Jonathan Wade Goldman, UCLA Medical Center, Los Angeles, CA*

Background: Approximately 30% of NSCLC tumors harbor *KRAS* mutations, for which there is no specific treatment. Abemaciclib is a potent and selective inhibitor of CDK4 & 6 approved for treatment of HR+, HER2- advanced breast cancer. In a Phase 1 study, abemaciclib showed greater clinical activity in patients with advanced NSCLC with *KRAS* mutant tumors versus *KRAS* wild type tumors. This study compared abemaciclib with erlotinib, both with best supportive care, in previously treated patients with advanced NSCLC and *KRAS* mutations. **Methods:** This was a global, Phase 3, comparator-controlled, multicenter, open-label trial for patients with confirmed stage IV NSCLC, detectable *KRAS* mutations in codons 12 or 13, with progressive disease after platinum-based chemotherapy and 1 additional line of therapy, measurable disease by RECIST v1.1, ECOG performance status 0-1, and adequate organ function. Patients were randomized 3:2 to receive either abemaciclib 200 mg PO Q12H or erlotinib 150 mg PO Q24H until disease progression or unacceptable toxicity. Primary objective was overall survival (OS). Secondary objectives included progression-free survival (PFS), objective response rate (ORR, complete response + partial response), and safety and tolerability. **Results:** A total of 453 patients were randomized, 270 to abemaciclib and 183 to erlotinib. Median OS was 7.4 months with abemaciclib and 7.8 months with erlotinib (HR [95% CI]: 0.97 [0.77, 1.22]; stratified log-rank, p = 0.77). Median PFS was 3.6 months with abemaciclib and 1.9 months with erlotinib (HR [95% CI]: 0.58 [0.47, 0.72]; stratified log-rank, $p < 0.001$). The ORR was 8.9% (95% CI: 5.5, 12.3%) with abemaciclib and 2.7% (0.4, 5.1%) with erlotinib (p = 0.01). The disease control rate was 54.4% (95% CI: 48.5, 60.4%) with abemaciclib and 31.7% (25.0, 38.4%) with erlotinib. There were no new safety signals with abemaciclib in this study. **Conclusions:** In previously treated patients with stage IV NSCLC harboring *KRAS* mutations, abemaciclib did not improve OS but demonstrated improvement in PFS and ORR compared with erlotinib. Further molecular subgroup analysis based on abemaciclib's mechanism of action is underway. Clinical trial information: NCT02152631.

9026 Poster Session (Board #349), Sun, 8:00 AM-11:30 AM

24-month overall survival from KEYNOTE-021 cohort G: Pemetrexed-carboplatin plus pembrolizumab as first-line therapy for advanced nonsquamous NSCLC. *First Author: Ryan D. Gentzler, University of Virginia, Charlottesville, VA*

Background: Cohort G of the phase 1/2 KEYNOTE-021 study (NCT02039674) evaluated pembrolizumab (pembro) + pemetrexed and carboplatin (PC) vs PC in first-line advanced nonsquamous NSCLC. With median follow-up of 10.6 mo, ORR (estimated treatment difference, 26%; $P = 0.0016$) and PFS (HR, 0.53; $P = 0.010$) significantly improved with pembro + PC vs PC. The HR for OS was 0.90 (95% CI, 0.42–1.91). We present results after approximately 2 y of follow-up. **Methods:** Pts with previously untreated stage IIIB/IV nonsquamous NSCLC without *EGFR* mutations/*ALK* translocations were randomized 1:1 to 4 cycles of carboplatin AUC 5 mg/mL/min + pemetrexed 500 mg/m^2 Q3W with or without pembro 200 mg Q3W for 2 y (maintenance pemetrexed permitted in both arms). Eligible pts with radiologic disease progression could cross over from PC to pembro. Response was assessed by BICR per RECIST v1.1. Primary endpoint was ORR; PFS and OS were secondary endpoints. *P* values are nominal. **Results:** 123 pts were randomized. As of Dec 1, 2017, median follow up was 23.9 mo (range, 0.8–35.1 mo). 11 pts in the pembro + PC arm and 2 in the PC arm completed randomized treatment. Among pts in the PC arm who discontinued/completed, 41/56 (73%) subsequently received anti–PD-(L)1 agents, including 26 who crossed over to pembro on study. ORR was 57% with pembro + PC vs 30% with PC ($P = 0.0016$). PFS was significantly improved with pembro + PC vs PC (HR, 0.53; 95% CI, 0.33–0.86; $P = 0.0049$). Median (95% CI) PFS was 24.0 (8.5–NR) mo for pembro + PC vs 9.3 (6.2–14.9) mo for PC. HR for OS was 0.56 (95% CI, 0.32–0.95; $P = 0.0151$). Median (95% CI) OS was not reached (24.5 mo–NR) for pembro + PC and 21.1 (14.9–NR) mo for PC; 24-mo OS rates were 67% and 48%, respectively. Grade 3–5 treatment-related AE incidence was 41% with pembro + PC vs 27% with PC. 3 pts had treatment-related fatal AEs (pembro + PC, n = 1; PC, n = 2). **Conclusions:** After median follow-up of approximately 24 mo, the risk of death for pembro + PC vs PC was reduced by nearly half (HR, 0.56; nominal $P = 0.0151$) despite a high crossover rate among patients in the PC arm. Improvements in PFS and ORR persisted, and median PFS in the pembro + PC arm was 24.0 mo compared to 9.3 mo in the PC alone arm. Clinical trial information: NCT02039674.

9027 Poster Session (Board #350), Sun, 8:00 AM-11:30 AM

Early clearance of plasma EGFR mutations as a predictor of response to osimertinib in the AURA3 trial. *First Author: Frances A. Shepherd, University Health Network, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: In the Phase III AURA3 trial (NCT02151981), osimertinib, a third-generation EGFR-TKI, had significantly greater efficacy than platinum-pemetrexed in patients (pts) with advanced NSCLC and T790M-mediated acquired resistance to first-line EGFR-TKI. We investigate whether the presence of plasma EGFR mutations at 3 and 6 wks post-osimertinib treatment (80 mg, once daily) is associated with clinical outcomes, and identify pre-existing genomic aberrations that may impact outcomes. **Methods:** EGFR mutation analysis (Ex19del/L858R/T790M) was conducted at baseline, wks 3 and 6, by droplet digital (dd)PCR (Biodesix). Next generation sequencing (NGS, Guardant Health; 73 genes) was conducted on baseline plasma samples to explore mechanisms of innate resistance. Clinical outcomes (median progression-free survival [mPFS], objective response rate [ORR]) were investigator assessed, per RECIST 1.1. **Results:** Of 207 pts with a valid plasma ddPCR result at baseline (all T790M+), 150 had detectable EGFR-TKI sensitizing mutations (EGFRm; Ex19del/L858R) and 57 did not. mPFS was 14.0 mo (95% CI 12.4, not calculable) in pts without detectable baseline EGFRm vs 8.3 mo (95% CI 6.9, 10.9) in pts with detectable baseline EGFRm; EGFRm allelic fraction in baseline plasma was not related to ORR or mPFS. Of the 129 pts with baseline EGFRm and evaluable plasma samples at wk 3, 48 had detectable EGFRm (EGFRm+) and 81 had undetectable EGFRm (EGFRm-). mPFS was 5.7 mo (95% CI 4.1, 9.7) in pts EGFRm+ vs 10.9 mo (95% CI 8.3, 12.7) in pts EGFRm-; hazard ratio (HR) 2.0 (95% CI 1.3, 3.2), p = 0.001; HR > 1 favors pts EGFRm-. ORR was 50% vs 82%, respectively. A similar trend was observed at wk 6 (n = 132): PFS, HR 2.8 (95% CI 1.8, 4.3), $p < 0.0001$. NGS of baseline plasma showed no association between pre-existing genomic aberrations (*TP53*, *BRAF*, *KRAS*, *MET/HER2* amp) and clinical outcome; additional analyses are ongoing. **Conclusions:** In pts with tissue T790M+ NSCLC and detectable baseline plasma EGFRm, continued presence of EGFRm at wks 3 and 6 was associated with less favorable outcomes with osimertinib. Early dynamic changes of plasma EGFR mutations may predict clinical outcome in pts receiving osimertinib for T790M+ NSCLC. Clinical trial information: NCT02151981.

9028 Poster Session (Board #351), Sun, 8:00 AM-11:30 AM

Association of STK11/LKB1 mutations with primary resistance to PD-1/PD-L1 axis blockade in PD-L1 positive non-squamous NSCLC. *First Author: Ferdinandos Skoulidis, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The genomic determinants of response to PD-1/PD-L1 axis blockade in non-squamous NSCLC are incompletely understood. We previously identified *STK11/LKB1* alterations as a major genomic driver of low tumor cell PD-L1 expression and primary resistance to PD-1 inhibitors in *KRAS*-mutant lung adenocarcinoma. A critical unanswered question is whether *STK11/LKB1* alterations predict for lack of response to PD-1/PD-L1 blockade independently of PD-L1 expression. Here, we report the impact of *STK11/LKB1* alterations on clinical outcomes with PD-1/PD-L1 inhibitors in PD-L1-positive non-squamous NSCLC. **Methods:** 66 patients with non-squamous NSCLC treated with PD-1/PD-L1 inhibitors at MDACC (61% pembrolizumab, 24% nivolumab, 8% atezolizumab, 5% durvalumab/tremelimumab) with available *STK11/LKB1* NGS-based genomic profiling and positive tumor cell PD-L1 expression (≥1%, based on the FDA-approved 22C3 pharmDx assay) were identified retrospectively. Response assessment was based on RECIST1.1. **Results:** In this PD-L1-positive population of non-squamous NSCLC, *STK11/LKB1* alterations were associated with significantly lower ORR to PD-1/PD-L1 blockade compared to tumors with intact *STK11/LKB1* status (ORR 0% versus 34.5%, P = 0.026). *STK11/LKB1*-mutant tumors exhibited significantly shorter progression-free survival (mPFS 1.7 months versus 19.3 months, HR 4.76, 95% CI 2.0-11.1, P = 0.00012, log-rank test) and overall survival (mOS 11.1 months versus 26.5 months, HR 14.3, 95% CI 3.4-50.0, P < 0.0001, log-rank test) with PD-1/PD-L1 blockade. Although fewer *STK11/LKB1*-mutant tumors expressed high (≥50%) levels of PD-L1 (45.5% versus 61.8%), the difference did not reach statistical significance (P = 0.5). **Conclusions:** *STK11/LKB1* genomic alterations are associated with *de novo* resistance to PD-1/PD-L1 inhibitors even among PD-L1-positive non-squamous NSCLC patients, suggesting that their effect is at least partially independent of PD-L1 expression. Evaluation of *STK11/LKB1* genomic status may enhance the predictive utility of a composite PD-1/PD-L1-inhibitor predictive biomarker panel incorporating PD-L1 expression and TMB.

9029 Poster Session (Board #352), Sun, 8:00 AM-11:30 AM

Meta-analysis exploring the effect of oncogenic driver mutations on outcome of metastatic non-small cell lung cancer (mNSCLC) patients (pts) treated with immune checkpoint inhibitors (ICI) or docetaxel (doc). *First Author: Abena Agyeman, U.S. Food and Drug Administration, Silver Spring, MD*

Background: Recent reports suggest that pts with mNSCLC with tumor EGFR mutations (EGFRm) receiving ICI as second line-plus (2L+) therapy may have better clinical outcomes with doc compared to ICI. We aimed to further investigate the role of ICI in pts with oncogenic driver mutations. **Methods:** We performed a patient-level meta-analysis on 4 randomized controlled, 2L+ trials of ICI versus doc controlling for EGFRm status, PD-L1 status, as well as common prognostic factors (e.g. race). A separate analysis was performed to assess the effect of KRASm, excluding EGFRm as a covariate. If EGFRm or KRASm status was unknown, pts were excluded from these analyses. A Cox proportional hazards model stratified by trial was used to estimate hazard ratios (HR) for EGFRm and KRASm. Median OS was estimated using Kaplan-Meier methods on aggregate data. **Results:** Treatment effect was evaluable in 2752 patients; 76% had EGFR mutation data and 17 % had KRAS mutation data. Of the 2078 pts with known EGFR status, 246 (12%) had EGFRm and 1832 (88%) had EGFR wildtype (wt). Of the 477 pts with known KRAS status, 136 (29%) had KRASm and 341 (71%) had KRASwt. The results of subgroup comparisons are summarized in the table. **Conclusions:** Pts with EGFRwt tend to have better outcomes than pts with EGFRm when treated with ICI. Pts with EGFRm may have longer OS when treated with doc than ICI, although this finding is inconclusive. The KRAS data is limited by small numbers, but it appears that KRASwt derive the expected benefit from ICI. Future studies should include full data capture of key oncogenic driver status on all NSCLC pts, and clarify the role of ICI on different biomarker subsets.

Subgroup comparison	Median OS; HR (95% CI)
EGFRm vs EGFRwt (Doc)	12.8 vs. 9.3; 0.86 (0.65, 1.13)
EGFRm vs EGFRwt (ICI)	9.4 vs. 12.8; 1.40 (1.10, 1.78)
ICI vs Doc (EGFRwt)	12.8 vs. 9.3; 0.72 (0.60, 0.87)
ICI vs Doc (EGFRm)	9.4 vs. 12.8; 1.18 (0.83, 1.68)
KRASm vs KRASwt (Doc)	8.8 vs. 11.0; 1.29 (0.92, 1.80)
KRASm vs KRASwt (ICI)	14.3 vs. 12.1; 0.79 (0.54, 1.16)
ICI vs Doc (KRASwt)	12.1 vs. 11.0; 0.64 (0.41, 0.99)
ICI vs Doc (KRASm)	14.3 vs. 8.8; 1.03 (0.75, 1.41)

9030 Poster Session (Board #353), Sun, 8:00 AM-11:30 AM

4-year overall survival for patients with advanced NSCLC treated with pembrolizumab: Results from KEYNOTE-001. *First Author: Enriqueta Felip, Vall d'Hebron University Hospital, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain*

Background: Pembrolizumab (pembro) has shown antitumor activity in patients (pts) with advanced NSCLC and is standard-of-care therapy for pts with PD-L1–expressing tumors (first-line, TPS ≥50%; previously treated, TPS ≥1%). KEYNOTE-001, an open-label phase 1b study, evaluated pembro monotherapy in treatment-naive or previously treated pts with advanced NSCLC (NCT01295827). We report a 4-y update of KEYNOTE-001. **Methods:** Pts had confirmed locally advanced/metastatic NSCLC and provided a contemporaneous tumor tissue sample for evaluation of PD-L1 levels by IHC using the 22C3 antibody. Pts received pembro 2 mg/kg Q3W or 10 mg/kg Q2W or Q3W. Primary efficacy endpoint was ORR. OS was a secondary endpoint. **Results:** As of data cutoff (Sep 1, 2017), among 550 pts enrolled (treatment-naive, n = 101; previously treated, n = 449), median (range) follow-up was 46.5 (37.7–63.8) mo. ORR (by investigator per irRC) was 41.6 % (95% CI, 31.9–51.8) for treatment-naive pts and 22.9% (95% CI, 19.1–27.1) for previously treated pts. Median OS was 22.3 mo (95% CI, 17.1–32.3) for treatment-naive pts and 10.5 mo (95% CI, 8.6–13.2) for previously treated pts; estimated 4-y OS rates were 27.2% and 16.4 %, respectively. Kaplan-Meier curves for OS appeared to plateau after 42 mo for treatment-naive pts and 36 mo for previously treated pts. Increased PD-L1 expression was associated with improved OS (Table). Immune-mediated AEs occurred in 24.8% of treatment-naive and 17.4% of previously treated pts. No additional grade 5 treatment-related AEs occurred (compared with 3-y follow-up; data cutoff Sep 1, 2016). **Conclusions:** Pembro provides long-term OS benefit for both treatment-naive and previously treated advanced NSCLC that expresses PD-L1. These data represent the longest efficacy and safety follow-up for pts with advanced NSCLC treated with pembro. Clinical trial information: NCT01295827.

OS in subgroups defined by PD-L1 TPS.

	Treatment-Naive (N = 101)			Previously Treated (N = 449)		
	n	Median (95% CI), mo	Est. 4-y rate	n	Median (95% CI), mo	Est. 4-y rate
TPS ≥50%	27	35.4 (20.3–NE)	48.1%	138	15.4 (10.6–18.8)	24.8%
TPS 1%–49%	52	19.5 (10.7–26.3)	NE	168	8.5 (6.0–12.6)	15.6%
TPS ≤1%		Not reported*		90	8.6 (5.5–10.6)	6.5%

NE = not estimable. *Due to small pt numbers (n = 12).

9031 Poster Session (Board #354), Sun, 8:00 AM-11:30 AM

Economic impact of next generation sequencing vs sequential single-gene testing modalities to detect genomic alterations in metastatic non-small cell lung cancer using a decision analytic model. *First Author: Nathan A. Pennell, Cleveland Clinic, Cleveland, OH*

Background: Metastatic non-small cell lung cancer (mNSCLC) patients (pts) should be tested for genomic alterations (GA) to inform treatment decisions. This study assesses the economic impact of next generation sequencing (NGS) vs sequential single-gene testing modalities for Center for Medicare and Medicaid Services (CMS) Medicare and US commercial payers. **Methods:** In a decision analytic model, newly diagnosed mNSCLC pts were modeled to receive PD-L1 and GA tests (*EGFR*, *ALK*, *ROS1*, *BRAF*, *MET*, *HER2*, *RET*, *NTRK1*) using 1) sequential tests, 2) exclusionary mutation (*KRAS*) test followed by sequential tests 3) panel test or 4) upfront NGS, including all GAs and *KRAS*. Pts in modalities 1-3 were tested for GAs with currently approved treatment (*EGFR, ALK, ROS1, BRAF*) followed by single-gene tests or NGS for other GAs (e.g., *HER2*); a proportion were assumed to need rebiopsy. Inputs included turnaround time, unit costs and mNSCLC prevalence based on literature, public data and expert opinion. Time to receive results and total cost (test + rebiopsy) were calculated for each modality and compared with NGS. **Results:** For hypothetical 1 million-member plans, an estimated 2,066 CMS Medicare and 156 commercially insured mNSCLC pts would be tested for GA. Estimated time to receive results was 2.0 weeks for NGS and panel, 2.7 and 2.8 weeks faster than exclusionary and sequential, respectively. Using CMS reimbursement, NGS represented savings of $1,393,678 vs exclusionary, $1,530,869 vs sequential and $2,140,795 vs panel. For commercial payers, NGS remained the least expensive by $3,809 (vs exclusionary) to $250,842 (vs panel). **Conclusions:** Our model estimated that upfront NGS leads to the same (as panel) or shorter (vs exclusionary and sequential testing) wait time for results and the lowest payer cost to establish GA status for newly diagnosed mNSCLC pts to inform treatment decisions.

	Sequential	Exclusionary	Panel	NGS
CMS Medicare N = 2 066				
Total cost	3 721 368	3 584 177	4 331 295	2 190 499
Savings with NGS	1 530 869	1 393 678	2 140 795	
Commercial N = 156				
Total cost	747 771	624 178	871 211	620 369
Savings with NGS	127 402	3 809	250 842	

9032 Poster Session (Board #355), Sun, 8:00 AM-11:30 AM

Lorlatinib in patients (Pts) with previously treated ALK$^+$ advanced non-small cell lung cancer (NSCLC): Updated efficacy and safety. *First Author: Benjamin Besse, Gustave Roussy Cancer Campus and University Paris-Sud, Villejuif, France*

Background: Despite advancement of 2nd generation (gen) ALK tyrosine kinase inhibitors (TKIs), ALK$^+$ NSCLC pts continue to develop resistance and CNS metastases (mets) become more difficult to manage. Lorlatinib, a potent brain-penetrant 3rd gen ALK/ROS1 TKI, has shown robust clinical activity in ALK$^+$ or ROS1$^+$ NSCLC pts, most of whom had CNS mets and failed ≥1 ALK TKI. **Methods:** This ongoing ph 2 study (NCT01970865) enrolled 275 pts with ALK$^+$ or ROS1$^+$ advanced NSCLC ± CNS mets in cohorts (ALK: EXP 1–5; ROS1: EXP 6) based on prior treatment; starting dose was lorlatinib 100 mg QD. Antitumor activity (by independent central review per RECIST 1.1), safety and biomarkers were evaluated. **Results:** In 198 ALK$^+$ pts assessed for antitumor activity (ITT population) in pooled subgroups (EXP 2–3A [only prior crizotinib ± chemotherapy (CT)], EXP 3B [only 1 prior 2nd gen ALK TKI ± CT], and EXP 4–5 [2 or 3 prior ALK TKIs ± CT]), lorlatinib led to rapid (median time to response 1.4 mo) deep and durable systemic and intracranial (IC) responses (Table). Of a total 139 pts in EXP 3B + EXP 4–5, 62, 47 and 8 received alectinib, ceritinib and brigatinib, respectively, as last ALK TKI prior to lorlatinib. Additional efficacy, including PFS, in all cohorts will be presented. The most common treatment-related AEs (TRAEs) and grade 3/4 TRAEs across all cohorts (N = 275) were hypercholesterolemia (84%/16%) and hypertriglyceridemia (66%/16%); 32% and 24% of pts had TRAEs that led to dose delays and reductions, respectively. No treatment-related deaths occurred; TRAEs led to permanent discontinuation in 8 pts. Antitumor activity was seen across a range of *ALK* resistance mutations, eg G1202R and G1202del. Clinical trial information: NCT01970865. **Conclusions:** Lorlatinib showed clinically meaningful benefit in ALK$^+$ NSCLC pts with ≥1 prior ALK TKI and was generally tolerable with AEs managed by dose modification or supportive therapy.

YH25448, a 3rd generation EGFR-TKI, in patients with EGFR-TKI-resistant NSCLC: Phase I/II study results. *First Author: Byoung Chul Cho, Severence Hospital, Seou, Republic of Korea*

Background: The epidermal growth factor receptor (EGFR) T790M mutation is one of the most common acquired resistance mechanism to EGFR tyrosine kinase inhibitors (TKIs). YH25448 is an oral, potent, irreversible EGFR TKI that is highly selective for activating (EGFRm) and T790M resistance mutations. **Methods:** Patients with EGFRm advanced NSCLC with acquired resistance to EGFR-TKIs with or without asymptomatic brain metastases were enrolled in an open-label, multicenter, phase I/II study with dose escalation and expansion cohorts. YH25448 was administered once daily at doses of 20 to 240 mg in a 21 day cycle. Patients were assessed for safety, tolerability, pharmacokinetics and efficacy. T790M status was confirmed in the expansion cohorts. **Results:** A total of 105 patients (median age 62 years, female 61%) were enrolled. The dose escalation cohort included 33 patients administered with 20 to 240 mg once daily across 6 dose levels, and 72 patients in the dose expansion cohort were administered with 40 to 240 mg. No dose-limiting toxicities were observed. The most common treatment-emergent adverse events (AEs) were pruritus (12%), decreased appetite (11%), rash (11%), and constipation (10%). AEs of grade 3 or higher were observed in 5% of the patients. Systemic exposure increased dose-dependently. Of the evaluable patients (n = 91) at data cut-off, the objective response rate (ORR) was 64% (95% confidence interval [CI], 53.0 to 73.6). The ORR for 76 of the T790M-positive patients was 67% (95% CI, 55.4 to 77.5), and for 15 of the T790M-negative patients was 47% (95% CI, 21.3 to 73.4). In patients with brain metastases (n = 9), the overall intracranial ORR was 56% (95% CI, 21.2 to 86.3). **Conclusions:** YH25448 was well tolerated and exhibits promising systemic and intracranial antitumor activity at multiple dose levels in EGFR T790M+ NSCLC patients. Clinical trial identifier: NCT03046992.

9034 Poster Session (Board #357), Sun, 8:00 AM-11:30 AM

***RET*-rearranged lung cancers: Immunophenotype and response to immunotherapy.** *First Author: Joshua K. Sabari, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: In patients with *RET*-rearranged lung cancers, multikinase inhibitors (e.g. cabozantinib and vandetanib) and specific (e.g. pemetrexed-containing) chemotherapy regimens have documented activity. In contrast, PD-L1 expression, tumor mutational burden (TMB), and the treatment outcomes of immunotherapy are not well characterized in this genomic subset. **Methods:** Patients with a pathologically confirmed diagnosis of lung cancer harboring a *RET* rearrangement were identified between January 2012 and December 2017. PD-L1 expression was determined by IHC (E1L3N Clone). TMB was calculated in tumors that underwent NGS (Mutations/Mb, MSK-IMPACT). Objective response rate (ORR) to immunotherapy was evaluated by RECIST. **Results:** 74 patients with *RET*-rearranged lung cancers were identified. The median age was 63 (range 34-80 years), 55% were women, and 68% were never smokers. The majority (97%) had adenocarcinoma and 85% had metastatic disease. In patients with sufficient tissue for analysis, tumor PD-L1 expression was as follows: PD-L1 ≥50% in 21% (5/24, 95% CI 5-37%), PD-L1 1-49% in 25% (6/24, 95% CI 8-42%), and PD-L1 0% in 42% (13/24, 95% CI 22-62%). The median TMB of *RET*-rearranged lung cancers was 3.3 Mt/Mb (range 0.82-9.84, n = 43) and lower than the median TMB of 5.7 Mt/Mb in unselected NSCLCs (n = 1,769, $p < 0.001$). 12 patients received PD-1/PD-L1 blockade and 1 patient received 2 lines: pembrolizumab (6), nivolumab (4), atezolizumab (2), and durvalumab (1). ORR by RECIST was 0% (0/5 evaluable). The median duration of therapy was 1.4 months (m) (range 0.5-8.7m). Responses were not enriched in those with positive PD-L1 expression (≥1%) nor in those with TMB > median of all NSCLCs. The overall survival of patients who received immunotherapy did not differ from patients who did not receive immunotherapy (n = 51): 18.2 vs 17.9m, p = 0.6. **Conclusions:** While PD-L1 expression occurs in a substantial proportion of *RET*-rearranged lung cancers, TMB is lower compared to unselected lung cancers, and response to immunotherapy is poor. RET-directed targeted therapy strategies and platinum doublet chemotherapy should be considered prior to single-agent immunotherapy.

9035 Poster Session (Board #358), Sun, 8:00 AM-11:30 AM

Multi-kinase RET inhibitor vandetanib combined with mTOR inhibitor everolimus in patients with RET rearranged non-small cell lung cancer. *First Author: Vivek Subbiah, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: *RET* fusions (RET+) occur in 1-2% of NSCLCs. Tumors eventually become refractory to multi-kinase RET inhibitor monotherapy. We evaluated the pre-clinical and clinical activity of the combination of Vandetanib (V), an inhibitor of RET, VEGF, and EGFR, and the mTOR inhibitor everolimus (E). **Methods:** Clinical activity of V + E was evaluated in pts with advanced NSCLC in a Phase 1 trial. V and E were administered orally QD in a 28 day cycle. Responses were assessed by RECIST 1.1. RET fusions were detected by FISH and/or or Next generation sequencing (NGS) in tumor tissue and/or plasma. Preclinical studies were performed using the *CCDC6-RET* + LC-2/ad NSCLC cells. **Results:** Among 19 stage IV NSCLC pts enrolled, median age was 59 yrs & 8 pts (42%) were males. 13 pts (93%) were RET+ by NGS and/or FISH. Concordance rate between the two tests was 40%. The overall ORR in 13 RET+ pts was 54% (7 PR). The ORR in RET+ by NGS was 70% (7 PR/10 patients) while the ORR in FISH+ patients was 20% (1 PR/5 patients). No responses were seen in NGS-/FISH+ patients (0/3 = 0%). The combination was active in RET+ NSCLC brain metastases (3/3) and in a cabozantinib progressor. The median PFS of all 13 RET+ patients was 4.4 months (95% CI 3.4, NR); the median PFS of RET NGS+ patients (n = 10) was 8 months (95% CI 0.1, 1.1). Grade 3/4 toxicities included diarrhea (21%), thrombocytopenia (16%), QTc prolongation (5%) and rash (5%). 17/ 19 (89%) pts required dose modifications after cycle 1 due to toxicity. Preclinical studies demonstrated that resistance to RET inhibition was associated with activation of the EGFR, VEGFR, and downstream mTOR pathways and that the combination of everolimus with the RET/VEGFR/EGFR inhibitor vandetanib abrogated this resistance in preclinical models. **Conclusions:** V+E has significant activity in RET+ NSCLC identified by NGS, with an ORR of 70% and a median PFS of 8 months. Preclinical data shows the V+E combination to be superior to either drug alone and may target potential resistance pathways. The combination merits further investigation in RET+ NSCLC. Clinical trial information: NCT01582191.

9036 Poster Session (Board #359), Sun, 8:00 AM-11:30 AM

Efficacy and safety of entinostat (ENT) and pembrolizumab (PEMBRO) in patients with non-small cell lung cancer (NSCLC) previously treated with anti-PD-(L)1 therapy. *First Author: Leena Gandhi, NYU Perlmutter Cancer Center, New York, NY*

Background: Treatment options are limited in pts who progress on anti-PD-(L)1 therapy. HDAC inhibitors have the potential to modulate myeloid-derived suppressor cell (MDSC) function and may synergize with PD-(L)1 inhibition. We report the preliminary results of a Phase 2 trial of entinostat (ENT), a class I selective histone deacetylase (HDAC) inhibitor, plus pembrolizumab (PEMBRO) in patients with NSCLC previously treated with anti-PD-(L)1 therapy. **Methods:** ENCORE-601 is an open-label study evaluating the combination of ENT + PEMBRO in pts with recurrent or metastatic NSCLC and prior progression on anti-PD-1/PD-L1 therapy. Pts were eligible irrespective of histology or baseline PD-L1 expression. Pts were treated with ENT 5 mg PO weekly and PEMBRO 200 mg IV Q3W. The primary endpoint was ORR as assessed by irRECIST. The study was designed as a Simon 2-stage study such that if 3 of 31 pts responded in Stage 1, the study would enroll up to 56 pts. The study was further revised to accrue up to 70 patients to increase statistical power and decrease Type I error. Tumor biopsies and blood samples for immune correlates were taken pre- and on-treatment in a subset of patients. **Results:** Of the first 57 patients enrolled, 17 had refractory disease to prior to PD-(L)1 therapy, and only 2 had a documented prior response. Median duration of prior PD-(L)1 therapy was $<$ 6 months and the median time from last dose of prior PD-(L)1 therapy was 65 days. To ENT + PEMBRO, 5 of 57 patients achieved a confirmed PR (ORR = 9%, 95% CI: 2.9-19.3). Of the responders, 4 had PD-L1 expression $<$ 1% in tissue collected at baseline. The median duration of response is 4.2 months, with 3 responders ongoing. 20 pts (35.1%) experienced Grade 3/4 related AEs; 6 pts (10.5%) experienced Grade 3/4 related irAEs (3 events of pneumonitis). The most frequent ($>$ 15%) related AEs (irrespective of grade) include fatigue, anemia, decreased appetite, and diarrhea. Evaluation of gene expression and circulating immune cells to identify biomarkers of response is in progress. **Conclusions:** ENT + PEMBRO demonstrated anti-tumor activity and acceptable safety in patients with NSCLC who have progressed on prior PD-(L)1 blockade. Clinical trial information: NCT02437136.

9037 Poster Session (Board #360), Sun, 8:00 AM-11:30 AM

Comparison of outcomes with PD-L1 tumor proportion score (TPS) of 50-74% vs 75-100% in patients with non-small cell lung cancer (NSCLC) treated with first-line PD-1 inhibitors. *First Author: Elizabeth Jimenez Aguilar, Dana-Farber Cancer Institute, Boston, MA*

Background: Among patients with NSCLC and a PD-L1 TPS $\geq$50%, the response rate to the PD-1 inhibitor pembrolizumab is ~45%. Whether certain subsets of patients with a PD-L1 TPS $\geq$50% are more likely to benefit from treatment with a PD-1 inhibitor is currently unknown. We compared outcomes among NSCLC patients treated with first-line PD-1 inhibitors and different PD-L1 TPS groupings: 50-74% vs 75-100%. **Methods:** We retrospectively analyzed patients who received a PD-1 inhibitor as first-line treatment for NSCLC with a PD-L1 TPS of $\geq$50% from the Dana-Farber Cancer Institute and Memorial Sloan Kettering Cancer Center. Clinicopathologic characteristics and clinical outcomes were compared among patients with a PD-L1 TPS of 50-74% vs 75-100%. Event-time distributions were estimated using Kaplan-Meier and compared with the log-rank test. **Results:** 112 patients were identified for inclusion in this study: 39.3% (N = 44) had a PD-L1 TPS of 50-74%, and 60.7% (N = 68) had a TPS of 75-100%. There were no significant differences in smoking history, histology, sex, *KRAS* or *EGFR* mutation status, and age between both groups of patients. In the entire cohort, the overall response rate (ORR) was 33.9%, median progression-free survival (mPFS) was 4.2 months (95% CI: 2.8-6.2), median overall survival (mOS) was 20.3 months (95% CI: 17.7-NR). Patients with TPS 75-100% had a significantly higher ORR (13.6% vs 47.1%, P $<$ 0.01), significantly longer mPFS (2.5 mo [95% CI: 1.8-4.5] vs 5.1 mo [95% CI: 3.8-7.4], P = 0.02), and higher estimated 12-month OS (76.4% vs 54.4%) compared to patients with TPS 50-74%. **Conclusions:** In the first-line setting for NSCLC, higher PD-L1 TPS levels of 75-100% is associated with improved clinical outcomes compared to patients with a TPS of 50-74%.

9038 Poster Session (Board #361), Sun, 8:00 AM-11:30 AM

Gemcitabine-cisplatin (GC) + necitumumab (N) versus GC as first-line treatment for stage IV squamous cell lung cancer (SqCLC): An open-label randomized multicenter phase Ib-II trial in Japan. *First Author: Hiroshige Yoshioka, Department of Respiratory Medicine, Kurashiki Central Hospital, Kurashiki, Japan*

Background: A randomized global phase III trial (SQUIRE) demonstrated statistically significant improvement in OS and PFS for GC+N versus GC in patients (pts) with advanced SqCLC. **Methods:** Phase Ib part was a single arm (GC+N) study to determine the recommended dose for the phase II part. Phase II part was a randomized study and pts were assigned on a 1:1 basis to GC+N or GC (G, 1250 mg/m^2 on Days 1 and 8 based on the result from the phase 1b part; C, 75 mg/m^2 on Day 1 of maximum four 3-week cycles; N, 800 mg on Days 1 and 8 continued until PD). The primary endpoint of phase II part was overall survival (OS). Secondary endpoints included progression-free survival (PFS), objective response rate (ORR), time to treatment failure (TTF), health outcomes and safety. **Results:** Of 183 pts randomized, each 90 and 91 pts received GC+N or GC in the phase II part. Baseline patient characteristics were balanced between arms. The OS was prolonged in GC+N compared with GC (Hazard ratio (HR) = 0.656 [95% Confident Interval, CI = 0.465, 0.926]; p = 0.0161). The median OS was 14.9 months (mos) and 10.8 mos for GC+N and GC, respectively. The HR for PFS was 0.562 [0.406, 0.777]; p = 0.0004, and the median PFS was 4.2 mos and 4.0 mos for GC+N and GC, respectively. The ORR was 51.1% and 20.9%, respectively; the HR for TTF was 0.588 [0.433, 0.800]; p = 0.0006. The analysis of health outcomes assessed by the Lung Cancer Symptom Scale and the EuroQol-5D suggested that QOL was not negatively impacted by the addition of N. No deaths occurred on treatment. Grade $\geq$3 adverse events with GC+N that showed a $>$ 5% increase over GC were neutrophil count decreased (42.2% vs. 35.2%), febrile neutropenia (12.2% vs. 3.3%), decreased appetite (11.1% vs. 4.4%) and dermatitis acneiform (5.6% vs. 0). The safety data obtained in the study were consistent with the safety profile expected for GC+N. **Conclusions:** The study demonstrates a clinically meaningful treatment benefit for GC+N in the first-line treatment of Japanese pts with stage IV SqCLC. GC+N was well tolerated. The totality of the efficacy data with the safety profile of N+GC demonstrates a favorable benefit-risk profile for this combination treatment. Clinical trial information: NCT01763788.

9040 Poster Session (Board #363), Sun, 8:00 AM-11:30 AM

Characterization of 1,233 NSCLCs with non-del19/L858R *EGFR* mutations (*EGFR*m) using comprehensive genomic profiling (CGP). *First Author: Sai-Hong Ignatius Ou, University of California Irvine School of Medicine, Irvine, CA*

Background: Exon 19 deletions (del19) and L858R are classic activating *EGFR*m with sensitivity to approved tyrosine kinase inhibitors (TKIs). Recently, FDA-approval of afatinib was broadened to include some more rare *EGFR*m (S768I, L861Q, G719X) in addition to del19/L858R. **Methods:** CGP was performed on 34,328 NSCLCs, of which 5,240 samples (15%; 4,592 tissue and 648 blood-based ctDNA) from 4,872 patients (pts) were positive for short variant *EGFR*m. Pts profiled both pre- and post-EGFR TKI were included. Variants of unknown significance were excluded from our analysis. Tumor mutational burden (TMB) was determined up to 1.2 Mbp of sequenced DNA. **Results:** Del19/L858R were identified in 76% of *EGFR*m NSCLC cases. However, less common *EGFR*m included exon 18 or 20 indels (11%), G719X (5.2%), L861Q (2.8%), extracellular domain (ECD, 2.6%), S768I (2.4%), E709X (1.7%), transmembrane domain (TMD, 0.1%), and other kinase domain (KD, 7.5%) mutations. Frequent mutations were: ECD: A289V/TD (20%), L62R (17%) and R108K (15%); TMD: V651M (75%); KD-other: V834L (9%), L833V (7%), V774M (7%), V769L (6%), and L861R (5%). No notable differences in pt age, gender or disease histology were observed between subsets, except that L861Q pts were more often female (76%, vs 66% all *EGFR*m, P = 0.02). $\geq$1 primary *EGFR*m was common in cases with E709X (100%), S768I (94%), TMD (75%), G719X (70%), KD-other (63%), ECD (57%), and L861Q (31%) relative to del19/L858R (7%), or other indels (2%). T790M co-occurred in 21% of del19/L858R cases, but only 4% of non-del19/L858R *EGFR*m cases. *KRAS*m co-occurred in 1% of del19/L858R cases, 0-3% of cases with G719X, L861Q, S768I, E709X, or exon 18 or 20 indels, and 8% of KD-other. *EGFR* amplification was present in 10-17% of cases with E709X, ECD, KD-other, G719X, or S768I, and 20-25% of remaining *EGFR*m subsets. Median TMB was lowest (2.6 mut/Mb) in cases with del19/L858R or other indels, and highest (5.2 mut/Mb) in cases with G719X or ECDm. Clinical outcomes will be presented for a subset of cases. **Conclusions:** Diverse non-del19/L858R *EGFR*m represent almost 25% of *EGFR*m NSCLC. Many of these *EGFR*m co-occur in a single sample, and may be targetable using currently approved or investigational EGFR TKIs.

9041 Poster Session (Board #364), Sun, 8:00 AM-11:30 AM

Safety and activity of durvalumab + tremelimumab in immunotherapy (IMT)-pretreated advanced NSCLC patients. *First Author: Edward B. Garon, UCLA Medical Center, Los Angeles, CA*

Background: The combination of anti-PD-L1 antibody durvalumab (D) with anti-CTLA-4 antibody tremelimumab (T) showed antitumor activity and manageable tolerability in IMT-naïve patients with advanced NSCLC in the dose-escalation part of a phase 1b study. Here we report safety and clinical activity in one of 3 expansion cohorts. **Methods:** Eligible patients had received up to 3 prior lines of therapy, including prior anti-PD-1 or anti-PD-L1 monotherapy to which they did not respond ("refractory") or responded and then progressed ("relapsed"). Patients had no subsequent systemic therapy until start of study treatment, and had not had any toxicity leading to discontinuation of prior IMT. Patients received D IV 20 mg/kg Q4W for up to 12 months and T IV 1 mg/kg Q4W with the first 4 cycles of D. **Results:** As of 27 Nov 2017, 78 patients received therapy and were followed for a median of 18.4 (0.7–28.0) months. 80% had non-squamous histology, 19% were *KRAS* mutant and 3% were *EGFR* mutant. 94% had received ≥2 lines of prior therapy, including 5 patients with 2 prior IMT. Median time to progression on prior IMT was 7.0 months in relapsed and 2.6 months in refractory patients. Treatment-related AEs were reported in 72% of patients; the most common were fatigue (26%), diarrhea (23%), and nausea (14%). Grade 3/4 treatment-related AEs occurred in 28% of patients, with diarrhea (6%) being most common. 5 patients (6%) discontinued due to a treatment-related AE, (diarrhea in 4%) and no treatment-related deaths occurred. Clinical outcomes are summarized in the Table. DCR24 was 21.8% (95% CI, 13.2–32.6); for these 17 patients, median duration of exposure was 9.5 months, compared with 6.1 months on prior IMT. **Conclusions:** D+T had a manageable safety profile in IMT-pretreated patients with prolonged stable disease or better seen in some patients. Clinical trial information: NCT02000947.

9042 Poster Session (Board #365), Sun, 8:00 AM-11:30 AM

Tumor mutation burden and efficacy of targeted therapy in patients with *EGFR* mutant lung cancers. *First Author: Michael David Offin, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Tumor mutation burden (TMB) is a biomarker of response to immune checkpoint blockade. The impact of TMB on outcomes with targeted therapies has not been explored. We hypothesized that TMB would inversely correlate with efficacy of targeted therapy in patients with *EGFR* mutant lung cancers proposing that additional mutations represent potential pathways for resistance with targeted therapies. **Methods:** We studied patients (pts) with metastatic *EGFR* mutant lung cancers with sensitizing exon 19 deletion (ex19del) or L858R variants treated with first/second generation tyrosine kinase inhibitors (TKIs) with pre-treatment targeted next generation sequencing (NGS; IMPACT) identified between January 2010 and September 2017. TMB was assessed in pre-TKI tissue defined as total non-synonymous mutations/Mb as assessed by the IMPACT platform. The effect of TMB on time on treatment (ToT) and overall survival (OS) were evaluated in univariate and multivariate analyses. **Results:** We identified 153 pts with metastatic *EGFR* mutant lung cancers profiled with MSK-IMPACT. Median TMB was 3.8 mutations/Mb (7.4 mutations/Mb for unselected lung cancers), but exhibited a wide range (0.82-17.9). In those with ≤ median TMB, ToT and OS were higher compared to those with > median TMB (ToT 17 vs. 10 months, HR 0.56, p = 0.006; OS 41 vs. 29 months, HR 0.52, p = 0.03). Within subgroups (never smokers, former smokers, TP53 co-mutant, age ≥ or < 65, man and woman), efficacy was consistently higher in those with ≤ median TMB. In multivariate analysis incorporating TMB, *TP53* status, and *EGFR* ex19del vs. L858R, ToT remained improved in those with TMB ≤ median (HR 0.93, p = 0.02) but OS was not significant (HR 0.94, p = 0.3). **Conclusions:** Low TMB is associated with longer time on treatment in patients with metastatic *EGFR* mutant lung cancers treated with targeted therapy. This relationship is the reverse of that is seen with immune checkpoint blockade. TMB can serve as a relevant biomarker in lung cancers, with varied implications based on the nature of therapy being used.

9043 Poster Session (Board #366), Sun, 8:00 AM-11:30 AM

Updated efficacy and safety data from the global phase III ALEX study of alectinib (ALC) vs crizotinib (CZ) in untreated advanced ALK+ NSCLC. *First Author: D. Ross Camidge, University of Colorado, Aurora, CO*

Background: The primary ALEX (NCT02075840) analysis showed superior investigator (INV)-assessed PFS with ALC vs CZ (HR 0.47, 95% CI 0.34–0.65, p<0.001; median 11.1 months [m] CZ, not estimable [NE] ALC) in untreated ALK+ NSCLC. We report updated data (cutoff Dec 1 2017). **Methods:** ALEX enrolled patients (pts) with stage IIIB/IV ALK+ NSCLC (by central IHC) and no prior systemic therapy for advanced NSCLC; asymptomatic CNS metastases (mets) were allowed. Pts were randomized 1:1 to receive ALC 600mg BID (n = 152) or CZ 250mg BID (n = 151). Primary endpoint: PFS (INV, RECIST v1.1), with q8w CNS imaging in all pts. Secondary endpoints: ORR, time to CNS progression, DOR, OS, and safety. **Results:** With 10m longer follow-up (median 22.8m CZ vs 27.8m ALC), ALC significantly reduced risk of disease progression/death by 57% vs CZ (ITT; stratified HR 0.43, 95% CI 0.32–0.58): median PFS (INV) was 34.8m ALC vs 10.9m CZ. Median PFS by baseline (BL) CNS mets status was 27.7m ALC vs 7.4m CZ (HR 0.35, 95% CI 0.22–0.56) in pts with, and 34.8m vs 14.7m (HR 0.47, 95% CI 0.32–0.71) in pts w/out BL CNS mets. In the BL CNS mets group, the number of pts who received WBRT (n = 16 ALC, n = 17 CZ) or SRS (n = 4 ALC, n = 6 CZ) was balanced, as was the number of BL lesions (median 2 per arm). Updated secondary endpoint data (INV): ORR 82.9% ALC (95% CI 75.95–88.51; n = 152) vs 75.5% CZ (95% CI 67.84–82.12; n = 151); median DOR 33.3m ALC (95% CI 31.1–NE; n = 126) vs 11.1m CZ (95% CI 7.5–13.0; n = 114), stratified HR 0.33, 95% CI 0.23–0.48. OS data are still immature (events ALC 28.3%, CZ 31.8%; stratified HR 0.76, 95% CI 0.50–1.15). Despite significantly longer treatment (Tx) duration with ALC (27.0m vs 10.8m), proportion of pts with grade 3–5 AEs (44.7% vs 51.0%), AEs leading to dose reduction (16.4% vs 20.5%) or interruption (22.4% vs 25.2%) were lower with ALC vs CZ. Proportion of pts with AEs leading to discontinuation: 13.2% each arm. Fatal AEs: 5% CZ (2 Tx-related AEs) and 4% ALC pts (0 Tx related). **Conclusions:** ALC 600mg BID showed superior efficacy vs CZ (PFS HR 0.43, median 34.8m ALC vs 10.9m CZ) in untreated ALK+ NSCLC, regardless of BL CNS mets, and favorable and durable tolerability despite longer Tx duration, consolidating ALC as the new standard of care. Clinical trial information: NCT02075840.

9044 Poster Session (Board #367), Sun, 8:00 AM-11:30 AM

Exome analysis to reveal genomic markers associated with better efficacy of nivolumab in lung cancer patients. *First Author: Corentin Richard, Research Platform in Biological Oncology, Center GF Leclerc, Dijon, France*

Background: Monoclonal antibodies targeting immune checkpoint inhibitors revolutionized the treatment of lung cancer. However, only one-quarter of non-small cell lung cancer patients (NSCLC) benefit from these new therapies. The assessment of PD-L1 tumor expression by IHC is used to select responder patients and is considered as the gold standard biomarker in many studies; however, this marker does not predict the absence of anti-PD-1 efficacy. Recent studies suggest that high tumor mutational burden (TMB) is associated with better efficacy of Nivolumab compared with chemotherapy. In addition, transcriptomic and exome analyses have revealed potential biomarkers needing further confirmation. It is thus of major importance to define biomarkers that efficiently predict Nivolumab efficacy. **Methods:** We performed somatic and constitutional exome analyses for 77 patients with NSCLC treated with Nivolumab. We studied: 1-tumor-related characteristics: aneuploidy, tumor copy number alteration clonality, mutational signatures, TMB, mutations in WNT, AKT, MAPK and DNA repair pathways, and 2-immunological characteristics: number of intratumoral TCR clones, HLA type, number of neoantigens, and Type I IFN mutation pathway; and 6 clinical parameters. **Results:** A high TMB per Mb, a high number of neoantigens, mutational signatures 1A and 1B, mutations in DNA repair pathways and a low number of TCR clones are associated with greater PFS. Using the least absolute shrinkage and selection operator method, we established an exome-based model with 9 parameters that could discriminate patients with good or poor PFS ($p < 0.0001$) and OS ($p = 0.002$) independently from clinical data. Moreover, this model had improved ability to predict outcomes compared with a PD-L1 clinical model with or without TMB (Area Under Curve: Clinical = 0.80, TMB = 0.81, exome-derived = 0.93). The model was externally validated on another cohort of 34 patients treated with Pembrolizumab (Rizvi *et al.*, 2015). **Conclusions:** Altogether, these data provide a validated biomarker that predicts the efficacy of Nivolumab or Pembrolizumab in lung cancer patients. Our biomarker appears to be superior to PD-L1 labelling and TMB models.

9045 Poster Session (Board #368), Sun, 8:00 AM-11:30 AM

BRAF-mutant non-small cell lung cancer (NSCLC): Patient (pt) characteristics and outcomes by class of mutation. *First Author: Ibiayi Dagogo-Jack, Massachusetts General Hospital, Boston, MA*

Background: *BRAF* mutations (muts) occur in 2-4% of NSCLC. Recent work suggests that *BRAF* muts may be grouped into 3 classes: 1) V600 muts that signal as monomers, 2) activating non-V600 muts that function as dimers, and 3) kinase-impaired non-V600 muts that require RAS input. Whether mut class is associated with specific clinicopathologic features or clinical outcome is unknown. **Methods:** We performed a retrospective analysis of NSCLC pts with *BRAF* muts treated at Massachusetts General Hospital and Dana-Farber Cancer Institute between 2006 and 2017 to determine clinicopathologic characteristics and estimate overall survival (OS). **Results:** We identified 237 pts with Stage I-IV BRAF-mutant NSCLC (107 (45%) class 1, 76 (32%) class 2, and 54 (23%) class 3). Most pts were white (85%) smokers (88%) with adenocarcinoma (90%). Smoking status was similar for pts with class 2 and 3 muts (3% vs 6% never-smokers, $p = 0.649$), but pts with class 1 muts were more likely to be never-smokers (22%; $p < 0.001$ vs class 2, $p = 0.011$ vs class 3). The frequency of concurrent *RAS* (KRAS or NRAS) co-alterations in class 1 was 1%, which was significantly lower than the frequency in class 2 (12%, $p = 0.002$) and class 3 (24%, $p < 0.001$). Nine (47%) of 19 kinase-dead tumors had *RAS* co-alterations. Among 140 pts with metastatic NSCLC, median OS was 40.1 months (mos, n = 69, 95% CI:17.5-56.1) for class 1, 13.9 mos (n = 39, 95% CI:7.4-18.7) for class 2, and 15.6 mos (n = 32, 95% CI 8.9-37.4) for class 3 pts. OS was not different for class 2 and 3 pts ($p = 0.591$), but presence of a class 1 mut was associated with improved OS (median 40.1 vs 15.6 mos when class 2 and 3 pts were pooled, HR = 0.5,95% CI 0.3-0.8, $p = 0.002$). When 40 pts who received therapies targeting the mitogen-activated protein kinase pathway were excluded, there was still a trend toward improved OS for class 1 muts (median 39.1 vs 13.9 mos for class 2 and 3 pts; HR = 0.6, 95% CI 0.3-1.0, $p = 0.059$). **Conclusions:** Pts with class 2 and 3 BRAF-mutant NSCLC share clinicopathologic features and outcomes that may be distinct from pts with class 1 muts. Our findings highlight the need for therapies that effectively target class 2 and 3 BRAF muts.

9046 Poster Session (Board #369), Sun, 8:00 AM-11:30 AM

Phase I/Ib study of pembrolizumab and vorinostat in patients with metastatic NSCLC (mNSCLC). *First Author: Andreas Nicholas Saltos, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

Background: The oral histone deacetylase inhibitor (HDACi) vorinostat (V) enhances tumor immunogenicity through several mechanisms and may augment response to PD-(L)1 blockade (IO). We report mature results from a phase I/Ib trial testing the combination of V with pembrolizumab (P) in mNSCLC. **Methods:** In phase I, pts with either IO-naïve or IO-pretreated mNSCLC were treated with P (200mg IV q3 wk) + V (200 or 400 mg PO daily). In phase Ib expansion, pts were required to have progressed on prior IO treatment. Primary endpoints were safety/tolerability; secondary endpoints included RR, PFS, DOR, and OS. Tissue and blood specimens from pre- and post-treatment were collected for correlative analyses to determine tumor gene expression changes, levels of myeloid-derived suppressor cells and changes in peripheral T-cell phenotype. **Results:** Between 3/2016 - 9/2017, Phase I: 14 pts were treated (4 at 200mg, and 10 at 400mg V dose); and Phase Ib: 20 pts were treated. Median age: 67 (range 38-82); Females: 11 (32%); ECOG 1: 32 (94%); and never/former/current smokers: 3/23/8 (9%/68%/23%). No DLTs were observed. The RP2D is P 200mg and V 400mg. Most common AE of any grade were fatigue (11%), anorexia (9%) and nausea/vomiting (8%). Most common G3 AE were myalgia, anemia and diarrhea. There were no G4/5 AEs. 3 (9%) pts had treatment discontinued due to toxicity. 30 pts are evaluable for response. PD-L1 expression was $\geq$ 1% in 18/30 (60%), and $\geq$ 50% in 11/30 (37%). 6 pts were IO-naïve and 24 IO-pretreated. 4 (13%) had PR (2 confirmed), 16 (53%) had SD, and 10 (33%) had PD for a disease control rate of 67%. In the IO-pretreated Ib cohort, 2 pts (1 confirmed; 1 pending repeat CT) had a PR and 10 had SD (8 confirmed). For IO-pretreated pts, mPFS was 3.2 months. For IO-naïve, mPFS was 7.6 months. Preliminary tumor RNA-seq studies showed increase in IFN gamma and HDACi target gene expression, including CXCL9. **Conclusions:** V + P was well tolerated. The combination demonstrates preliminary anti-tumor activity despite progression on prior IO treatment and gene expression changes consistent with mechanism of HDACi action. A randomized phase II portion of this study, examining P combined with V vs. placebo in immunotherapy naïve pts, is ongoing. Clinical trial information: NCT02638090.

9047 Poster Session (Board #370), Sun, 8:00 AM-11:30 AM

Patient-reported outcomes (PROs) in the randomized, phase III IMpower150 study of atezolizumab (atezo) + chemotherapy (chemo) ± bevacizumab (bev) vs chemo + bev in 1L nonsquamous metastatic NSCLC (mNSCLC). *First Author: Martin Reck, LungenClinic Grosshansdorf, German Center for Lung Research, Grosshansdorf, Germany*

Background: Atezo (anti–PD-L1) + bev (anti-VEGF) + chemo prolonged PFS vs bev + chemo in patients (pts) with 1L nonsquamous mNSCLC in the randomized, Phase III IMpower150 study. PRO data, including symptom burden, functioning and health-related quality of life (HRQoL), were evaluated to assess overall clinical benefit in each treatment (Tx) arm. **Methods:** Pts received atezo 1200 mg + carboplatin (C) AUC 6 + paclitaxel (P) 200 mg/m^2 (Arm A) or atezo + bev 15 mg/kg + C + P (Arm B) vs bev + C + P (Arm C) IV q3w for 4 or 6 cycles per investigator decision, then maintenance atezo, atezo + bev, or bev, respectively. PRO data were collected using the EORTC QLQ-C30 and QLQ-LC13 questionnaires. Prespecified analyses included the mean change from baseline in symptoms, functioning and HRQoL and time to deterioration (TTD) in lung cancer symptoms. Clinically meaningful change was defined as a $\geq$10-point change in score from baseline. **Results:** PRO completion rates were high ($\geq$70% through cycle 23 for all arms). Mean changes from baseline indicated that a clinically meaningful worsening ($\geq$10-point change) was not observed in any arm through cycle 13 ($\approx$25% of pts remain in Arm C); HRQoL and physical functioning scores minimally decreased (Arm A: -2.83 and -3.39; Arm B: -1.8 and -3.98; Arm C: -1.92 and -2.6) with concurrent numerical worsening in Tx-related symptom scores (e.g., fatigue, constipation, nausea/vomiting). Following chemo completion, scores returned to baseline or numerically improved. HRQoL, physical functioning and Tx-related symptoms were comparable between Arms B and C. No difference was observed between arms in the TTD in lung cancer symptoms assessed. All arms reported numerical improvement in multiple lung cancer symptoms while on Tx. **Conclusions:** These data suggest that prolonged PFS in Arm B was achieved without compromising HRQoL or physical functioning despite higher Tx-related AEs than Arm C. PRO data reflected a minimal Tx burden across arms, further reduced following chemo discontinuation. Overall, PRO data support the positive benefit:risk of the clinical data with atezo + bev + chemo in 1L nonsquamous mNSCLC. Clinical trial information: NCT02366143.

9048 Poster Session (Board #371), Sun, 8:00 AM-11:30 AM

Detection and clearance of *RET* variants in plasma cell free DNA (cfDNA) from patients (pts) treated with LOXO-292. *First Author: Geoffrey R. Oxnard, Dana-Farber Cancer Institute, Boston, MA*

Background: LOXO-292 is a novel, highly-selective, small molecule RET inhibitor in clinical development for pts with advanced cancers harboring oncogenic *RET* alterations (e.g. non-small cell lung cancer [NSCLC], medullary thyroid cancer [MTC], papillary thyroid cancer [PTC], and any other cancer). Here we study modulation of *RET* variant allele frequencies (AF) in plasma cfDNA with LOXO-292 therapy. **Methods:** LOXO-292 is being studied in an ongoing Phase 1 study in pts with advanced solid tumors, with enrollment enriched for pts with *RET* alterations (NCT03157128). Blood is collected pretreatment, after 15 days of treatment, and at each restaging for cfDNA analysis by next-generation sequencing (NGS, Guardant). **Results:** As of 1/5/18, 57 pts were enrolled (35 *RET* fusion+ (27 NSCLC, 7 PTC, 1 other), 20 *RET*-mutant MTC, 2 other) to 7 doses (20mg QD→160mg BID). 213 plasma samples were collected. Here we report on 44 pts with plasma NGS results available. Of 41 pts enrolled based on a *RET* variant detected in a tumor sample, concordant *RET* alterations were detected in 26 (63%) of the corresponding pre-treatment plasma samples, including 15/22 (68%) pts with *RET*-fusion NSCLC and 8/12 (67%) pts with *RET*-mutant MTC. Median AF was higher for MTC (6.9%) than NSCLC (0.7%). In negative pre-treatment samples, peak AF for other detected alterations was low (0.3% median), suggesting low tumor DNA shed into plasma. Of 18 pts with a detectable pre-treatment plasma *RET* alteration and day 15 plasma NGS, *RET* alteration AF decreased by a median of 92%, with complete clearance in 7 pts (39%). Day 15 plasma clearance was observed at multiple doses (20-60mg BID), and was more common in *RET* fusion-positive (55%) than *RET*-mutant (14%) pts. Data for additional pts will be updated at the time of presentation. **Conclusions:** The rapid clearance of *RET* variants from plasma cfDNA on LOXO-292 supports its observed clinical activity across a range of doses, tumor types and *RET* alterations. NGS of plasma cfDNA can detect a range of targetable *RET* variants, though tumor genotyping remains critical if the initial plasma NGS is negative. Serial plasma genotyping warrants continued study as an early pharmacodynamic marker for novel targeted therapies. Clinical trial information: NCT03157128.

9049 Poster Session (Board #372), Sun, 8:00 AM-11:30 AM

Prognostic relevance of tumor sequencing in metastatic lung adenocarcinomas. *First Author: Ronglai Shen, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Routine next generation sequencing (NGS) testing for patients with lung cancer allows the rapid identification of a broad array of targetable molecular drivers. We hypothesized that the results of routine NGS testing, exploring both driver and non-driver oncogenes, could be used to develop a prognostic risk score for patients with metastatic lung adenocarcinoma. **Methods:** We employed an ensemble penalized proportional hazards model to derive a genetic risk score using sequencing results of 341 cancer associated genes in 1,054 patients with metastatic lung adenocarcinoma. A 3-fold cross-validation was used to obtain unbiased estimates of prediction accuracy. **Results:** A total of 341 genes mutated at least once across the cohort were included in the analysis. The most frequently mutated genes were TP53 (55%), KRAS (30%), EGFR (29%), STK11 (18%), KEAP1 (18%). Mutations in TP53, KRAS, STK11, KEAP1, and SMARCA4 were associated with poor prognosis. Based on the risk score, patients were categorized into risk groups. Patients in the low risk group had a median overall survival of 32.8 months (95% CI: 26.3-38.5) as compared to 7.3 months (95% CI 5.5-10.9) in the high risk group. The three-year survival probability is 47% in the low risk group versus 12% for the high risk group. Concurrent mutations in both STK11 and KEAP1 had the largest adverse prognostic implications. While overall mutation burden and clonal heterogeneity were moderately associated with survival, they did not provide additional prognostic value over the genetic risk score system. The risk score remains a significant independent predictor after adjusting for clinical variables (age, sex, smoking history). **Conclusions:** Using the results of routine NGS testing, we developed a molecular prognostic risk score for patients with metastatic lung adenocarcinoma. These results demonstrate that NGS testing for patients with lung cancer can be used not only to identify targetable molecular drivers, but also be leveraged to develop a powerful molecular scoring system that can be used for stratification in clinical trials as well as comparisons of patient populations derived from real world data.

9050 Poster Session (Board #373), Sun, 8:00 AM-11:30 AM

An open-label, multicenter, phase II single arm trial of osimertinib in non-small cell lung cancer patients with uncommon EGFR mutation (KCSG-LU15-09). *First Author: Myung-Ju Ahn, Samsung Medical Center, Seoul, Korea, Republic of (South)*

Background: Approximately 10% of EGFR mutants harbor uncommon mutations, which represent a heterogeneous group of rare molecular alterations within exons 18-21 and the sensitivity to EGFR TKIs is variable. Osimertinib is a potent irreversible inhibitor of both sensitizing EGFR mutation and T790M. In preclinical data, the potency of osimertinib against uncommon EGFR mutants other than exon 20 insertion was fairly good. Here we present the efficacy and safety of osimertinib in patients with uncommon EGFR mutation positive NSCLC. **Methods:** Patients with histologically confirmed metastatic or recurrent NSCLC with activating EGFR mutation other than exon 19 deletion, L858R, T790M and insertion in exon 20 were eligible. Patients received 80mg of osimertinib per oral daily until progression or unacceptable toxicity. Response was assessed every 8 weeks by investigator. The trial was registered with ClinicalTrials.gov, number NCT03424759. **Results:** Between Mar 2016 and Oct 2017, 36 patients were enrolled. Median age was 59.5, 61% male, 44% never smoker, 97% adenocarcinoma. 61% of patients were treated as first-line therapy. The most common mutations are G719A/C/D/S/X (19, 52.8%) followed by L861Q (9, 25%), S768I (8, 22%), and others (4, 11%). The overall response rate was 50.0% (95% CI 32.8-67.2) and DCR was 88.9% (95% CI 78.1-99.7). Seven patients (77.8%) with L861Q mutation achieved partial response; 10 (52.6%) with G719A/C/D/S/X mutation; three (37.5%) with S768I mutation. At data cutoff (Nov, 2017), the median PFS was 9.5 months (range 1.0-20.1) and median duration of response was 7.0 months (95% CI 4.7-9.3). The most common adverse events were rash (n = 11, 30.6%), anorexia (n = 8, 22.2%), and diarrhea (n = 7, 19.4%). Grade 3 or 4 AEs were reported in 8 of 36 patients (22%), but all of AEs were manageable. **Conclusions:** Osimertinib showed highly active and durable in NSCLC patients harboring uncommon EGFR mutation with manageable safety profile, consistent with previous reports. Further analysis will be updated. Clinical trial information: NCT03424759.

9051 Poster Session (Board #374), Sun, 8:00 AM-11:30 AM

Dendritic-cell vaccine (DCVAC) with first line chemotherapy in patients with stage IV NSCLC primary analysis of phase 2, open-label, randomized, multicenter trial. *First Author: Libor Havel, Thomayer's Hospital, 1st Faculty of Medicine of Charles University in Prague, Prague, Czech Republic*

Background: Immunotherapy for induction of tumor cell specific immune responses destroying tumor cells, has emerged as a promising treatment modality in lung cancer (LuCa). Autologous DCVAC can present tumor antigens to elicit a durable immune response. We hypothesized that adding DCVAC to the standard of care chemotherapy (ct) could prolong progression-free survival (PFS) and overall survival (OS). **Methods:** This study evaluated the efficacy and safety of DCVAC/LuCa (active cellular immunotherapy based on dendritic cells) concomitantly added to ct (carboplatin/paclitaxel) - Arm A (A) vs DCVAC/LuCa + immune modulators (IFN-α and hydroxychloroquine) - Arm B (B) vs ct - Arm C (C) in NSCLC patients (pts). Randomization 1:1:1; pts in A and B received up to 15 doses of DCVAC, ct was given 4-6 cycles in A and C. Stage IV NSCLC was confirmed histologically or cytologically, ECOG 0-1 pts were eligible. Stratification was done by histology subtype and smoking history. Primary efficacy analysis compared A vs C only as enrollment to B was closed early based on Sponsor's assessment of further clinical development potential, there were no safety concerns or signals. **Results:** 112 pts at 12 sites were randomized (A/45 B/29 C/38). Patients characteristics were comparable across the study groups with the exception of gender (m/f, %: 50/50 (A) and 26/74 (C) and smoking history (75 % of smokers in A, 97 % in C). Median follow up time was 14.1 months, range 0.032-29,765. Median OS was 15.5 months in A compared to 11.8 months in C, hazard ratio (HR) 0.56, p-value 0.05, 95% CI, data maturity 65%. Median PFS was 6.73 in A and 5.65 months in C HR 0.64, p-value 0.05, 95% CI, data maturity 81%. Overall response rate was 45% in A vs 22.9% in C. Most TEAEs were related to ct (anemia [37%-A, 32%-C], neutropenia [48% in A, 21%-C], thrombocytopenia [28% in A, 27% in C]). There were no grade $\geq$ 3 TEAEs solely related to DCVAC. Most common leukapheresis-related AEs were haematoma and hypotension. **Conclusions:** Addition of DCVAC-based immunotherapy to the standard of care chemotherapy significantly improved OS in stage IV NSCLC. Clinical trial information: EudraCT 2014-003084-37.

9052 Poster Session (Board #375), Sun, 8:00 AM-11:30 AM

Association of EGFR and HER-2 exon 20 mutations with distinct patterns of response to immune checkpoint blockade in non-small cell lung cancer. *First Author: Marcelo Vailati Negrao, Department of Thoracic / Head and Neck Medical Oncology - The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Immune checkpoint blockade has led to unprecedented durable clinical benefit in metastatic non-small cell lung cancer (NSCLC), but response rates are low for patients with targetable driver mutations. EGFR and HER-2 exon 20 mutations account for ~4% of NSCLC, but outcomes for these patients when treated with immune checkpoint blockade have not been previously reported. **Methods:** We queried GEMINI, a MD Anderson Lung Cancer Moon Shot funded database for prospective collection of clinical information for patients with NSCLC, for patients with driver mutations in EGFR exon 19, 20, 21 and HER-2 exon 20 and treated with immune checkpoint inhibitors. We assessed overall survival (OS), progression-free survival (PFS) and overall response rate (ORR). **Results:** From 2014 to 2018, 90 patients with classic EGFR mutations (exon 19 del + exon 21 L858R, n = 38), EGFR exon 20 mutations (n = 36; no T790M included) and HER-2 exon 20 mutations (n = 16) had been treated with checkpoint inhibitors. Compared to classic EGFR mutants, EGFR exon 20 mutants demonstrated a higher disease control rate at 6 and 12 months as well as higher ORR. Also, EGFR exon 20 mutants demonstrated significantly higher PFS (HR 0.45, p = 0.002) and OS (HR 0.2, $p < 0.001$) (Table). These differences remained significant in multivariate analysis after adjusting for age, smoking status, radiation prior to treatment initiation and treatment with concurrent agents such as chemotherapy and/or radiation. HER-2 exon 20 mutants had similar ORR and PFS compared to classic EGFR mutants (HR 1.1, p = 0.8) (Table). **Conclusions:** EGFR exon 20 mutations are associated with superior outcome from immune checkpoint inhibitors compared to classic EGFR and HER-2 exon 20 mutations. Further studies on PD-L1 status and tumor mutation burden in these molecularly-defined groups are ongoing to address potential underlying mechanisms associated with these findings.

	EGFR exon 20 N = 36	Classic EGFR N = 38	HER-2 exon 20 N = 16

9053 Poster Session (Board #376), Sun, 8:00 AM-11:30 AM

Efficacy and safety results of ramucirumab in combination with osimertinib in advanced T790M-positive *EGFR*-mutant NSCLC. *First Author: David Planchard, Gustave Roussy, Villejuif, France*

Background: Progression of *EGFR*-mutant non-small cell lung cancer (NSCLC) occurs in most patients (pts) despite initial benefit with a first-line EGFR tyrosine kinase inhibitor (TKI). A first- or second generation EGFR TKI + a VEGF- or EGFR-directed monoclonal antibody (mAb) has shown promising results in pts with EGFR-mutant NSCLC. **Methods:** This ongoing, single-arm, Phase 1study (NCT02789345) enrolled pts with T790M-positive *EGFR*-mutant (Ex19del or L858R) NSCLC with prior progression on first-line EGFR TKI therapy. The primary phase 1b objective was assessment of safety/tolerability of ramucirumab (Ram), a VEGFR2 mAb, + osimertinib (Osi), a novel third-generation EGFR TKI. Key secondary efficacy endpoints were investigator assessed objective response rate (ORR), disease control rate (DCR), duration of response (DOR), and progression-free survival (PFS). **Results:** Pts (N = 25) were 45-80 years (median 64) with ECOG-PS 0 (n = 3) or 1 (n = 22) and tobacco history of current (n = 5), former (n = 8), or never (n = 12). Pts received Ram 10mg/kg IV (Day 1 Q2W) + Osi 80mg QD. At interim analysis, median therapy duration was 13 cycles (IQR: 6-16) for Ram and 13 cycles (IQR: 7-15) for Osi. Median follow-up was 7.2 months (90% CI: 6.51, 7.92). All pts had ≥1 treatment-related adverse event (TRAE), most commonly hypertension (44%), diarrhea (32%), stomatitis (24%). Grade (G) 3 TRAEs were hypertension (8%), platelet count decreased (8%), anemia (4%), congestive heart failure (CHF) (4%), neutrophil count decreased (4%). No G4 TRAEs were reported. Ram was discontinued for G3 CHF in a 76-year-old pt, who subsequently experienced a G5 TRAE of subdural hemorrhage ~7 weeks after the last dose of Ram. Fifteen pts remain on study drug. ORR was 76% (19/25), with CR 4% (1/25), PR 72% (18/25), SD 16% (4/25), PD 4% (1/25), and non-evaluable 4% (1/25). DCR was 92%. Median DOR was not reached (90% CI: NR, NR). DOR rate at 6 months was 81.6% (90% CI: 59.0, 92.4). Median PFS was not reached (90% CI: 5.49, NR). PFS rate at 6 months was 64.0% (90% CI: 43.7, 78.6) with 64% of pts censored. **Conclusions:** Ram + Osi demonstrated encouraging anti-tumor activity. The safety profile was consistent with monotherapy for each drug, with no additive toxicities. Clinical trial information: NCT02789345.

9054 Poster Session (Board #377), Sun, 8:00 AM-11:30 AM

Survival disparities among African American (AA) patients (pts) with *EGFR*-mutated non-small cell lung cancer (NSCLC). *First Author: Haiying Cheng, Department of Medical Oncology, Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, NY*

Background: Little is known about whether AA pts with *EGFR*-mutated NSCLC exhibit similar clinical characteristics and outcomes compared to non-AA pts. **Methods:** We retrospectively reviewed the cancer registry at Montefiore Medical Center, a community-based academic center, for lung cancers diagnosed between 01/2009 and 12/2015 (n = 2773). We restricted our analyses to nonsquamous NSCLC pts with available pathology (n = 1350). EGFR testing was performed via PCR-based technology spanning exons 18-21 (n = 672) during that period. **Results:** Our patient population was 38% AA, 45% White, and 17% other. The *EGFR* mutation rate was 15% (98/672) in all pts, compared to 13% (35/266) in AA and 16% (63/406) in non-AA. The mutational spectrum varied by race with Del 19, L858R and uncommon mutations being 46%, 23% and 31% in AA, compared to 43%, 35% and 22% in non-AA. Among pts with *EGFR*-mutated NSCLC, AA pts had shorter survival in comparison to non-AA pts (p = 0.015, using cox proportional hazard model after adjusting for smoking, gender and age) (2-yr survival rates: 33% vs. 61%), which was evident for earlier stages (I-III) (p = 0.0078) (2-yr survival rates: 50% vs. 87%) and suggested for metastatic disease (p = 0.10). However, there was no evidence for racial disparity in survival among patients with *EGFR* wild type (wt) (p = 0.80) (2-yr survival rates: 38% vs. 39%). Further, AA pts were heavier than non-AA pts with *EGFR* mutations (75.1 kg vs. 65.6 kg, p = 0.012). No significant differences were identified for age at diagnosis, gender, presenting stages, smoking history, socioeconomic status, and the standard uses of EGFR TKIs between AA and Non-AA. The similar survival among EGFR wt pts argues further against the treatment disparity between AA and non-AA pts. **Conclusions:** This is the first report of inferior survival among AA NSCLC pts with *EGFR* mutations, relative to non-AA pts. These results may be related to higher frequency of uncommon mutations or possibly PK differences secondary to higher average weight. Confirmation studies in larger pt cohorts and further investigation on how weight difference and tumor biology may contribute to the racial disparity in survival are warranted.

9055 Poster Session (Board #378), Sun, 8:00 AM-11:30 AM

Prevalence and prognosis of DNA repair deficiency in squamous cell carcinoma (SCC) patients enrolled on the S1400 LungMAP study. *First Author: Taofeek Kunle Owonikoko, Emory University, Atlanta, GA*

Background: DNA homologous recombination repair deficiency (HRRD) is a vulnerability that has been exploited for PARP inhibitor therapy. This concept is currently being evaluated in S1400G substudy of LungMAP where HRRD(+) SCC patients are treated with a PARP inhibitor, talazoparib. We assessed the prevalence and characteristics of HRRD(+) SCC patients screened on LungMAP. **Methods:** All patients receive Foundation One NGS screening platform for enrollment on LungMAP sub-studies. HRRD is defined as genetic alteration predicted to have functional consequence in genes involved in HRR (ATM, ATR, BARD1, BRCA1, BRCA2, BRIP1, CHEK1, CHEK2, FANCA, FANCC, FANCD2, FANCF, FANCM, NBN (NBS1), PALB2, RAD51, RAD51B (RAD51L1), RAD54L, RPA1) but also define a key subgroup based on a set of the best clinically validated genes: ATM, ATR, BRCA1, BRCA2, and PALB2 . Survival was measured from the date of sub-study assignment. **Results:** Biomarker results were available for 1244 eligible patients screened between June 2014 and October 2017. HRRD was detected in 190 (15.3%) patients, higher than the 9% rate assumed for the design of S1400G substudy. HRRD(+) and HRRD(-) patients did not differ in terms of median age (67 vs. 66 years); male gender (68% vs. 67%); race (85% vs. 84% and 11% vs. 9% for White and Black) or tobacco exposure (94% vs. 95%). BRCA2 alteration was the most frequent of the HRRD gene alterations. Survival was not different by HRRD(+) versus HRRD(-) status (HR[95%CI]: 1.11 [0.91-1.37], p = 0.29). Alterations in BRIP1 (0.58 [0.28-1.23]; p = 0.16), CHK2 (0.43[0.16-1.15]; p = 0.09), FANCM (1.48[0.87-2.52]; p = 0.15) and FANC-A/C/D2 (1.70[1.07-2.72]; p = 0.03) showed a trend in prognostic association. **Conclusions:** HRRD is frequent in SCC and could define a large subset of SCC for targeted therapy if validated in the ongoing S1400G substudy of LungMAP.

	Overall prevalence	Prevalence among HRRD alterations
BRCA2	3.9%	23.0%
FANCM	2.0%	11.7%
BRCA1	1.7%	9.9%
BRIP1	1.3%	7.5%
ATM	1.1%	6.6%
PALB2	1.1%	6.6%
ATR	1.0%	6.1%
CHEK2	1.0%	5.6%
FANCA	0.8%	4.7%
FANCC	0.7%	4.2%
FANCD2	0.4%	2.3%
BARD1	0.3%	1.9%
CHEK1	0.3%	1.9%
FANCF	0.2%	1.4%
RAD51L1	0.2%	1.4%
RAD51	0.2%	1.4%
NBN	0.2%	0.9%
RAD51B	0.2%	0.9%
RAD54L	0.2%	0.9%
RPA1	0.2%	0.9%

9056 Poster Session (Board #379), Sun, 8:00 AM-11:30 AM

Differential outcomes in patients with uncommon EGFR exon 19 mutations. *First Author: Tyler Stewart, Yale New Haven Hospital, New Haven, CT*

Background: Exon 19 deletions (ex19 dels) account for ~50% of EGFR-mutant NSCLCs. The E746_A750 ex19 del accounts for 75% of these cases. Two frequent uncommon ex19 dels are L747_P753 > S and L747_A750 > P. Studies have largely grouped outcomes of ex19 dels together despite mutational differences. We previously demonstrated *in vitro* that erlotinib and osimertinib suppress phosphorylation of EGFR (pEGFR) in the E746_A750 and L747_P753 > S mutants, but do not effectively suppress pEGFR in the L747_A750 > P mutant, whereas afatinib suppresses pEGFR in all 3 mutant types. Here we investigate the clinical outcomes in patients (pts) with various EGFR ex19 dels treated with erlotinib. **Methods:** We assessed progression free survival (PFS), duration on treatment (DOT) and overall survival (OS) in pts with EGFR exon 19 dels (E746_A750, L747_P753 > S or L747_A750 > P) who received erlotinib as first-line therapy for advanced disease. Primary resistance was defined as progression on first scan after initiation of therapy. **Results:** 32 pts met criteria: 24 with the common E746_A750 mutation, and 4 each with the L747_P753 > S and L747_A750 > P mutations. Patients with the L747_A750 > P mutation demonstrated significantly worse PFS, DOT and OS than those with the E746_A750 and L747_P753 > S mutations (see Table). There was no difference between the E746_A750 and L747_P753 > S groups. Two of four pts with L747_A750 > P mutations demonstrated primary resistance to erlotinib, whereas no pts with E746_A750 or L747_P753 > S mutations exhibited primary resistance. **Conclusions:** This study shows differential clinical outcome to EGFR-directed therapy within EGFR ex19 del tumors, specifically that pts with ex19 del L747_A750 > P have inferior outcomes versus those with E746_A750 or L747_P753 > S when treated with erlotinib. Understanding outcomes with other EGFR inhibitors based on the specific EGFR del 19 mutation present may allow for more precise treatment that results in superior patient outcomes.

Outcomes by EGFR Exon 19 Mutations (Months)

	E746_A750 (n = 24)	L747_P753 > S (n = 4)	L747_A750 > P (n = 4)	p-value
PFS	11.7	13.1	4.1	0.0003
DOT	14.8	14.3	5.9	0.0001
OS	47.0	36.4	14.1	0.0031

9057 Poster Session (Board #380), Sun, 8:00 AM-11:30 AM

Correlation between nivolumab exposure and treatment outcome in NSCLC. *First Author: Stijn L.W. Koolen, Department of Medical Oncology, Erasmus MC Cancer Institute, Rotterdam, Netherlands*

Background: Treatment with anti-PD-1 therapy is subject to large inter-individual variation in clinical outcome. This may be influenced partly by differences in nivolumab exposure between patients. The objective of the current analysis was to investigate whether an exposure-response relationship exists for nivolumab-treated NSCLC patients. **Methods:** 84 patients started nivolumab treatment between May 5th 2016 and August 1st 2017 and were included for prospective collection of serum samples prior to each nivolumab cycle. Clinical data were collected until November 1st 2017. Patients were classified according to best objective response (BOR) according to RECIST v1.1 and the occurrence of grade ≥3 toxicities according to CTCAE v4.03. Geometric mean nivolumab trough concentrations after 2, 4, and 10 weeks of treatment were compared using ANOVA with respect to BOR and *t*-test with respect to toxicity in patients without dose delays until that particular time point. **Results:** 76 patients were evaluable for analysis; 4 patients had no follow-up tumor evaluation, and 4 patients had no follow-up blood sample. At each time point, partial responders (PR; n = 15) had higher geometric mean trough concentrations when compared to patients with progression (PD; n = 33): at 2 weeks : 27.4 μg/mL (95% CI: 22.3 – 33.6 μg/mL) vs. 18.7 μg/mL (95% CI: 16.7 – 20.9 μg/mL; p = 0.001; 47% higher), at 4 weeks: 46.2 μg/mL (95% CI: 37.4 – 57.0 μg/mL) vs. 30.2 μg/mL (95% CI: 25.0 – 36.4 μg/mL; p = 0.008; 53% higher), at 10 weeks: 79.4 μg/mL (95% CI: 60.7 – 103.8 μg/mL) vs. 45.8 μg/mL (95% CI: 35.6 – 58.9 μg/mL; p = 0.002; 73% higher). Moreover, PR patients had higher trough concentrations when compared to patients with stable disease (SD; n = 28) at week 2 (p = 0.034) and at week 4 (p = 0.047). Exposure was not significantly related to the occurrence of grade ≥3 toxicity (n = 15) at any time point. **Conclusions:** This analysis shows that NSCLC patients with an objective response to nivolumab have significantly higher nivolumab exposure than patients with early progressive disease, indicating an exposure-response relationship. Further clinical research is needed to explain and quantify this relation. If confirmed, more rational and individualized dosing-strategies can improve patient outcome.

9058 Poster Session (Board #381), Sun, 8:00 AM-11:30 AM

Durvalumab in ≥ 3rd-line advanced NSCLC: Updated results from the phase 2 ATLANTIC study. *First Author: Marina Chiara Garassino, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: The Phase 2 ATLANTIC study investigated the anti-PD-L1 antibody durvalumab in heavily pretreated pts with advanced NSCLC. Here we report updated results for two of the three pt cohorts (defined by tumor PD-L1 expression and *EGFR/ALK* mutation status) for which data have reached further maturity. **Methods:** ATLANTIC (NCT02087423) is an open-label, single-arm trial of advanced NSCLC pts who had progressed after ≥2 regimens. After initially enrolling all-comers, the study was restricted to pts with PD-L1-expressing tumors (≥25% of tumor cells [TC]). Pts received durvalumab 10 mg/kg IV every 2 weeks ≤12 months. The primary endpoint was ORR by independent central review (ICR) using RECIST v1.1 in pts with TC ≥25%. Pts in Cohort 1 were *EGFR+/ALK+* and pts in Cohorts 2 (not reported) and 3 (TC ≥90% only) were *EGFR−/ALK−*. Interim results were reported for a prior data cutoff (DCO; June 3, 2016). **Results:** As of the latest DCO (November 7, 2017), 444 pts had received durvalumab, 111/68 in Cohorts 1/3. Median age was 61.0 years in both cohorts, 0.9%/29.4% had squamous histology, and the mean number of prior therapies in each cohort was 3.8/2.6. Median OS was 13.3/13.2 months, with a 1-year OS rate of up to 53%, in pts with higher PD-L1 expression (Table). Grade ≥3 treatment-related AEs (CTCAE v4.03) occurred in 5.4%/19.1%. Immune-mediated AEs were manageable, occurring with similar incidences as that reported previously for the earlier DCO. Clinical trial information: NCT02087423. **Conclusions:** These findings demonstrate durable efficacy and a promising effect on OS with durvalumab in a subset of heavily pretreated, advanced NSCLC pts.

9059 Poster Session (Board #382), Sun, 8:00 AM-11:30 AM

A randomized phase 2 study of abemaciclib versus docetaxel in patients with stage IV squamous non-small cell lung cancer (sqNSCLC) previously treated with platinum-based chemotherapy. *First Author: Giorgio V. Scagliotti, Department of Oncology - University of Torino, Turin, Italy*

Background: Abemaciclib is a potent and selective inhibitor of CDK4 & 6 approved for treatment of HR+, HER2- metastatic breast cancer. In a Phase 1 study, abemaciclib showed activity in pts with advanced and/or metastatic NSCLC. This Phase 2 study evaluated the safety and efficacy of abemaciclib vs docetaxel in pts with Stage IV sqNSCLC previously treated with platinum-based chemotherapy. **Methods:** This multicenter, randomized, open-label trial, evaluated abemaciclib (200 mg PO every 12 hours daily) vs docetaxel (75 mg/m^2 IV on Day 1); both on 21 day cycle until disease progression. Adults with confirmed Stage IV NSCLC with measurable disease, ECOG PS ≤1, and who progressed during/after platinum-based chemotherapy were eligible. Pts were randomized 2:1 to receive abemaciclib or docetaxel. Primary endpoint was investigator-assessed PFS. Key secondary endpoints were ORR, DCR, OS, and safety. **Results:** 159 pts were randomized to abemaciclib (N = 106) and docetaxel (N = 53). Median age was 64 years. 84.3% pts were men. In ITT pts 125 PFS events were observed with median PFS of 2.5 m (95% CI: 1.7, 2.9) for abemaciclib and 4.2 m for docetaxel (95% CI: 2.8, 5.7; stratified HR: 1.77 [95% CI: 1.17, 2.67]; P = .0068). ORR was 2.8% (95% CI: 0.0, 6.0) for abemaciclib and 20.8% (95% CI: 9.8, 31.7) for docetaxel. The DCR (CR + PR + SD) was 50.9% (95% CI: 41.4, 60.5) for the abemaciclib treatment arm and 64.2% (95% CI: 51.2, 77.1) for the docetaxel treatment arm. Median OS was 7.0 m (95% CI: 5.0, 8.8) for abemaciclib and 12.4 m for docetaxel (95% CI: 7.1, 16.0; stratified HR: 1.33 [95% CI: 0.88, 2.02]; P = .1746). Exploratory biomarker data will be available at the meeting. The most common TEAEs with abemaciclib were anemia and diarrhea. **Conclusions:** In this Phase 2 study, single agent abemaciclib 200 mg did not improve the progression-free survival time over docetaxel; the instantaneous rate of disease progression/death at any given time point was higher with abemaciclib vs docetaxcel. No specific safety concerns were observed. Clinical trial information: NCT02450539.

9060 Poster Session (Board #383), Sun, 8:00 AM-11:30 AM

PD-L1 expression, tumor mutation burden and response to immune checkpoint blockade in patients with *HER2*-mutant lung cancers. *First Author: Wei-Chu Victoria Lai, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: *HER2* mutations are present in 3% of lung cancers. Response to immune checkpoint blockade (ICB) in this subset of lung cancers is unknown. We evaluate the landscape of PD-L1 and tumor mutation burden (TMB) in *HER2*-mutant lung cancers (*HER2*m) and their response to ICB. **Methods:** Patients (pts) with advanced *HER2*m were identified retrospectively. PD-L1 expression was determined by immunohistochemistry (IHC); TMB was estimated by next-generation sequencing (NGS) using MSK-IMPACT. Objective response rate (ORR) to ICB was determined using RECIST v1.1. Kaplan-Meier was used for PFS and OS analyses. **Results:** We identified 122 pts with *HER2*m, of whom 87 had PD-L1 IHC and 84 had NGS. 26 pts with known activating mutations in *HER2*m were treated with ICB. PD-L1 expression was < 1% in 67 (77%), 1-49% in 9 (10%), and ≥50% in 11 (13%) pts. PD-L1 expression was lower when compared to an unselected cohort (n = 578) of lung cancers profiled at our center (p = 0.006). Median TMB (5.7 Mt/Mb, range 0.8-91.8) was the same as the median TMB of an unselected cohort (n = 3000) of lung cancers (p = 0.21). In those treated with ICB, ORR was 12% (3/26, 95% CI 3-30%), including 3 PR, 8 SD, 15 PD. In the 3 responders: none had an *HER2* YVMA mutation; 2 (66%) had PD-L1 ≥50%; 2 (66%) had TMB ≥median; median response duration was 3.4 months (range 1.4-21.2); and 1 (33%) remained on treatment with PR. From the start of ICB, median PFS was 1.9 months (95% CI 1.5-4.0), and median OS was 10.4 months (95% CI 5.9-NR). **Conclusions:** In pts with *HER2*-mutant lung cancers, PD-L1 expression is lower but TMB is similar to unselected lung cancers. Response to PD-(L)1 blockade is uncommon in pts with *HER2*-mutant lung cancers, but treatment with ICB can still be considered, particularly in the context of high PD-L1 expression or higher TMB.

9061 Poster Session (Board #384), Sun, 8:00 AM-11:30 AM

Brigatinib (BRG) in crizotinib (CRZ)-refractory ALK+ non–small cell lung cancer (NSCLC): Efficacy updates and exploratory analysis of CNS ORR and overall ORR by baseline (BL) brain lesion status. *First Author: Rudolf M. Huber, University Hospital of Munich, Thoracic Oncology Centre Munich, Munich, Germany*

Background: ALTA (NCT02094573) evaluated 2 doses of the ALK inhibitor BRG post-CRZ. Overall ORR contains both CNS and extra-CNS target lesion data. **Methods:** In ALTA, stratification included BL CNS disease (+/−). Pts were randomized to BRG 90 mg qd (arm A) or 180 mg qd with a 7-day lead-in at 90 mg (arm B). To differentiate CNS and extra-CNS efficacy we compared CNS ORR with overall ORR by BL CNS status. **Results:** 222 pts were randomized (n = 112/110, arm A/B); 71%/67% had BL CNS lesions. Of 247/204 total target lesions in A/B, 38 (15%) and 32 (16%), respectively, were in the CNS; 28 (25%) pts in A and 23 (21%) in B had ≥1 target CNS lesion. Median follow-up was 19.6/24.3 mo. Per independent review, CNS ORR in pts with measurable BL CNS lesions (n = 26/18, A/B) was 50%/67%; in pts with any BL CNS lesions (n = 81/74, A/B), median intracranial PFS (iPFS) was 12.8/18.4 mo. Table shows long-term overall efficacy updates by BL CNS status. Dose reductions or discontinuations due to AEs (A/B): 7%/29% and 4%/11%. **Conclusions:** With > 24 mo follow-up, the recommended BRG 180 mg dose (with lead-in) continues to demonstrate long PFS and iPFS and high CNS ORR. Comparable CNS ORR (67%) and overall ORRs in pts with (61%) or without (55%) BL CNS target lesions support BRG's broad whole-body activity. Clinical trial information: NCT02094573.

Crizotinib in patients (pts) with MET-amplified non-small cell lung cancer (NSCLC): Updated safety and efficacy findings from a phase 1 trial. *First Author: D. Ross Camidge, Medical Oncology Department, University of Colorado, Aurora, CO*

Background: MET amplification (amp) has been reported in a subset of NSCLC with the frequency varying depending on the definition used. Crizotinib, an ALK/ROS1/MET inhibitor approved in ALK- or ROS1-positive NSCLC, also has proven clinical activity in cases of MET exon 14 alterations and MET amp. Here we present an updated analysis of crizotinib in pts with low, medium (med), and high (hi) levels of MET amp in advanced NSCLC. **Methods:** In this ongoing, open-label, multicenter, phase 1 trial (NCT00585195), MET amp was locally tested; pts with MET/CEP7 ratios ≥1.8 were eligible. Pts received crizotinib 250 mg BID and were assigned to categories based on low (≥1.8–≤2.2), med (> 2.2–< 5), or hi (≥5) MET/CEP7 ratios. The latter 2 thresholds were revised to > 2.2–< 4 and ≥4; data were then reanalyzed to better delineate predictive biomarkers of response. Selected endpoints included best overall response (BOR) per RECIST v1.0, time to tumor response (TTR), progression-free survival (PFS), duration of response (DOR) and safety. **Results:** At data cut-off (31 Oct 2017), 40 pts were treated; 3 had no MET amp. Baseline characteristics were comparable among the revised amp categories. Median TTR was 8.0 wk (range, 7.1–9.1). BOR, DOR, and PFS are shown in the. 3 MET hi pts remain on treatment. The adverse event profile in this cohort was consistent with the established safety profile of crizotinib. **Conclusions:** Pts with NSCLC with hi MET amp (MET/CEP7 ≥4) showed clinically meaningful antitumor activity with rapid and durable responses. Crizotinib was generally well tolerated. Coincidence with MET exon 14 alterations and other targets of crizotinib is being explored. Clinical trial information: NCT00585195.

9063 Poster Session (Board #386), Sun, 8:00 AM-11:30 AM

A multicenter phase II study of low-dose erlotinib in frail patients with EGFR mutation-positive, non-small cell lung cancer: Thoracic oncology research group (TORG) trial 1425. *First Author: Kazuhiko Yamada, Division of Respirology, Neurology, and Rheumatology, Department of Internal Medicine, Kurume University School of Medicine, Kurume, Japan*

Background: We previously reported that low-dose erlotinib has a certain degree of efficacy with lower toxicity in patients with non-small cell lung cancer (NSCLC) harboring epidermal growth factor receptor (*EGFR*) mutations (Eur J Cancer 2015). This multicenter phase II study was undertaken to investigate the efficacy and safety of low-dose erlotinib for those patients with frailty. **Methods:** Chemotherapy-naïve NSCLC patients with *EGFR* mutations who had frailty were enrolled and received erlotinib 50 mg/d. Dose escalation was allowed to those with stable disease after 4 weeks. Patient's frailty was defined as follows: (Group 1) 20 to 74 years of age with Eastern Cooperative Oncology Group performance status (PS) ≥2 or Charlson Comorbidity Index (CCI) ≥6 points; (Group 2) 75 to 80 years of age with PS ≥1 or CCI ≥6 points; (Group 3) ≥81 years of age with any PS and CCI. The primary endpoint was independent review committee (IRC)-confirmed objective response rate (ORR) to the low-dose erlotinib, with target ORR of 65% and threshold of 50% (SWOG two-stage design). **Results:** Eighty patients were enrolled between December 2014 and April 2017: males/females 26/54; median age 80 (range 49-90); Group 1/2/3 15/28/37; Ad/Sq/Others 76/1/3. *EGFR* mutation types were: exon 19/21 42/38. All 80 patients were included in efficacy and safety analysis. The IRC-confirmed ORR was 60.0% (90%CI: 50.2-69.2%), and the primary endpoint was met. The disease control rate was 86.3% (90%CI: 78.3-92.1%). Median progression-free survival was 9.2 months. Although overall survival data are immature, median survival time and 1-year survival rate were 26.3 months and 68.9%, respectively. Toxicities were generally mild, with a few grade 3 or more toxicities. There was no case of interstitial lung disease or treatment-related death. **Conclusions:** This is the first prospective study evaluating low-dose erlotinib for frail patients with *EGFR* mutation-positive NSCLC. Low-dose erlotinib is active and could be a treatment option for those patients. Clinical trial information: UMIN 000015949.

9064 Poster Session (Board #387), Sun, 8:00 AM-11:30 AM

Time to treatment discontinuation (TTD) as a pragmatic endpoint in metastatic non-small cell lung cancer (mNSCLC): A pooled analysis of 8 trials. *First Author: Yutao Gong, US Food and Drug Administration, Silver Spring, MD*

Background: Progression-free survival (PFS) is an important efficacy endpoint in oncology trials. However, clinical trials increasingly allow treatment beyond objective radiographic progression (TBP) for patients deriving clinical benefit from therapy. Furthermore, treatment discontinuation due to toxicity is increasingly uncommon in trials of targeted therapies. Thus, TTD may represent a practical endpoint for real-world evidence (RWE) studies. **Methods:** We pooled data from patients (pts) with mNSCLC treated on 13 arms of 8 randomized controlled trials of tyrosine kinase inhibitors (TKI), immune checkpoint inhibitors (ICI), or chemotherapy (Chemo) initiated between 2007-2014; 3 chemo arms with planned discontinuation without maintenance therapy were excluded. We measured the pt-level correlation (corr) between TTD and PFS within each drug category (EGFR TKI; ALK TKI; ICI; or Chemo), and determined rates of disparity between TTD and PFS greater than 3 months. **Results:** 2369 pts met criteria for analysis. 1868 pts (79%) had a TTD event, and 1638 pts (69%) had a PFS event. Overall, median TTD was 5.7 months, and median PFS was 6.6 months. Pt-level analysis of the difference between PFS and TTD revealed recurring outliers (TABLE), with early TTD seen on chemo (PFS-TTD > 3 months in 10.9% of pts) and late TTD seen on TKI (TTD-PFS > 3 months in 12.1% of pts). Overall, the correlation between TTD and PFS was 0.91, stronger in pts treated with TKI or ICI (0.92) and weaker in pts treated with chemo (0.78; TABLE). **Conclusions:** Pt-level analysis indicates TTD is strongly correlated with PFS in contemporary trials of pts with mNSCLC, particularly those treated with TKI or ICI. Among pts treated with TKI or ICI, TTD exceeds PFS by > 3 months in several cases. These results indicate a need for further investigation of TTD across cancers and treatments to assess its role as an endpoint in RWE studies.

Subgroup	N	Median PFS	Median TTD	Corr	Early TTD %	Late TTD %
All	2369	5.7	6.6	0.91	5.2	7.3
EGFR TKI	595	12.1	10.9	0.95	0.7	10.9
ALK TKI	475	12.6	13.3	0.89	3.0	13.5

Chemo	718	2.8	4.2	0.78	10.9	0.6

9065 Poster Session (Board #388), Sun, 8:00 AM-11:30 AM

Predictive value of CD73 expression in *EGFR*-mutation positive non-small-cell lung cancer patients received immune checkpoint inhibitors. *First Author: Hidenobu Ishii, Division of Respirology, Neurology, and Rheumatology, Department of Internal Medicine, Kurume University School of Medicine, Kurume, Japan*

Background: CD73 dephosphorylates and converts extracellular adenosine monophosphate to adenosine, leading to immune escape of malignancies. Although epidermal growth factor receptor (*EGFR*) mutation-positive NSCLC showed high expression of CD73, the predictive relevance of CD73 expression in patients with *EGFR* mutation received immune checkpoint inhibitors (ICIs) is unknown. **Methods:** We screened 67 patients with Stage I-III *EGFR* mutation-positive NSCLC received complete resection (cohort A), 17 patients with advanced or recurrent NSCLC received immune checkpoint inhibitors after resistance to EGFR-TKI treatment (cohort B), and 31 patients with *EGFR* mutation-negative NSCLC treated with ICIs. CD73 expression was evaluated by immunohistochemical analysis, and tumors with staining in over 50% of tumor cells were scored as high expression. **Results:** In cohort A, the high CD73 expression group showed relatively shorter disease-free survival and overall survival than the low CD73 group in patients with Stage I-III *EGFR* mutation-positive NSCLC received complete surgical resection. In cohort B, the overall response rate of ICIs was significantly higher in patients with high CD73 expression than those with low CD73 expression (66.7% versus 0%, $p = 0.006$), and the high CD73 expression group showed significantly longer progression-free survival (PFS) than low CD73 group (median 16.0 months versus 1.2 months, $p = 0.024$). Meanwhile, there was no significant difference in PFS of ICIs between in the high and low CD73 expression groups of *EGFR* mutation-negative NSCLC (median PFS; 2.8 months versus 2.8 months, $p = 0.394$). **Conclusions:** In patients with *EGFR* mutation-positive NSCLC, expression of CD73 may predicts a favorable outcome of ICIs treatment unlike in *EGFR* mutation-negative patients.

9066 Poster Session (Board #389), Sun, 8:00 AM-11:30 AM

Impact of central nervous system (CNS) involvement in advanced non-small cell lung cancer (NSCLC) patients (pts) treated with immune checkpoint inhibitors (ICI). *First Author: Lizza Hendriks, Gustave Roussy, Department of Medical Oncology, Villejuif, France*

Background: CNS metastases (CNS+) are frequent in NSCLC. Unfortunately, pts with (untreated) CNS+ are often excluded from ICI clinical trials so that their outcome on ICI is largely unknown. **Methods:** Retrospective data collection of all consecutive advanced ICI treated NSCLC pts in 2 French centers (nov 2012 – jan 2018). Progression free survival (PFS), overall survival (OS), intracranial objective response rate (iORR) and site of progression (PD) (CNS, extracranial or both) on ICI was collected. Active brain metastases (BM) were defined as non-irradiated new and/or growing lesions on brain imaging < 6 weeks before ICI start. **Results:** 483 pts were included, 65% male, 84% WHO PS 0-1, median age 64 years, 75% nonsquamous, 10% targetable driver mutations, 37% known PD-L1 (66% $\geq$1% expression). ICI treatment was median 2nd line (range 1-12), 95% had monotherapy PD(L)-1 inhibition. 137 pts (28%) had CNS+ at start ICI, 93% had only BM, the others had BM +/- leptomeningeal metastases. 42% had active CNS+. CNS+ pts had significantly more often a smoking history compared to CNS- pts (97 vs 91% $p = 0.02$), were younger (61 vs 64 years, $p = 0.002$), had more often adenocarcinoma (73 vs 62%, $p = 0.04$), and had a higher number of organs with metastases (3.3 vs 2.4, $p < 0.001$). Baseline characteristics did not differ for active vs non-active CNS+. With a median follow-up of 16 mo (95% CI 14-21 mo), median iORR, PFS and OS were not significantly different for those with CNS+ vs CNS- and active CNS+ vs non-active CNS+ (table). CNS failure was significantly more often in CNS+ pts vs CNS- pts (CNS only PD: 12% vs 5%, CNS and extracranial PD: 19% vs 6%: $p < 0.001$). The proportion of CNS failure did not differ significantly for active and non-active CNS+ ($p = 0.12$). **Conclusions:** (Active) CNS involvement does not negatively impact outcome on ICI although CNS failure is more common in CNS+ compared to CNS- pts.

Pts, nr	iORR in evaluable pts (%)	Median PFS (95% CI), months	p-value	Median OS (95% CI), months	p-value

9067 Poster Session (Board #390), Sun, 8:00 AM-11:30 AM

Immune-related adverse events and nivolumab outcomes in non-small cell lung cancer patients: A multi-institutional, retrospective cohort study. *First Author: Rebecca Jane Moor, Princess Alexandra Hospital & University of Queensland, Brisbane, Australia*

Background: Immune checkpoint inhibitors are routinely used in Non Small Cell Lung Cancer (NSCLC) patients following progression on first-line therapy. Immune-related Adverse Events (IrAEs) have been associated with the efficacy of PD-1 inhibitors in melanoma. The association between the development of IrAEs and efficacy of nivolumab remains unclear in NSCLC. **Methods:** We retrospectively collected data from patients who received nivolumab for advanced NSCLC on an Open Access Program across seven oncology institutions in Queensland, Australia, and analyzed whether there was an association between outcomes and the development of immune-related toxicity. **Results:** One hundred and ninety six patients were enrolled to this ethics committee approved audit – 77 females (39%) and 119 (61%) males; PS 0-1 (62%); PS 2-3 (38%); median age 67 (range 42-84). An objective response was recorded in 24% of patients; partial response (47/196) with one complete response, in addition 28% (55/196) had stable disease. The median overall survival was 9.2 months; 13.4 months in PS 0-1 patients and 4.2 months in PS 2-3 patients. At 1 year, the overall survival rate was 42%; 57% in patients with PS 0-1 and 18% in PS 2-3 patients. The presence of IrAEs of any grade occurred in 36% of patients and was associated with a longer median PFS of 5.9 months versus 2.3 months (P value < 0.01, 95% CI) in patients with no immune toxicity on Kaplan Meier analysis. The median OS of patients experiencing an IrAE was 24.3 months compared with 6.5 months without (P value < 0.01, 95% CI). A durable clinical benefit was observed in 72% of patients who developed at least one IrAE versus 37% in those without any immune mediated toxicity. Analysis of the prognostic relevance of routine histological, hematological and biochemical parameters is ongoing with a multivariate analysis planned. **Conclusions:** Nivolumab had clinically significant long-term benefits in the treatment of locally advanced and metastatic NSCLC with 12 month survival rates in keeping with clinical trials in PS 0-1 patients. The development of IrAEs was associated with improved outcomes including median PFS, OS and higher rates of clinical response in this cohort.

9068 Poster Session (Board #391), Sun, 8:00 AM-11:30 AM

Next generation sequencing (NGS) based mutation profiling and heterogeneity of resistance mechanisms to AZD9291. *First Author: Jun Zhao, Beijing Cancer Hospital, Beijing, China*

Background: AZD9291, a third-generation epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI), is active against patients with *EGFR* T790M-mutant non–small cell lung cancer (NSCLC) who failed prior treatment with EGFR TKIs. However, acquired resistance to AZD9291 is inevitable. In this study, we retrospectively analyzed mechanisms of acquired resistance to AZD9291 in advanced NSCLC. **Methods:** A total of 293 advanced lung adenocarcinoma patients with signs of AZD9291 resistance were enrolled in the study from January to October 2017. Tissue biopsy was the first choice for mutation profiling, and ctDNA testing was used as an alternative. All samples were analyzed using next-generation sequencing based ER-Seq method, which enables simultaneously assess single-nucleotide variants, insertions/deletions, rearrangements, and somatic copy-number alterations across at least 59 genes (59-1021). **Results:** At resistance, 3 molecular subtypes emerged: 66 cases (22.5%) lost original *EGFR* activating mutation and T790M mutation; 130 cases (44.4%) lost the T790M mutation despite detecting of the underlying *EGFR* activating mutation; 97 cases (33.1%) maintained both *EGFR* activating mutation and T790M mutation. Known resistance mechanisms detected in 11/66 (16.7%), 56/130 (43.1%), 62/97 (63.9%) cases respectively for all the 3 subtypes. The most frequently known mechanism was *EGFR* C797S which was identified in 60 cases, while *EGFR* L792H/V, G796S, L718Q/V, G719A, and E709K were in 27 cases. Activating mutations of PI3K-AKT-mTOR signaling, amplification of the *MET*, activating mutation / amplification of *ERBB2*, *ALK*/*ROS1*/*RET* fusion, activating mutation of *BRAF*, or *KRAS* were identified in 37, 16, 14, 9, 8, 5 patients respectively. Moreover, 24 cases had *Rb1* loss of function mutation. Co-occurrence of resistance mechanisms were observed in 31 patients. **Conclusions:** There was a high frequency of inter and intra-patient heterogeneity of resistance mechanisms after AZD9291 therapy. Comprehensive NGS analysis may facilitate the broad exploration of potential resistance mechanisms.

9069 Poster Session (Board #392), Sun, 8:00 AM-11:30 AM

Mechanisms of acquired resistance to MET tyrosine kinase inhibitors (TKIs) in MET exon 14 (METex14) mutant non-small cell lung cancer (NSCLC). *First Author: Mark M. Awad, Dana-Farber Cancer Institute, Boston, MA*

Background: Non-small cell lung cancers (NSCLC) harboring METex14 activating mutations can respond dramatically to treatment with MET TKIs, but the mechanisms of acquired resistance to these therapies are not well understood. **Methods:** We performed next generation sequencing on serial plasma samples and/or tumor biopsies and one autopsy case from patients with METex14 mutant NSCLC to identify mechanisms of resistance to the type 1 MET TKI crizotinib and the type 2 MET TKI glesatinib. **Results:** Samples from 12 patients with METex14 mutant NSCLC were included in this analysis. In 4 cases (33%), acquired MET alterations were identified including one case with amplification of the mutated METex14 allele and three cases with MET tyrosine kinase domain secondary site mutations; in two of these cases, more than one MET resistance mutation was present in the same patient. Secondary mutations in MET included H1094Y, G1163R, L1195F, L1195V, D1228N, Y1230H, and Y1230S. In 4 cases (33%), bypass track activation was identified, including massive genomic amplification of wild-type *KRAS*, *BRAF*, and/or *EGFR*. In 4 cases (33%), the resistance mechanism was not identifiable. A case of acquired resistance to glesatinib with acquired amplification of the mutated METex14 allele had a confirmed partial response after switching to crizotinib. Data from resistant preclinical models and patient-derived cell lines and mouse xenografts will be presented. **Conclusions:** Novel therapeutic strategies will be needed to delay or overcome multiple complex mechanisms of acquired MET TKI resistance in METex14 mutant NSCLC.

9070 Poster Session (Board #393), Sun, 8:00 AM-11:30 AM

Immuno-oncology biomarker study in a large cohort of LC-SCRUM-Japan: Assessment of PD-L1 expression and tumor mutation burden in non-small cell lung cancer patients treated with immune checkpoint inhibitors. *First Author: Kiyotaka Yoh, Department of Thoracic Oncology, National Cancer Center Hospital East, Kashiwa, Japan*

Background: PD-L1 high expression and high tumor mutation burden (TMB) are reported to be correlated with high sensitivity to immune checkpoint inhibitor (ICI) in non-small cell lung cancer (NSCLC). This immuno-oncology biomarker study is ongoing as part of nationwide genomic screening by LC-SCRUM-Japan. Planned accrual is 1000 patients. **Methods:** Lung cancer patients enrolled in LC-SCRUM-Japan were primarily screened with targeted next-generation sequencing with Oncomine™ Comprehensive Assay (OCA) and monitored clinical course and survival every 6 months. To explore new biomarkers for ICI in the treatment of NSCLC, further analyses of 4 immunohistochemistry (IHC) assays for PD-L1 expression (22C3, 28-8, SP263 and SP142) and whole-exome sequencing (WES) to determine TMB level were conducted in 1000 and 400 patients, respectively. **Results:** Among 1635 patients with lung cancer enrolled in LC-SCRUM-Japan between Feb 2017 and Jan 2018, 621 NSCLC patients were enrolled in this immuno-oncology biomarker study. The results of PD-L1 IHC with 420 patients, OCA with 380 patients, WES with 50 patients, were analyzed at data cutoff point of Jan 4, 2018. Median TMB level by WES was 72 (2 to 515) and median TMB level by OCA was 7.6 mutation/Mb (0 to 30.8). There was no significant association between each PD-L1 expression and TMB by WES. TMB by OCA had a weak correlation with TMB by WES (R^2= 0.31). Seventy-seven patients treated with ICI were evaluable for clinical response. Among 6 responders to ICI, TMB level by WES was various (19, 26, 26, 109, 144, and 249). Of these, 2 had both high TMB by WES (≥ median 72) and PD-L1 high expression; 2 had TMB low/PD-L1 high; 1 had TMB high/PD-L1 low: 1 had TMB low/PD-L1 low but high TMB by OCA (15.4 mutation/Mb). **Conclusions:** High TMB level appears to produce high sensitivity to ICI in patients with NSCLC, independent of PD-L1 high expression. Based on WES analyses in a large cohort, the findings to explore a precise predictive immuno-oncology biomarker to maximize the therapeutic benefits will be reported at the meeting.

9071 Poster Session (Board #394), Sun, 8:00 AM-11:30 AM

Refining the sensitivity of plasma cell-free DNA (cfDNA) genotyping by controlling for plasma tumor content. *First Author: Catherine Meador, Department of Medicine, Brigham and Women's Hospital, Boston, MA*

Background: Plasma cfDNA genotyping has been widely adopted for NSCLC diagnosis due to its convenience and high positive predictive value. However, limited assay sensitivity means negative plasma genotyping requires reflex tumor testing. We hypothesized that quantification of plasma tumor content could be used to aid interpretation of results. **Methods:** EGFR T790M plasma genotyping results were studied from patients (pts) with pretreated EGFR mutation-positive (EGFRm) advanced NSCLC and confirmed tumor T790M from two multicenter trials (AURA, AURA3). Quantitative plasma genotyping was performed for AURA using BEAMing (Sysmex) and for AURA3 using next-generation sequencing (NGS, Guardant) and droplet digital PCR (ddPCR, Biodesix). Using EGFR Ex19del/L858R allele frequency (driver AF) as an adequacy assessment, T790M sensitivity was studied across a range of plasma tumor content. **Results:** Overall T790M sensitivity from AURA was 70%, but 96% (95/99) in pts with detected driver AF > 0.5% and 39% (15/38) in pts with detected driver AF ≤0.5% (Table). In AURA3, T790M sensitivity with NGS (66%) and ddPCR (61%) increased to 97% for both methods (173/178 and 112/115) in pts with detected driver AF > 1% (Table). Combining AURA and AURA3 data (BEAMing and NGS), T790M false negative rate was 48% (54/112) with detected driver AF ≤1%, and 3% (9/265) with detected driver AF > 1%. **Conclusions:** In pts with pretreated EGFRm NSCLC and T790M-negative plasma genotyping, high driver AF suggests a low likelihood of missed T790M, but missed T790M is common in pts with low driver AF. While a negative plasma result should trigger reflex tumor testing, these emerging data may inform the decision to proceed with tumor biopsy, especially in high-risk pts. Investigations are planned to study whether cfDNA adequacy assessments are broadly applicable in pts with NSCLC undergoing plasma testing. Clinical trial information: NCT01802632; NCT02151981.

9072 Poster Session (Board #395), Sun, 8:00 AM-11:30 AM

Pooled overall survival and safety data from the pivotal phase II studies (NP28673 and NP28761) of alectinib in ALK-positive non-small cell lung cancer (NSCLC). *First Author: Sai-Hong Ignatius Ou, Chao Family Comprehensive Cancer Center, University of California, Orange, CA*

Background: Alectinib, a highly selective inhibitor of ALK tyrosine kinase, has demonstrated systemic and central nervous system activity in ALK+ NSCLC. Two single-arm, open-label phase II studies (NP28673; global [NCT01801111] and NP28761; North American [NCT01871805]) have previously demonstrated robust overall survival (OS) in crizotinib-resistant ALK+ NSCLC (Yang et al, J Thorac Oncol 2017). We report final pooled phase II OS and safety data after a longer duration of follow-up. **Methods:** Patients with locally advanced or metastatic ALK+ NSCLC (possible prior chemotherapy) who had progressed on or were intolerant to crizotinib, received twice-daily alectinib 600mg orally until progression, death or withdrawal. This pooled analysis assessed OS and safety after a median follow-up of 92.3 weeks (almost 2 years) (NP28673 105.5 weeks, data cut-off 27 October 2017; NP28761 75.7 weeks, data cut-off 12 October 2017). **Results:** The pooled data set included 225 patients. At the time of final data cut-off 53.3% of patients had died, 39.1% were alive and in follow-up, and 7.6% had withdrawn consent or been lost to follow-up. Alectinib demonstrated a median OS of 29.1 months (95% CI: 21.3–39.0) in the pooled analysis (NP28673 29.2 months [95% CI: 21.5–44.4]; NP28761 27.9 months [95% CI: 17.2–NE]). Mean dose intensity 94.2%. Grade ≥3 adverse events (AEs; any cause) occurred in 44.0% of patients, with no AE term reported in >4% of patients. The most common AEs (any grade) included constipation (39.1%), fatigue (35.1%), edema peripheral (28.4%), myalgia (26.2%) and nausea (24.0%). Despite the longer treatment duration (median 48.6 weeks), alectinib demonstrated a tolerable safety profile consistent with previous studies; 14.7% of patients experienced AEs leading to dose reductions, 37.3% of patients experienced AEs leading to dose interruptions or modifications and 6.2% of patients experienced AEs leading to withdrawal. **Conclusions:** This pooled phase II analysis demonstrated a median OS of >2 years in patients with pretreated ALK+ NSCLC receiving alectinib. In addition, alectinib was well tolerated over a median treatment duration of almost one year (48.6 weeks). Clinical trial information: NP28673; NCT01801111; NP28761; NCT01871805.

9073 Poster Session (Board #396), Sun, 8:00 AM-11:30 AM

Comparative effectiveness of carboplatin-pemetrexed (Carbo-Pem) with vs. without bevacizumab (Bev) in patients with advanced non-squamous (Sq) non-small cell lung cancer (NSCLC). *First Author: Stephen Joseph Bagley, Division of Hematology/Oncology, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA*

Background: The majority of patients with advanced non-sq NSCLC do not have high programmed death ligand 1 (PD-L1) expression or a targetable genetic alteration. Carbo-pem-bev is commonly used as first-line therapy in these patients, but it is unknown whether the addition of bev to carbo-pem improves overall survival (OS). **Methods:** Using nationally representative electronic health record data from Flatiron Health, we performed a retrospective cohort study of patients diagnosed with advanced non-sq NSCLC from 2011-2017 who received ≥1 cycle of carbo-pem, with/without bev, as initial systemic therapy for metastatic disease. Patients with alterations in epidermal growth factor receptor (EGFR) or anaplastic lymphoma kinase (ALK) were excluded. The survival impact of adding bev to carbo-pem was assessed using a Cox proportional hazards model. **Results:** Patient characteristics are listed in Table 1 (n = 5,264). Median follow-up time and OS were 31 (IQR 16-49) and 10.2 (95% CI 9.8-10.8) months (mo), respectively. After adjusting for the covariates in Table 1, the addition of bev was associated with improved OS (median 12.1 vs 8.8 mo; HR 0.80, 95% CI 0.74-0.85, $p < 0.001$). In a sensitivity analysis of patients with known Eastern Cooperative Oncology Group Performance Status (ECOG PS) (N = 2,708), the effect of bev was similar (HR 0.79, 95% CI 0.72-0.88, $p < 0.001$). **Conclusions:** In this large, real-world dataset, the addition of bev to first-line carbo-pem for metastatic non-sq NSCLC was associated with improved OS. To our knowledge, this is the first study to address whether bev improves outcomes when added to carbo-pem.

9074 Poster Session (Board #397), Sun, 8:00 AM-11:30 AM

Therapeutic and prognostic impact of genetic alterations identified in nationwide genome screening for squamous cell lung cancer (LC-SCRUM-Japan). *First Author: Tomohiro Sakamoto, Tottori University, Yonago, Japan*

Background: A variety of genetic alterations have been identified in squamous cell lung cancer (SqLC), but the clinical relevance of them remains poorly understood. We have prospectively analyzed advanced SqLC patients for multi-gene alterations and have followed up clinical course of the patients, establishing a large-scale clinico-genomic database in our nationwide genome screening project (LC-SCRUM-Japan). **Methods:** Since March 2015 to December 2017, 3316 advanced non-small cell lung cancer patients from 251 institutions had been enrolled in the LC-SCRUM-Japan, and 470 of them were histologically SqLC. Submitted tumor samples were subjected to a next-generation sequencing system, Oncomine Comprehensive Assay, enabling the analysis of < 160 cancer-related genes. **Results:** Among 409 available SqLC samples, potentially targetable gene alterations were detected in 196 (48%). Based on the gene alterations, the patients were categorized into 4 types, consisting of 40 (10%) with genetic alterations of FGFR family (FGFR type; 26 *FGFR1* amp, 12 *FGFR1/2/3/4* mut, 1 *FGFR3* amp and 1 *FGFR3* fus), 67 (16%) with those of the PI3K pathway (PI3K type; 46 *PIK3CA* mut/amp, 18 *PTEN* mut and 3 *AKT* mut), 49 (12%) with other oncogene alterations (AdC-like type; 24 *EGFR* mut/amp, 14 *KRAS* mut, 6 *ALK* mut/fus and 5 *ERBB2* amp) and others. Mutations in *TP53*, *CDKN2A*, *STK11* and *RB1* were also detected in 57/13/7/5%, respectively, but these were not significantly correlated between the 4 types. The overall survival (OS) of the patients with FGFR type tended to be shorter than that of PI3K and AdC-like types (median OS, 8.8 vs 18.8 months; p = 0.09). The efficacy of platinum-containing chemotherapies or immune checkpoint inhibitors was not significantly different among the 4 types in the current follow-up data. **Conclusions:** Through the nationwide screening, a series of genetic alterations have been identified in advanced SqLC and *FGFR* gene alterations were related to poor prognosis. Our large-scale integrative clinico-genomic database enables us to elucidate the clinical significance of genetic alterations, contributing the development of genotype-directed therapeutic strategy for SqLC patients.

9075 Poster Session (Board #398), Sun, 8:00 AM-11:30 AM

Hyperprogression after immunotherapy: Clinical implication and genomic alterations in advanced non-small cell lung cancer patients (NSCLC). *First Author: Youjin Kim, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of (South)*

Background: Hyperprogressive disease (HPD) emerges as a new subset of patients treated with immune-oncology (IO) agent. The definition of HPD is not yet clearly established, and it is unclear which patient is rapidly progressing after IO treatment. We investigated clinical features and potential genomic markers associated with HPD after IO therapy. **Methods:** We performed a retrospective clinical and radiological analysis of advanced NSCLC patients treated with single IO at Samsung Medical Center(July 2014 to December 2017). CT scans were quantitatively analyzed in terms of tumor volume and tumor growth rate (TGR) by comparing prior vs upon IO. We extracted tumor volume for each metastatic organ, classifying into HPD and non-HPD by volume-based growth kinetics. We also performed deep targeted sequencing of 375 of genes. **Results:** Of 220 evaluable patients37 patients (17%) were classified as HPD. 26 (70%) were male, 24 (65%) smoker, 25 (68%) ≧ 65 years, 10 (27%) ECOG PS ≧ 2, 31(84%) adenocarcinoma. Compared to non-HPD population, HPD was not associated with higher tumor burden at baseline, nor with gender, smoking status, PD L1 status, line of chemotherapy, prior radiotherapy. With median follow up of 20 months(m), mPFS and mOS were 4.4m (95% CI: 2.8-6.0), 12m (95% CI: 9.4, 16.0), respectively. HPD patients had significantly lower mPFS (1.2 vs 4.1m, p = < .000), mOS (7.1 vs.15.9m, p = 0.09). Further details with genomic profiling will be presented. **Conclusions:** HPD(defined by tumor growth kinetics) occurs in 17% of 220 advanced NSCLC patients after single-agent checkpoint inhibitors. Genomic profiles may help to identify patients at risk for HPD on IO.

9076 Poster Session (Board #399), Sun, 8:00 AM-11:30 AM

Rare targetable drivers (RTD) in NSCLC: PD-L1 expression, tumor mutation burden (TMB), microsatellite instability (MSI) and outcomes with immune check-point inhibitors (ICPi). *First Author: Elizabeth Dudnik, Thoracic Cancer Unit, Davidoff Cancer Center, Rabin Medical Center, Petah Tikva, Israel*

Background: The efficacy of ICPi in NSCLC with RTD is unknown. **Methods:** 82 consecutive patients (pts) with RTD (non-EGFR/ALK) were selected from the Davidoff Cancer Center database. The correlation between RTD type and TMB, MSI (by FoundationOne™ algorithm), and PD-L1 was analyzed. ORR, PFS with ICPi (RECIST 1.1) and OS were assessed; uni- and multivariate OS analysis was done. **Results:** Median age 63y (31-97); males 46%; smokers 50%; adenoca 87%. PD-L1, TMB, and MSI were assessed in 61%, 58%, and 57% pts, respectively (Table). Of 77 pts with advanced disease, 44 received ICPi. ORR with ICPi was 16%; median PFS was 3.2 mo (95% CI, 2.6-5). With median follow-up since ICPi initiation of 7.8 mo [IQR 4.2-14], 19/44 (43%) pts died, median OS was 16.2 mo (95% CI, 8.4-NR). No correlation was seen between OS with ICPi and PD-L1 (p-0.6), TMB (p-0.9), or RTD type (p-0.9). With median follow-up since advanced disease diagnosis (AdvDisDx) of 15 mo [IQR 7.2-24], 40/77 (52%) pts died, median OS was 32 mo (95% CI, 19.9-44.9) and 13 mo (95% CI, 6.6-15.9) for pts who were and were not exposed to ICPi, respectively (log rank test-6.3, p-0.01). In the multivariate analysis, ICPi exposure (p-0.04), targeted agents exposure ($p < 0.01$) and ECOG PS ($p < 0.01$) were the only variables which correlated with OS since AdvDisDx. **Conclusions:** Rare targetable drivers in NSCLC are associated with low/intermediate TMB, MSI stable status and variable levels of PD-L1 expression. ICPi outcomes are comparable to those of unselected NSCLC pts and largely unpredictable. ICPi exposure has independent impact on OS.

Identification of osimertinib resistance mechanisms in Chinese NSCLC patients: Analysis from AURA17 trial. *First Author: Min Hu, IMED Asia, AstraZeneca, and Dizal (Jiangsu) Pharmaceutical Co., Ltd, Shanghai, China*

Background: Osimertinib is approved for metastatic NSCLC patients with EGFR T790M mutation after progression from EGFR-TKI therapy. Despite impressive tumor responses, drug resistance usually develops. Mechanisms of resistance to osimertinib are emerging, while resistance studies with large cohorts of Chinese patients are still lacking. Here we reported a resistance profile of osimertinib using plasma samples from 76 Chinese patients who had progressed by DCO2 (Nov. 4, 2016) of AURA17 study (NCT02442349), the pivotal trial for China market approval. **Methods:** Serial plasma cell-free DNA (cfDNA) were collected from baseline until progressive disease (PD) by investigator assessment. Capture-based 75-gene NGS panel was used to identify resistance mechanisms to osimertinib by comparing paired plasma cfDNA at baseline and PD. Droplet digital PCR was used to dynamically monitor EGFR mutation changes during treatment course. Association of cfDNA biomarkers with objective response rate (ORR) and progression-free survival (PFS) was analyzed. **Results:** 61 out of the 76 patients had detectable EGFR sensitizing mutations (L858R or Ex19Del) in their cfDNA samples at PD. Among them, 8 had acquired EGFR C797S, all *in cis* with T790M, with no enrichment for either L858R or Ex19Del (5:3). The median time of C797S detection from plasma was 2.8 (1.4-8.4) months prior to PD. EGFR amplification, L718Q, I744T, C775Y, G796S/D and T854I mutations were found in 13 patients. Aberrations in bypass tracks including ERBB2/3, FGFR3, HRAS, JAK1/2, MET, MTOR, NTRK1, PIK3CA, *etc.* were observed in 35 patients. Clearance of EGFR sensitizing mutations at weeks 3 or 6 of treatment was associated with favorable ORR (69.7% *vs.* 33.3% and 74.3% *vs.* 33.3%) and PFS (6.9 *vs.* 4.0 and 7.1 *vs.* 4.1 months, respectively). Presence of T790M at PD was correlated with longer PFS (8.2 *vs.* 4.2 months). **Conclusions:** Our study revealed diverse mechanisms of resistance to osimertinib in Chinese NSCLC patients. As the current subset has shorter PFS compared to the overall AURA17 population (6.2 *vs.* 9.7 months), analysis of plasma samples from patients who progressed by 24 months after last subject first dose (LSFD) is ongoing for a more comprehensive view. Clinical trial information: NCT02442349.

9078 Poster Session (Board #401), Sun, 8:00 AM-11:30 AM

Early prediction of outcomes to PD1 inhibitors in non-small cell lung cancer (NSCLC) using next generation sequencing (NGS) of plasma circulating tumor DNA (ctDNA). *First Author: Nicolas Guibert, Toulouse University Hospital, Toulouse France*

Background: Patient selection for PD-1 inhibitors in NSCLC is still based on imperfect screening biomarkers, including PD-L1 tumor expression and tumor mutational burden. We hypothesized that pretreatment molecular profile of ctDNA and its early kinetics during treatment could represent a reliable and non-invasive approach to determine response. **Methods:** Up to 4 serial plasma samples were prospectively collected from patients with advanced NSCLC treated with nivolumab as second line therapy: *i)* pretreatment, *ii)* at 1 month, *iii)* at the first CT-scan, *iv)* at progression. Plasma NGS was performed using InVisionSeq, tagged amplicon sequencing of hotspots and coding regions from 36 genes. The early kinetics (1 month) of ctDNA through treatment was analyzed along with specific baseline alterations as early indicators of response to immunotherapy. **Results:** 80 specimens from 33 patients underwent NGS. Alterations in ctDNA were detectable in 25/33 baseline samples. The most frequently detected alterations at baseline were TP53 (54.4%); KRAS (33.3%); STK11 (24.2%); and NFE2L2 (9%). Lack of detectable ctDNA at baseline in 6/8 patients correlated with progressive disease (PD). Studying 23 patients for whom serial specimens were available with ctDNA detected at baseline, plasma response (kinetics of ctDNA between baseline and 1 month specimens) was correlated with clinical outcomes (RECIST) in 18/23 cases (11/13 with overall response (OR) or stable disease (SD) and 7/10 with PD). Furthermore, ctDNA demonstrated potential predictive ability on outcomes by analyzing specific alterations and type of nucleotide change (transversion vs transition). Transversions in KRAS and TP53 were detected in 13/14 baseline cases demonstrating clinical benefit (OR+SD) while 8/11cases from patients who went on to have PD were enriched with transitions or STK11 co-mutations with TP53 or KRAS transversions. **Conclusions:** Plasma cell-free DNA analysis using NGS could be an additional screening assay to identify patients likely to derive benefit from anti-PD-1 therapy, particularly when tissue is unavailable.

9079 Poster Session (Board #402), Sun, 8:00 AM-11:30 AM

Dissecting the prognostic role of common EGFR-mutations of metastatic NSCLC in TKI era: A systematic review and subgroup meta-analysis. *First Author: Feng-Che Kuan, Department of Hematology and Oncology, Chang-Gung Memorial Hospital, Chiayi, Taiwan*

Background: Del19 is a good prognostic factor comparing to L858R regarding progression-free survival (PFS). In TKI era, whether Del19 is also good prognostic factor in overall survival (OS) and these two common mutations respond equally to reversible and irreversible TKIs are not elucidated. **Methods:** A systematic review and subgroup meta-analysis was undertaken to explore the differential efficacy toward frontline reversible and irreversible TKIs between the common mutations. Extracted overall response rate (ORR), PFS or OS were expressed in risk ratio (RR) or hazard ratio (HR) by random-effects model. The pooling of survival curves was expressed in median and interquartile range (IQR). **Results:** From inception to December 30, 2017, total 20 randomized controlled trials (RCT) and 21 retrospective cohort studies (RCS), comprising of 3,380 patients with Del19 and 2,687 patients with L858R were included in this analysis. Under first-generation (1G) TKIs, Del19 had better ORR, PFS and OS ($RR_{Del19/L858R}$= 1.19, 95% CI: 1.10-1.28; PFS $HR_{Del19/L858R}$= 1.25, 95% CI: 1.14-1.37; OS $HR_{Del19/L858R}$= 1.37, 95% CI: 1.19-1.57). Under second-generation (2G) TKIs, Del19 had no significantly better ORR/PFS ($RR_{Del19/L858R}$= 1.04, 95% CI: 0.94-1.16; $HR_{Del19/L858R}$= 1.18, 95% CI: 0.99-1.42). Under 1/2G TKIs, Del19 is good prognostic factor for OS ($HR_{Del19/L858R}$= 1.35, 95% CI: 1.20-1.52). The pooled median PFS of 1G TKIs was 12.53 (IQR: 11.45-13.70) in Del19 and 10.33 months (IQR: 9.51-11.29) in L858R. The pooled median PFS of 2G TKIs was 14.95 (IQR: 12.01-17.69) and 13.55 months (IQR: 11.33-16.31), respectively. In addition, the pooled median OS of 1G TKIs was 29.48 (IQR: 25.88-33.56) in Del19 and 22.95 months (IQR: 20.54-26.32) in L858R. The pooled median OS of 2G TKI was 32.08 (IQR: 27.86-33.40) and 26.63 months (IQR: 21.15-34.14), respectively. **Conclusions:** In comparison with L858R, Del19 is a good prognostic factor for RR/PFS under 1G TKIs and for OS under 1/2G TKIs. Common mutations respond differently to reversible and irreversible TKIs. Further study targeting on L858R are warranted to fulfill this unmet need in TKI era.

9080 Poster Session (Board #403), Sun, 8:00 AM-11:30 AM

Subgroup analysis of histology in ALTER0303: Anlotinib hydrochloride as 3rd line and further line treatment in refractory advanced NSCLC patients (pts). *First Author: Ying Cheng, Jilin Cancer Hospital, Jilin, China*

Background: In the ALTER0303 trial (NCT02388919), anlotinib hydrochloride was used as subsequence therapy for adult IIIB/IV NSCLC pts who progressed after at least 2 lines of prior systemic therapies. It has demonstrated that anlotinib significantly prolonged OS and PFS in advanced NSCLC pts as 3rd line treatment. Here we report the efficacy of anlotinib in pts with different histology, including adenocarcinoma (ACC), squamous cell carcinoma (SCC) and so on. **Methods:** 437 pts were randomised in a 2:1 ratio to receive anlotinib (12 mg QD from day 1 to 14 of a 21-day cycle) or placebo till progression or intolerable toxicity. Pts harboring EGFR or ALK mutations must had received previously targeted therapies. Primary endpoint is OS. Histology was the pre-stratified factor. **Results:** For the ACC pts (n=336), PFS and OS were both significantly improved in the anlotinib arm, and the most common grade ≥3 treatment-related AEs were hypertension and hypertriglyceridemia. Furthermore, in the subgroup of pts with SCC (n=76), remarkable advantages in PFS were observed in the anlotinib arm as well. Hypertension, hyponatremia and hemoptysis were the most common AEs in SCC NSCLC. (Data presented in the Table) **Conclusions:** In the ALTER0303 trial, a significant improvement in PFS was found in anlotinib treated pts from both subgroups (ACC and SCC). This is indicating that using anlotinib as subsequence therapy strategy not only led to the improvement in OS and PFS for advanced ACC pts, but also prolonged PFS of the SCC pts. Anlotinib could be an appropriate option for this difficult-to-treat NSCLC pts as subsequence treatment regardless of the histology. Clinical trial information: NCT02388919.

9081 Poster Session (Board #404), Sun, 8:00 AM-11:30 AM

Frequency of brain metastases and outcomes in patients with *HER2-, KRAS-, and EGFR*-mutant lung cancers. *First Author: Mark G. Kris, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: *HER2* mutations are oncogenic drivers in 3% of lung cancers. Here we describe the frequency and course of patients with *HER2* mutant lung cancers with spread to brain and compare results to individuals with *KRAS*- and *EGFR*-driven cancers. **Methods:** We compared cohorts of consecutive patients with *HER2*-(n = 98), *KRAS*- (n = 200) and *EGFR*- (n = 200) mutant lung cancers. Multivariate logistical regressions adjusted for follow-up length were performed to evaluate baseline and subsequent development of brain metastases and survival from the date of diagnosis of stage IV disease. **Results:** In total, brain metastases occurred in 41% of 498 patients (95% CI 37 to 45%). At diagnosis of stage IV disease, 19% (19/98) in the *HER2* cohort, 24% (48/200) in *KRAS*, and 31% (62/200) in *EGFR* had brain metastases (p= 0.8). Among those without brain metastases at baseline, 34% (27/79) of patients with *HER2* vs 11% (16/152) with *KRAS* ($p < 0.001$), vs 23% (32/138) with *EGFR* (p= 0.048) developed brain metastases during treatment. The overall incidence of brain metastases was 47% (46/98) in patients with *HER2*, 32% (64/200) with *KRAS)*, and 47% (94/200) with *EGFR* (p = 0.73). The occurrence of any brain metastases imparted a shorter median survival in patients with *HER2-* (25 vs 30 months, $p< 0.001$) and *EGFR-* (29 vs 92 months, $p < 0.001$) driven cancers but not with *KRAS* (14 vs 21 months, p= 0.44). The median overall survival was 1.6 years (range 1.3 – 2.2 years) for *HER2*, 1.1years (range 0.8 – 1.3 years) for *KRAS*, and 3.0 years (range 2.5 – 4.0 years) for *EGFR* ($p< 0.0001$). **Conclusions:** In our patients with lung cancers driven by *HER2, KRAS*, and *EGFR*, brain metastases occurred in 41% overall. The risk is numerically higher with *HER2* and *EGFR* than *KRAS*. While the incidence of brain metastases in patients with *HER2* mutant lung cancers is numerically lower than *EGFR* at diagnosis, it rises over the disease course to 47%, equal that of *EGFR*. Among those without brain metastases at baseline, a greater number of patients with *HER2*-mutant tumors subsequenty developed brain metastases during treatment compared to the *EGFR* and *KRAS* cohorts. With one third of patients with *HER2* mutant lung cancers developing brain metastases during treatment, close surveillance is critical.

9082 Poster Session (Board #405), Sun, 8:00 AM-11:30 AM

Can duration of response be used as a surrogate endpoint for overall survival in advanced non-small cell lung cancer? *First Author: Boris M Pfeiffer, Merck KGaA, Darmstadt, Germany*

Background: Surrogate endpoints for overall survival (OS) in advanced non-small cell lung cancer (NSCLC), such as overall response rate (ORR) and progression-free survival, are prone to bias due to crossover and unbalanced post-progression therapy or inconsistent response assessment criteria. This study aimed to evaluate the surrogacy of duration of response (DoR) for OS in phase III trials adjusted for crossover, unbalanced post-progression treatment, insufficient information and inconsistent response criteria. **Methods:** The analysis was based on systematic literature review and data extraction. The relationship between absolute differences in median DoR and in median OS was assessed using the correlation coefficient (R). Additionally, the relationship of the combination of ORR and DoR, which may be a better surrogate for OS because it captures both the frequency and duration of response, with OS was evaluated. The bias arising from different definitions of ORR and DoR was addressed in a subset analysis on RECIST-based trials and WHO-based trials. Further stratification by reported definition of DoR, either from start of treatment (randomization) or onset of response, was performed. **Results:** ORR, DoR, and OS values were reported in 20 trials (8,382 patients). The correlation coefficient of DoR with OS was 0.356 (95% CI: 0.000-0.690). 8 trials defined response according to RECIST criteria and 11 trials defined DoR from the first documented response. In these subsets, the correlation was 0.630 (95% CI: 0.000–0.924) and 0.572 (95% CI:0.000–0.873), respectively. The correlation coefficient of the combination of DoR and ORR with OS was 0.790 (95% CI: 0.535–0.913). In the RECIST-based trials and trials defining DoR from first documented response, the correlation coefficients of the combination of ORR and DoR with OS were 0.742 (95% CI: 0.079–0.950) and 0.887 (95% CI: 0.614–0.971), respectively. **Conclusions:** Evaluation of DoR as a surrogate for OS should take into consideration both response assessment criteria and ORR. The adjustment with ORR gives a better estimate of the treatment effect and can be used jointly with DoR as a surrogate endpoint to predict OS benefit.

9083 Poster Session (Board #406), Sun, 8:00 AM-11:30 AM

Concurrent genomic alterations in lung adenocarcinoma with a *MET* exon 14 skipping mutation. *First Author: Julia Rotow, University of California, San Francisco, San Francisco, CA*

Background: *METex14* oncogenic driver mutations are present in 2-4% of lung adenocarcinoma. While second-site *MET* mutations have been reported at MET TKI resistance, the factors influencing response to MET TKI therapy are not yet fully characterized. The landscape of co-occurring genetic alterations, which correlates with treatment response in EGFR-mutant NSCLC, is incompletely understood in *METex14* NSCLC. **Methods:** Targeted exome sequencing of cell-free DNA (cfDNA) obtained via the clinical Guardant360 assay for co-occurring alterations (somatic variants, copy-number alterations) in 68 cancer-associated genes within 70 samples from 65 patients with advanced stage *METex14* NSCLC. Synonymous mutations and those with predicted neutral or unknown functional impact were excluded. **Results:** 81.4% of *METex14*-positive samples contained concurrent genomic alterations, with a mean of an additional 2.6 (range 0-20) alterations/sample. Mutations or amplifications in *TP53* (44.6% of patients), CDK4 (13.8%), EGFR (12.3%), and NF1 (12.3%) were most common. Pathway analysis identified receptor tyrosine kinases (40%), cell cycle mediators (29.2%), and the MAPK pathway (26.2%) as frequently altered. Alterations in the MAPK pathway have not yet been implicated in TKI resistance in *METex14* NSCLC. We identified two patients with newly acquired MAPK pathway alterations (*KRAS* amplification, *KRAS G12D* mutation) at MET TKI resistance. **Conclusions:** The cfDNA from patients with *METex14* NSCLC frequently contains additional oncogenic co-alterations. Among downstream *MET* signaling mediators there is a high rate of concurrent MAPK pathway alterations in *METex*14 NSCLC, as well as newly acquired MAPK pathway alterations at resistance to MET TKI therapy. The MAPK pathway is a potential therapeutic target to enhance treatment responses in *METex14* NSCLC.

9084 Poster Session (Board #407), Sun, 8:00 AM-11:30 AM

Immune-related adverse events to predict survival in patients with advanced non-small cell lung cancer treated with nivolumab: A multicenter analysis. *First Author: Biagio Ricciuti, Clinical Oncology, S. Maria della Misericordia Hospital, Perugia, Italy*

Background: Anti-PD1 or anti-PD-L1 are the current standard of care for platinum-pretreated advanced non-small cell lung cancer (NSCLC) patients (pts), having shown to prolong survival as compared to chemotherapy in second line setting. Pts treated with these drugs not infrequently experience the so-called immune-related adverse events (irAEs), which we hypothesize reflect antitumor responses. In this study we investigated whether irAEs were associated with nivolumab efficacy in pts with advanced NSCLC. **Methods:** We conducted a retrospective study of pts with advanced NSCLC treated with nivolumab between Oct 2013 and Sept 2017. IrAEs were defined as AEs having immunological basis that required monitoring and interventions. We identified two groups according to the development of irAEs and evaluated the ORR, PFS and OS. **Results:** In a cohort of 127 pts, (median [range] age, 63 [30-81] years; 84 men [66.1%], 43 women [33.9%]; 34 [26.8%] with squamous (Sq) histology, 93 [73.2%] with Nsq histology), irAEs occurred in 57 of 127 study pts (44.8%). Six of them (10.5%) experienced grade 3 or higher irAEs. ORR and DCR were significantly higher in pts with irAEs (68.8% versus 4.8%, $P < 0.0001$ and, 79.6% versus 20.3% $P < 0.0001$, respectively). The median PFS was significantly longer in the irAEs group (8.6 [95%CI 4.3-11.7] versus 2.1 [95%CI 1.7-2.4] months, $P < 0.001$). Median OS was also significantly longer in pts with irAEs (17.4 [95%CI 8-28.8] versus 3.7 months [95%CI 2.7-4.6], $P < 0.0001$). Importantly, pts with ≥ 2 irAEs had a significantly prolonged OS as compared to those who developed 1 irAE (median NR versus 11.9 months, P = 0.04). Multivariate analysis confirmed that irAEs were significantly associated with improved survival outcomes, with HR of 0.27 (95% CI, 0.17-0.43; $P < 0.001$) for PFS and 0.36 (95% CI, 0.22 to 0.59; $P < 0.001$) for OS. **Conclusions:** In this multicenter study the development of irAEs was a strong predictor of prolonged OS in NSCLC pts treated with nivolumab. Of note, pts who developed ≥ 2 irAEs had a more pronounced survival benefit as compared to pts with only one event. Further studies are required to investigate the molecular mechanisms underlying this association.

9085 Poster Session (Board #408), Sun, 8:00 AM-11:30 AM

Contribution of nationwide genome screening in Japan (LC-SCRUM-Japan) to the development of precision medicine for non-small cell lung cancer. *First Author: Takashi Seto, Department of Thoracic Oncology, National Kyushu Cancer Center, Fukuoka, Japan*

Background: A nationwide genome screening project in Japan (LC-SCRUM-Japan) has been established for the development of lung cancer precision medicine. **Methods:** Since 2013, non-squamous non-small lung cancer patients have been screened for ALK/ROS1/RET fusions using RT-PCR and FISH, and since 2015, they have also analyzed for 143 gene alterations using a next-generation sequencing (NGS) system, Oncomine™ Comprehensive Assay. Based on the molecular screening and the monitoring of clinical course and patient survival, a large-scale integrative clinico-genomic database has been established. **Results:** As of December, 2017, 251 institutions were participating and 4371 patients had been enrolled. The success rates of RT-PCR and NGS were 95% and 92%, respectively. Of 3919 available samples, a total of 1568 actionable gene alterations (382 KRAS mut, 193 ERBB2 mut/amp, 142 ROS1 fus, 100 RET fus, 98 MET skip/amp, 97 BRAF mut, 97 ALK fus, 96 PIK3CA mut, 54 FGFR1 amp, 13 NRAS mut, 6 AKT1 mut, 6 FGFR2/3 fus, 4 NRG1 fus, 2 NTRK3 fus and others) were detected in 1505 samples (38%). The concordance rates of the results in ALK, ROS1 and RET fusion detection between NGS and the corresponding RT-PCR were 0.98, 0.99 and 0.99, respectively. Through this screening, a total of 793 genotype-matched patients to molecular-targeted clinical trials were identified, and 136 of them (17%) were enrolled into the trials. Of the 2345 patients analyzed by NGS, the survival data were available in 1298 (55%). The patients with actionable gene alterations who were treated with targeted agents (n = 136) had significantly longer overall survivals than those not treated with targeted agents (n = 401) or the patients without actionable gene alterations (n = 761) (median survival [95%CI], 4.2 [2.4-8.2.] vs. 3.4 [2.3-5.8] vs. 2.3 [1.9-2.8] years, respectively; p = 0.01). **Conclusions:** LC-SCRUM-Japan contributes to the development of precision medicine, especially for ROS1, RET, ERBB2, BRAF and MET-positive lung cancers. In addition to the tissue-based molecular screening, a NGS assay with liquid biopsy was started in December 2017 and is now ongoing in the LC-SCRUM-Japan.

9086 Poster Session (Board #409), Sun, 8:00 AM-11:30 AM

Early determination of benefit or futility in treating NSCLC using the LCSS 3-Item Global Index (3-IGI). *First Author: Richard J. Gralla, Albert Einstein College of Medicine - Jacobi Medical Center, Bronx, NY*

Background: Early assessment of the effect of treatment for advanced NSCLC can prevent unnecessary exposure to toxic and costly therapy while aiding in decision making to change treatment if necessary. Analysis in mesothelioma (Symanowski *JCO* 2014) suggested that a 20% decline from baseline after 2 cycles of chemotherapy in the 3-Item Global Index of the LCSS identified patients unlikely to benefit. The 3-IGI (global distress, activities, QL) takes < 2 minutes to assess. **Methods:** 164 patients with NSCLC receiving chemotherapy or check point inhibitors were prospectively evaluated with the LCSS at baseline and every 3 weeks using electronic media. Patients were also randomized 1:1 so that their physicians knew the results of the LCSS immediately in half of the patients. **Results:** Patients: Stage IV 92%; first line 73%; female 43%; median PS 1; mean age 63. The LCSS was completed after 2 cycles of treatment and prior to planning for the next cycle (generally 6 weeks after baseline; representing 91% of the 148 patients living). Patients with a 20% decline in the 3-IGI compared with baseline had a median survival of 7.6 months, contrasted to 15.8 months for those without this degree of 3-IGI decline (p = 0.01); 1 year survivals = 26% versus 62%. Even with the marked PRO decline after 2 treatment cycles, patients in the 20% decline group received a median of 2.3 more cycles of the same chemotherapy (median cost = $10,712 / patient). In the 50% of patients for which their physicians knew the ongoing LCSS results, fewer chemotherapy cycles and imaging studies were performed, but the differences were not significant (p = 0.8). **Conclusions:** Assessing change from baseline with the 3-IGI of the LCSS identifies after only 2 cycles of treatment those patients who have poor response and survival outcomes if continued on the same therapy. This PRO assessment is rapid, easy and inexpensive. Physicians need to consider the impact of change on decision options given that even when physicians were aware of the worsening PRO they often did not act on the findings. Responding to 3-IGI changes can result in better decisions concerning continuing or changing treatment, lessening toxicity, and savings in cost of unhelpful treatment. Support: NIH/NCI R01 CA157409 Clinical trial information: NCT01924416.

9087 Poster Session (Board #410), Sun, 8:00 AM-11:30 AM

Landscape of EGFR-dependent and independent mechanisms of osimertinib resistance in EGFR-mutant NSCLC patients. *First Author: Xiuning Le, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Osimertinib is a third generation EGFR TKI, however, the mechanisms of resistance to osimertinib have been incompletely described, and there are currently no targeted regimens known to be effective for these patients. We evaluated clinical and genetic characteristics of patients who received osimertinib for *EGFR*-mutant NSCLC. We also provide treatment experience after progression on osimertinib. **Methods:** Using the MD Anderson GEMINI database and Moffitt Cancer Center dataset, we identified patients treated with osimertinib and performed clinical outcome analysis. Molecular profiling analysis was performed at the time of progression when available. **Results:** 118 patients were identified. Median PFS on osimertinib was 8.8 months (95% CI, 6.5 to 11). Overall survival from diagnosis was 76.7 months (95% CI, 42.5 to 111). 71 patients had disease progression. Upon progression, osimertinib was continued in 44 of 71 patients with 21 (48%) received local consolidation radiation. The osimertinib continued patients had longer second PFS compared to the ones discontinued. For patients who progressed on osimertinib, 42 had molecular profiling upon progression. A total of 22 genes/pathways were observed to have recurrent alterations. In addition to two cases with germline T790M, 19 cases retained and 21 cases lost detectable T790M mutation. Among T790M-retained cases, tertiary EGFR mutations of C797S/G and L792H (11 cases) in EGFR gene, and MET amplification (5 cases), were the most common mechanisms of resistance. In T790M-lost cases, PIK3CA mutation (2 cases), MET amplification, and small cell transformation, but not additional EGFR resistance mutations, were observed. Other resistance- associated alterations included FGFR amplification and RET fusion. Preclinical studies verified that osimertinib resistance could be reversed by targeting a subset of these alterations. **Conclusions:** We found continuation of osimertinib beyond first progression may offer clinical benefit. Osimertinib resistance is associated with diverse mechanisms. The loss of T790M was common, and the majority of resistance was associated with EGFR-independent, as in some cases targetable, mechanisms.

9088 Poster Session (Board #411), Sun, 8:00 AM-11:30 AM

Demographic composition of lung cancer trials: FDA analysis. *First Author: Lola A. Fashoyin-Aje, U.S. Food and Drug Administration, Silver Spring, MD*

Background: Lung cancer is the leading cause of cancer death; in the US non-small cell lung cancer (NSCLC) accounts for 80% of the lung cancer diagnoses. Enrollment of a diverse population in clinical trials (CTs) of new cancer drugs may provide information regarding the safety and efficacy of treatments in demographic subgroups that are disproportionately represented among new cases of, and deaths from, cancer. This analysis characterizes the demographics of patients enrolled in CTs submitted to FDA in support of marketing applications for FDA-approved NSCLC drugs. **Methods:** Reviewed datasets in the applications of original approval for new NSCLC drugs (2011- 17), and pooled demographic data from CTs that provided primary safety and efficacy data for drug approval. **Results:** This table illustrates enrollment by demographics at all sites and in the US. **Conclusions:** Enrollment of females is slightly higher (54%) than predicted based on corresponding incidence rates (48%) for this subgroup in the Surveillance, Epidemiology, and End Results database. Enrollment of younger patients is also higher than predicted based on incidence rate; patients < 65 years comprise 68% of all enrolled patients compared to 28% of new cases. These differences may be attributable, in part, to the number of CTs for new drugs for biomarker-defined NSCLC subtypes that occur more frequently in females and younger patients than in NSCLC in general. In contrast, there is lower representation of racial/ethnic minority patients (< 1%) and patients ≥ 65 years of age (32%) in these CTs than predicted by incidence rates (65.9, 83.7, 312 and 15 cases per 100,000 in patients who are White male, Black male, > 65 years, and < 65 years, respectively). Targeted enrollment of racial/ethnic minorities and older patients is needed to improve their access to CTs; such efforts may facilitate an assessment of safety and efficacy in these subgroups.

9089 Poster Session (Board #412), Sun, 8:00 AM-11:30 AM

Phase I/II study of the A2AR antagonist NIR178 (PBF-509), an oral immunotherapy, in patients (pts) with advanced NSCLC. *First Author: Alberto Chiappori, Department of Thoracic Oncology, Moffitt Cancer Center, Tampa, FL*

Background: ATP is catabolized to adenosine in the tumor microenvironment, leading to excess adenosine and immunosuppressive effects via immune checkpoint protein adenosine 2A receptor (A2AR). NIR178 is an oral A2AR antagonist that selectively binds and inhibits A2AR, reactivating T cell-mediated antitumor immune response. This Phase I/II study evaluated NIR178 in previously treated pts with advanced NSCLC (NCT02403193). **Methods:** Pts (ECOG PS 0–1) had received ≥1 prior line of therapy; EGFR/ALK pts had failed prior TKI therapy. Objectives: primary – determine MTD of single-agent NIR178; secondary – efficacy endpoints, PK, and evaluation of PD-L1 expression. **Results:** At 13 Dec 2017 data cut-off, 24 pts had been treated: median age 68 yrs, 46% male; 79% received prior immunotherapy; 22/24 (92%) pts had discontinued (due to progression [n = 13], death [n = 2], AEs [n = 2] or other reasons [n = 5]) and 2/24 (8%) pts remained on treatment. Dose levels evaluated: 80 (n = 3), 160 (n = 3), 320 (n = 7), 480 (n = 6), 640 mg BID (n = 5). There was 1 DLT: Gr 3 nausea (640 mg). The most frequent (≥20%) any-Gr AEs regardless of causality were nausea (67%), fatigue (63%), dyspnea (46%), vomiting (33%), chest pain and other (29%), gastroesophageal reflux disease, anemia, diarrhea (all 25%), anorexia, back pain, generalized muscle weakness and cough (all 21%). Drug-related Gr 3 AEs were pneumonitis (8%) and nausea (4%); no Gr 4 AEs were reported. Potential immune-related any-Gr AEs were rash (8%), pneumonitis (8%), hypothyroidism, increased ALT/AST (all 4%). NIR178 systemic exposure (Cmax, AUC) increased more than proportionally with dose. Efficacy data for 17/24 treated pts demonstrated responses and SD across the dose range, including 1 confirmed CR (480 mg) and 1 PR (80 mg), both in immunotherapy-naïve pts. Durable SD > 44 wks with tumor shrinkage was observed in 2 ongoing immunotherapy-exposed pts. Disease control was seen in pts with both high and low baseline PD-L1 expression. **Conclusions:** NIR178 was well tolerated; AEs were manageable and there were no Gr 4 drug-related AEs. Immune-related AEs may indicate immune stimulation. Clinical benefit was observed in immunotherapy-exposed and -naïve pts irrespective of PD-L1 status. Clinical trial information: NCT02403193.

9090 Poster Session (Board #413), Sun, 8:00 AM-11:30 AM

Avelumab (anti–PD-L1) in patients with platinum-treated advanced NSCLC: 2.5-year follow-up from the JAVELIN Solid Tumor trial. *First Author: Arun Rajan, Thoracic and Gastrointestinal Oncology Branch, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: Avelumab, a human anti–PD-L1 IgG1 monoclonal antibody, is an approved treatment for metastatic Merkel cell carcinoma in various countries and platinum-treated advanced urothelial carcinoma in the US. In phase 1b studies, avelumab has shown antitumor activity and acceptable safety in patients with advanced NSCLC. Here, we report long-term data for avelumab in patients (pts) with platinum-treated NSCLC. **Methods:** In a phase 1b cohort of JAVELIN Solid Tumor (NCT01772004), pts with stage IIIB–IV NSCLC unselected for PD-L1 status, with progression after platinum doublet therapy, received avelumab 10 mg/kg Q2W as second-line (2L) or later treatment until confirmed progression, unacceptable toxicity, or withdrawal. PD-L1 expression was assessed using PD-L1 IHC 73-10 assay. Time-to-event endpoints were estimated using Kaplan-Meier methods. **Results:** 184 pts received avelumab. At data cutoff on Feb 15, 2017, median follow-up was 33.9 months (range, 31.0-40.7) and 9 pts (4.9%) remained on treatment. 58 pts (31.5%) had received ≥2 prior lines of therapy for advanced disease. The objective response rate (ORR) was 14.1% (95% CI, 9.4-20.0), including complete response in 1.1%, and median duration of response was 17.5 months (95% CI, 6.9-21.4). Progression-free survival (PFS) rates at 6 months and 1 yr (95% CI) were 24.2% (18.1-30.8) and 16.5% (11.3-22.5). Overall survival (OS) rates at 1 and 2 yrs (95% CI) were 42.5% (35.1-49.7) and 25.0% (18.7-31.8). In evaluable pts with PD-L1+ (n = 122) and PD-L1− (n = 20) tumors (> 1% tumor cell cutoff), ORR (95% CI) was 16.4% (12.1-21.5) vs 10.0% (2.7-24.5), the 1-yr PFS rate was 19.1% (12.3-27.0) vs 5.0% (0.3-20.5), median OS was 11.1 (8.4-17.3) vs 4.6 (2.8-12.5) months, and the 2-yr OS rate was 30.0% (21.7-38.7) vs 17.1% (4.4-37.0), respectively. Safety findings were consistent with earlier analyses; 14.7% had a grade ≥3 treatment-related adverse event, most commonly (> 1%) infusion-related reaction (2.2%), lipase increase (1.6%), and pneumonitis (1.1%), and no treatment-related deaths occurred. **Conclusions:** Avelumab as 2L or later therapy is associated with durable responses and long-term OS in pts with platinum-treated advanced NSCLC. Clinical trial information: NCT01772004.

9091 Poster Session (Board #414), Sun, 8:00 AM-11:30 AM

Association of pre-existing thyroid autoimmunity with the development of thyroid dysfunction induced by nivolumab. *First Author: Shiro Kimbara, Department of Thoracic Oncology, National Cancer Center Hospital, Tokyo, Japan*

Background: Thyroid dysfunction (TD) induced by immune checkpoint inhibitors is not sufficiently understood. The purpose of this study was to identify risk factors and the clinical course of TD induced by nivolumab. **Methods:** Patients with advanced solid tumors who were treated with nivolumab from March 2009 through March 2016 at the National Cancer Center Hospital were eligible. Thyroid function and anti-thyroid antibodies from the preserved serum samples among patients treated with nivolumab were evaluated retrospectively. The biochemical diagnosis of TD was determined in accordance with the guidelines of ATA, AACE, and the Endocrine Society. We defined thyroid autoimmunity as presence of anti-thyroid antibodies including anti-thyroid peroxidase antibody (TPOAb) and anti-thyroglobulin antibody (TgAb) before nivolumab. **Results:** One-hundred and eighty-nine patients with advanced solid tumors who were treated with nivolumab from March 2009 through March 2016 at the National Cancer Center Hospital were eligible for this study. Twenty-three (12%) of 189 patients developed TD, including 17 cases of hypothyroidism and 20 of thyrotoxicosis. Thyrotoxicosis followed by hypothyroidism occurred in 14 cases. There were significant difference between patients who developed TD (n = 23) and who did not (n = 166) in thyroid autoimmunity ($p < 0.001$) and elevated TSH ($p = 0.01$) at baseline. Next, we performed further analysis among 168 patients with sufficient assessment of anti-thyroid antibodies. Fourteen of 35 patients (40%) with thyroid autoimmunity developed TD, versus nine of 133 (7%) without (odds ratio 9.19; 95% confidence interval [CI]: 3.53-23.9). In multivariate analysis, elevated TSH and TgAb at baseline were significantly associated with the development of TD, with odds ratios of 7.36 (95% CI: 1.66-32.7) and 26.5 (95% CI: 8.18-85.8), respectively. Interestingly, thyrotoxicosis followed by thyrotoxicosis did not develop in 5 of 6 patients who received steroid therapy on the onset of thyrotoxicosis due to any reasons such as other irAEs and a symptom relief for brain metastasis. **Conclusions:** Patients with preexisting TgAb and elevated TSH before nivolumab treatment were at high risk for TD.

9092 Poster Session (Board #415), Sun, 8:00 AM-11:30 AM

Genetic aberrations related to increased risks of brain metastasis in non-small cell lung cancer (GASTO-1036). *First Author: Delan Li, Sun Yat-Sen University Cancer Center, Guangzhou, China*

Background: Metastatic cancer to the brain has a poor prognosis and subject patients to limited therapeutic options. Lung cancer represents the most common primary tumor giving rise to brain metastasis (BM). Understanding molecular alterations that are associated with increased risks of BM is of great importance to develop more effective intervention and therapeutic strategies for patients. **Methods:** Sixty-one non-small cell lung cancer (NSCLC) patients who underwent surgery for BM removal between 2000 and 2016 were retrospectively studied. Twenty-five patients had synchronous brain metastatic tumors at diagnosis, while the rest had metachronous presentation of BM during the course of their disease progression. We performed mutation profiling using targeted next-generation sequencing for 416 cancer-relevant genes on resected FFPE tumor samples of both lung and brain lesions of these patients. BM-free survival and disease-free survival were assessed in the metachronous cohort by using Kaplan-Meier test and Cox regression model. **Results:** Mutations of oncogenes and tumor suppressors, such as *EGFR*, *TP53, KRAS, PIK3CA,* and gene fusions *(ALK* and *RET)*, were identified in a total of 85% (52/61) of the patients, which were highly concordant between BM and primary lung tumors, albeit discordance was also observed suggesting a unique genetic evolution. Mutations targeting CDKs/CDK inhibitors, PI3K pathway, *MET* and *ERBB2* are more enriched in the metastatic brain foci than the primary lung tumor, suggesting the association of those genes with increased risks of developing BM. Indeed, patients with activated PI3K pathway were found to have significantly shorter BM-free survival (hazard ratio = 8.77, $p < 0.001$) as well as shorter disease-free survival (hazard ratio = 7.43, $p < 0.001$). In addition, activation of WNT pathway, in particular, missense mutations of *CTNNB1*, also tends to be associated with higher risks for disease spread and developing BM from NSCLC. **Conclusions:** Our findings shed lights on genetic concordance and divergence of primary lung and brain metastatic tumors, and also show that activated PI3K and WNT pathways are significantly associated with increased risks of brain metastasis in NSCLC.

9093 Poster Session (Board #416), Sun, 8:00 AM-11:30 AM

Long-term efficacy and outcomes with sequential crizotinib followed by alectinib in *ALK*+ NSCLC. *First Author: Jessica Jiyeong Lin, Massachusetts General Hospital, Boston, MA*

Background: Alectinib was recently approved for first-line treatment of advanced ALK+ NSCLC based on the ALEX trial, which demonstrated improved PFS with first-line alectinib compared to crizotinib. However, crossover was not allowed in ALEX. As standard therapy for ALK+ patients relapsing on crizotinib is treatment with a second-generation ALK inhibitor, such as alectinib, a more appropriate control arm would have been sequential crizotinib and alectinib, rather than crizotinib alone. We therefore evaluated outcomes of patients sequentially treated with crizotinib and alectinib. **Methods:** We identified 94 *ALK*+ NSCLC patients treated with crizotinib followed by alectinib. Medical records were reviewed to determine clinical outcomes and post-alectinib resistance mechanisms. **Results:** The median PFS on crizotinib and alectinib were 8.1 months (95% CI, 6.4-10.6) and 13.1 months (95% CI, 8.2-19.4), respectively. The median interval from crizotinib discontinuation to initiation of alectinib was 8 days (range, 1-304). Five patients (5.3%) switched to alectinib due to toxicity, 1 (1.1%) due to patient preference, and 88 (93.6%) due to progression (pattern: CNS only, n = 39; extracranial only, n = 37; both CNS/extracranial, n = 12). The median combined PFS for sequential crizotinib and alectinib was 22.9 months (95% CI, 17.1-30.5). Of note, among 68 patients who received crizotinib as first-line and alectinib as second-line therapy, the median combined PFS was shorter at 17.1 months (95% CI, 13.3-23.6). The 5-year OS for the overall cohort from the diagnosis of metastatic disease or from initiation of crizotinib was 66% (95% CI, 51-77%) and 59% (95% CI, 44-72%), respectively. Twenty-nine patients underwent a tumor biopsy following progression on alectinib. Of these, 20 (69%) had an *ALK* resistance mutation, including: 10 (50%) G1202R, 6 (12%) I1171N, 1 (5%) I1171S, 1 (5%) I1171T, and 2 (10%) V1180L. **Conclusions:** These findings serve as a historical comparator for first-line alectinib trials including ALEX. While sequential therapy with crizotinib and alectinib can provide significant benefit, this analysis suggests patients may derive greater benefit from first-line alectinib, supporting upfront use of alectinib.

9094 Poster Session (Board #417), Sun, 8:00 AM-11:30 AM

Preliminary Phase II results of a multicenter, open-label study of nazartinib (EGF816) in adult patients with treatment-naïve *EGFR*-mutant non-small cell lung cancer (NSCLC). *First Author: Dong-Wan Kim, Seoul National University Hospital, Seoul, Korea, Republic of (South)*

Background: Nazartinib (EGF816) is a third-generation EGFR-TKI selective for activating and T790M mutations while sparing wild-type EGFR. In the Phase I part of a Phase I/II multicenter study of nazartinib in *EGFR*-mutant NSCLC (NCT02108964), the recommended Phase II dose was 150 mg QD. Preliminary safety and efficacy results are presented from the Phase II expansion in treatment-naïve patients (pts) with *EGFR*-mutant NSCLC. **Methods:** Pts (ECOG PS 0−1) received nazartinib 150 mg QD. Primary objective: evaluation of antitumor activity (overall response rate [ORR]) per blinded independent review committee (BIRC). Secondary objectives: characterization of safety/tolerability, and further efficacy endpoints (including time to response and progression-free survival [PFS]). **Results:** At the data cut-off 31 Aug 2017, 40 pts had been enrolled; median age 63.5 years, 70% Asian, 65% female, 52.5% ECOG PS 1, 16/40 (40%) pts had brain metastases at screening; 3/40 (7.5%) pts had discontinued (2 due to progressive disease and 1 due to AE) and 37/40 (92.5%) pts remained on treatment. Median duration of exposure was 16.1 wks. The most frequent (≥20%) any-grade (Gr) AEs were maculopapular rash (30%), diarrhea (28%), and stomatitis (23%). Gr 3 AEs occurred in 10/40 (25%) pts, most commonly (≥5%) maculopapular rash in 4/40 (10%) pts and hypokalemia in 2/40 (5%) pts; there were no Gr 4 AEs. Pts (n = 24) who were enrolled ≥15 weeks before the data cut-off date were considered evaluable. In these pts, the confirmed ORR by BIRC was 67% (1 CR/15 PRs); the unconfirmed ORR by BIRC was 75% (1 CR/17 PRs, including 2 pts with unconfirmed PRs still ongoing at the data cut off); disease control rate was 96%. Duration of response and PFS data were still immature at the data cut-off. **Conclusions:** Oral nazartinib demonstrated a tolerable safety profile; maculopapular rash, atypical of EGFR-TKIs, was managed with minimal dose adjustment. Promising efficacy in treatment-naïve pts with *EGFR*-mutant NSCLC was seen despite a high number of pts with brain metastases. At the data cut-off, 37/40 pts were still on treatment. Clinical trial information: NCT02108964.

9095 Poster Session (Board #418), Sun, 8:00 AM-11:30 AM

An amplicon-based liquid biopsy for detecting *ALK* and *ROS1* fusions and resistance mutations in advanced non-small cell lung cancer (NSCLC) patients. *First Author: Laura Mezquita, Department of Cancer Medicine, Gustave Roussy Cancer Campus, Paris-Sud University, Villejuif, France*

Background: Circulating tumor DNA (ctDNA), is a surrogate material for somatic mutation (mut) detection, such as *EGFR* in NSCLC patients (pts). However, the applicability for the detection of *ALK*/*ROS1* fusions and resistance mut. is poorly described. The aim of this study was to evaluate an amplicon-based *ctDNA* assay for detecting *ALK*/*ROS1* fusions and mut. in a cohort of *ALK*/*ROS1*+ NSCLC pts. **Methods:** Advanced *ALK*/*ROS1*+ NSCLC pts were prospectively enrolled from Dec 2016 to Dec 2017 in our institution. The analysis of *ALK*/*ROS1* mut, *EML4-ALK* (variant 1,2,3) and *ROS1* fusions (with partner genes *CD74*, *SLC34A2*, *SDC4* and *EZR*) in ctDNA were performed using InVisionFirst™ **Results:** 51 pts were included (43 *ALK*, 8 *ROS1); ALK/ROS1* status was confirmed by *ALK* IHC (26) and FISH (40). The median prior tyrosine kinase inhibitors (TKI) received was 2 (0-4). Blood samples (n = 127) were collected before TKI (n = 9), during (n = 120) or at progression (PD) (n = 25) in 45 pts that received TKI (13 crizotinib, 32 next-gen. TKI) or other therapies (n = 6). Before TKI, *ALK*/*ROS1* ctDNA fusions were detected in 86% of pts (5/6 *ALK*; 1/1 *ROS1*). In samples at PD, 64% had fusions detected (15/22 *ALK*; 1/3 *ROS1*). Overall, 16 pts had a positive fusion in blood (5 *EML4-ALK* variant 1-2, 8 variant 3, 2 *CD74-ROS1*, and 1 *SLC34A2-ROS1* (13 *ALK*, 3 *ROS1*). By contrast, a minority (13%) of samples collected during clinical response, were positive (8/69 *ALK*; 2/11 *ROS1). ALK* mut were detected in 30% of blood samples at PD to TKI (6/17): 17% (1/5) post-crizotinib (*G1269A*, *R1264K*, *L1196Q*, *F1164L*, *C1156Y*), and 45% (5/11) post next-gen. TKI (all *G1202R*), all of them associated with the *ALK* variant 3. No *ROS1* mut were detected. Complex *ALK* mut were observed in 2 pts variant 3 (post crizotinib and lorlatinib). Other *non-ALK* mut were found in 47% of samples at PD: *TP53* (5), *NFE2L2* (4), *PTEN* (2), *KRAS* (1) and *PI3KCA* (1). Complex *ALK* mut + *non-ALK* mut were found in 4 (24%) samples; exclusively others *non-ALK* mut were found in 4 samples. This could explain TKI resistance in 24%. **Conclusions:** Routine liquid biopsy detects *ALK/ROS1* fusions in untreated NSCLC pts and reflects treatment sensitivity in TKI exposed pts. It is also an accurate tool to assess TKI resistance.

9096 Poster Session (Board #419), Sun, 8:00 AM-11:30 AM

Real-world treatment patterns and survival of BRAF V600-mutated metastatic non-small cell lung cancer patients. *First Author: Leora Horn, Vanderbilt University Medical Center, Nashville, TN*

Background: There is limited evidence on clinical outcomes in patients with BRAF-mutated non-small cell lung cancer (NSCLC) treated outside the controlled environs of clinical trials. To address this gap, we described treatment patterns and survival in such patients evaluated and treated at selected US academic cancer centers in 2009 -2016. **Methods:** This was a cross-sectional, retrospective medical record review of BRAF V600-mutated metastatic NSCLC patients from 7 centers. Participants in current/ previous BRAF-related clinical trials were excluded. Onset of metastatic NSCLC defined the index date, which was required to occur ≥6 months before the record abstraction date. We described treatment patterns and used Kaplan-Meier analyses for overall survival (OS). **Results:** The study included 72 patients. At index, median age [range] was 65 [44 to 90] years, 61.1% were female, 66.7% were current/former smokers, and 70.8% had Stage IV NSCLC at diagnosis. Fifty-two patients received ≥1 line of systemic therapy for metastatic disease. Platinum-based doublet chemotherapy was the most common first-line (1L) regimen (76.9% of 1L recipients); no patient received 1L targeted therapy (TT). Of the 33 second-line (2L) treatment recipients 30.3% received TT, and 10 patients received TT in ≥3 lines. At time of review, 38 patients were deceased. Median (95%CI) OS from the index date was 31.0 (14.5, 63.8) months for all patients, and 45.9 (16.1, 62.4) months from 1L initiation among 1L recipients. Median (95%CI) OS was 56.5 (13.4, 89.1) months from metastatic onset for TT recipients and 27.2 (10.6, 64.6) months in those not treated with TT. Patients (26) who had a BRAF test result < 3 months from metastatic onset had substantially shorter median survival (14.1 months) than patients (21) who had a test result ≥3 months after onset (52.7 months). **Conclusions:** These findings indicate that survival expectations of BRAF V600-mutated metastatic NSCLC patients may be higher than metastatic NSCLC patients without an oncogenic driver. The data also show patients who received TT had numerically longer OS from metastatic onset than patients receiving usual care, adding to the evidence on the importance of TT in BRAF V600-mutant NSCLC.

9097 Poster Session (Board #420), Sun, 8:00 AM-11:30 AM

Randomized phase II trial evaluating treatment with EGFR-TKI versus EGFR-TKI associated with anti-estrogen in women with non-squamous advanced stage NSCLC: IFCT-1003 LADIE trial. *First Author: Julien Mazieres, Hôpital Larrey, Centre Hospitalier Universitaire Toulouse, Toulouse, France*

Background: The incidence of lung cancer is increasing dramatically in women with recent findings as the preferential involvement of the EGFR pathway and the potential impact of hormonal factors in women. Preclinical data have shown that the combination of an EGFR-TKI with an anti-estrogen could overcome resistance to EGFR-TKI. **Methods:** IFCT-1003 LADIE Trial was a 2x2 arms parallel open-label randomized phase II trial. PS 0-2 post-menopausal women with advanced stage lung adenocarcinoma were treated with gefitinib (G 250 mg/day) vs. G + fulvestrant 500 mg / month with a supplementary dose at day 15 (G+F) in the EGFR mutated group (EGFR+) in 1st or 2nd line setting or with erlotinib (E 150 mg/day) vs. E + fulvestrant (E+F) in the EGFR wild-type group (EGFR WT) in 2nd or 3rd line setting until progression or unacceptable toxicity. Primary objective was progression-free survival (PFS) at 3 and 9 months for EGFR WT and EGFR+ patients, respectively. **Results:** From 02/2012 to 03/2017, 204 pts (G 104, G+F 100) and 175 (E 87, E+F 88) were enrolled in the EGFR+ and EGFR WT cohorts respectively. The median number of fulvestrant injections was 10 in the G+F group and 3 in the E+F group. The tolerance was correct (grade 3/4: 24.2% in the G+F group *vs* 21.3% in the G group, 16.0% in the E+F group *vs* 13.8% in the E group) and no treatment-related death. In the EGFR+ cohort, the primary endpoint was reached as 54 pts in the G+F group were non-progressive at 9 months. Nevertheless, addition of F to G was not associated with significant better PFS (9.9 *vs* 10.1 months) or OS (22.1 *vs* 29.9 months). In the EGFR WT cohort, the primary endpoint was not reached as 29 patients were non-progressive at 3 months. Here also, addition of F to E was not associated with better outcome (PFS 1.8 *vs* 2.0 and OS 10.0 *vs* 7.3 months). No PFS difference was observed in the subgroup of patients with positive staining for REα. **Conclusions:** Addition of fulvestrant to EGFR-TKI is feasible and is associated with good PFS in the EGFR mutated group. Nevertheless, the lack of benefit associated with the combination of fulvestrant to EGFR-TKI does not support its future development in a phase 3 trial in women with NSCLC. Clinical trial information: NCT01556191.

9098 Poster Session (Board #421), Sun, 8:00 AM-11:30 AM

Targeting NFE2L2 mutations in advanced squamous cell lung cancers with the TORC1/2 inhibitor TAK228. *First Author: Paul K. Paik, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Despite efforts over the past decade, no targeted treatments exist for pts w/ SQCLC. Analyses by TCGA and others (Paik Cancer Disc 2015) have identified a heretofore untargeted, frequently mutated oncogene (NFE2L2)/tumor suppressor (KEAP1) pair, each mutated in ~20% of pts w/ SQCLC. NFE2L2 encodes Nrf2, a transcription factor involved in the oxidative stress response which is targeted for degradation by Keap1. NFE2L2 mutations occur exclusively in an exon 2 hotspot that encodes the Neh2 domain (aa.1-86), which is the binding site for Keap1. Mutations in this region disrupt Keap1 binding, leading to Nrf2 nuclear translocation and increased mTOR signaling through regulation of RagD (Shibata Cancer Res 2010). We now report translational studies and prelim results from a phase 2 trial of the oral TORC1/2 inhibitor TAK228 in SQCLC pts with these mutations. **Methods:** Cytotoxicity, signaling, and xenograft experiments were performed using LK-2 SQCLC cells harboring an NFE2L2 E79K mutation treated with TAK228, everolimus, rapamycin, or deforolimus. Pts w/ prev treated stage IV SQCLC w/ NFE2L2 mutations are eligible for an NCI CTEP single-institution phase 2 study of TAK228 3mg po qd (continuous 28 day cycles; NCT02417701). 1^0 endpoint: ORR. 2^0 endpoint: PFS. The study utilizes a Simon 2-stage design with H0 = 5% (N≥1/5 responses), HA = 40% (N≥2/10 responses). **Results:** TAK228 exhibited significantly increased anti-tumor activity over TORC1 rapalogs in LK-2 cells. TAK228 alone was cytotoxic at sub-[μM] (IC50 68nM); all other rapalogs had IC50s $>$ 10μM. This was assoc with an 80% decrease in downstream pS6 . Tumor response (-55% shrinkage) was also seen in an LK-2 xenograft treated with TAK228. No anti-tumor/growth inhibitory response was seen with any other rapalog. N = 4 pts have been treated on the clinical trial (exon 2 del, D29H, F37V, W24C). 2 related-SAEs (G3 hyperglycemia, G3 confusion) were seen; no other $>$ G2 AEs reported. ORR = 25% (1 PR, 3 SD, 0 PD). Prolonged response is present, with DOR = 11mo, 8mo, 5.5mo, and 1mo, all ongoing. **Conclusions:** TAK228 is well-tolerated w/ evidence of pre-clinical and clinical activity in NFE2L2 mutant SQCLC. The trial has met its first-stage endpoint and has expanded to N = 10 patients. Clinical trial information: NCT02417701.

9099 Poster Session (Board #422), Sun, 8:00 AM-11:30 AM

Final results of a phase I prospective trial evaluating the combination of stereotactic body radiotherapy (SBRT) with concurrent pembrolizumab in patients with metastatic non-small cell lung cancer (NSCLC) or melanoma. *First Author: Allison M. Campbell, Yale University School of Medicine, Department of Therapeutic Radiology, New Haven, CT*

Background: We report final Phase I results of a Phase I/II prospective trial assessing safety and tolerability of SBRT and concurrent pembrolizumab. **Methods:** Eligible patients had metastatic NSCLC or melanoma and ≥ 2 sites of disease. Patients who had received prior anti-PD1 therapy were eligible if their disease had progressed by RECIST criteria; these patients received SBRT at enrollment. Immunotherapy naïve patients were treated with 200 mg of pembrolizumab q3 weeks until disease progression, then received SBRT. After SBRT, patients received pembrolizumab q3 weeks until disease progression. Patients were assigned to an SBRT dose escalation arm based on target location: either in the lung (arm A) or elsewhere (arm B). **Results:** 24 patients were enrolled (melanoma n=5; NSCLC n=19). 9 patients had received prior anti-PD-1 therapy and therefore got SBRT at enrollment. 15 patients were immunotherapy naïve and received a mean of 8.3 cycles of pembrolizumab before disease progression and SBRT. The target SBRT dose of 30 Gy in 3 fractions was reached for each arm. No dose limiting toxicities (DLTs) were observed within 60 days of SBRT. Non-hematologic toxicities of $>$ grade 2 occurring during the 60 day DLT window or during subsequent pembrolizumab treatment are presented in the table below, with immune-related adverse events noted. 5 of 24 patients (21%) had an immune mediated grade 2 or 3 adverse event during post SBRT immunotherapy. Patients received pembrolizumab for a mean of 19.8 weeks post-SBRT (range 0-52 weeks) before disease progression. **Conclusions:** Dose escalation to 30 Gy in 3 fractions was completed for both arms without dose limiting toxicity. Combination therapy was well tolerated. Preliminary efficacy data indicates that addition of SBRT to a single site resulted in a mean of 19.8 weeks of continued response. Clinical trial information: NCT02407171.

9100 Poster Session (Board #423), Sun, 8:00 AM-11:30 AM

EGFR reporting in stage IV adenocarcinoma of the lung: Demographic predictors of EGFR testing and survival. *First Author: Shagufta Shaheen, Loma Linda University Medical Center, Loma Linda, CA*

Background: Tyrosine Kinase inhibitors (TKI) have changed the treatment paradigm in patients with stage IV adenocarcinoma of the lung (AdenoCa) harboring epidermal growth factor receptor (EGFR) mutation. Currently there are no guidelines for reflex pathologic testing or mandatory reporting of these mutations. **Methods:** Data for age, sex, race/ethnicity, SES, diagnosis year and EGFR mutation status (+/-) in Stage IV lung AdenoCa (2005-2015) were extracted from the population-based California Cancer Registry (CCR). Logistic regression assessed the proportion of AdenoCa patients that received EGFR testing by age, socioeconomic status quintile (SES), gender and race/ethnicity. Proportional hazards analysis evaluated survival by EGFR status. Among EGFR positive patients, demographic factor adjusted, lung cancer specific Cox proportional mortality hazards ratios (HR) were compared for use of TKI (Y/N). **Results:** Of the 23,674 patients, 3,916 (17%) had EGFR results in their report; this percentage increased for ordinally higher SES quintiles (Trend $p < 0.001$). Odds of EGFR testing (Y/N) increased from 2005 to 2015 ($p < 0.001$) and the odds ratio was higher for females vs. males (OR = 1.20;95%CI = 1.11-1.30;$p < 0.001$). Odds of EGFR testing was higher for Asian/Other and lower for non-Hispanic black patients vs. non-Hispanic white (OR = 1.32;95%CI = 1.20-1.45;$p < 0.001$ and OR = 0.86; 95%CI = 0.74-0.99;p = 0.002), respectively. Among EGFR tested patients, 1,173 (30%) were positive, 2,618 (67%) negative and 125 (3%) had unknown status. Median survival time was 858 days and 390 days for TKI (Y/N). Adjusted HR for TKI (Y/N) was 0.61; 95%CI = 0.58-0.64; $p < 0.001$). **Conclusions:** These findings reveal that, in spite of EGFR testing recommendations, only about 17% of patients had evidence of testing. The trend for higher testing prevalence in higher SES quintiles and during recent years is consistent with more comprehensive insurance and improving compliance. These findings reveal remarkably increased survival for EGFR positive patients treated with TKI. These findings underscore the need for reflex pathologic testing for EGFR mutations in advanced lung AdenoCa to improve patient outcomes and avoid delays in treatment.

9101 Poster Session (Board #424), Sun, 8:00 AM-11:30 AM

Clinical utility of plasma-based digital next-generation sequencing (NGS) in patients with advance-stage lung adenocarcinomas with insufficient tumor samples for tissue genotyping. *First Author: Jon Zugazagoitia, Medical Oncology Department. Hospital 12 de Octubre, Madrid, Spain*

Background: Approximately 20 % of tumor biopsies from patients with advanced-stage lung adenocarcinomas yield insufficient tissue for successful molecular subtyping. In this study, we have analyzed the clinical utility of NGS of cell-free circulating tumor DNA (ctDNA) in patients with inadequate tumor samples for tissue genotyping. **Methods:** We prospectively selected consecutive patients with advanced-stage lung adenocarcinomas with insufficient tissue for *EGFR*, *ALK* or *ROS1* genotyping across 12 Spanish institutions (January-September 2017). Cases with known alterations in any of these genes were ineligible. ctDNA NGS was performed by Guardant Health (Guardant360, Redwood City, CA), using a hybrid-capture-based 73-gene panel. Variants were deemed actionable if they were part of the OncoKB precision oncology knowledge database, and classified in 4 levels based on their clinical or preclinical evidence for drug response. All patients provided informed consent. **Results:** We included 93 patients; 48 (52 %) were treatment naïve. Eighty-three patients (89 %) had detectable levels of ctDNA, and none of the clinical characteristics predicted ctDNA detection. Level 1-4 actionable drivers were detected in 53 patients (57 %) in the entire cohort and 29 patients (60 %) in the treatment naïve subgroup, of which 13 (14 %) and 7 (15 %) respectively had level 1-2A drivers (FDA-approved and standard-care biomarkers according to lung cancer guidelines). The majority of patients with actionable drivers had clinically relevant co-mutations (n = 46, 87 %), without significant differences across the 4 actionable subgroups. Thirteen patients (14 %) received genotype-matched therapies, the majority of which achieved clinical benefit. Seven treatment-naïve patients (15 %) received targeted drugs as their first-line therapy. Most patients with level 1-2A (85 %), but a minority with level 2B-4 drivers (5 %), received targeted therapies. **Conclusions:** ctDNA NGS (Guardant360) detects actionable drivers and allows timely initiation of genotype-matched therapies in lung adenocarcinoma patients with insufficient tumor for tissue genotyping.

9102 Poster Session (Board #425), Sun, 8:00 AM-11:30 AM

Association of CDKN2A gene alteration with high expression of PD-L1. *First Author: Yan Zhang, Department of Cancer Biology, Mayo Clinic, Jacksonville, FL*

Background: Gene CDKN2A, which encodes for p16INK4a/p14ARF is known to be important growth suppressor gene. CDKN2A gene alteration has been reported in non-small cell lung cancer (NSCLC). However, the demographic and clinical features of NSCLC with CDKN2A, coexisting gene alteration and association with immunotherapy biomarkers such as PD-L1 and tumor mutation burden are unknown. **Methods:** Tumor next-generation sequencing data from 197 NSCLC patients who are diagnosed at Mayo Clinic FL are retrospectively analyzed. Patients with CDKN2A gene alterations are identified. Data including demographic feature, clinical feature, coexisting gene alteration and association with immunotherapy biomarkers such as PD-L1 and tumor mutation burden are investigated. **Results:** One hundred ninety-seven patients with NSCLC were identified, and 49 (24.8%) had CDKN2A gene alteration, including 32 gene loss, 4 somatic mutations and 3 deletions. The medium age of patients with CDKN2A gene alteration was 66.7. It was slightly more predominant in male than female (53.1% versus 46.9%) and more in smoker than never-smoker (65.3% versus 34.7%). Among patients with CDKN2A gene alteration, 83.7% (41/49) were found in lung adenocarcinoma, 10.2% were found in lung squamous cell carcinoma and 6.1% were found in other histology. The most common coexisting gene alterations associated with CDKN2A are CDKN2B (61%) followed by TP53 (51%), KRAS (35%), EGFR (14.2%), STK11 (12.2%), MET (10%), PI3KCA (10%), HER-2 (8%), ALK (4%), BRAF (2%). Interestingly, 65% of patients with CDKN2A gene alteration were found to have expression of PD-L1 (defined by $>$ 1% PD-L1). Among them, 61.5% patients have high expression of PD-L1 (defined by $>$ 50% PD-L1). Patients with CDKN2A gene alteration are also associated with high tumor mutation burden (8.77mutation/mb). **Conclusions:** CDKN2A gene alteration is commonly seen in NSCLC. Co-existing driver mutations such as EGFR, MET, HER-2, ALK, BRAF are found. Immunotherapy related biomarkers such as high expression level of PD-L1 and tumor mutation burden are found common in patients with CDKN2A gene alteration, indicating the likelihood of clinical benefit to immunotherapy and warrant further investigation in a larger, prospective study.

9103 Poster Session (Board #426), Sun, 8:00 AM-11:30 AM

The effect of thoracic radiation on overall survival and their association with systemic immune therapy in stage IV NSCLC: Findings from the National Cancer Database. *First Author: Feng-Ming Spring Kong, Indiana University School of Medicine, Dept of Radiation Oncology, Indianapolis, IN*

Background: The role of thoracic radiation (TRT) is controversial for stage IV non-small cell lung cancer (NSCLC). A prospective study of 29 patients reported superior progression free survival with radical TRT. This study aimed to report the overall survival (OS) effect of TRT and examine whether the OS effect varies with the timing of TRT regarding to systemic therapy. **Methods:** Stage IV patients from the national cancer database (NCDB) 2005-2014 formed the base of the study population. TRT, dose and time effects were analyzed individually in patients treated with non-immune systemic therapy or immune therapy. The primary endpoint was OS. Kaplan-Meier test was used for the OS analysis. **Results:** A total of 334,702 patients were eligible. Median survival time (MST) was 5.2 months (mo). Younger age, female gender, non-African American, lower Charlson comorbidity score, and any TRT were all significantly associated with favorable OS (all $P < 0.001$). In 326,287 patients receiving non-immune systemic therapy, TRT was a significant factor for favorable OS (HR = 0.964, 95%CI 0.955-0.974, $P < 0.001$). Comparing to those receiving TRT before non-immune systemic therapy (n = 5,500, MST = 8.8 mo), patients with concurrent TRT-systemic treatments (within 30 days of systemic therapy) had significantly worse OS (n = 20,099, MST = 7.2 mo, $P < 0.001$), while patients receiving TRT after systemic therapy had the best OS (n = 6,064, MST = 11.2 mo, $P < 0.001$). In 4,639 patients treated with immune therapy, TRT was associated with significantly worse OS (n = 512, MST = 11.1 mo, $P < 0.001$), comparing to immune therapy alone (n = 4,127, MST = 14.1 mo). Patients received concurrent TRT had worst OS (n = 177, MST = 7.4 mo, $P < 0.001$), comparing to TRT before immune therapy (n = 165, MST = 12.2 mo) and TRT after immune therapy (n = 138, MST = 13.2 mo, P = 0.086). **Conclusions:** In patients with stage IV NSCLC, TRT seemed to be associated with better OS in those treated with non-immune systemic therapy but worse overall survival in patients receiving immune therapy. Concurrent TRT with any systemic therapy including immune therapy was associated with worse survival.

TPS9104 Poster Session (Board #427a), Sun, 8:00 AM-11:30 AM

ECHO-306/KEYNOTE-715: A phase 3 study of first-line epacadostat plus pembrolizumab with or without platinum-based chemotherapy vs pembrolizumab plus platinum-based chemotherapy plus placebo for metastatic non–small cell lung cancer (mNSCLC). *First Author: Rina Hui, Westmead Hospital, Westmead, Australia*

Background: Novel combination treatments targeting broad immunosuppression in the tumor microenvironment may improve survival. The indoleamine 2,3-dioxygenase 1 (IDO1) intracellular enzyme and PD-1 receptor both suppress T-cell–mediated antitumor immunity, are co-expressed in multiple tumor types, and are correlated with poor prognosis. Epacadostat (E) is a potent and highly selective oral inhibitor of IDO1. Pembrolizumab (P) ± chemotherapy is a first-line treatment option for mNSCLC. Because promising efficacy and minimal additive toxicity were observed with E + P in mNSCLC in the phase 1/2 ECHO-202/KEYNOTE-037 study, this phase 3 global study (NCT03322566) was initiated to evaluate first-line E + P, E + P + chemotherapy, and E-matched placebo + P + chemotherapy in patients with mNSCLC unselected by PD-L1. **Methods:** Eligible patients: aged $\geq$18 years, stage IV NSCLC (no *EGFR* mutation or *ROS1*/*ALK* translocations), ECOG PS $\leq$1, no untreated brain metastases, no prior systemic therapy for mNSCLC, and no prior IDO1 inhibitors or immune checkpoint therapies. Patients (~1062) will be randomized 1:1:1 and stratified based on ECOG PS (0 vs 1), PD-L1 status (tumor proportion score $<$ 50% vs $\geq$50%), tumor histology (squamous vs nonsquamous), and region (East Asia vs non-East Asia). Treatment includes E 100 mg BID, P 200 mg Q3W, paclitaxel 175–200 mg/m^2 + carboplatin AUC 5–6 Q3W $\times$ 4 cycles (squamous), or pemetrexed 500 mg/m^2 + cisplatin 75 mg/m^2 or carboplatin AUC 5 Q3W $\times$ 4 cycles followed by pemetrexed 500 mg/m^2 Q3W (nonsquamous). Patients receive treatment up to 2 years (35 cycles of P), or until disease progression, intolerable toxicity, or investigator/patient decision to withdraw. Primary endpoints: OS and PFS. Secondary endpoints: ORR, duration of response, safety, and tolerability. Exploratory endpoints: patient reported outcomes, E pharmacokinetics, pharmacodynamics, and potential correlations between baseline biomarkers and clinical activity (OS, PFS, ORR). Tumor response will be assessed centrally per RECIST v1.1. Adverse events will be graded per CTCAE v4.0. Clinical trial information: NCT03322566.

TPS9105 Poster Session (Board #427b), Sun, 8:00 AM-11:30 AM

MORPHEUS: A phase Ib/II multi-trial platform evaluating the safety and efficacy of cancer immunotherapy (CIT)-based combinations in patients (pts) with non-small cell lung cancer (NSCLC). *First Author: Melissa Lynne Johnson, Sarah Cannon Research Institute, Nashville, TN*

Background: CIT has demonstrated a significant survival benefit in multiple cancers. Despite this, only subsets of pts experience durable response with CIT monotherapy. Thus, CIT combinations may be needed to address the mechanisms that allow cancers to escape anti-tumor immunity. However, a large number of potential combinations would have to be tested in order to identify an effective CIT combination. The MORPHEUS platform consists of multiple, global, open-label, randomized, Phase Ib/II trials designed to assess the impact of CIT combinations in pts with different tumor types. The randomized trial designs allow comparison of a single control arm vs multiple CIT combination arms. These trials will aid development of CIT combinations by identifying early signals and will have the flexibility to open new treatment (Tx) arms with novel CIT combinations and to close arms that show minimal clinical activity or unacceptable toxicity. Various CIT combinations that simultaneously enhance immune cell priming and activation, tumor infiltration and/or recognition of tumor cells for elimination will be evaluated. Here we describe a MORPHEUS Phase Ib/II trial in pts with metastatic NSCLC, a population likely to benefit from CIT-based combinations. **Methods:** MORPHEUS-Lung (NCT03337698) will enroll 2 cohorts (C): C1 will enroll pts who are Tx naive for metastatic NSCLC and have high tumor PD-L1 expression (TPS $\geq$ 50% per Dako 22C3 or VENTANA SP263); C2 will enroll pts who have progressed on prior platinum and anti–PD-L1/PD-1 Tx given concurrently or sequentially, regardless of tumor PD-L1 expression levels. Pts with non-squamous and squamous NSCLC will be included; those with an *EGFR* mutation or *ALK* gene rearrangement will be excluded. Pts will be randomized to the control arm or one of several experimental arms (2 for C1; 5 for C2). Pts experiencing loss of clinical benefit or unacceptable toxicity may be eligible to switch to a different CIT combination arm. Safety measures and investigator-assessed ORR (RECIST v1.1) are primary endpoints. PFS, OS, DCR and DOR are among the secondary endpoints. Exploratory biomarkers will also be examined. Clinical trial information: NCT03337698.

TPS9106 Poster Session (Board #428a), Sun, 8:00 AM-11:30 AM

A phase 2 study of poziotinib in patients with EGFR or HER2 exon 20 mutation-positive non-small cell lung cancer. *First Author: Zandong Yang, Inovio Pharmaceuticals, Plymouth Meeting, PA*

Background: Poziotinib is a novel, oral, quinazoline-based pan-HER inhibitor that irreversibly blocks signaling through the EGFR family of tyrosine-kinase receptors, including human epidermal growth factor receptor (HER1/ErbB1/EGFR), HER2 (ErbB2), and HER4 (ErbB4), which leads to inhibition of the proliferation of tumor cells that overexpress these receptors or activated by EGFR or HER2 exon 20 mutations. There is no FDA approved targeted therapy for EGFR or HER2 exon 20 insertion mutant NSCLC. Chemotherapy remains the standard of care for metastatic disease with severe side effects and modest efficacy. Preclinical testing indicates that poziotinib is more active than currently approved tyrosine kinase inhibitors against cell lines with a range of *EGFR* exon 20 mutations *in vitro* when using the standard Ba/F3 model. An ongoing investigator-initiated study at MD Anderson is showing that poziotinib is effective at reducing tumor size in patients with EGFR or HER2 exon 20 mutations. The primary endpoint of this Phase 2 study is to evaluate the Objective Response Rate (ORR) to poziotinib in patients with EGFR or HER2 positive non-small cell lung cancer (NSCLC). Secondary endpoints are to evaluate the Disease Control Rate (DCR) and Duration of Response (DoR) in this group of patients. **Methods:** This is an open-label, multicenter study evaluating the efficacy and safety of poziotinib in patients with histologically or cytologically confirmed NSCLC with a documented EGFR or HER2 exon 20 insertion mutation. Patients with T790M point mutations will be excluded. Patients will be enrolled into one of two cohorts based on documented EGFR (Cohort 1; n = 87) or HER2 (Cohort 2; n = 87) exon 20 mutations. Both cohorts are enrolling simultaneously. Patients must be 18 years of age, have an ECOG score $\leq$2, and have adequate tumor tissue from biopsy or surgical procedure to enable molecular profiling. The starting dose of poziotinib is 16 mg PO daily with possible dose reductions to 14 mg and 12 mg for tolerability issues. Patients will be treated until either progression or intolerable adverse events. Response will be assessed by an Independent Image Review. Study enrollment began in October 2017. Clinical trial information: NCT 03318939.

TPS9107 Poster Session (Board #428b), Sun, 8:00 AM-11:30 AM

Phase 1/2 study of mRNA vaccine therapy + durvalumab (durva) $\pm$ tremelimumab (treme) in patients with metastatic non-small cell lung cancer (NSCLC). *First Author: Leena Gandhi, NYU Perlmutter Cancer Center, New York, NY*

Background: Vaccine therapies stimulate the immune system to attack cancer cells (active immunotherapy), whereas checkpoint inhibitors block immune inhibition (passive immunotherapy). Several PD-1 and PD-L1 blocking antibodies are approved for NSCLC. This study combines active and passive immunotherapies to determine if the addition of a mRNA vaccine can enhance the activity of checkpoint blockade. The vaccine BI 1361849 (comprising 6 mRNAs encoding for selected tumor-associated antigens: MUC1, survivin, NY-ESO-1, 5T4, MAGE-C2 and MAGE-C1) is combined with 1 or 2 checkpoint inhibitors (durva [anti-PD-L1] $\pm$ treme [anti-CTLA-4]). **Methods:** This ongoing Phase 1/2, open-label study (NCT03164772) evaluates the safety and efficacy of BI 1361849 when administered with durva (Arm A) or durva + treme (Arm B) in NSCLC patients. In arm A, an initial dose-evaluation phase follows a 3+3 design to determine the dose of durva (1500 or 750 mg) to be given with the vaccine. Arm B uses the durva dose from Arm A, with the addition of 75 mg treme. In the expansion phase, 20 patients are treated in each arm. To aid in the evaluation of immune responses, there is an additional control group (n = 10), which receives the checkpoint inhibitors only. Study treatment is administered over 12 (28-day) cycles. Durva (x 12 doses) and treme (x 4 doses) are administered intravenously every 28 days. The vaccine is administered on 1 to 3 days over each of the 12 cycles using a device that provides a needle-free intradermal administration. The primary endpoint is safety/tolerability per CTCAE, including dose-limiting toxicity during dose evaluation. Secondary endpoints are progression-free survival and objective response rate at 8 and 24 weeks, disease control rate, response duration, and overall survival, with tumor response evaluated by RECIST and immune-related RECIST. Exploratory objectives include effects on tumor microenvironment and evaluation of immune responses. Enrollment opened 20Dec2017. Clinical trial information: NCT03164772.

TPS9108 Poster Session (Board #429a), Sun, 8:00 AM-11:30 AM

A trial of CV301 in combination with anti-PD-1 therapy versus anti-PD-1 therapy in subjects with non-small cell lung cancer. *First Author: Arun Rajan, Thoracic and Gastrointestinal Oncology Branch, Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: Despite recent therapeutic advances in non-small cell lung cancer (NSCLC), an unmet medical need remains for most patients. Pembrolizumab (pembro) is approved in first-line treatment of patients with NSCLC as a single agent when PD-L1 expression is $>$ 50% and in combination with chemotherapy when PD-L1 expression is $<$ 50%. It is believed that a fraction of non-responders to pembro lack an adequate tumor-directed immune response. CV-301 is a poxviral-based vaccine comprising a prime-boost strategy with Modified Vaccinia Ankara (MVA) prime and fowlpox boost. The viral vectors encode 2 tumor associated antigens, CEA and MUC-1, as well as 3 costimulatory molecules (B7.1, ICAM-1 and LFA-3, called TRICOM). Current preclinical and mechanistic evidence suggests that CV-301 can generate a tumor-directed immune response in NSCLC, potentially increasing the clinical benefit associated with pembro. **Methods:** This open-label, multi-center trial will evaluate the combination of CV301 and pembro. The phase 1 trial, an evaluation of safety of ascending doses of CV301, has been completed. The vaccine was well tolerated with no DLTs. The phase 1b portion is currently enrolling at least 6 patients with NSCLC in the maintenance setting of pembro and will continue pembro in combination with CV301 with a goal to establish safety of the combination. Safety monitoring will occur every two weeks. If safety is established, the randomized Phase 2 portion will enroll 176 subjects, randomized 2:1 to receive maintence pembro in combination with CV301 (2) or alone (1). Maintenance setting is defined as the period following 11 weeks of initial treatment, after which chemotherapy would be complete in the $<$ 50% PD-L1 expression group. To be eligible, patients must have stable disease or objective response at the time of radiographic evaluation (approximately 11-12 weeks after initiation of first line therapy). Preliminary efficacy will be analyzed during the Phase 2 cohort based on the Intent-to-Treat population, comprising overall survival (primary), progression-free survival and overall response rate (secondary). Clinical trial information: NCT02840994.

TPS9109 Poster Session (Board #429b), Sun, 8:00 AM-11:30 AM

ECHO-305/KEYNOTE-654: A phase 3, randomized, double-blind study of first-line epacadostat plus pembrolizumab vs pembrolizumab plus placebo for metastatic non–small cell lung cancer (mNSCLC) with high PD-L1 levels. *First Author: Mark M. Awad, Dana-Farber Cancer Institute, Boston, MA*

Background: The indoleamine 2,3-dioxygenase 1 (IDO1) intracellular enzyme and PD-1 receptor both suppress T-cell–mediated antitumor immunity, are coexpressed in multiple tumor types, and are correlated with poor prognosis. Epacadostat (E) is a potent and highly selective oral inhibitor of IDO1. Pembrolizumab (P; PD-1 inhibitor) is the standard of care for treatment-naive mNSCLC with high PD-L1 expression (tumor proportion score [TPS] ≥50%) and no *EGFR* or *ALK* genomic aberrations. Because encouraging activity and minimal additive toxicity were previously observed with E + P in mNSCLC in the phase 1/2 ECHO-202/KEYNOTE-037 study, this phase 3 global trial (NCT03322540) was initiated to compare E + P vs P + E-matched placebo as first-line treatment for patients with PD-L1 high mNSCLC. **Methods:** Eligible patients: aged ≥18 years, stage IV NSCLC (no *EGFR*-sensitizing mutation or *ROS1*/*ALK* translocations), TPS ≥50%, ECOG PS ≤1, no prior systemic therapy for mNSCLC, and no prior IDO1 inhibitors or immune checkpoint therapies. Approximately 588 patients will be randomized 1:1 to E 100 mg oral BID + P 200 mg IV Q3W or P + E-matched placebo, and stratified by tumor histology (squamous vs nonsquamous), ECOG PS (0 vs 1), and geographical location (East Asia vs non–East Asia). Patients receive treatment until disease progression, intolerable toxicity, investigator/patient decision to withdraw, or until they have received up to 35 cycles of E + P or P + placebo (~2 years). Eligible patients may continue study treatment beyond initial radiographic progression. Patients may discontinue treatment after confirmed complete response. Primary endpoints include PFS and OS. Secondary endpoints include ORR, duration of response, safety, and tolerability. Exploratory endpoints include patient-reported outcomes, E pharmacokinetics, pharmacodynamics, and potential relationship between baseline biomarkers and clinical activity (PFS, OS, ORR). Tumor response will be assessed by a blinded central review, per RECIST v1.1 criteria. Adverse events will be monitored throughout the study and graded per CTCAE v4.0. Clinical trial information: NCT03322540.

TPS9110 Poster Session (Board #430a), Sun, 8:00 AM-11:30 AM

Phase 1 study of the anti-HER3 antibody drug conjugate U3-1402 in metastatic or unresectable EGFR-mutant NSCLC. *First Author: Pasi A. Janne, Dana-Farber Cancer Institute, Boston, MA*

Background: While outcomes for patients with EGFR-mutant NSCLC have significantly improved with the use of EGFR tyrosine kinase inhibitors, there remain limited treatment options for many patients once they develop resistance to these agents. The HER3/ERBB3 oncogene is overexpressed in many cancers, including NSCLC, and higher expression is correlated with poorer outcomes. U3-1402 is a HER3-targeting antibody-drug conjugate (ADC) of high drug-to-antibody-ratio (DAR = 7 to 8) with a novel linker and topoisomerase I inhibitor payload. **Methods:** This is a multicenter Phase 1, Dose Escalation, and Dose Expansion study of U3-1402 in metastatic or unresectable adenocarcinoma NSCLC subjects harboring EGFR-activating mutation who (a) are T790M mutation-negative after disease progression during treatment with erlotinib, gefitinib, or afatinib or (b) develop disease progression while on osimertinib. Eligible subjects are at least 18 years of age, have ECOG PS 0 or 1, have radiological documentation of disease progression while receiving continuous treatment with erlotinib, gefitinib, afatinib, or osimertinib, have at least one measurable lesion per RECIST v1.1, have adequate bone marrow and organ function, do not have mean QTc prolongation to > 470 ms for females and > 450 ms for males, and do not have spinal cord compression or clinically active brain metastases. In Dose Escalation, subjects receive U3-1402 via intravenous infusion in 21-day cycles. In Dose Escalation, escalation of U3-1402 dosing is based on dose-limiting toxicity data in subjects, guided by the modified Continuous Reassessment Method (mCRM). In Dose Expansion, subjects receive U3-1402 at the recommended dose for expansion (RDE) determined in Dose Escalation. Primary objectives are to determine the safety, tolerability, and RDE of U3-1402. Secondary objectives are to assess the pharmacokinetic parameters of U3-1402 and its components, and to assess antitumor activity of U3-1402 (RECIST v1.1). Enrollment to cohort 1 began in January 2018. Clinical trial information: NCT03260491.

TPS9111 Poster Session (Board #430b), Sun, 8:00 AM-11:30 AM

A phase 1b trial of RORγ agonist LYC-55716 in combination with pembrolizumab to evaluate safety, efficacy, and immune biomarker profiles in patients with metastatic non-small cell lung cancer. *First Author: D. Ross Camidge, University of Colorado-Denver, Aurora, CO*

Background: LYC-55716 is a first-in-class oral, small-molecule agonist of the retinoic acid receptor–related orphan receptor γ (RORγ) being developed as an immuno-oncology agent for solid tumors. In preclinical studies, LYC-55716 reduces tumor growth and enhances survival by reprogramming immune cell gene expression for improved anti-tumor effector functions and decreased immunosuppressive mechanisms. RORγ agonist treatment decreases expression of PD-1 and other co-inhibitory receptors, which may diminish checkpoint inhibition within the tumor microenvironment (TME). Additionally, in syngeneic tumor models, the addition of RORγ agonists enhances the activity of PD-1/PD-L1 inhibitors, which is associated with increased number and activation of tumor-infiltrating lymphocytes and decreased immune suppression. An open-label, multicenter Phase 1b trial is ongoing to assess the safety and tolerability of combining LYC-55716 and pembrolizumab (L+P) to treat patients with non–small cell lung cancer (NSCLC). **Methods:** The Phase 1b trial (NCT03396497) will evaluate the occurrence of dose-limiting toxicities (DLTs) and determine the recommended Phase 2 dose of L+P in adults with metastatic NSCLC receiving pembrolizumab treatment. Following a screening period, a run-in cohort (n = 3) will receive L+P to monitor for adverse reactions. If no DLTs occur, the main study cohort (n = 15) will receive L+P until disease progression or unacceptable toxicity. Planned pre-/post-treatment tumor biopsies and blood samples will be collected in the main study cohort. Primary endpoints are safety (monitoring of adverse events, physical examination, and lab results) and incidence of DLTs during the run-in period and further treatment. Secondary endpoints for the main cohort include profiling of immune biomarker changes, objective response rate and duration of response, and pharmacokinetics. Patients will be followed for progression-free and overall survival. Clinical trial information: NCT0336497.

TPS9112 Poster Session (Board #431a), Sun, 8:00 AM-11:30 AM

Phase I/II study of nivolumab and ipilimumab combined with nintedanib in advanced NSCLC. *First Author: Sonam Puri, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

Background: Combination immunotherapy with nivolumab and ipilimumab has proven clinical activity in NSCLC. There is growing evidence to suggest that the tumor microenvironment (TME) may interfere with effective immune recognition, even in the presence of checkpoint inhibitors. Unpublished preclinical data from our group demonstrates that human lung cancer derived cancer-associated fibroblasts (CAFs) inhibit tumor infiltrating lymphocyte activation and are potentially immunosuppressive. Targeting the TME may represent an important synergistic approach in immunotherapy. Nintedanib is an orally available triple kinase inhibitor that is active against NSCLC, inhibits CAFs, and targets VEGFR, FGFR and PDGFR. Based on these observations a phase IB/II trial of the combination of nintedanib, nivolumab and ipilimumab was initiated in NSCLC patients. **Methods:** This is a single institution, investigational, non-randomized, parallel assignment phase I/II clinical trial of patients with locally advanced or metastatic NSCLC. Eligible patients can be immunotherapy naïve or with disease progression following immunotherapy. Primary objective of phase I is to determine the tolerability of concurrent administration of the proposed regimen. Three dose levels of nintedanib (100mg, 150 mg and 200 mg twice daily) are given with fixed doses of nivolumab (3mg/kg every 2 weeks) and ipilimumab (1mg/kg every 6 weeks). Dose escalation will be done by the modified continuous re assessment method (O, Quigley et al, 1990). Phase II is divided into two single arm cohorts (Arm A: Treatment or immunotherapy naïve; Arm B: Immunotherapy pretreated). Enrollment to phase II will be done by the Bayesian two-stage design method. The primary objective of phase II is to determine the efficacy of the combination regimen in NSCLC. Key secondary objectives are overall survival and progression free survival. The sample size calculation of 18 patients in phase I and 80 patients in phase II assumes 18 months for accrual and 2-3 years for follow up. Enrollment to phase I was started on 29th January 2018 and to date 1 patient has been enrolled. Serial blood and tumor biopsies are obtained to evaluate potential predictive and resistance mechanisms. Clinical trial information: NCT03377023.

TPS9113 Poster Session (Board #431b), Sun, 8:00 AM-11:30 AM

Phase I/II trial of dasatinib and osimertinib in patients with advanced *EGFR*-mutant non-small cell lung cancer. *First Author: Chul Kim, Georgetown University, Washington, DC*

Background: Epidermal growth factor receptor (EGFR) mutations are one of the most common driver oncogenes in non-small cell lung cancer (NSCLC). While the presence of these mutations predicts sensitivity to tyrosine kinase inhibitors (TKIs), a small but non-negligible subset of patients do not respond to EGFR-TKIs, suggesting intrinsic resistance. Moreover, acquired resistance to EGFR-TKIs is inevitable. In preclinical studies, overexpression of Cripto-1, a member of the EGF–Cripto-1/FRL-1/Cryptic protein family, contributes to the development of intrinsic resistance to EGFR-TKIs through the activation of the Src-tyrosine kinase pathway. In EGFR-mutant mouse models, we demonstrated synergy between erlotinib and Src inhibition. *In vitro* experiments showed increased synergy when using osimertinib, a third generation EGFR inhibitor with dasatinib, a SRC inhibitor. Based on these data, we initiated a phase I/II trial to explore the feasibility and benefit of combining osimertinib and dasatinib in patients with EGFR-mutant NSCLC. **Methods:** This is an open-label, single-arm phase I/II trial of osimertinib and dasatinib in treatment-naïve patients with advanced EGFR-mutant NSCLC (NCT02954523). Patients with sensitizing *EGFR* mutations as well as those with T790M mutation are eligible. Patients with pleural or pericardial effusions at study entry are excluded. The primary endpoint of the phase I part is to establish a safe and tolerable phase II dose of osimertinib and dasatinib. The endpoint of the phase II part is the reduction of the proportion of patients who progress or have stable disease lasting 4 months or less (definition of intrinsic resistance). For the phase II portion, a two-stage design with a total of 28 patients will be used. The null hypothesis that the proportion of patients with intrinsic resistance is at least 30% will be tested against the alternative hypothesis that the true proportion of patients with intrinsic resistance is at least 10% (alpha one-sided 5%, power 85%). Accrual is underway at Georgetown University and Hackensack University Medical Center. Using tumor and serum samples, the role of Cripto-1 in mediating resistance to osimertinib will be elucidated. Clinical trial information: NCT02954523.

TPS9114 Poster Session (Board #432a), Sun, 8:00 AM-11:30 AM

Trial in progress: Multicenter observational study to evaluate the relationship between gut bacterial flora and their therapeutic or adverse effects in advanced non-small cell lung cancer patients treated with nivolumab. *First Author: Takashi Yokoi, Department of Thoracic Oncology, Kansai Medical University Hirakata Hospital, Osaka, Japan*

Background: Nivolumab is one of the standard therapies for pretreated advanced non-small cell lung cancer (NSCLC). A correlation between PD-L1 expression on tumor cells and antitumor effects of nivolumab has been shown especially in non-squamous NSCLC. However, PD-L1 expression is an insufficient biomarker because of the weak correlation. It is therefore important to explore better biomarkers. In recent years, the antitumor effects of immune checkpoint inhibitors have been shown to depend on distinct *Bacteroides* species in preclinical mouse models. This multicenter observational study was planned to evaluate the relationship between gut bacterial flora and their therapeutic or adverse effects on advanced NSCLC patients treated with nivolumab. **Methods:** We prospectively collect microbiome samples from patients with NSCLC who will be treated with nivolumab. Gut (fecal) microbiome samples are collected at treatment initiation and after four doses of nivolumab. We will analyze the trend of gut microbiome differences The key inclusion criteria are histologically or cytologically proven NSCLC, pretreated NSCLC without any immune checkpoint inhibitor, ECOG PS 0-2, one or more measurable lesions, and written informed consent. The key exclusion criteria are previous or active interstitial pneumonia, autoimmune disease, exposure to corticosteroids or antibiotics, and previous or active inflammatory bowel disease. Clinical trial information: UMIN000026375.

TPS9115 Poster Session (Board #432b), Sun, 8:00 AM-11:30 AM

eXalt3: Phase 3 randomized study comparing ensartinib to crizotinib in anaplastic lymphoma kinase (ALK) positive non-small cell lung cancer (NSCLC) patients. *First Author: Leora Horn, Vanderbilt University Medical Center, Nashville, TN*

Background: Ensartinib (X-396) is a novel, potent ALK small molecule tyrosine kinase inhibitor (TKI) with additional activity against MET, ABL, Axl, EPHA2, LTK, ROS1 and SLK. Ensartinib is well-tolerated and has shown promising activity in NSCLC patients in a phase 1/2 study in patients that were both ALK TKI naïve and patients that received prior crizotinib, as well as those with CNS metastases. The safety profile of ensartinib appears to be different than other ALK TKIs. **Methods:** In this global, phase 3, open-label, randomized study, approximately 270 patients with ALK+ NSCLC who have received no prior ALK TKI and up to one prior chemotherapy regimen will be randomized with stratification by prior chemotherapy (0/1), performance status (0-1/2), brain metastases at screening (absence/presence), and geographic region (Asia /other), to receive oral ensartinib (225 mg, once daily) or crizotinib (250mg, twice daily) until disease progression or intolerable toxicity. Eligibility also includes patients $\geq$ 18 years of age, stage IIIB or IV ALK+ NSCLC. Patients are required to have measurable disease per RECIST 1.1, adequate organ function, and an ECOG PS of $\leq$2. Adequate tumor tissue (archival or fresh biopsy) must be available for central testing. The primary endpoint is progression-free survival assessed by independent radiology review based on RECIST v. 1.1 criteria. Secondary efficacy endpoints include overall survival, response rates (overall and central nervous system [CNS]), PFS by investigator assessment, time to response, duration of response, and time to CNS progression. The study has $>$ 80% power to detect a superior effect of ensartinib over crizotinib in PFS at a 2-sided alpha level of 0.05. Phase 3 recruitment began in June, 2016 and currently has 98 active sites in 20 countries. The duration of recruitment will be approximately 24 months. This study is registered with. Clinical trial information: NCT02767804.

TPS9116 Poster Session (Board #433a), Sun, 8:00 AM-11:30 AM

A multicenter, randomized, double-blind, placebo-controlled phase III study of apatinib or placebo plus gefitinib as first-line treatment in patients with *EGFR*-mutant advanced non-small cell lung cancer (NSCLC). *First Author: Hongyun Zhao, State Key Laboratory of Oncology in South China, Caner Center, Sun Yat-sen University, Guangzhou, China*

Background: Dual inhibition of epidermal growth factor receptor (EGFR) and vascular endothelial growth factor (VEGF) pathway is becoming an encouraging strategy in the treatment of advanced NSCLC. Apatinib is a tyrosine kinase inhibitor that selectively inhibits the VEGF receptor-2. Our phase I study of Apatinib plus Gefitinib has shown a manageable tolerability profile and promising antitumor activity with an anticipated progressive-free survival (PFS) $>$ 14 mos. This phase III study aims to evaluate the efficacy and safety of Apatinib or placebo plus Gefitinib as first-line treatment in patients (pts) with stage IIIB-IV NSCLC harboring an activating *EGFR* mutation. **Methods:** Treatment-naïve stage IIIB or IV NSCLC pts with *EGFR* 19 Del or 21 L858R mutation are enrolled. Other inclusion criteria include ECOG PS of 0 or 1, $\geq$1 measurable lesion according to RECIST v1.1 and adequate organ function. Eligible pts will be randomized in a 1:1 ratio to receive either Apatinib or Placebo 500 mg QD plus Gefitinib 250 mg QD until progressive disease or unacceptable toxicity. Stratified randomization is based on *EGFR* mutation status, gender and ECOG PS. The primary endpoint is PFS. Secondary endpoints include overall survival, objective response rate, disease control rate, time to progression, duration of response, quality of life and the safety profile. Independent Data Monitoring Committee and Independent Review Committee will be used in this study. According to previous report (erlotinib plus bevacizumab *vs.* erlotinib alone: 16.0 *vs.* 9.7 mos, HR 0.54, Lancet Oncol, 15(11):1236-1244), it was assumed that the estimated median PFS would be 15 mos in the Apatinib + Gefitinib group and 10 mos in the Placebo + Gefitinib group. To detect a 5-mos improvement of PFS in Apatinib + Gefitinib group at a two-sided significant level of 0.05 and a power of 0.8, allowing for a dropout rate of 20%, the sample size should be 155 patients per group. In total, 310 patients will be enrolled in this trial at 30 sites in China. From August 2017, 100 patients have been enrolled. Clinical trial information: NCT02824458.

TPS9117 Poster Session (Board #433b), Sun, 8:00 AM-11:30 AM

Afatinib in combination with pembrolizumab in patients (pts) with stage IIIB/IV squamous cell carcinoma (SCC) of the lung. *First Author: Benjamin Philip Levy, Johns Hopkins University School of Medicine, Sidney Kimmel Comprehensive Cancer Center, Sibley Memorial Hospital, Washington DC, MD*

Background: Afatinib and pembrolizumab have demonstrated improvements in the outcomes of pts with SCC of the lung and are approved as monotherapy. Afatinib is a selective and irreversible ErbB family blocker with activity against all homo- and heterodimers formed by ErbB family members EGFR (ErbB1), HER2 (ErbB2), ErbB3, and ErbB4. Pembrolizumab is a humanized IgG4 monoclonal antibody with potent receptor-blocking activity for PD-1. Given the efficacy of these agents as monotherapy in chemo-refractory lung SCC, concurrent inhibition of PD-1 and EGFR pathways represents a promising approach to improve clinical outcomes in lung SCC. **Methods:** Study 1200.283 (NCT03157089; LUX-Lung IO/Keynote 497) is a phase II, single-arm study (n = 5062). Eligible pts have stage IIIB/IV lung SCC, progressed during/after first-line platinum-based chemotherapy, and have an ECOG PS 0/1. Prior immune checkpoint inhibitor or EGFR targeted therapy are prohibited. A safety run-in will be performed in 12 pts, using afatinib (starting dose 40 mg/day, with potential dose de-escalation to 30 mg) with pembrolizumab (200 mg every 3 weeks) to assess the safety and confirm the recommended Phase II dose (RP2D) based on dose limiting toxicities observed during the first cycle. In the main trial, afatinib at the RP2D, in combination with pembrolizumab, may be continued for a maximum of 35 cycles. In case of toxicity, afatinib dose reduction to 30/20 mg will be permitted. Primary endpoint is objective response (OR; complete response [CR] or partial response [PR] [RECIST v1.1]). Further endpoints include disease control (CR, PR, stable disease), duration of OR, PFS, OS, and pharmacokinetics. All pts will provide a fresh or archived tumor tissue sample to measure PD-L1 expression and mRNA expression of genes involved in the immune system. Exploratory biomarkers include the evaluation of immune status by determination of tumor infiltrating cells (e.g. CD8+ cells) or TH1-type cytokines, and blood biomarkers related to the emergence of resistance at progression. This study is conducted in the US, Spain, France, Turkey, and Korea. As of January 2018, enrollment in the safety run-in is complete (n = 12). Clinical trial information: NCT03157089.

9500 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

External validation of the 8th Edition Melanoma Staging System of the American Joint Committee on Cancer (AJCC): Effect of adding EORTC sentinel node (SN) tumor burden criteria on prognostic accuracy in stage III. *First Author: Max Fullah Madu, Netherlands Cancer Institute, Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands*

Background: Now that effective adjuvant therapy has arrived in melanoma, accurate staging and patient selection to optimize a risk/benefit ratio is crucial. The new 8th Edition AJCC staging system for melanoma aims to improve risk stratification. The goal of this study was to externally validate the prognostic and discriminatory ability for survival of the 8th Edition in comparison to the 7th. **Methods:** Analysis of a prospective cohort of patients treated in the Netherlands Cancer Institute for AJCC 7/8th Edition stage III melanoma between 2000 and 2016. Stage III melanoma was defined as regional lymph node metastases, with or without concurrent local recurrence, (micro)satellite or in-transit metastases. Prognostic factors for melanoma-specific survival (MSS) and distant metastasis-free survival (DMFS) were analyzed. Survival differentiation of the 7th and 8th edition was assessed with log-rank tests and Cox proportional hazards models. Discriminatory ability was compared using the area under the curve (AUC) of the receiver operating statistic (ROC) obtained with Cox models. **Results:** 640 patients were included with a median follow-up of 59 months (interquartile range 32-108). Median MSS was 138 months, DMFS 96 months. Age, Breslow thickness, ulceration of the primary tumor and number of positive lymph nodes (N) were significant prognostic parameters for MSS and DMFS. The 8th Edition performed similarly to the 7th in terms of survival discrimination, but failed to differentiate MSS between stage IIIA and IIIB after correction for sex and age. Both in 7th and 8th edition stage IIIA melanoma, patients with an SN metastasis size < 1 had excellent DMFS and MSS. **Conclusions:** The AJCC 8th edition staging system differentiates survival slightly worse than the 7th edition. Survival in both 7th and 8th edition stage IIIA melanoma is heterogeneous and can be sub-classified according to EORTC SN tumor burden, which can aid clinical decision-making concerning adjuvant therapy.

9501 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Final analysis of DECOG-SLT trial: Survival outcomes of complete lymph node dissection in melanoma patients with positive sentinel node. *First Author: Ulrike M. Leiter, Department of Dermatooncology, University of Tübingen, Tuebingen, Germany*

Background: The multicenter DeCOG-SLT trial assessed in a randomized phase 3 trial whether complete lymph node dissection (CLND) resulted in increased survival compared with observation in patients with positive sentinel node biopsy (SLNB). This study now gives an update three years after inclusion of the last patient. **Methods:** Outcomes of 473 patients in the intent-to-treat population (ITT) randomly assigned into the DeCOG trial were evaluated with an additional 3 years follow-up observation after randomization has ended. A total of 233 patients was analyzed in the observation group, 240 in the CLND group. The primary endpoint was distant metastasis-free survival (DMFS); recurrence-free (RFS) and overall (OS) survival were secondary endpoints. **Results:** Patient enrolment was performed from January 2006 to December 2014 followed by an observation period from January 2015 to December 2017. The median follow-up time was 72 months (95% CI 67.2;76.8) No significant treatment-related difference was seen in the 5-years DMFS: 68% (90%CI: 62.1%;72.5%, 79 events) in the observation arm and 65% (90%CI: 59.3%;70.5%, 85 events) in the CLND arm (HR1.08 (90%CI 0.83; 1.39), P = 0.65). The 5 years RFS (HR 1.01 (90%CI 0.8; 1.28), P = 0.94) and OS (HR 0.99 (90%CI 0.74; 1.31), P = 0.93), also showed no differences with respect to the treatment arms. The 5-year DMFS differed according to the tumor load in the SLNB, but again not between CLND and observation arm ($\leq$ 1.0 mm: 78.7% vs 72.5%, HR 1.12, P = 0.58 and $>$ 1.0 mm 54.7% vs 51.7%, HR 0.98, P = 0.95) Regional lymph node metastases occurred in 10.8% of the CLND and in 16.3% of the observation arm (P = 0.11) The multivariate proportional hazard regression analysis revealed tumor thickness and tumor load in the SLNB to be independent prognostic factors for RFS, DMFS and OS. **Conclusions:** After a median follow-up time of 72 months there was no survival benefit in melanoma patients with positive SLNB undergoing CLND compared to observation only. Clinical trial information: NCT02434107.

9502 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Adjuvant therapy with nivolumab (NIVO) versus ipilimumab (IPI) after complete resection of stage III/IV melanoma: Updated results from a phase III trial (CheckMate 238). *First Author: Jeffrey S. Weber, New York University Perlmutter Cancer Center, New York, NY*

Background: In the initial report of data from CheckMate 238, at a minimum follow-up of 18 mo, NIVO demonstrated significantly longer recurrence-free survival (RFS) vs IPI in patients (pts) with resected stage III or IV melanoma. Here, we report updated efficacy results from this phase III study with an additional 6 mo of follow-up. **Methods:** Eligible pts included those $\geq$15 yrs of age who underwent complete resection of stage IIIB/C or IV melanoma. 906 pts were randomized 1:1 (stratified by disease stage and PD-L1 status at a 5% cutoff) to receive NIVO 3 mg/kg Q2W (N=453) or IPI 10 mg/kg Q3W for 4 doses, then Q12W (from week 24) (N=453) for up to 1 yr, or until disease recurrence or unacceptable toxicity. The primary endpoint was RFS; distant metastasis-free survival (DMFS) in pts with stage III disease was an exploratory endpoint. **Results:** At a minimum follow-up of 24 mo, RFS continued to be significantly longer for NIVO vs IPI (hazard ratio 0.66, $P<0.0001$), with 171/453 and 221/453 events, respectively. The 24-mo RFS rates were higher for NIVO vs IPI in subgroups defined by disease stage, PD-L1 expression, and *BRAF* mutation status (Table). DMFS also continued to be significantly longer for NIVO vs IPI, with 24-mo rates of 70.5% and 63.7%, respectively (hazard ratio 0.76, P=0.034). Subsequent therapies were received by 31.1% of pts in the NIVO group and 41.1% in the IPI group. Per protocol, there was no additional safety assessment for the current analysis given that all pts had been off study treatment $>$100 days at the time of the previous data cutoff. **Conclusions:** With extended follow-up, NIVO demonstrated a sustained efficacy benefit vs IPI in pts with resected stage III/IV melanoma at high risk of recurrence, regardless of disease stage, PD-L1 expression, or *BRAF* mutation status. Clinical trial information: NCT02388906.

	NIVO	IPI
RFS, 24-mo rates; % (N)		
ITT population	62.6% (453)	50.2% (453)
Stage IIIB	70.8% (165)	60.7% (148)
Stage IIIC	58.0% (203)	45.4% (218)
Stage IV	58.0% (82)	44.3% (87)
PD-L1 ≥5%	75.5% (152)	58.4% (154)
PD-L1 <5%	55.2% (275)	45.5% (286)
***BRAF* mutant**	61.9% (187)	51.7% (194)
***BRAF* wild-type**	63.5% (197)	46.2% (212)

9503 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

4-year survival and outcomes after cessation of pembrolizumab (pembro) after 2-years in patients (pts) with ipilimumab (ipi)-naive advanced melanoma in KEYNOTE-006. *First Author: Georgina V. Long, Melanoma Institute Australia, The University of Sydney, Mater Hospital, and Royal North Shore Hospital, Sydney, Australia*

Background: KEYNOTE-006 (NCT01866319) established superiority of pembro over ipi in advanced melanoma. We provide 4-y outcomes, long-term data for pts who completed 2 y pembro, and data for second course. **Methods:** Eligible pts (N = 834) were randomly assigned 1:1:1 to receive pembro 10 mg/kg Q2W, pembro 10 mg/kg Q3W, or ipi 3 mg/kg Q3W for 4 doses. Treatment was continued for 2 y (pembro only; completed defined as $\geq$94 weeks of pembro and discontinued with at least SD) or until disease progression, intolerable toxicity, or pt/investigator decision to discontinue. End points were OS and ORR per irRC by investigator review. Upon PD, eligible pts could receive an additional 1 y pembro. **Results:** At data cutoff (Dec 4, 2017), median follow-up was 45.9 mo (range, 0.3-50.0). 4-y OS rate was 42% in the pooled pembro arms (n = 556) and 34% in the ipi arm (n = 278); ORR was 42% and 17%. Median DOR was NR for pembro (range, 1.0+ to 46.1+ mo) or ipi (1.1+ to 45.6+ mo); 62% pembro- and 59% ipi-treated pts had a response lasting $\geq$42 mo. In treatment-naive pts, 4-y OS rates were 44% in the pooled pembro arms (n = 368) and 36% in the ipi arm (n = 181); ORR was 47% and 17%. Median DOR was NR for pembro (range, 1.6+ to 46.0+ mo) or ipi (1.1+ to 42.2+ mo); 65% pembro- and 68% ipi-treated pts had a response lasting $\geq$42 mo. Of 556 pts, 103 (19%) completed the protocol-specified 2-y pembro (28 CR, 65 PR, 10 SD). Median follow-up was 20.3 mo after pembro completion; 89 (86%) pts did not progress and 14 pts had PD (prior response 2 CR, 9 PR, 3 SD). Eight pts (prior response 3 CR [including 1 pt who discontinued early with CR and then progressed], 4 PR, and 1 SD) received second-course pembro but 3 discontinued (1 each due to PD, interstitial pneumonia, and infection). Median duration of second-course pembro was 9.7 mo; BOR was 1 CR, 1 PR, 5 SD, and 1 PD. 1 pt with SD had subsequent PD. 5 pts had a TRAE during second-course pembro; there were no grade 3/4 TRAEs or deaths. **Conclusions:** Pembro provides durable antitumor activity in treatment-naive or -experienced pts with advanced melanoma. Of pts who completed 2 y pembro, 86% were progression free at 20 mo. Pembro is safe and provides additional antitumor activity as second-course treatment. Clinical trial information: NCT01866319.

9504 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Overall survival in COLUMBUS: A phase 3 trial of encorafenib (ENCO) plus binimetinib (BINI) vs vemurafenib (VEM) or enco in *BRAF*-mutant melanoma. *First Author: Reinhard Dummer, University of Zurich Hospital, Department of Dermatology, Zurich, Switzerland*

Background: Combined BRAF/MEK inhibitor therapy is standard of care in advanced *BRAF*V600-mutant melanoma. COLUMBUS Part 1 evaluated ENCO 450 mg once daily (QD) + BINI 45 mg twice daily (BID;COMBO450) vs VEM 960 mg BID or ENCO 300 mg QD (ENCO300) in patients (pts) with advanced *BRAF*V600-mutant melanoma. The primary study endpoint was progression-free survival (PFS); median PFS was 14.9 vs 7.3 mo for COMBO450 vs VEM; hazard ratio (HR): 0.54 (2-sided $P< 0.001$). Here we report a planned analysis of overall survival (OS), a secondary endpoint of the study. **Methods:** Pts with advanced/metastatic *BRAF*V600-mutant melanoma, untreated or progressed on/after first-line immunotherapy, were stratified by disease stage, Eastern Cooperative Oncology Group Performance Status and prior first-line immunotherapy. Pts in Part 1 were randomized 1:1:1 to COMBO450 (n = 192), ENCO300 (n = 194), or VEM (n = 191). Tumor responses and progression were assessed by blinded independent central review. An analysis of OS was planned after 232 events in the COMBO450 and VEM arms combined. **Results:** As of data cutoff,105, 106, and 127 events contributed to the OS analysis in the COMBO450, ENCO300, and VEM arms, respectively; median follow-up across arms was 21.5 mo. Median OS was 33.6 mo (95% CI, 24.4-39.2) with COMBO450, 23.5 mo (95% CI, 19.6-33.6) with ENCO300, and 16.9 mo (95% CI, 14.0-24.5) with VEM. Risk of death was reduced with COMBO450 vs VEM (HR, 0.61 [95% CI, 0.47-0.79]; nominal 2-sided $P< 0.001$). Updated median PFS was 14.9 mo (95% CI, 11.0–20.2) with COMBO450, 9.6 mo (95% CI, 7.4–14.8) with ENCO300, and 7.3 mo (95% CI, 5.6–7.9) with VEM. PFS was longer with COMBO450 vs VEM (HR, 0.51 [95% CI, 0.39–0.67]). Updated response rates, safety data, and information on 2nd-line therapy will be presented at the meeting. **Conclusions:** The best-in-class median PFS of 14.9 and median OS of 33.6 mo suggest that COMBO450 is a promising new regimen for treatment of *BRAF*-mutant melanoma. SPONSOR: Array BioPharma Inc. Clinical trial information: NCT01909453.

9505 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Nivolumab (Nivo) as neoadjuvant therapy in patients with resectable Merkel cell carcinoma (MCC) in CheckMate 358. *First Author: Suzanne Louise Topalian, Johns Hopkins Bloomberg/Kimmel Institute for Cancer Immunotherapy and Kimmel Cancer Center, Baltimore, MD*

Background: MCC is a rare, aggressive skin cancer commonly associated with the oncogenic Merkel cell polyomavirus (MCPyV). The PD-1/PD-L1 immunosuppressive pathway is often upregulated in MCC, and advanced metastatic MCC is responsive to PD-1 blockade. Here we report the first trial of anti–PD-1 in the neoadjuvant setting for resectable MCC. **Methods:** In the phase 1/2 CheckMate 358 trial of nivo anti–PD-1 in virus-associated cancers (NCT02488759), patients (pts) with resectable MCC received nivo 240 mg IV on D1 and D15. Surgery was planned on D29. Tumor regression was assessed radiologically before surgery, and microscopically in the surgical specimen. Immunohistochemistry (IHC) was used to assess tumor MCPyV status and tumor PD-L1 expression. Data were analyzed as of August 7, 2017 with a median follow-up of 54.1 wks. **Results:** 25 pts with resectable MCC, AJCC stage IIA–IV, received ≥1 dose of nivo. Median age was 70 yrs (range 22–88). Among 18 patients' tumors evaluated by IHC, 8 (44%) were MCPyV+, and 6 (30%) were PD-L1+ (1% cutoff). 22 of 25 (88%) pts had surgery at ~D29 without significant delay; 3 pts did not have surgery on trial, 1 due to rapid tumor progression and 2 due to grade 2–3 adverse events (AEs). Among 20 pts with pre/post nivo CT scans, 16 (80%) had tumor regression (range 13%–100% reduction), including 9 (45%) with > 30% reduction. Among 17 resections evaluated for pathologic response by central investigator review, 11 (65%) had a major pathologic response (MPR, defined as ≤10% residual viable tumor cells), including 8 (47%) complete responses. MPRs and radiologic responses were seen in virus+/− tumors and in PD-L1+/− tumors. Treatment-related AEs were reported in 36% (any grade) and 4% (grade 3–4) of pts, with no new safety signals. Among 21 pts followed after surgery, all were progression-free at 6 mo; 2 pts had relapsed at 12 mo. **Conclusions:** Nivo administered for 4 wks before surgery in MCC was safe and induced substantial radiologic and pathologic tumor regressions in 45% and 65% of patients, respectively. In some pts, this obviated the need for more extensive surgery. The majority of operated patients remain tumor-free at 12 mo. Data will be updated per a March 2018 database lock. Clinical trial information: NCT02488759.

9506 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Durable tumor regression and overall survival (OS) in patients with advanced Merkel cell carcinoma (aMCC) receiving pembrolizumab as first-line therapy. *First Author: Paul Nghiem, University of Washington and Fred Hutchinson Cancer Center, Seattle, WA*

Background: Merkel cell carcinoma (MCC) is an aggressive skin cancer often caused by the Merkel cell polyomavirus (MCPyV). Clinical trials of PD-1-axis blocking agents in aMCC have demonstrated increased progression free survival (PFS) compared to historical data from patients (pts) receiving chemotherapy, but data on response durability and OS are limited. Here we report outcomes from the expanded phase 2 Cancer Immunotherapy Trials Network-09 trial of pembrolizumab (PEM, anti-PD-1) in the first-line setting (NCT02267603). **Methods:** Adults with aMCC, naïve to systemic therapy for aMCC, received PEM (2 mg/kg Q3W) for up to 2 yrs. Responses per RECIST v1.1 were assessed centrally based on CT scans performed at 12 wks and Q9W thereafter. Tumor MCPyV status was assessed by serum antibody titer and/or IHC for MCPyV oncoprotein. Preliminary results from the first 26 pts have been reported (Nghiem NEJM 2016). We now include data from an expansion cohort of 24 pts. **Results:** 50 pts (43 stage IV, 7 unresectable stage IIIB) were enrolled 01/2015 – 05/2017. 80% of pts were ≥65 yrs of age. As of 06/21/17, median follow-up was 8.6 mo (range 0.4 - 29 mo). Among tumors from 49 pts, 65% were MCPyV+. Of 42 pts with ≥21 wk follow-up, confirmed ORR was 50% (95% CI 34.2-65.8; CR 19%, PR 31%). ORR was 52% and 44% in pts with MCPyV (+) and (-) tumors, respectively. Median PFS was not reached (NR; 95% CI 2.9 mo - Not Estimable). OS rate at 18 mo was 68% and median OS was NR, comparing favorably to historical first-line chemotherapy data (18 mo OS rate ~30%; Iyer 2016 & Cowey 2017). Among 21 confirmed responders, median response duration was NR (range 3.9+ to 25.6+ mo). Treatment-related adverse events (TRAE) of any grade (CTCAE v4.0) were seen in 47/50 pts (94%); 15 pts (30%) experienced a grade ≥3 TRAE, including 1 treatment-related death. TRAEs led to discontinuing PEM in 6 pts (12%). **Conclusions:** These results represent the longest observation to date of patients with aMCC receiving first-line anti-PD-1, and demonstrate durable tumor control, a favorable OS rate, and a manageable safety profile. An additional 7.5 mos of follow-up and correlative studies including tumor PD-L1 expression will be presented. Clinical trial information: NCT02267603.

9507 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Two-year efficacy and safety update from JAVELIN Merkel 200 part A: A registrational study of avelumab in metastatic Merkel cell carcinoma progressed on chemotherapy. *First Author: Paul Nghiem, University of Washington Medical Center at South Lake Union, Seattle, WA*

Background: Merkel cell carcinoma (MCC) is a rare, aggressive skin cancer with poor prognosis. Studies of second-line chemotherapy for metastatic MCC (mMCC) have reported median progression-free survival (PFS) of up to 3 months and no benefit to overall survival (OS). Avelumab, a human anti–PD-L1 monoclonal antibody, is approved in several countries for the treatment of mMCC. Here, we report updated efficacy and safety data from part A of the pivotal, single-arm, phase 2, JAVELIN Merkel 200 trial of avelumab in patients (pts) with mMCC and ≥2 y of follow-up. **Methods:** Pts with mMCC and progression on prior chemotherapy received avelumab 10 mg/kg intravenously every 2 weeks until disease progression or intolerable adverse event (AE). Objective response rate (ORR), duration of response (DOR), and PFS were evaluated by independent review per RECIST v1.1; OS and AEs (per NCI CTCAE v4.0) were also evaluated. **Results:** As of Sep 26, 2017, 88 pts were followed for a median of 29.2 mo (range 24.8-38.1). The median duration of treatment was 3.9 mo (range 0.5-36.3); treatment was ongoing in 9 pts (10.2%). The confirmed ORR of 33.0% (95% CI 23.3-43.8; complete response in 11.4%) remained unchanged from previous analyses at 1 y and 18 mo; responses were ongoing in 19 of 29 pts, including 12 pts with > 2 y response duration. Median DOR had not been reached (range 2.8-31.8 mo; 95% CI 18.0-not estimable). Durable responses led to stable rates of PFS (29% at 1 y, 29% at 18 mo, and 26% at 2 y). Median OS was 12.6 mo (95% CI 7.5-17.1) and the 2-y OS rate was 36% (50% at 1 y and 39% at 18 mo). Clinical activity was observed across all pt subgroups, irrespective of tumor PD-L1 and MCPyV status. The AE profile remained consistent with previous analyses: 67 pts (76.1%) had a treatment-related AE (TRAE), 10 pts (11.4%) had a grade ≥3 TRAE, 20 pts (22.7%) had an immune-related AE, and no treatment-related deaths occurred. **Conclusions:** At ≥2 y of follow-up, avelumab shows continued durable responses and meaningful survival outcomes in pts with mMCC, exceeding the outcomes associated with cytotoxic chemotherapy. Efficacy and safety results confirm the lasting clinical benefit of avelumab in pts with mMCC. Clinical trial information: NCT02155647.

Interim analysis of a randomized, open-label phase 2 study of talimogene laherparepvec (T-VEC) neoadjuvant treatment (neotx) plus surgery (surgx) vs surgx for resectable stage IIIB-IVM1a melanoma (MEL). *First Author: Robert Hans Ingemar Andtbacka, Huntsman Cancer Institute at the University of Utah, Salt Lake City, UT*

Background: There is no approved neotx for resectable stage IIIB-IVM1a MEL. T-VEC, an HSV-1-based oncolytic virus, may reduce the risk of developing visceral and bone metastases in unresectable Stage IIIB-IVM1a MEL (Andtbacka SSO 2015). We conducted a randomized study to evaluate the effect of neotx T-VEC in high risk resectable MEL (NCT02211131). **Methods:** Patients (pts) with resectable stage IIIB/C/IVM1a MEL, ≥ 1 injectable cutaneous, subcutaneous, or nodal lesions ≥ 10 mm, and no systemic tx 3 mos prior were randomized 1:1 to 6 doses/12 wks of T-VEC followed by surgx (Arm 1) vs upfront surgx (Arm 2). T-VEC was given at standard dosing until surgx, no injectable tumors, or intolerance. This interim analysis was planned for when the 75th pt in Arm 1 completed the safety follow-up visit (30+ days post surgx). **Results:** 150 pts were randomized (76 Arm 1, 74 Arm 2). Of all pts, ≥ 94% had no prior radio/systemic tx, 91% had prior surgx and 84% had no plans for adjuvant tx. 75% in Arm 1 and 93% in Arm 2 had surgx as planned. Of the 19 pts who did not have surgx in Arm 1, 11 had progressive disease. In Arm 2, 17 pts recurred within 14 wks post-surgx. For pts who had surgx in Arm 1, the pathological complete response (pCR) rate was 21%. Negative margin resection (R0) rates were 56.1% for Arm 1 and 40.6% for Arm 2 (80% CI: 3-28% for the difference). For all randomized pts, pCR rate in Arm 1 was 15.8%; R0 rates were 42.1% (Arm 1) vs 37.8% (Arm 2). Overall response (OR) rate (CR+PR) in Arm 1 was 14.7% (80% CI: 9-22%). In the safety set (73 pts in Arm 1, 69 pts in Arm 2), tx-emergent adverse events (TEAE) was 93% in Arm 1 (1 grade 4 pain, no grade 5) and 45% in Arm 2 (all ≤ grade 3). In Arm 1, preop AE was 89.5% (most common: pyrexia 35%) and intra/postop AE was 29.8% (most common: seroma 5.3%). In Arm 2, intra/postop AE rate was 45% (most common: pain 7.2%). 17.8% (Arm 1) vs 2.9% (Arm 2) pts had an SAE; of these, 5.5% (Arm 1) and 2.9% (Arm 2) were deemed surgx-related. **Conclusions:** 12 wks of neo T-VEC produced a pCR rate in stage IIIB-IVM1a MEL higher than observed by ORs and may account for the higher R0 margin in Arm 1. No unexpected toxicities were noted. The primary analysis of RFS is ongoing. Clinical trial information: NCT02211131.

Vismodegib in neoadjuvant treatment of locally advanced basal cell carcinoma: First results of a multicenter, open-label, phase 2 trial (VISMONEO study). *First Author: Laurent Mortier, Université Lille, Centre Hospitalier Régional Universitaire de Lille, Lille, France*

Background: Surgery is the main treatment of basal cell carcinoma. In locally advanced basal cell carcinoma (laBCC), surgery may cause functional or aesthetic damages. Neoadjuvant administration of vismodegib in laBCC may reduce tumor size, facilitate resection and potentially reduce functional and aesthetic consequences of surgery. VISMONEO was conducted to assess efficacy and safety of vismodegib in the neoadjuvant treatment of laBCC. **Methods:** VISMONEO (NCT02667574) is an open-label, non-comparative, multicenter, phase II study. Patients with at least one histologically confirmed BCC of the face, inoperable or operable with functional or major aesthetic sequelae risk were included. Oral vismodegib 150 mg once-daily was administered for a period of 4 to 10 months, before surgery. Surgery was done once the best response under vismodegib was observed. Primary endpoint was the percentage of BCC patients with tumor down-staging following surgical resection after neoadjuvant vismodegib. Downstaging was defined according to a six-stage surgical classification related to the aesthetic and functional risk of the surgery. **Results:** 55 patients with laBCC were included. Median age of the patients was 73.1 years. At inclusion, 4 were inoperable, 15 were operable with a major functional risk and 36 were operable with a minor functional risk or a major aesthetic risk. Mean size of target lesion was 47.3 mm (SD = 27,2mm). 44 patients had a procedure after vismodegib treatment (80.0%, 95%CI [67 to 90]). Of these 44 responders, 27 had a complete response proved by biopsy. Main adverse events were dysgeusia, muscle spasms, alopecia, fatigue and weight loss (20 % of patients with grade ≥ 3) **Conclusions:** Neoadjuvant vismodegib allows a downstaging of surgical procedure for laBCCs in functionally sensitive locations. Final data will assess quality of long-term local control. Clinical trial information: NCT02667574.

Neoadjuvant (neo) immune checkpoint blockade (ICB) in patients (Pts) with high-risk resectable metastatic melanoma (MM). *First Author: Rodabe Navroze Amaria, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Nivolumab (nivo) and combination ipilimumab (ipi) + nivo are highly active in pts with unresectable and stage IV MM. Nivo is also safe and effective adjuvant treatment for MM pts with resected stage III disease. Preclinical studies demonstrate that neo ICB may be more effective than adjuvant treatment, but the safety and efficacy of neo ICB in pts is unknown. We designed a randomized trial to assess the safety and activity of neo nivo +/- ipi ICB in pts with high-risk, resectable MM. **Methods:** We conducted a non-comparative randomized phase II study for pts with resectable, clinically detectable stage III or oligometastatic stage IV MM. Pts were randomized to receive neo nivo 3mg/kg IV every 2 weeks for up to 4 doses (Arm A) or neo ipi 3mg/kg + nivo 1mg/kg IV every 3 weeks for up to 3 doses (Arm B) prior to surgery, then nivo 3mg/kg IV every 2 weeks for 13 doses (Arms A and B) after surgery (NCT02519322). Planned total accrual was 40 pts (1:1 randomization) with stratification by stage and PD-L1 status. The primary endpoint was pathologic complete response (pCR) rate. **Results:** The trial was closed after 23 pts were enrolled (12 to Arm A, 11 to Arm B). Neo nivo achieved 25% pCR and 25% radiographic response rate (RR), but 17% were unable to undergo surgery due to rapid disease progression during neo therapy. All pts on neo ipi + nivo underwent surgery, and the pCR and RR rates were 45% and 73%, respectively. Grade 3 treatment related adverse events occurred in 8% of pts on Arm A and 73% on Arm B. **Conclusions:** Neo treatment with nivo +/- ipi can produce pCR in high-risk resectable MM. While neo nivo was well tolerated, RRs were lower than observed in stage IV pts and some pts experienced rapid progression that precluded surgery. Neo ipi + nivo achieved higher RRs but with high toxicity. This data provides a foundation for further optimization and testing of neo ICB. Clinical trial information: NCT02519322.

Epacadostat plus nivolumab for advanced melanoma: Updated phase 2 results of the ECHO-204 study. *First Author: Adil Daud, University of California, San Francisco, San Francisco, CA*

Background: Indoleamine 2,3-dioxygenase 1 (IDO1) enzyme-induced immunosuppression in the tumor microenvironment supports tumor cell evasion of immune surveillance. Epacadostat (E) is a potent and selective oral inhibitor of the IDO1 enzyme. ECHO-204 is an open-label, phase (P) 1/2 study of E plus PD-1 inhibitor nivolumab (N) in patients (pts) with advanced cancer. Updated efficacy and safety/tolerability outcomes for the P2, advanced (unresectable or stage IV) melanoma cohort are reported. **Methods:** Pts received E (100 or 300 mg PO BID) plus N (240 mg IV Q2W). Response was assessed every 8 weeks (RECIST v1.1). Safety/tolerability was assessed in pts receiving ≥1 study treatment dose. PD-L1 expression was assessed (Dako 28-8 assay; PD-L1 positive: ≥1% tumor cell staining). **Results:** As of 29 Oct 2017, all of the planned 50 pts were enrolled in the P2 expansion cohort (n = 40 treatment naive for advanced disease). Median (range) duration of follow-up was 417 days (70 to 617 days). Across all pts, overall response rate (ORR) was 62% (31/50; 9 complete response [CR], 22 partial response [PR]) and disease control rate (DCR; CR + PR + stable disease) was 78% (39/50). In treatment-naive pts, ORR was 65% (26/40; 8 CR, 18 PR) and DCR was 80% (32/40); responses were observed in both PD-L1-positive pts (75% ORR [9/12]; 92% DCR [11/12]) and PD-L1-negative pts (56% ORR [9/16]; 69% DCR [11/16]); the majority (88%; 23/26) of responses were ongoing at data cutoff; duration of response ranged 55+ to 565+ days (median not reached); rate of progression-free survival at 6 and 12 months was 77% and 63%, respectively (median not reached); and the rate of overall survival at 12 months was 92% (median not reached). In the overall population (N = 50), the rate of grade ≥3 treatment-related adverse events (TRAEs) was 48% with E 300 mg BID (n = 42; most common grade ≥3 TRAEs: rash [19%], ALT increase [12%]) and 13% with E 100 mg BID (n = 8; pneumonitis [13%] was the only grade ≥3 TRAE). Eight pts discontinued treatment due to TRAEs (all E 300 mg BID). There was no AE-related death. **Conclusions:** E + N continues to show promising antitumor activity in pts with advanced melanoma and is generally well tolerated. E 100 mg BID is the selected dose for P3 studies of E + N in pts with advanced cancer. Clinical trial information: NCT02327078.

9512 Poster Discussion Session; Displayed in Poster Session (Board #339), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Phase 2 trial of the IDO pathway inhibitor indoximod plus checkpoint inhibition for the treatment of patients with advanced melanoma. *First Author: Yousef Zakharia, University of Iowa Hospitals and Clinics, Holden Comprehensive Cancer Center, Iowa City, IA*

Background: The indoleamine 2,3-dioxygenase (IDO) pathway is a key counter-regulatory mechanism that, in cancer, is exploited by tumors to prevent and evade anti-tumor immunity. Inhibitors of the IDO pathway, such as indoximod, are an increasingly validated class of potential cancer therapeutics. Pre-clinical data and an increasing body of clinical data support evaluating the combination of a checkpoint inhibitor (CI) with an IDO pathway inhibitor as potential treatment for advanced melanoma. **Methods:** Advanced melanoma patients were enrolled in a single arm Phase 2 trial evaluating the addition of indoximod to standard of care CI as approved for melanoma. Prior therapy excluding CI was allowed. Investigators administered their choice of approved CI (pembrolizumab (P), nivolumab (N), ipilimumab (I). Indoximod was administered continuously (1200mg po BID), concurrent CI dosed per approved US label. Study endpoint was best overall response (overall response rate (ORR) = complete response (CR) + partial response (PR)) per site reported RECIST 1.1. **Results:** 102 patients were enrolled in Phase 2. 70 patients with unresectable stage III or IV cutaneous or mucosal melanoma were treated with P and had an on treatment imaging meeting the per protocol, pre-specified definition of evaluable for efficacy (EE). Additionally, 15 patients had uveal melanoma, 4 received I, 4 received N, and 1 was never treated. 8 patients came off study prior to the first on-treatment imaging study. The ORR for the EE population was 55.7% (39/70, 36 confirmed) with CR of 18.6% (13/70, all confirmed). Median PFS was 12.4 months (95% CI 9.0-NA). Archival tissue was available from 41 of 70 EE patients. The PD-L1 staining $\geq$ 1% was 54% (22/41). The combination was well tolerated and most common AEs regardless of attribution were fatigue, nausea, pruritus. An additional 21 patients have been enrolled to a biopsy cohort. **Conclusions:** The combination of indoximod and pembrolizumab demonstrates an ORR of 55.7%, CR 18.6% which compares favorably with reported ORR for P alone (33%). Updated data including biopsy cohort will be presented. Clinical trial information: NCT02073123.

9513 Poster Discussion Session; Displayed in Poster Session (Board #340), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Phase 1b/2, open label, multicenter, study of the combination of SD-101 and pembrolizumab in patients with advanced melanoma who are naïve to anti-PD-1 therapy. *First Author: Antoni Ribas, UCLA Johnson Comprehensive Cancer Center, Los Angeles, CA*

Background: SD-101 is a CpG-ODN agonist of TLR9. Pembrolizumab is a PD-1 inhibitor. DV3-MEL-01 (NCT02521870) assesses safety and preliminary efficacy of the combination of SD-101 and pembrolizumab in stage IIIC-IV melanoma. **Methods:** Phase 1b evaluated SD-101 at multiple doses injected in a single tumor Q1W x 4 then Q3W x 7 in combination with a fixed dose of pembrolizumab (200 mg IV Q3W); both drugs started on D1. Phase 2 is evaluating SD-101 at 8 mg in 1 lesion and 2 mg/lesion in 2-4 lesions beginning 21 days after the first dose of pembrolizumab. First scan was performed at D64, after 6 weeks of combination therapy. Per-protocol best overall responses (ORR) were assessed per investigator using RECIST v1.1/ irRECIST at $\geq$ D127 after at least 15 weeks of combination therapy. The per-protocol population comprised patients who received $\geq$ 1 dose of each drug and had $\geq$1 post-baseline scan. ITT results are not presented below. **Results:** 9patients enrolled in phase 1b; 54 in phase 2: median age 67 y, male 67%, Stage IVM1a/b 27%, Stage IVM1c 37%, LDH $>$ ULN 22%, treatment naive 70%. SD-101 safety profile consists of transient flu-like symptoms. Frequently observed Grade $\geq$3 treatment-related AEs were myalgia 9%, headache 9%, fatigue 9%, chills 7%, and malaise 5%. Immune-related AEs (irAEs) have been reported in 17%. With protocol specified scans on D64 and D127, half of responses were observed $\geq$ D127 with early discontinuation from PD occurring before D127. The per-protocol ORR was 60% or 15/25 (CR 12%/PR 48%/SD 16%[DCR = 76%]/PD 24%) (median f/u = 223 d).15 pts had CR or PR of 19 with $\geq$ D127 scans; 6 pts with D64 scans discontinued with PD before D127. Non-evaluable pts (n = 5) without post-baseline scans discontinued from study prior to D64: 1 irAE (gr2 pneumonitis), 1 withdrew consent, and 3 clinical PD. **Conclusions:** The combination of SD-101 and pembrolizumab appears to be showing promising response rates compared to those expected with pembrolizumab alone. The combination is well tolerated with no evidence of an increased rate of irAEs. Clinical trial information: NCT02521870.

9514 Poster Discussion Session; Displayed in Poster Session (Board #341), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Phase II trial of pembrolizumab (pembro) plus 1 mg/kg ipilimumab (ipi) immediately following progression on anti-PD-1 Ab in melanoma (mel). *First Author: Daniel Olson, University of Chicago, Chicago, IL*

Background: Immunotherapy with anti-PD-1 + CTLA-4 Abs improves response rates over anti-PD-1 Ab alone; however, the utility of this combination after first line anti-PD-1 is unknown. We report the first prospective data evaluating pembro + low dose ipi immediately following progression on anti-PD-1 (NCT02743819). **Methods:** Patients (pts) with mel and measurable disease, no autoimmunity, and no prior anti-CTLA-4 who had progressed immediately prior on an anti-PD-1 (or non-CTLA4 combination) were eligible. Prior BRAF inhibitor was allowed (none received it). Pts received pembro 200 mg + ipi 1 mg/kg Q3W for 4 doses, then pembro alone. The primary endpoint was response rate (RR) as assessed by irRECIST. An optimal Simon two-stage design was employed to test the null hypothesis of a 10% RR vs 30% alternative (1-sided alpha 0.10, 90% power, $\geq$2/12 RR to continue to total of $\geq$6/35). The data analysis cutoff date was January 2, 2018. **Results:** 22 patients have been accrued with 17 evaluable for the primary endpoint (4 have not yet had their first imaging evaluation and 1 was not enrolled). Prior treatment included 21 on anti-PD-1 alone and 1 on combination with IDO inhibitor. Median length of treatment on prior anti-PD-1 was 5.6 months among all 22 pts. The study met its interim efficacy analysis with 5/12 responses to move to stage 2. Among the 17 response-evaluable pts there were 2 CR, 6 PR (47% RR), and 5 SD for disease control rate (DCR) of 76% and rejection of the null hypothesis. Progression-free survival at 6 months was 75% (CI 47%-90%). All responses are ongoing. At last follow-up, 8 pts have gone off treatment with 14/22 (64%) having any drug-related and 3/22 (14%) $\geq$ grade 3-4 drug-related AE (hyperglycemia, acute kidney injury and skin tissue disorder, diarrhea and rash acneiform). Among 11 response-evaluable pts with staining results currently available, RR and DCR were 67% and 100% in PD-L1+ (n = 3) and 50% and 88% in PD-L1 negative (n = 8) tumors. Further biomarker analysis is underway. **Conclusions:** Pembro + 1 mg/kg ipi is tolerable and has antitumor activity in pts with mel who have progressed immediately prior on an anti-PD-1 Ab. The trial sample size has been expanded to further explore this regimen. Clinical trial information: NCT02743819.

A phase 2 study to evaluate the safety and efficacy of Intratumoral (IT) injection of the TLR9 agonist IMO-2125 (IMO) in combination with ipilimumab (ipi) in PD-1 inhibitor refractory melanoma. *First Author: Adi Diab, Department of Melanoma Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: PD-1/L1 inhibitors have transformed MM treatment, however many patients (pts) remain refractory. Subsequent treatment options including ipi offer modest benefit (~13% respond) (Long, SMR 2016). IT IMO, a Toll-like receptor 9 agonist, may improve response to ipi by activating innate and adaptive immune responses to overcome immune escape. Tumor biopsies obtained from both injected/local and uninjected/distant lesions during earlier studies show maturation of the mDC1 subset (CD1c+CD303-), upregulation of PD-L1 by tumor cells, and an IFNα response gene signature. On treatment(week 8) biopsies of uninjected/distant tumors show expression of CD56+ and Ki67+ effector CD8+T cells in responding pts, indicative of an abscopal effect. Initial clinical experience with IMO + ipi is promising resulting in the selection of 8mg as the RP2D. Here we report an analysis of the first 15 subjects that received 1+ doses of study drugs. **Methods:** This is a phase 2 study for adults with unresectable or MM refractory to a PD-1 inhibitor pts are eligible if they have an accessible tumor for IT administration of IMO. 8mg IMO is administered to a single tumor during weeks 1,2,3,5,8, and 11 along with ipi per the product label. The primary endpoint is overall response rate (ORR) using a 2-stage design. **Results:** A total of 24 pts have been treated with IMO + ipi including pts that received injections to deep visceral lesions and lymph nodes. Grade 3 /4 Immune-related AE were observed in 6 subjects [hypophysitis (N = 2), hepatitis (1), Gastritis (1), Guillain-Barre syndrome (1), Colitis (1), Neutropenia (1)]. These responded well to standard measures. Of 24 pts treated at the RP2D of 8mg, 15 were assessed for response with 47% ORR of and 67% disease control rate (1 Complete Response, 6 Partial Response(3 confirmed), 3 Stable disease). Phase 2 accrual is ongoing. **Conclusions:** IMO + ipi is a robust strategy to revive the immune response in PD-1/L1resistant tumors and the demonstrated substantial clinical benefit including durable responses in this clinically challenging pt population. This data supports the initiation of a phase 3 study compared to ipi alone. Clinical trial information: NCT02644967.

5-year survival outcomes in patients (pts) with advanced melanoma treated with pembrolizumab (pembro) in KEYNOTE-001. *First Author: Omid Hamid, The Angeles Clinic and Research Institute, Los Angeles, CA*

Background: Pembro has demonstrated robust antitumor activity and safety in several studies of advanced melanoma, including KEYNOTE-001, -002, and -006. Here, we describe the 5-year outcomes for all pts and for those who were treatment naive in the phase 1b KEYNOTE-001 study (NCT01295827). **Methods:** Pts aged ≥18 y with previously treated or treatment-naive, advanced or metastatic melanoma received pembro 2 mg/kg Q3W, 10 mg/kg Q3W, or 10 mg/kg Q2W until disease progression, intolerable toxicity, or pt/investigator decision to withdraw. The Kaplan-Meier method was used to estimate OS and PFS. ORR and PFS were based on immune-related response criteria by investigator assessment. Data cutoff was Sep 1, 2017. **Results:** KEYNOTE-001 enrolled 655 pts (151 treatment naive; 504 previously treated). After a median follow-up of 55 mo (range, 48-69), 35 pts are on pembro treatment. 63% (n = 412) of all pts died. The estimated 5-year OS rate was 34% in all pts and 41% in treatment-naive pts, similar to the 4-year rates of 38% and 48%, respectively. Median OS was 23.8 mo (95% CI, 20.2-30.4) in all pts and 38.6 mo (95% CI, 27.2-NR) in treatment-naive pts. 5-year PFS rates were 21% in all pts and 29% in treatment-naive pts; median PFS was 8.3 mo (95% CI, 5.8-11.1) and 16.9 mo (95% CI, 9.3-35.5) in all pts and treatment-naive pts, respectively. Median response duration was not reached; 73% of all responses and 82% of treatment-naive responses were ongoing at data cutoff; the longest response observed in all pts was ongoing at 66 mo. Treatment-related AEs (TRAEs) occurred in 86% (n = 562) of pts, including 17% (n = 114) with grade 3/4 TRAEs and 7.8% (n = 51) who discontinued because of a TRAE. **Conclusions:** Pembro provides a 5-year OS rate of 34% in pts with previously treated and treatment-naive advanced melanoma, with a 5-year OS rate of 41% in treatment-naive pts. These data, representing the longest follow-up for pembro to date in any cancer, confirm the durable antitumor activity and tolerability of pembro in advanced melanoma. Clinical trial information: NCT01295827.

Utility of 1-year FDG-PET (PET) to determine outcomes from anti-PD-1 (PD1) based therapy in patients (pts) with metastatic melanoma (MM). *First Author: Aaron C. Tan, Royal North Shore Hospital, St Leonards, Australia*

Background: PD1 based therapy has durable clinical activity for some pts with MM, however there are few predictors of long-term response and the optimal duration of therapy is unknown. Whether PET imaging may assist with this remains unclear. **Methods:** A prospectively assembled cohort of consecutive pts treated at a single center with PD1 based therapy from May 2013 to Sep 2017, who underwent baseline and 1-year PET was examined retrospectively. Demographics, disease features, treatment, response and outcome data were collected. 1-year response was determined using RECIST for CT and EORTC criteria for PET, and was coded as complete response (CR or CMR), partial response (PR or PMR), stable disease (SD or SMD) or progressive disease (PD or PMD) on CT and PET, respectively. **Results:** 118 pts were evaluated with median follow-up 21.0 mo and 98% remain alive. PD1 based therapy included pembrolizumab (50%) or nivolumab (13%) monotherapy, and combination therapy (with iplimumab, TVEC or epacadostat/placebo in 37%). At 1-year, 25% of pts had CR, 60% PR and 15% SD/PD on CT, while 68% had CMR, 17% PMR and 15% SMD/PMD on PET (Table). RECIST progression-free survival (PFS) was improved in pts with CMR vs non-CMR (median not reached [NR] vs 19.8 mo; HR 0.09; $p < 0.01$), and in the pts with CMR, PFS was not statistically different between pts with CMR+CR vs CMR+PR/SD (median NR in both groups; $p = 0.11$). In pts with PR on CT, PFS was improved in pts with PR+CMR vs PR+non-CMR (median NR vs 21.3 mo; HR 0.12; $p < 0.01$). In the 80 pts with CMR, median time on treatment was 14.8 mo, 60% had discontinued treatment with median follow-up post discontinuation 9.9 mo, and 99% had ongoing response. **Conclusions:** Whilst only a small proportion of pts who survive one year with PD1 based therapy have a complete response on CT, most have a complete metabolic response on PET, and 99% have ongoing response. PET may have utility in predicting long-term benefit and guide discontinuation of therapy. Prospective evaluation using PET at earlier intervals is warranted.

Transcriptomic and immunophenotypic profiles of melanoma tissue from patients (pts) treated with anti-PD-1 +/- ipilimumab to define mechanisms of response and resistance. *First Author: Tuba Nur Gide, Melanoma Institute Australia, The University of Sydney, Sydney, Australia*

Background: Immune checkpoint blockade improves the survival of patients with metastatic melanoma, but many patients fail to respond to immunotherapy and the lack of accurate predictors of response or progression remains a major clinical problem. We investigated potential mechanisms of response and resistance to anti-PD1 +/- ipilimumab. **Methods:** 141 melanoma biopsies from advanced melanoma pts treated with anti-PD-1 monotherapy (n= 54), or anti-PD1 + ipilimumab (n= 51) were classified as responders (CR/PR/SD > 6 mo) or non-responders (SD≤6 mo/PD) based on RECIST. The transcriptomic and immunophenotypic profiles of 105 baseline (PRE) and 36 early-during treatment (EDT) tumor biopsies from pts treated with monotherapy (n= 33 responders, n= 21 non-responders) or anti-PD-1 + ipilimumab (n= 38 responders, n= 13 non-responders) were characterized via RNA sequencing and multiplex immunofluorescence. **Results:** Responders to monotherapy displayed increased expression of genes associated with a Type 1 interferon response, tissue-resident T-cells and drug targets (TIGIT, ADAR, ADORA2A, CD137, IDO1 and LAG3) (diff. $p < 0.05$). Genes unique to anti-PD-1 + ipilimumab responders included T-cell and NK-cell genes EOMES, CD48, CD96, and FASLG. Non-responders displayed significantly higher expression of genes associated with WNT signaling along with novel hypoxic and metabolic pathways, including CA9 and NABP1 ($p < 0.05$). Non-responders with high CD8/PD-L1 densities expressed novel immune drug targets (IDO1 expressed by 37% of monotherapy non-responders, ICOS (37%), TNFRSF9 (26%), LAG3 (16%), TIGIT (16%) and ADORA2A (16%)). In contrast, TIL-low tumors displayed a lack of expression of the aforementioned targets (42% of monotherapy and 86% of anti-PD-1 + ipilimumab non-responders). **Conclusions:** These findings demonstrate that combinations of novel drug targets may provide clinical benefits in non-responding and non-CR responding patients with high TILs. TIL-low non-responders may require modulation of WNT, hypoxic and metabolic pathways to overcome resistance, facilitating the development of novel synergistic drug targets.

Primary analysis of phase 2 results for cemiplimab, a human monoclonal anti-PD-1, in patients with metastatic cutaneous squamous cell carcinoma (mCSCC). *First Author: Danny Rischin, Peter MacCallum Cancer Centre, East Melbourne, Australia*

Background: CSCC is rivaled only by basal cell carcinoma as the most common cancer in the US. There is no standard of care for patients with mCSCC; hence there is a significant unmet need in these patients. Cemiplimab (REGN2810) treatment at 3 mg/kg Q2W demonstrated encouraging preliminary activity in CSCC in a phase 1 study (ASCO 2017, #9503). We present the primary analysis of the mCSCC cohort from the pivotal phase 2 study (NCT02760498; data cutoff date Oct 27, 2017). **Methods:** Patients with mCSCC (defined as nodal and/or distant) received cemiplimab 3 mg/kg by intravenous infusion over 30 minutes every 2 weeks (Q2W). Tumor measurements were performed every 8 weeks. The primary objective was to evaluate overall response rate (ORR; complete response [CR] + partial response [PR]) according to independent central review (per RECIST 1.1 for scans; modified WHO criteria for photos). Duration of response (DOR) was a key secondary endpoint. Durable disease control rate (DDCR) was defined as stable disease or response for ≥16 weeks. **Results:** 59 patients were enrolled (54 M/ 5 F; median age: 71.0 years [range: 38–93]; ECOG performance status: 0 and 1 in 23 and 36 patients, respectively). 33 patients (55.9%) had received prior systemic therapy and 50 (84.7%) had received prior radiotherapy. Median duration of follow-up was 7.9 months (range: 1.1–15.6). ORR by central review was 47.5% (95% CI: 34.3–60.9; 4 CRs and 24 PRs). Responses were observed irrespective of prior systemic therapy. Median DOR has not been reached. Only 3 responding patients had subsequent disease progression at the time of data cut-off. DDCR was 61% (95% CI: 47.4–73.5). Median time to response was 1.9 months (range: 1.7–6.0). The most common adverse events (AEs) regardless of attribution (all grades, ≥Grade 3) were diarrhea (27.1%, 1.7%), fatigue (23.7%, 1.7%), and nausea (16.9%, 0.0%). Immune-related AEs ≥Grade 3 (per investigator assessment) occurred in 10.2% of patients. **Conclusions:** In the largest prospective study reported in patients with mCSCC, cemiplimab 3 mg/kg Q2W showed substantial activity and durable responses with an acceptable safety profile. Clinical trial information: NCT02760498.

9520 Poster Session (Board #347), Mon, 1:15 PM-4:45 PM

Ipilimumab combined with stereotactic radiosurgery in melanoma patients with brain metastases: A multicenter, open label, phase 2 trial. *First Author: Laurent Mortier, Université Lille, Centre Hospitalier Régional Universitaire de Lille, Lille, France*

Background: Brain metastasis commonly occur in patients with metastatic melanoma (MM) and are managed with surgery or stereotactic radiosurgery (SRS) and/or systemic treatment based on BRAF status and prior treatment. After SRS alone, the median survival is poor (5.6 months). Ipilimumab (Anti CTLA-4) was the first checkpoint inhibitor to demonstrate a survival benefit in patients with metastatic melanoma. The median survival was more recently estimated at 6 months after initiation of ipilimumab alone for brain metastasis. No prospective studies have evaluated the use of ipilimumab in combination with stereotactic radiosurgery for the treatment of brain metastasis from MM. **Methods:** This open-label, multi-center, phase 2 study (NCT02662725) evaluated the efficacy of one administration of ipilimumab (10 mg/kg) followed by SRS and the maintenance ipilimumab in a cohort of patients with MM brain metastases. Inclusion criteria included: patients of 18 years or older, performance status 0-1, fewer than 4 brain metastases on MRI. The primary objective was to show an increase at least 50% of the median overall survival time of patients receiving SRS alone. The secondary endpoints were to determine the safety profile of the combination, the intra- and extra-brain response rate. This study was supported by Bristol-Myers Squibb. **Results:** 57 patients (32 males) were enrolled. Median age was 54 (47-67). The study met his primary endpoint: median survival time was 13.2 m, higher than the median survival time of 5.6 m in the reference population (HR = 0.29; 95%CI = 0.19 to 0.39; $p < 0.0001$). The disease control rate was 49% (28/57). The most serious treatment-related adverse events were colitis (10.5%), hepatitis (10.5%), hypophisitis (8.77%) and headhache (8.77%). One radionecrosis was observed. **Conclusions:** High dose Ipilimumab plus SRS seemed effective with a manageable safety profile in patients with brain MM. Considering that this is the best survival rate ever observed in this setting, these results seem to confirm a synergy in the combination of immunotherapy and radiotherapy and should be confirmed in a randomized trial. Clinical trial information: NCT02662725.

9521 Poster Session (Board #348), Mon, 1:15 PM-4:45 PM

Redirected T cell lysis in patients with metastatic uveal melanoma with gp100-directed TCR IMCgp100: Overall survival findings. *First Author: Takami Sato, Sidney Kimmel Medical College at Thomas Jefferson University, Philadelphia, PA*

Background: IMCgp100 is a bispecific biologic comprised of a soluble T cell receptor recognizing the gp100 antigen fused to a scFV anti-CD3 and redirects T cell lysis of melanoma cells expressing gp100. Safety and preliminary efficacy of IMCgp100 were assessed in a Ph 1/2 study in metastatic UM (mUM). **Methods:** HLA-A*0201+ pts with mUM were treated with QW dosing of IMCgp100 *iv* at Cycle 1, Day 1 (C1D1, 20 mcg) and C1D8 (30 mcg), followed by the escalated dose administered at C1D15 and beyond. **Results:** Pts with mUM (n = 19), elevated LDH (87%), liver metastases (100%), and median of 4 prior therapies (0 – 8) were treated across 4 doses (54 to 73 mcg) in Ph 1; 23 pts were treated in the Ph 2 RP2D (68 mcg) expansion cohort. Related AE included pruritus (90%), pyrexia and fatigue (84%), and hypotension (74%). Gr 3/4 related AE include AST elevation, erythema and hypotension (all, 16%). Ten of the 19 pts in Ph 1 were treated at or above the RP2D. Objective PR by RECIST in Ph 1 were observed in 2 pts and minor responses in 4 pts (6/19 responses); median duration of response was 30.6 wk. One year PFS rate by irRC was 66% (95% CI [39, 83]). One year OS rate in Ph 1 was 74% (95% CI [48, 88]). Median OS in this cohort has not been reached (median follow up of 15.9 mo). The PKPD relationship of exposure was modeled with extent and duration of lymphocyte trafficking. The EC50 for lymphocyte extravasation to the periphery was estimated at 1.4 ng/mL. At high doses, maximal trafficking of 50% was observed compared to baseline. The extent of lymphocyte trafficking is saturable, however the duration was dose dependent. The EC90 represents the dose of 70 mcg, supporting the RP2D. In the full cohort (n = 42), rash of Gr $\geq$2 within the first 3 weeks of dosing is associated with prolonged OS when compared to pts with mild (G1) or no occurrence of rash (HR 0.122, 95% CI [0.03, 0.45], p = 0.0015). **Conclusions:** IMCgp100 is tolerable with the intra-patient escalation dosing regimen and leads to prolonged OS. A potential association of prolonged OS with rash severity was observed. PKPD modeling demonstrates a relationship between lymphocyte trafficking and exposure to IMCgp100. Pivotal trials in the setting of metastatic UM continue to enroll (NCT03070392, NCT02570308). Clinical trial information: NCT02570308.

9522 Poster Session (Board #349), Mon, 1:15 PM-4:45 PM

Efficacy and safety of cobimetinib (C) combined with vemurafenib (V) in patients (pts) with *BRAF*^{V600} mutation–positive metastatic melanoma: analysis from the 4-year extended follow-up of the phase 3 coBRIM study. *First Author: Brigitte Dreno, Dermatology Departement, CHU Nantes, Nantes, France*

Background: The coBRIM study demonstrated that first-line C+V improved progression-free (PFS) and overall survival (OS) compared with placebo (P)+V in pts with *BRAF*^{V600}-mutated advanced melanoma. We report updated survival outcomes and safety after extended follow-up. **Methods:** coBRIM was a double-blind, multicenter study in which 495 patients were randomized to receive C (60 mg once daily for 21 days followed by a 7-day rest period in each 28-day cycle; n = 247) or P (n = 248) in combination with V (960 mg twice daily). PFS and OS were primary and secondary endpoints, respectively. **Results:** At database closure, median follow-up duration for the overall intent-to-treat population was 18.6 months (range, 0.5–55.1 months); 176 pts (71%) in the C+V arm and 190 pts (77%) in the P+V arm had discontinued the study, with the most common reason being death (C+V = 148 pts [60%]; P+V = 162 pts [65%]). Median PFS among pts receiving C+V was 12.6 months (95% confidence interval [CI], 9.5–14.7 months) vs 7.2 months (95% CI, 5.6–7.5 months) in pts receiving P+V. Median OS among pts receiving C+V was 22.5 months (95% CI, 20.3–28.8 months) vs 17.4 months (95% CI, 15.2–20.5 months) in pts receiving P+V. A greater proportion of pts receiving C+V were alive at 1, 2, 3 and 4 years vs pts receiving P+V (Table). Median duration of treatment in the C+V arm was 9.0 months (range, 0.1–53.1 months) for C and 9.2 months (range, 0.3–53.3 months) for V. Pts in the P+V arm had a shorter median duration of treatment of 5.6 months (range, 0.2–43.9 months) for P and 5.7 months (0.2–53.2 months) for V. Grade 3/4 adverse events (AEs) were reported in 75% and 61% of pts in the C+V and P+V arms, respectively. Grade 5 AEs were reported in 2% of pts in each study arm. A larger proportion of pts discontinued C+V (19%) versus P+V (10%) due to AEs. **Conclusions:** Extended follow-up of the phase 3 coBRIM study confirmed the survival benefit of C+V over P+V. No new safety signals were observed. Clinical trial information: NCT01689519.

	Landmark OS, % (95% CI)	
	C+V	P+V
1-year	74.5 (68.9–80.1)	63.8 (57.6–70.0)

9523 Poster Session (Board #350), Mon, 1:15 PM-4:45 PM

Comprehensive genomic profiling of advanced Merkel cell carcinoma to reveal insights into immunotherapy response. *First Author: Todd Cory Knepper, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

Background: Merkel Cell Carcinoma (MCC) is a rare and aggressive neuroendocrine skin malignancy. Recently, high response rates to immune checkpoint inhibitor therapy (ICT) have been demonstrated, but predictive factors for response are lacking. We therefore performed immunogenomic analyses on a cohort of MCC patients (pts) with concurrent review of clinical outcomes. **Methods:** A retrospective chart review was performed to collect demographic, clinical, disease, treatment, and outcomes variables on 57 pts with advanced MCC whose tumors underwent comprehensive genomic profiling by FoundationOne testing. Genomic data were analyzed for recurrent alterations, tumor mutational burden (TMB, calculated as the number of non-driver somatic, coding mutations per megabase of genome sequenced), and mutational signatures. Presence of Merkel Cell Polyomavirus (MCPyV) was evaluated by de novo assembly of non-human sequencing reads. **Results:** MCC TMB demonstrated a striking bimodal distribution between TMB high ($\geq$20 mutations/mb) and TMB low ($<$ 6 muts/mb) with only 4 pts having an intermediate TMB. Overall, 21/57 (36.8%) MCC samples were TMB high (median 63 muts/mb) and all carried mutations in TP53, RB1, or NOTCH1. 21/21 (100%) TMB high pts had a mutational signature consistent with UV damage. 21/32 (65.6%) TMB low (median 1 mut/mb) pts were positive for MCPyV integration as opposed to 0/25 (0%) TMB high or intermediate pts (P = 1.03e-07, Fisher's exact). 34/57 (59.6%) pts were treated with at least one ICT. Within this group, response to ICT dramatically impacted overall survival with 15/15 (100%) responders vs. 3/19 (15.8%) non-responders alive at date of last contact and significantly prolonged survival ($p < 0.0001$, Kaplan-Meier). 7/11 (64%) pts classified as TMB high responded to ICT compared with 8/23 (35%) low/intermediate TMB pts (p = 0.13). Viral status in the TMB low group had no significant impact on response rates, with MCPyV integration detected in 6/8 (75.0%) responders and 9/13 (69.2%) non-responders. **Conclusions:** Response to ICT leads to high rates of durable overall survival in advanced MCC. High TMB and prolonged UV exposure, but not viral status, are associated with higher responsiveness to ICT.

9524 Poster Session (Board #351), Mon, 1:15 PM-4:45 PM

Association between hospital volume and overall survival (OS) of stage 3 and 4 cutaneous malignant melanoma (MMel). *First Author: Anuhya Kommalapati, University of South Carolina, Columbia, SC*

Background: Therapeutic advances altered the course of MMel in the last decade. The therapeutic and survival disparities of MMel were evaluated based on hospital volume using the National Cancer Data Base (NCDB). **Methods:** Patients with MMel diagnosed between 2004 & 2015 were included and classified into tertiles based on hospital volume. Cox regression analysis was performed to adjust for covariates, including patient demographics, tumor characteristics, LDH, insurance & therapy received. Kaplan Meier estimates of OS were compared with log-rank test. **Results:** A total of 50, 254 MMel patients were treated at 1317 facilities. The median age at diagnosis was 62 & 67 y for stages 3 & 4, respectively. The median annual facility volumes were 10 & 6 patients/yr for stages 3 & 4, respectively. Multivariable analysis showed that facility volume was an independent predictor of OS ($p < 0.0001$). Stage 3 (n = 34, 666): Hospitals were classified into (T: mean cases/year) T1: < 4.56; T2:4.57-15.25; T3:≥15.2 cases/year. The unadjusted median OS by facility volume was: T1: 77 months (m), T2: 94 m, and T3: 124 m ($P < .0001$). Compared with patients treated at T3 facilities, patients treated at lower-tertile facilities had significantly higher risk of death [T2 hazard ratio (HR), 1.11 (95% CI, 1.06-1.16); T1 HR, 1.18 (CI, 1.09-1.27)]. Stage 4 (n = 15,588): T1:1-3; T2: 3-8.67; T3: > 8.68. The unadjusted median OS by facility volume for stage 4 MMel was: T1: 6 m, T2: 8 m, and T3: 11 m ($P < .0001$). Compared with patients treated at T3 facilities, patients treated at lower-tertile facilities had significantly higher risk of death [T2 HR, 1.18 (CI, 1.13-1.23); T1 HR, 1.21 (CI, 1.14-1.30)]. Patients at T3 facilities (vs T1) were more likely to receive chemotherapy (36 vs 27%) and immunotherapy (27 vs 12%) ($p < 0.01$). **Conclusions:** Patients who were treated for MMel at high-volume centers (> 15 cases in stage 3; > 8 cases/yr in stage 4) had significantly improved survival and were more likely to receive chemotherapy and immunotherapy for stage 4 disease.

	Therapy received %						Survival %			
	Stage 3			Stage 4			Stage 3		Stage 4	
	Surgery	Chemo	Immuno	Surgery	Chemo	Immuno	3 yr%	5 yr%	3 yr%	5 yr%

9525 Poster Session (Board #352), Mon, 1:15 PM-4:45 PM

Interim analysis of a prospective, randomized, double blind, placebo controlled, phase IIb trial of the TLPLDC vaccine to prevent recurrence in resected stage III or IV melanoma patients. *First Author: John William Myers, San Antonio Military Medical Center, San Antonio, TX*

Background: The autologous tumor lysate, particle loaded, dendritic cell (TLPLDC) vaccine has been shown to be safe and immunogenic while producing objective tumor responses in a variety of metastatic patients (pts). Here, we present the pre-specified interim results of a randomized, double blind phase IIb trial (NCT02301611) assessing the TLPLDC vaccine to prevent recurrences in high risk melanoma pts. **Methods:** Stage III & IV resectable melanoma pts were identified prior to definitive surgery and consented for tumor collection. Pts were re-consented for treatment and randomized 2:1 (vaccine (V): placebo (P)). TLPLDC or placebo vaccines were initiated within 3 mos of completion of standard of care (SoC) therapies. Intradermal inoculations were given at 0, 1, 2, 6, 12, and 18 mos. Pts were followed for recurrence per SoC, and the primary endpoint is 2 yr disease-free survival (DFS). The interim was pre-specified at 6 mos from the 120th randomization. Survival analysis was performed on the intention-to-treat (ITT) and per treatment (PT) populations. The latter excludes early recurrences during the primary vaccine series (PVS) (up to 6 mos). **Results:** The trial randomized 120 patients (V = 83, P = 37). There were no clinicopathologic or treatment-related differences between the groups except for median age (V = 65 yrs, P = 57 yrs, p = 0.02). There were 3:1 stage III:IV in both groups. Study-wide, only 33% of pts experienced treatment-related adverse events (AEs) with 98.6% being grade 1-2. There were no serious AEs or immune-mediated AEs. In the ITT analysis, there was no difference in recurrence (V = 56.6%, P = 54.1%, p = 0.65) at a median f/u of 11.9 mos. In the PT analysis (V = 51, P = 30), there was a trend toward decreased recurrences in the TLPLDC arm (V = 29.4%, P = 43.3%, p = 0.07) at a median f/u of 12.6 mos. **Conclusions:** The TLPLDC vaccine is safe with minimal toxicity. Among pts completing the PVS period (6 mos), there is a strong trend toward fewer recurrences in the TLPLDC arm. This benefit will be confirmed at the primary analysis of 2 yr DFS; however, these early data provide an encouraging signal that a phase III trial for efficacy may be warranted. Clinical trial information: NCT02301611.

9527 Poster Session (Board #354), Mon, 1:15 PM-4:45 PM

Adjuvant ipilimumab compared with observation in completely resected Merkel cell carcinoma (ADMEC): A randomized, multicenter DeCOG/ADO study. *First Author: J?Rgen C. Becker, Translational Skin Cancer Research, Deutsches Konsortium für Translationale Krebsforschung (DKTK), Essen, Germany*

Background: Merkel cell carcinoma (MCC) is a rare, immunogenic, and highly aggressive skin cancer. Almost 40% of patients with completely resected MCC will relapse within the first two years after initial diagnosis. Currently, there is no accepted adjuvant systemic therapy for MCC. This study was conducted to determine if an immune modulating therapy with ipilimumab improves the disease-free survival (DFS) of MCC patients. **Methods:** Within 12 weeks after complete resection of primary or locoregional metastatic MCC, patients were randomly assigned to four doses of 3mg/kg ipilimumab i.v. every 3 weeks or observation. The primary end point of the study was DFS; secondary endpoints included adverse events and overall survival at 12 months. Futility analysis was performed after screening 20% of the planned patient number. **Results:** At the time of futility analysis, 47 patients had been screened and 40 patients enrolled. Four patients had to be excluded after randomization due to protocol violations or withdrawal of informed consent (ipilimumab = 1; observation = 3). Median follow-up was 22.3 months. Groups were well-balanced with regard to demographics, histology, and tumor stage. DFS was not significantly different between ipilimumab and observation (hazard ratio, 1.8; CI, 0.3 to 10; P = 0.48). However, patients in the treatment arm had a significantly increased incidence of adverse events by 4-fold, i.e. in more than 80% of the patients, compared to the observational arm, which was most relevant for adverse events of grade > = 3. **Conclusions:** Given the lack of efficacy of ipilimumab in preventing disease progression of MCC together with the pronounced toxicity, it was decided to stop enrollment of further patients into this study because a significant survival benefit was unlikely to be achieved as predicted by the futility analysis even across the originally planned cohort. Adjuvant ipilimumab should not be considered in MCC patients. Currently adjuvant nivolumab is tested in comparison to observation to improve DFS. Clinical trial information: NCT02196961.

9528 Poster Session (Board #355), Mon, 1:15 PM-4:45 PM

A phase Ib study of JS001, a humanized IgG4 mAb against programmed death-1 (PD-1) combination with axitinib in patients with metastatic mucosal melanoma. *First Author: Jun Guo, Peking University Cancer Hospital and Institute, Beijing, China*

Background: There was no standard treatment for metastatic mucosal melanoma. Preclinical data showed that axitinib increases the infiltration of immune cells and reduces the suppressive capacity of monocytic MDSCs in an intracranial mouse melanoma model. JS001 is a humanized IgG4 mAb against programmed death-1 (PD-1) with clinical activity in metastasis melanoma.This study is a phase Ib dose-escalation study to evaluate the safety, tolerability, pharmacokinetics, and preliminary efficacy of JS001 combination with axitinib in patients with metastatic mucosal melanoma. **Methods:** Eligibility criteria include: histologically confirmed metastatic mucosal melanoma, archival or fresh tumor biopsy, ECOG PS 0-1, no prior system treatment. The patients will receive JS001 (1mg/kg or 3 mg/kg IV Q2W) combined axitinib (5 mg BID) in dose-finding and dose-expansion parts and treatment will be given until confirmed disease progression, unacceptable toxicity, withdrawal, or study termination. After the MTD or the optimal biological dose is identified, an expansion cohort of 30 patients were enrolled to further characterize the safety and efficacy. Other objectives include pharmacokinetics, pharmacodynamics, immunogenicity and tumor tissue biomarkers. **Results:** Enrollment began in April 2017. The majority of melanomas is mucosal origin included esophagus, nasopharynx, rectal melanoma and vaginal melanoma. As of February 10, 2018, enrollment has been completed with 33 patients. No dose-limiting toxicities (DLTs) were reported during dose escalation. 30 patients were treated with JS001 (3 mg/kg) combined axitinib (5mg Bid). The most common treatment-related AEs were grade 1/2, including hypertension, hand-foot skin reaction, oral ulcer, hypothyroidism and fever. Among 24 evaluable patients, no patient have complete response, 12 patients have partial response, and 9 pts achieve stable disease, for an ORR of 50% and a DCR of 87.5%. 10 out of 12 PR pts still have ongoing response. **Conclusions:** JS001 combined with axitinib may benefit for patients with metastatic mucosal melanoma.we will report all results during 2018 asco annual meeting. Clinical trial information: NCT03086174.

9529 Poster Session (Board #356), Mon, 1:15 PM-4:45 PM

Prediction of response and toxicity to immune checkpoint inhibitor therapies (ICI) in melanoma using deep neural networks machine learning. *First Author: Zarmeena Dawood, The Ronald O. Perelman Department of Dermatology, New York University School of Medicine, New York, NY*

Background: Challenges in treating melanoma patients with ICI include treatment resistance and adverse events, both of which can lead to discontinuation of treatment. Histopathology of metastatic melanoma lymph nodes (LN) reveal varying histological composition(s) of malignant melanocytes and host LN reactions to tumor. Here we tested the hypothesis that deep machine learning on H&E images of metastatic melanoma LN prior to ICI can predict response and/or toxicity. **Methods:** H&E slides of metastatic and normal LN resected from melanoma patients (n = 45) prior to receiving ICI were digitized and annotated for regions of interest. The Inception v3 Convolutional Neural Network (CNN) was first trained to distinguish tumor LN (n = 56) from independent normal LN (n = 57). Images were tiled (299x299 pixels) at 20X magnification and partitioned into training (70%), validation (15%) and testing (15%) sets. CNNs were next trained on two classifications: 1) complete/partial response (n = 15) vs. progression of disease (n = 30) and 2) no (n = 14) vs. severe (n = 12) toxicity. Images from response (n = 45) and toxicity (n = 26) datasets were partitioned into 80% training and 20% testing sets followed by 5-fold cross validation. Predictive accuracy was measured by area under the curve (AUC) of receiver operating characteristics (ROC) plots. Sensitivity (SEN) and specificity (SPEC) were calculated at the optimal cut-off point of ROC curves. **Results:** Melanoma-infiltrated LNs were unambiguously distinguished from normal LNs with AUC = 1.00 per slide. Three-class training (tumor vs. lymphocytes vs. connective tissue) reported an average per-slide AUC of 0.99 [CI, 0.98-1.00], with 0.96 SEN & SPEC. In predicting response to ICI, machine learning algorithm showed AUC of 0.76 with 0.71 SEN & 0.64 SPEC. Severe toxicity was predicted with AUC of 0.70 and with 0.71 SEN & 0.64 SPEC. The AUC standard error of mean (SEM) was 0.09 for both analyses. **Conclusions:** Our data suggest that deep neural networks have the potential to predict patient response and toxicity to ICI with an accuracy of 70%. Independent larger datasets in clinical trial setting are pre-requisite to support validity of this novel approach.

9530 Poster Session (Board #357), Mon, 1:15 PM-4:45 PM

Efficacy and safety of entinostat (ENT) and pembrolizumab (PEMBRO) in patients with melanoma progressing on or after a PD-1/L1 blocking antibody. *First Author: Sanjiv S. Agarwala, St. Luke's Hospital, Easton, PA*

Background: Immune checkpoint inhibitors (ICIs) have improved prognosis for pts with advanced melanoma, but there is an unmet need for pts who progress after ICI. In this group, we reported that ENT, a class I selective histone deacetylase (HDAC) inhibitor, in combination with PEMBRO showed promising activity, through alteration of the immunosuppressive tumor microenvironment. Here we report the first 34 pts with further information on both prior therapies and pre/on treatment tumor samples. **Methods:** ENCORE-601 is a multicohort study evaluating ENT + PEMBRO. Pts enrolled in Cohort 3 had unresectable or metastatic melanoma, were previously treated with a PD-(L)1-blocking antibody, and experienced progression on or after therapy. The enrollment target was 34 pts and revised to 52 to increase statistical power and decrease Type I error. Pts were treated with ENT 5 mg PO weekly and PEMBRO 200 mg IV Q3W. Primary endpoint was ORR as assessed by irRECIST. Tumor biopsies and blood samples for immune correlates were obtained pre- and on-treatment. **Results:** Of the first 34 patients, 14 had refractory disease to prior PD-(L)1 therapy, and only 2 had a documented prior response. Median duration of prior PD-(L)1 therapy was $<$ 6 months and the median time from last dose was 65 days. 22 pts had prior ipilimumab and 6 had progressed on a BRAF inhibitor. With ENT + PEMBRO, 6 of 34 pts achieved a confirmed PR (ORR = 18%, 95% CI: 6.8-34.5), and 10 pts continue on study (3 have been on treatment $>$ 1 year). Frequent ($>$ 15%) related AEs include nausea, fatigue, diarrhea, and pruritus. Preliminary analysis of gene expression in pts with tumor samples pre- and on-treatment (n = 9) indicates increased inflammation in the tumor microenvironment after treatment; a decrease in MDSCs (–35.7%) and an increase in CD8+ T cells (47.4%) was also observed. **Conclusions:** ENT + PEMBRO continues to demonstrate promising anti-tumor activity and acceptable safety in patients with melanoma who have progressed on prior PD-(L)1 blockade. Preliminary biomarker analysis supports the hypothesis that the addition of ENT restores inflammation in the tumor microenvironment necessary for successful re-treatment with an anti–PD-(L)1. Clinical trial information: NCT02437136.

9531 Poster Session (Board #358), Mon, 1:15 PM-4:45 PM

Treatment-free survival (TFS), a novel outcome applied to immuno-oncology (IO) agents in advanced melanoma (AM). *First Author: Meredith M. Regan, Dana-Farber Cancer Institute, Boston, MA*

Background: Conventional measures, such as median progression-free survival, may suboptimally characterize the full impact of IO agents. Patients (pts) discontinuing IO agents may experience periods of disease control without needing subsequent systemic anticancer therapy (Rx). We propose TFS to simultaneously characterize the antitumor activity and adverse events of this period. Here we present the antitumor activity seen in the TF periods following IO therapy in AM. **Methods:** Data were pooled from 1077 pts initiating Rx in CheckMate 067 and 069 trials of ipilimumab (I) and nivolumab (N) as monotherapy and combination for AM (407 N+I, 313 N, 357 I). I was given for 4 doses; N was given until progression/intolerability. We defined TFS as the area between Kaplan-Meier (KM) curves for 2 conventional time to event endpoints: (A) duration of protocol Rx (randomization until Rx cessation) and (B) subsequent Rx-free survival (randomization until initiation of subsequent Rx or death). We estimated overall survival (OS). Area under each KM curve was estimated by the 36 mo restricted mean time to event. Area under the OS curve until 36 mo was partitioned as time on protocol Rx (mean A), TFS (mean B-A), and post-subsequent Rx time (mean OS-B), and summarized as percentage of the 36 mo period. **Results:** At 36 mo, 58% N+I, 52% N, 36% I pts were alive. Few pts remained on protocol Rx (11% N+I, 17% N, 0% I) and many pts were surviving free of subsequent Rx (47% N+I, 37% N, 15% I). 36 mo restricted mean OS was longer for N+I and N than I (Table). Mean TFS was 31% of time for N+I vs 13% for N, as N+I had shorter mean protocol Rx duration and longer time until subsequent Rx, and 24% for I. Clinical trial information: NCT01844505 and NCT01927419. **Conclusions:** Defining TFS by the area between KM curves for time to protocol Rx cessation and time to subsequent Rx or death, showed AM pts receiving N+I spent more time free of any Rx compared to N or I, and will allow integration of toxicity data to also characterize patient well-being while treatment free.

Restricted mean time, mo (% of 36 mo period)	N+I	N	I
OS	25.7 (72%)	24.9 (69%)	21.4 (59%)
Duration of protocol Rx, A	10.3 (29)	13.9 (39)	2.6 (7)
TFS, B-A	11.1 (31)	4.6 (13)	8.7 (24)
Time after subsequent Rx initiation, OS-B	4.3 (12)	6.4 (18)	10.1 (28)

9532 Poster Session (Board #359), Mon, 1:15 PM-4:45 PM

Activity of targeted therapy after failure of first-line immunotherapy in BRAF-mutant metastatic melanoma. *First Author: Cathy Yi Xia, Melanoma Institute Australia, Sydney, Australia*

Background: There are limited data regarding the best sequence of targeted and immunotherapy in patients (pts) with BRAF-mutant melanoma. Some studies suggest lower activity of immunotherapy after BRAF/MEK inhibitors (BRAF/MEKi), but there are no data examining BRAF/MEKi after immunotherapy. **Methods:** Consecutive patients with BRAF-mutant metastatic melanoma from 6 centers treated with 1 or more lines of immunotherapy then subsequent BRAF/MEKi were identified. Disease characteristics, treatment details, RECIST response and survival data were retrospectively examined. If pts ceased BRAF/MEKi for toxicity prior to first response assessment, response was deemed progressive disease (PD). **Results:** 79 pts were included, with V600E (85%), V600K (13%), V600M (1%) and V600R (1%) mutations. 56% pts were treated with first-line ipilimumab, 21% with PD1 antibodies, 15% with combination ipilimumab/nivolumab, and 5% with other PD1 combinations. Median duration of immunotherapy was 10.9 weeks, and best response was partial response (PR) in 11%, stable disease (SD) in 17%, and PD in 72% pts. 20% of pts had 1 or more further lines of systemic treatment prior to BRAF/MEKi. At commencement of BRAF/MEKi, median age was 60 years, 68% were stage M1c, 25% had brain metastases, 57% had elevated LDH, 24% were ECOG 2/3. Median interval from last dose of immunotherapy was 6 weeks. 55 (70%) pts received combination BRAF+MEKi, 22 (28%) BRAFi alone, and 2 (3%) MEKi alone. 10/79 (13%) pts ceased BRAF/MEKi due to toxicity, 2 prior to first response, and median treatment duration was 21 weeks. 59% pts had a RECIST response (5% CR), 11% had SD and 29% had PD. Median PFS was 4.4 months (3.5 - 6.2). 65% pts had subsequent treatment, including PD1 antibodies in 50%. Median OS from BRAF/MEKi commencement was 18.0 months (14.6 - 40.3), and 39% were alive at 3 years. In the 35 (44%) pts that had received prior PD1 antibodies, the response rate was 66%, median PFS 4.1 months (2.4 - 6.8) and median OS 13.6 months (10.2 – NR). **Conclusions:** BRAF/MEKi have efficacy in pts previously treated with immunotherapy. Despite pts having more adverse disease characteristics than seen in first line trials, response rates may be similar, however PFS appears shorter.

9534 Poster Session (Board #361), Mon, 1:15 PM-4:45 PM

Pembrolizumab as first line therapy in patients with unresectable squamous cell carcinoma of the skin: Interim results of the phase 2 CARSKIN trial. *First Author: Eve Maubec, AP-HP Dermatology department, Avicenne hospital, Université Paris 13, Bobigny, France*

Background: Patients (pts) with advanced squamous cell carcinoma of the skin (SCCS) have a poor prognosis. Response rate (RR) of 46% with an anti PD-1 (REGN2810) was recently shown in 25 pre-treated pts. CARSKIN is an open-label, phase II study evaluating pembrolizumab (Pembro) in unresectable SCCS. We report preliminary efficacy and safety findings. **Methods:** Chemotherapy naive pts who had unresectable SCCS, with an ECOG PS of < 2 were eligible. Baseline PD-L1 expression was centrally assessed on tumor. Pembro kindly provided by Merck was administered IV (200 mg Q3W) for a period up to 24 mths. CT evaluation was performed at baseline, 9, 15, 24 wks and thereafter Q12W and was independently reviewed. The primary endpoint was RR at 15 wks (RECIST criteria). Using Simon two-stage design, ≥ 4 responses were required out of 19 pts in stage 1 to continue accrual to 39 pts. Results of stage 1 are reported. **Results:** Nineteen pts (6, 7 and 6 with local, regional and distant metastasis, respectively) were recruited between March and July 2017, of which 15 (79%) were male. Median age was 80 yrs (range, 61-88); 61% of pts were PS 1. Median number of Pembro infusions was 9 (range, 0-13). Median follow-up was 7 mths. Seventeen pts were evaluable for tumor response, and 19 for toxicity. RR at 15 wks in the ITT population was 42 % (95% CI: 23–63%) corresponding to 7 PR (2 unconfirmed) and 1 CR. Disease control rate at 15 wks was 58% (11/19 including 3 SD). Only 1 responder progressed. Median PFS is 7 mths and median OS is not reached. There was no Pembro-related death or SAE. One pt discontinued Pembro due to grade 2 colitis. Pembro-related AE occurred in 63% of pts, the most frequent AEs being rash (32%), pruritus (16%), fatigue (26%), dysthyroidism (10%), and diarrhea (10%). Baseline PD-L1 expression was positive in 11 cases (58%). Median PD-L1 expression (Q1-Q3) was 28% (1-75%) in responders vs 0% (0-3%) in non-responders at 15 wks (P = .15). **Conclusions:** As first line treatment, pembrolizumab monotherapy provided encouraging clinical activity characterized by a high RR and durable response and was well tolerated in these elderly pts. The second stage of CARSKIN is ongoing. Clinical trial information: NCT02883556.

9535 Poster Session (Board #362), Mon, 1:15 PM-4:45 PM

Radioembolization for treatment of uveal melanoma hepatic metastasis: Results of a phase II, single institution, prospective trial. *First Author: Carin F. Gonsalves, Sidney Kimmel Medical College of Thomas Jefferson University, Philadelphia, PA*

Background: The liver is the first site of metastasis in $>$ 90% of uveal melanoma (UM) patients. Transarterial catheter directed therapies have been used to control growth of liver tumors and prolong overall survival (OS). We report results of the first prospective, phase II trial using radioembolization ([RE] Y-90 resin microspheres) for treatment of UM hepatic metastases. **Methods:** Between November 2011 and January 2017, RE was performed on 24 treatment naïve patients [Group A (13 men; median age 63; range, 29 -77)] and 24 patients who progressed after immunoembolization [Group B (9 men; median age 59, range, 34-77)]. Patients received unilobar or lobar treatments separated by 3-5 weeks. Patients were followed for 1 month for acute toxicity and every 3 months for delayed toxicity (CTCAE v 3.0). MR, CT and PET imaging was obtained every 3 months to evaluate for tumor response (PFS; RECIST) and extrahepatic disease. Results: Group A: Unilobar (n = 7) or bilobar (n = 17) RE was performed (median dose, 32.6 mCi; range, 17.7-56.1). One patient was removed from the trial for incomplete lobar treatment. RE response included PR (n = 7), SD (n = 13) and PD (n = 3). Median PFS was 8.1 months (range, 3.3 - 33.7). Median OS was 18.9 months (range, 6.5 -66.9) with 4 surviving patients (range, 14.0-66.9 months). One year survival was 61%. Extrahepatic disease occurred in 17 patients (median, 6.3 months; range, 3.3 – 11.9). Group B: Unilobar (n = 5) or bilobar (n = 19) RE was performed (median dose, 35.0 mCi; range, 19.2 -50.8). RE response included PR (n = 6), SD (n = 8) and PD (n = 10). One patient withdrew from the trial. Median PFS was 4.3 months (range, 2.5 -18.6). Median OS was 19.1 months (range, 4.8-68.4) with 5 surviving patients (range, 18.6 – 68.4 months). One year survival was 70%. Extrahepatic disease occurred in 15 patients (median, 5.5 months; range 0.8-9.9). No procedure-related complications occurred. Grade 3 treatment-related toxicities included transient leukopenia (n = 2), nausea/vomiting (n = 1) and pain (n = 1). **Conclusions:** RE is a safe and effective treatment for UM hepatic metastases and should be considered as a treatment option for patients with and without prior transarterial catheter directed therapies. Clinical trial information: NCT01473004.

9536 Poster Session (Board #363), Mon, 1:15 PM-4:45 PM

Relapse after cessation of PD-1 based therapy for complete responders in metastatic melanoma. *First Author: Khang Nguyen, Princess Alexandra Hospital, Brisbane, Australia*

Background: Treatment of metastatic melanoma using programmed death (PD-1) inhibitor has revolutionised systemic therapy, with a proportion able to achieve a durable complete response (CR). Little is known about the longterm relapse rate after cessation of therapy and the outcomes on re-induction. **Methods:** A retrospective review of patients (pts) who ceased PD-1 therapy after achieving CR was conducted across five institutions. The primary outcome was rate of relapse and response to therapy after relapse. **Results:** 182 pts that ceased PD-1 therapy following CR were included. Relapse occurred in 19 pts (10.44%), BRAF wildtype (N = 13), BRAF mutant (N = 6). Median follow-up post cessation was 22 (5-34) months. The mean duration on therapy prior to cessation was 16 (3-32) months and the mean interval between cessation of therapy and relapse was 14 (1-33) months. Relapse occurred in a site of new disease (N = 5) and in a site of prior disease (N = 14). On relapse, 12 pts were rechallenged with PD-1 therapy. Currently these pts were in CR (n = 3), partial response (n = 1), stable disease (N = 4) and progressive disease (PD) resulting in death (n = 1) or were waiting restaging (n = 3). Remaining relapses were treated with gamma knife (n = 1, this pt died following PD), gamma knife and PD-1 therapy (n = 1, pt in CR) or surgical resection (n = 3, all in CR). Two pts are waiting restaging following commencement of LAG3 inhibitor (n = 1) or topical imiquimod (n = 1). One pt elected for nil intervention following relapse and is alive with PD. **Conclusions:** Emerging data is suggesting that cessation of PD-1 based therapy for complete response is possible with durable disease control. This to date is the largest cohort of pts who have been followed up post cessation for complete response to describe patterns of relapse and response to subsequent re-challenge. Further long term follow-up of current trials is needed.

9537 Poster Session (Board #364), Mon, 1:15 PM-4:45 PM

Second-line avelumab treatment of patients (pts) with metastatic Merkel cell carcinoma (mMCC): Experience from a global expanded access program (EAP). *First Author: John Walker, University of Alberta, Edmonton, AB, Canada*

Background: Avelumab is a human anti–PD-L1 IgG1 antibody that showed a favorable efficacy and toxicity profile in pts with mMCC and progressive disease (PD) on or after chemotherapy (CT) in the phase 2 JAVELIN Merkel 200 trial (JM 200; NCT02155647), leading to accelerated approval in the US and Europe. We describe real-world experience with avelumab in a global EAP for pts with mMCC. **Methods:** Pts participating in the EAP (NCT03089658) had stage IV mMCC and PD on or after CT or were ineligible for CT. In contrast to JM 200, pts in the EAP could have ECOG performance status of 2, treated brain metastases, or immunosuppressive conditions with sponsor medical approval. Pts received avelumab 10 mg/kg IV Q2W until PD or unacceptable toxicity. A 3-mo supply of avelumab for approved pts was provided to treating physicians; additional re-supply was allowed for pts who had complete response (CR), partial response (PR), stable disease (SD), or clinical benefit per treating physician assessment. No central imaging was obtained. **Results:** Between Jan 2016 and Jan 2018, 460 requests for avelumab were received from 37 countries: 395 were approved, 45 were medically rejected for various reasons (eg, incorrect diagnosis, lack of appropriate prior therapy, incomplete information), and 37 were withdrawn. Most requests were from France (n = 97), Italy (n = 69), and Australia (n = 46). Median age was 74 y (range, 28-95), and 65.7% of pts were male. Among 131 response-evaluable pts, the objective response rate was 51.1%, including CR in 22.1% (n = 29) and PR in 29.0% (n = 38; including 1 pt with HIV); 19.1% (n = 25) had SD and 29.8% (n = 39) had PD. Durable responses were observed in immune-competent and immunosuppressed pts. Updated data will be presented. The safety profile was similar to that of JM 200. The EAP is ongoing but will close in 2018 (US closed in April 2017) with regulatory approval in multiple countries. **Conclusions:** The avelumab EAP rapidly enrolled many pts with mMCC and answered an unmet, urgent medical need for pts ineligible for clinical trials or for whom no approved alternative treatments were available. In a real-world setting, avelumab demonstrated safety and efficacy consistent with JM 200. Clinical trial information: NCT03089658.

9538 Poster Session (Board #365), Mon, 1:15 PM-4:45 PM

Clinical and economic outcomes associated with sequential treatment in *BRAF* mutant advanced melanoma patients. *First Author: Ahmad A. Tarhini, Cleveland Clinic Taussig Cancer Institute, Cleveland, OH*

Background: Patients with *BRAF* mutant advanced melanoma can use immunotherapies (IO) and BRAF+MEK inhibitors. We evaluated the clinical and cost outcomes associated with treatment sequences for *BRAF* mutant advanced melanoma. **Methods:** A discrete event simulation was developed to estimate cost (USD) and life-years (LYs), over patient lifetime. In the absence of head-to-head trial data, a matching adjusted indirect treatment comparison (MAIC) was conducted. Treatment sequences and corresponding efficacy data sources are presented below (table). Safety and cost data were obtained from published literature. **Results:** Treatment sequences starting with IO followed by BRAF+MEK appear to be associated with 3.7–5.2 years of additional survival vs sequences starting with BRAF+MEK followed by IOs. This was primarily due to a longer treatment-free interval (TFI) of 2.5–4.4 years after first-line (1L) IOs and longer time on BRAF+MEK as second-line (2L) post-IO therapy. LYs and TFI were higher with sequences starting with anti-PD-1+anti-CTLA-4 vs anti-PD-1 alone. Sequences starting with anti-PD-1 +anti-CTAL4 ($77,918) or anti-PD-1 monotherapy ($85,813) had lower average cost/LY compared to BRAF+MEK ($107,266). **Conclusions:** Initiating 1L treatment with IO appeared to provide longer survival benefit compared to BRAF+MEK, driven by long TFI and, in many cases, lack of subsequent therapy need, leading to lower average cost/LY. Because these data may be biased by unaccounted for and unknown factors, findings will require validation in prospective randomized clinical trials (EA6134 - NCT02224781).

1L	2L	Total Costs ($)	Total LYs	Cost per LY ($)
BRAF+MEK[1]	**Anti-PD-1**[2]	$345,693	3.22	$107,266
Anti-PD-1+Anti-CTLA-4[3]	**BRAF+MEK**[3]	$656,692	8.43	$77,918
Anti-PD-1[3,a]	**BRAF+MEK**[3]	$595,727	6.94	$85,813

9539 Poster Session (Board #366), Mon, 1:15 PM-4:45 PM

A phase II study of JS001, a humanized PD-1 mAb, in patients with advanced melanoma in China. *First Author: Zhihong Chi, Peking University Cancer Hospital and Institute, Beijing, China*

Background: JS001, a humanized IgG4 antibody specific for human PD-1, has demonstrated favorable safety profile and promising anti-tumor activity in phase I clinical trial. **Methods:** This multi-center, open-label, phase II registration study is designed to evaluate safety and efficacy of JS001 in advanced melanoma patients who have failed systemic treatment. JS001 is given at 3 mg/kg IV Q2W until disease progression or intolerable toxicity. (Clinical Trial ID: NCT03013101). **Results:** Enrollment was completed by 9/15/2017 with 128 melanoma subjects enrolled (51 acral, 21 mucosal, 18 chronically sun-damaged (CSD), and 38 Non-CSD or origin unknown). As of 1/4/2018, among 121 evaluable subjects, all had at least two evaluations per RECIST1.1 by independent radiologic review committee. 1 CR, 24 PR and 48 SD were observed for an ORR at 20.7% and a DCR at 60.3%. ORR was lower in acral (14.3%) and mucosal (0%) subtypes when compared with CSD (35.3%) and non-CSD (33.3%). Nevertheless, significant DCRs were achieved in acral (53.1%) and mucosal (42.1%) melanoma subjects. Additional factors have been analyzed for correlation with clinical responses (Table 1). Median duration of response has not been reached, as most responses (23/25) are ongoing. There is no treatment related death in the study. The most common treatment related AEs were grade 1/2, including proteinuria (25%), ALT increase (25%), rash (22%), hyperglycemia (20%), amylase increase (18%), leukopenia (17%), anemia (16%), vitiligo (16%), AST increase (16%), pruritus (14%) and hypothyroidism (13%). Treatment related grade 3/4 AEs occurred in 18% subjects. **Conclusions:** This is the first reported large scale prospective anti-PD-1 clinical study in advanced melanoma subjects with an emphasis on acral and mucosal subtypes. Anti-PD-1 mAb appears more efficacious for CSD and non-CSD than acral and mucosal subgroups. Patients will be continuously monitored for safety and efficacy readouts (DOR, PFS and OS). Clinical trial information: NCT03013101.

Tolerance and efficacy of BRAF plus MEK inhibition in patients with melanoma who have received PD-1 based therapy. *First Author: Karim Saab, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Combined BRAF and MEK inhibition (BRAF-MEK) is a standard therapy for BRAF V600 mutant melanoma, but doses and adverse event (AE) profiles were defined in trials conducted largely before the era of PD-1 based frontline therapy. The tolerance, AE profile, rates of hospitalization, and efficacy are not well defined for BRAF-MEK in the post-PD-1 setting. **Methods:** A sequential cohort of patients (pts) with BRAF V600 mutant melanoma who received combined BRAF+MEK following prior PD-1 based therapy was assembled from 4 tertiary care centers in the US and Australia. Dose modification (mod) was defined as a treatment break, dose reduction, or planned intermittent dosing due to AEs. Rates of hospitalization, emergency room (ER) visits, and discontinuation due to AEs were collected, and OS was calculated using Kaplan-Meier methods from time of BRAF-MEK start. **Results:** 78 pts were identified; 48 (62%) male, median age (range) was 58 (26-88). Most primaries were cutaneous (82%) or unknown (12%). V600 mutations were -E in 71 (91%) and -K in 7 (9%). Most pts had M1c or M1d stage (80%); performance status was 0 (22%), 1 (57%) and 2-3 (21%). LDH was high in 54%. 55 pts (71%) were BRAF-naïve. 81 total BRAF-MEK regimens were utilized; 68 (84%) dabrafenib-trametinib (DT); 12 (15%) vemurafenib-cobimetinib (VC); 1 other. Median (range) interval between last PD-1 dose and BRAF-MEK start was 35 days (1-410). Most common AE for DT was fever (88%) and for VC was rash (83%). Atypical AEs included cytopenias (12%) and central nervous system events (7%). 25 (31%) had an AE-related hospitalization and 18 (22%) an ER visit. 12 pts (15%) stopped BRAF-MEK for AEs. 68 of 81 regimens (84%) had ≥1 dose mod; median time to first dose mod was 14 days, 59 (87%) occurred within 90 days, and 70% involved fever. Among BRAF-naïve pts, after median follow-up of 12.5 months (mo), median time on BRAF-MEK was 6 mo and median OS was 15 mo. **Conclusions:** The majority of patients receiving BRAF-MEK inhibitors after PD-1 therapy require dose interruptions, and a significant minority require hospitalization or ER utilization for AEs. In this higher-risk population, median time on therapy and OS may be inferior to those in published Phase 3 trials.

9541 Poster Session (Board #368), Mon, 1:15 PM-4:45 PM

Efficacy and genetic analysis for a phase II multicenter trial of HF10, a replication-competent HSV-1 oncolytic immunotherapy, and ipilimumab combination treatment in patients with stage IIIb-IV unresectable or metastatic melanoma. *First Author: Robert Hans Ingemar Andtbacka, Huntsman Cancer Institute at the University of Utah, Salt Lake City, UT*

Background: HF10, a bioselected replication-competent oncolytic virus derived from HSV-1, has been evaluated in combination with ipilimumab (ipi) in a Phase II trial (NCT02272855) in unresectable/unresected Stage IIIB-IV melanoma pts. Herein we report the recent efficacy and gene expression findings correlating with responders. **Methods:** HF10 injected into single or multiple tumors (1×10^7 $TCID_{50}$/mL/dose, up to 5mL depending on tumor size and numbers); 4 injections q1wk; then up to 15 injections q3wk. Four ipi IV infusions (3 mg/kg; concurrent with HF10) were administered q3wk. AEs assessed per CTCAE 4.0. Tumor responses were assessed per mWHO and irRC at 12, 18, 24, 36 and 48 wks for patients (pts) continuing on HF10 monotherapy. Primary endpoint was Best Overall Response Rate (BORR) at 24 wks. Evaluation of correlative studies (nCounter PanCancer Immune Profiling Panel) including tumor biopsy was performed at baseline and on Days 85 and 169. **Results:** 46 pts were enrolled and treated: 59% men, median age 67 yrs (range 28 to 91); disease stage 20% IIIB, 43% IIIC and 37% IV; 57% were treatment naïve and 43% with ≥ 1 prior cancer therapy for unresectable/metastatic melanoma. HF10+ipi combination was well tolerated. HF10 adverse event (AE) profile was similar in combination with ipi as in HF10 monotherapy. 28.3% pts had treatment-related ≥G3 AEs, and the majority of ≥G3 AEs were due to ipi. Of the 44 efficacy evaluable pts, irRC BORR at 24 weeks was 41% (18% irCR and 23% irPR); disease stability rate was 68% (27% irSD). As of Feb 07, 2018, median PFS was 19 months and median overall survival was 26 months. Responding tumors exhibited an activation of the adaptive immune response with increased total tumor infiltrating lymphocytes and CD8+ T-cells, and decreased CD4+ T-cells. **Conclusions:** The combination HF10 and ipilimumab treatment demonstrated a favorable benefit/risk profile and encouraging antitumor activity in advanced melanoma pts by inducing immune-cell infiltration in the tumor microenvironment. Clinical trial information: NCT02272855.

9542 Poster Session (Board #369), Mon, 1:15 PM-4:45 PM

BRAF/MEK inhibition in melanoma patients with rare BRAF mutations. *First Author: Jessica Cecile Hassel, Section of DermatoOncology, Department of Dermatology and National Center for Tumor Diseases, University Hospital Heidelberg, Heidelberg, Germany*

Background: BRAF/MEK inhibition is standard of care in patients (pts) with a BRAF V600E/K mutated melanoma. Efficacy data for pts with less frequent BRAF mutations are limited so far. **Methods:** 71 metastatic melanoma pts with rare activating BRAF mutations (excluding BRAF V600E/K) treated at 13 melanoma centers with either a BRAF inhibitor (i) or MEKi monotherapy or the combination were included. BRAF mutation, patient and disease characteristics, response and survival data were examined. **Results:** 41 (58%) pts harbored a rare BRAF V600 mutation and 30 (42%) a non V600 mutation (Table). The most frequent mutations were V600R (30 pts, 42%) and K601E (10 pts, 14%). The median age was 61 years, 75% were male. Most melanomas were of cutaneous origin (84%) and a nodular subtype (40%). At treatment start, most pts had stage IV M1c (44%) or M1d melanoma (28%) (AJCC 2017), and 40% had an elevated LDH. Most pts received combined BRAFi/MEKi (48%) or BRAFi monotherapy (45%). In the 41 pts with V600 mutations (30 = V600R, 4 = V600D) the response rate (RR) to single agent BRAFi and combination BRAFi/MEKi was 33 and 61%, respectively. Median PFS was 3.7 months and 8.2 months. In the 30 pts with non-V600 mutations (10 = K601E, 6 = L597Q/S) the RR to BRAFi was 7%, to MEKi 40% and to combination treatment 36%. Median PFS was 1.6 vs 4.8 vs 3.8 months. **Conclusions:** Patients with rare BRAF mutations can respond to targeted therapy. Pts with non-V600 mutations are less likely to respond to BRAFi monotherapy, but activity with MEKi alone or in combination with BRAFi appears more promising.

BRAF genotype	Treatment	N	ORR (CR + PR)	Median PFS (in months)	Median OS (in months)
V600	Total	41	20 (49%)	7.3	16.1
	BRAFi	18	6 (33%)	3.7	10.5
	MEKi	0	-	-	-
	BRAFi/MEKi	23	14 (61%)	8.2	31.1
V600R	Total	30	14 (50%)	6.5	14.8
	BRAFi	12	3 (25%)	3.7	8.9
	MEKi	0	-	-	-
	BRAFi/MEKi	18	11 (61%)	8.2	31.1
Non-V600	Total	30	7 (23%)	2.5	7.8

9543 Poster Session (Board #370), Mon, 1:15 PM-4:45 PM

Phase II trial of pembrolizumab (MK-3475) in metastatic cutaneous squamous cell carcinoma (cSCC). *First Author: Ragini Reiney Kudchadkar, Winship Cancer Institute, Atlanta, GA*

Background: cSCC is the second most common skin cancer in the U.S. with over 700,000 new cases and 2000 deaths per year. Though most cSCCs are curable with surgery or radiation, 5% metastasize and are treated typically with platinum-based chemotherapy and EGFR inhibitors as standard of care. These agent have overall response rates (ORR) of only10-20%. No current treatments have been shown to improve overall survival. **Methods:** Clinical activity of pembrolizumab in metastatic cSCC patients not curable by surgery or radiation was evaluated. Primary objective was to establish the ORR of pembrolizumab in metastatic cSCC per RECIST 1.1 Secondary objectives were 6-month progression-free survival (PFS) and 1 year overall survival. The study was conducted with Simon's optimal two-stage design, with goal of 12 patients in the first stage with 3 or more responses would lead to stage two that would include an additional 13 patients. Patients were treated with pembrolizumab 200mg IV every 3 weeks for up to 2 years. Normal skin, blood, and tumor tissue were obtained for biomarker studies including PD-L1, expression of co-stimulatory and co-inhibitory molecules on and functionality of T cell populations. **Results:** Ten subjects (2 females) with a median age of 68.7 years are reported. All subjects were Caucasian. ORR was 40%, with 10% (1) complete response (CR),30% (3) partial responses (PR), 10% (1) stable disease (SD) 10% (n = 1), progressive disease (PD) 20% (n = 2), and 3 subjects are not yet evaluable. Three subjects had prior chemotherapy, 2 of the 3 had PD, 1 subject not yet evaluable. All patients with CR, PR, and SD are yet to progress at current follow up. No subject deaths have occurred on study. Two grade 3 related-adverse events were noted, hepatitis and pneumonitis. No unexpected adverse events related to treatment have occurred. Median PFS and OS has not been reached as of February 2018. Further follow up as well as biomarker correlates will be presented. **Conclusions:** Pembrolizumab has significant clinical activity in cSCC. Expansion into the second stage of the trial is indicated. Further follow up is needed in order to establish survival benefit for these patients. Clinical trial information: NCT02964559.

9545 Poster Session (Board #372), Mon, 1:15 PM-4:45 PM

Hyperacute toxicity with combination ipilimumab (ipi) and anti-PD1 immunotherapy. *First Author: Helen Clare Dearden, Melanoma Institute Australia, Sydney, Australia*

Background: Combination ipi and nivolumab is approved for advanced melanoma and is in trials across oncology. Toxicity (tox) most often occurs 6-10 wks into treatment. Whether early tox is harder to manage or influences treatment efficacy is unknown. **Methods:** Consecutive metastatic melanoma patients (pts) who developed hyperacute (HA) tox, defined as grade (G) 2 or higher (2+) tox within 21 d of receiving combination immunotherapy (ipi + PD1), were retrospectively identified from 9 centres. Demographics, disease characteristics, tox and outcome data were examined. **Results:** 80 pts developed HA tox, at a median (med) 10 d (range 1-21). Pts had med age 55y, 66% were stage IV M1c/d, 49% had elevated LDH, 14% were ECOG 2. 61 (76%) pts were treatment naïve, 9 had received prior BRAF inhibitors, 4 ipi, 2 PD1 antibodies. Most frequent HA tox was colitis (n = 23), rash (n = 17), hepatitis (n = 9), endocrine (n = 9), pneumonitis (n = 6), and neurotoxicity (n = 4). 39% were G2, 54% G3, 8% G4. 48% required treatment beyond oral steroids, including IV steroids (21%), infliximab (18%), and other immunosuppression (9%) including mycophenolate and IVIG. Pts required a med 45 days on $>$ 10mg prednisone equivalent. 83% of HA colitis pts required treatment beyond oral steroids (22% IV steroids, 61% infliximab), with a med 75 d on $>$ 10mg prednisone. 20% pts received further combination therapy, 48% permanently discontinued all immunotherapy. 48% pts developed additional tox (10% had 3+ further tox), and 31% with G3-4 HA tox developed another G3-4 tox without further therapy. The overall response rate (ORR) was 54%, and after a med 11.6 mo follow-up, med PFS was 8.74 mo. Patients with G2 tox had a similar ORR but greater PFS than those with G3-4 tox (65% vs 47%, p = 0.19; 10.2 vs 2.8 mo, p = 0.01). There was no difference in ORR and PFS by type or duration of immunosuppression. **Conclusions:** Hyperacute toxicities from combination immunotherapy are varied. Many pts require treatment beyond oral steroids and for a prolonged duration, and pts are at risk of further severe tox. Efficacy in such pts appears similar to trial populations, although severe tox may correlate with worse outcomes. The degree and duration of immunosuppression does not appear to influence the efficacy of immunotherapy.

9546 Poster Session (Board #373), Mon, 1:15 PM-4:45 PM

Ipilimumab and radiation in patients with unresectable melanoma brain metastases: A multicenter, open label, phase-2, Spanish Melanoma Group (GEM) study (NCT-2013-001132-22). *First Author: Jose A. Lopez-Martin, Medical Oncology Department, Hospital 12 de Octubre, Madrid, Spain*

Background: Laboratory and clinical experiences suggest that radiotherapy may be synergistic with anti-CTLA-4 strategies. This hypothesis is explored in melanoma patients (pts) with brain metastases (BM) not candidate to surgery/radiosurgery. **Methods:** Single arm phase-2 trial evaluating Ipilimumab (IPI) and whole brain RT (WBRT), in pts with melanoma and unresectable BM. Endpoints: Primary: 1-year overall survival (OS@1y). Secondaries: progression free survival (PFS), objective response rate (ORR) and safety. Main eligibility criteria: first-BM episode, non-suitable for radical therapy; Barthel Index $>$ 10; RTOG-RPA class-2; measurable disease; Karnofsky $>$ 70%; LDH $<$ 2 xULN; no rapid clinical deterioration; dexamethasone $<$ 16 mg/d. Treatment: IPI 3mg/Kg q3weeks (4 cycles); WBRT 30Gy in 10 fractions (or equivalent). Evaluable pts: Safety $>$ 1 IPI dose. Efficacy: complete WBRT and $>$ 1 IPI dose. Trial required 56 evaluable pts to detect an 35% OS@1y, assuming the historical 20% OS in this population (α:0.05, β:0.8; 1-stage Fleming design). **Results:** From April/2014 to January/2017, 58 pts were included; 51 completed WBRT and $>$ 1 IPI dose. Demographic characteristics: Age (median/range) 63 (37/85). Male/Female 36/22. Karnofsky (100/90; 80/70) 42. 16. BM (1, $>$ 1, nonspecified) 14; 43; 1. Barthel Index ($>$ 15; 10-15) 56; 2. Steroids at baseline 31 (53,4%). Prior treatments (1, $>$ 1) 20 (34,5%), 9 (15,5%). Previous BRAF/MEKinhibitors 18 (31%). Liver metastases 16 (27,6%). Treatment intensity: WBRT: completed in 55 pts (3 early termination). IPI 4/3/2/1 doses: 31/10/10/7 pts. Efficacy: OS@1y: 31.8% (95%CI 18.8-44.8%). 15 pts are alive $>$ 1 year. Median PFS: 4.8mo (95%CI 2.2-3.4). Median OS 5.8mo (95%CI 3.6-5.9). Safety: Serious AEs: 40 pts (69%). Treatment-related SAEs: 11 pts (19%). IPI-related: ALT/AST (4), diarrhea (4), intestinal perforation (1), headache (1). RT-related: headache and vomiting (1). **Conclusions:** Concomitant IPI+WBRT is feasible and there were no unexpected safety issues. Steroids at baseline do not impair the effect of IPI in this population. OS@1y in this trial is higher than the historical results. Clinical trial information: 2013-001132- 22.

9547 Poster Session (Board #374), Mon, 1:15 PM-4:45 PM

Sex differences in tolerability to Anti-PD1 therapy: Are we all equal? *First Author: Narjust Duma, Mayo Clinic, Rochester, MN*

Background: Immune related adverse events (IRAEs) have emerged as a serious clinical problem in the use of immune checkpoint inhibitors. The etiology and risk factors for these potentially life-threatening adverse events remain unknown. Therefore, we assessed sex differences in tolerability to anti-PD1 therapy. **Methods:** All patients (pts) with metastatic melanoma treated with anti-PD1 therapy at Mayo Clinic Rochester from 2014 to 2017 were reviewed. Ocular melanoma cases were excluded. Kaplan-Meier method was used for time-to-event analysis. **Results:** 245 pts were identified, 148 (60%) were men, 30 (12%) were premenopausal (Pre-M) (≤52 years) and 67 (27%) were postmenopausal (Post-M) women. Baseline characteristics were similar among groups (Table 1). Pre-M women were more likely to experience IRAEs compared to Post-M women and men (67% vs. 60% vs. 46%, $p < 0.04$). In 23% of Pre-M women anti-PD1 therapy was discontinued due to irAE (men 12%). Pre-M women were more likely to experience endocrinopathies (35% vs. 10%, $p < 0.02$) and cutaneous reactions (25% vs. 15%, $p < 0.02$) compared to men. All cases of diabetic ketoacidosis were observed in Pre-M women (n = 6). No differences in grade ≥3 toxicities were seen across groups. Pts with IRAEs were more likely to have a radiographic response to anti-PD1 therapy regardless of sex (68% vs. 44%, $p < 0.002$). There was a trend towards better PFS in men with IRAEs compared to men without IRAEs (16.5 months vs. 9.7 months, $p < 0.05$). **Conclusions:** Pre-M Women were more likely to experience IRAEs compared to Post-M women and men. An association between IRAEs and response to therapy was also observed. Larger studies are needed to confirm these results and investigate etiologic mechanisms underlying these associations.

Characteristics	Pre-M % (n)	Post-M % (n)	Men % (n)	p value
Liver metastasis	33 (10)	33 (22)	30 (45)	0.91
Lung metastasis	47 (14)	30 (20)	42 (62)	0.16
Prior GM-CSF	43 (13)	27 (18)	18 (27)	0.01
Prior radiation	37 (11)	54 (36)	59 (87)	0.08
Prior chemotherapy	13 (4)	16 (11)	18 (27)	0.79
IRAEs	67 (20)	60 (40)	46 (68)	0.04
≥3 grade IRAEs	50 (10)	43 (17)	31 (21)	0.12
Discontinuation of anti-PD1 due to toxicity	23 (7)	15 (10)	12 (18)	0.37

9548 Poster Session (Board #375), Mon, 1:15 PM-4:45 PM

A randomized phase Ib/II study of the selective small molecule axl inhibitor bemcentinib (BGB324) in combination with either dabrafenib/trametinib or pembrolizumab in patients with metastatic melanoma. *First Author: Oddbjorn Straume, Department of Oncology, Haukeland University Hospital, Bergen, Norway*

Background: Upregulation of the receptor tyrosine kinase Axl has been linked with both a reduced response to PD-1 blockade and the development of therapy resistance to BRAF directed therapies in melanoma. Bemcentinib (BGB324) is a first-in-class orally bioavailable selective inhibitor of Axl which is currently explored in several ph II clinical trials. BGBIL006 (NCT02872259) is an open label phase Ib/II trial designed to explore whether combination with bemcentinib improves ORRs to standard of care therapies in pts with metastatic melanoma (MM). **Methods:** Dose escalation of bemcentinib in combination with 150mg twice daily / 2mg daily D/T in newly diagnosed, BRAF pos. MM with high tumour load followed a 3+3 design (part 1). In part 2, pts were randomized 2:1 to receive D/T or pembro +/- bemcentinib at RP2D, respectively, based on mutation status and tumour load. Pts were allowed to switch D/T with pembro and *vice versa* upon progression (part 3). Tumor responses were assessed per investigator using RECIST v1.1. Plasma protein biomarker levels were measured using the DiscoveryMap v3.3 panel (Myriad RBM) in a selection of pts pre-dose and at C2D1. **Results:** In part 1, 6 newly diagnosed pts were enrolled (age 34-71, male 66%, LDH > 1 x ULN 50%). There was1 dose limiting toxicity (G3 rash). As of Feb 7 2018, a further 13 pts have been enrolled into part 2 of the study. The most common treatment-related AEs (TRAEs) were diarrhea (42%), pyrexia (37%), fatigue (31%) and rash (31%). Grade 3 TRAEs were observed in 3 (16%) pts. No G4 AEs or treatment related deaths occurred. The bemcentinib RP2D (200 mg daily) is well tolerated in combination with both D/T and pembro with AE profiles consistent with those reported for either therapeutic approach alone. Protein biomarkers candidates predictive of pt benefit following bemcentinib treatment were identified. **Conclusions:** Bemcentinib can be administered in combination with established first line therapies in patients with melanoma. Safety and efficacy as well as biomarker candidates will continue to be explored. Clinical trial information: NCT02872259.

9549 Poster Session (Board #376), Mon, 1:15 PM-4:45 PM

Outcomes of metastatic melanoma (MM) patients (pts) after discontinuation of anti-Programmed-Death 1 (PD1) therapy without disease progression. *First Author: Gustavo Schvartsman, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The optimal duration of PD1 therapy for MM pts that do not progress remains unknown. There is limited information available about long-term outcomes of patients that discontinue treatment due to toxicity. **Methods:** Our institutional database was queried to identify stage IV or unresectable stage III MM pts that received single-agent anti-PD1 from January 1, 2012, to July 31, 2016, with at least 6 months of clinical follow-up. Pts that discontinued PD1 therapy for reasons other than progression were identified, including maximal clinical benefit (MCB) and toxicity. MCB was defined as either completion of two years or discontinuation per physician's discretion. Data on demographics, tumor characteristics, treatment variables and outcomes were collected. **Results:** From 580 MM pts treated with PD1, 41 pts discontinued treatment for MCB and 34 for intolerable toxicity (75 total). 56% of pts achieved a complete response (CR), 35% partial response (PR), and 9% stable disease (SD). Response rate was similar among patients discontinuing therapy due to MCB (93%) and toxicity (88%), but CR rates were higher in the MCB group (76% vs 32%, $p < 0.001$). Median time on PD1 was 19.5 months in the MCB group and 6.5 months in the toxicity group; median time to response was 2.9 months, and median time to CR was 7.3 months. With median follow-up of 16 months after discontinuation, 89% were disease-free and 93% were alive; 6 patients died; no deaths were due to disease progression, and 3 were due to PD1 treatment complications. 8 pts progressed (3 in the MCB group, 5 in the toxicity group). 2 out of 3 in the MCB group were successfully rechallenged with PD1 (1 CR, 1 PR) and one had surgery and is still off therapy. One pt in the toxicity group was rechallenged, 2 are receiving ipilimumab, one had a single brain lesion resected (still off therapy) and one died of cardiac arrest while on T-VEC. No baseline factors were associated with relapse. **Conclusions:** Anti-PD1 was safely discontinued in the majority of MM pts, and no deaths due to disease progression were seen. Further prospective validation of early discontinuation for MM pts achieving MCB is warranted to prevent unnecessary toxicity and financial costs.

9550 Poster Session (Board #377), Mon, 1:15 PM-4:45 PM

Phase 1 study to evaluate safety and efficacy of nivolumab (nivo) + ipilimumab (ipi) + external beam radiotherapy (RT) in patients with metastatic melanoma. *First Author: Michael A. Postow, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: RT causes immunologic effects that enhance the efficacy of immune checkpoint blockade in preclinical models. No prospective clinical trial data exist for the safety and efficacy of combining RT with the nivo + ipi combination. **Methods:** We conducted a prospective study (NCT02659540) where patients with metastatic melanoma were treated with nivo (1 mg/kg) + ipi (3 mg/kg) every 3 weeks (Q3W) for up to 4 doses, with optional nivo maintenance Q2W per standard of care. Following the first nivo + ipi dose, patients were treated with conventionally fractionated RT (30 Gy in 10 fractions) to one melanoma metastasis. Treatment-related (TRAE) and treatment-emergent (TEAE, all causality) adverse events within the first 24 weeks of immunotherapy initiation were summarized overall and by CTCAE grade. Objective response rate (ORR) was assessed by RECIST 1.1 outside and within the irradiated fields. ORR rates were provided with binomial 95% confidence intervals (CI). **Results:** Ten patients (median age: 65 [range: 28-86] years; 6 female) received at least 1 dose of study therapy and were included in the safety analyses. One patient withdrew consent prior to efficacy assessment and was excluded from efficacy analyses. All patients had ≥1 any grade (G) TEAE. G3/4 TRAE occurred in 4 patients (40%), and G3/4 TEAE occurred in 7 patients (70%). G3/4 TRAE were anemia, thrombocytopenia, increased lipase, and pruritus. ORR outside of the irradiated field was 44% (4/9, 95% CI: 14-79%). Responses were also seen within the irradiated fields. Two patients died due to disease progression. **Conclusions:** This first prospective study in a small group of patients suggests it is safe to combine conventionally fractionated RT with nivo + ipi. Based on acceptable G3/4 TRAE in this fully accrued cohort testing conventionally fractionated RT, accrual is ongoing to a second cohort where patients receive higher dose per fraction RT with nivo + ipi. Clinical trial information: NCT02659540.

9551 Poster Session (Board #378), Mon, 1:15 PM-4:45 PM

42-month follow-up of sonidegib efficacy and safety in advanced basal cell carcinoma: Final analysis from BOLT. *First Author: Michael Robert Migden, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Sonidegib is a hedgehog pathway inhibitor (HPI) approved in the United States for the treatment of adult patients with locally advanced basal cell carcinoma (laBCC) not amenable to curative surgery or radiotherapy; and in Switzerland and Australia also for metastatic basal cell carcinoma (mBCC). Here we report the final analysis at 42 months from the phase 2 BOLT study, the longest follow-up data available from a clinical trial of an HPI. **Methods:** BOLT was a randomized, double-blind, multicenter, phase 2 study. HPI treatment–naïve patients (N = 230) with advanced BCC (laBCC, n = 194; mBCC, n = 36) not amenable to curative surgery/radiotherapy were randomized 1:2 to sonidegib 200 mg, or to 800 mg QD, respectively. Data analyses were performed at 6, 12, 18, 30, and 42 months. The primary endpoint was objective response rate (ORR) per central review. Secondary endpoints included rate of complete response, duration of response (DOR), time to tumor response (TTR), progression free survival (PFS), and safety. **Results:** Primary and secondary endpoint results were very similar to the 30-month data (Table). Tumor responses were durable in patients with either subtype of advanced BCC (≥23 months). The safety profile of sonidegib was manageable and consistent with prior analyses. **Conclusions:** Efficacy was maintained at the 42-month analysis, with no new safety signals identified. These data continue to support sonidegib's durability of response in patients with advanced BCC. Proactive management of adverse effects may prolong treatment duration and improve outcomes.Clinical trial information: NCT01327053.

Sonidegib efficacy at 6, 30 and 42 months in advanced bcc by central review.

Characterization of complete responders to combination nivolumab (nivo) and ipilimumab (ipi) in patients (pts) with advanced, unresectable melanoma. *First Author: Allison Betof Warner, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Among pts who discontinue treatment with nivo + ipi due to toxicity with a partial response or complete response (CR), ~30% ultimately progress. Less is known about whether pts who achieve CR to nivo + ipi maintain the CR after discontinuing treatment and how progression occurs. **Methods:** We conducted a single-institution (Memorial Sloan Kettering Cancer Center), retrospective analysis of checkpoint inhibitor naïve pts with advanced, unresectable melanoma treated with at least one dose of nivo + ipi and ≥6 months of follow-up from time of first treatment (n = 201). Pts with acral, uveal and mucosal melanoma were excluded. CR was defined by absence of radiographically apparent disease or after a biopsy showed no viable melanoma in radiographically apparent residual tissue. Overall survival (OS) was calculated by the Kaplan-Meier method. **Results:** Of the 201 pt cohort with a median follow-up of 27 months (mos) among survivors, the median OS has not been reached. Estimated 24-month OS is 74.5%. 56 pts (28%) achieved CR. Estimated 24-month OS among the pts in CR is 93.5%. Of the 56 pts with CR, only 2 (4%) remain on anti-PD-1 maintenance. 34 (61%) discontinued immunotherapy for toxicity, and 20 (36%) discontinued for reasons other than toxicity (i.e. protocol completion, CR, pt preference). Among the CR pts who discontinued therapy, 50 remain in CR (longest duration of CR = 71 mos) with a median follow-up of 20.5 mos from time of CR. 4 of the 56 pts ultimately had disease progression (PD); none of these pts was on treatment at time of PD (range of treatment duration: 1-16 mos). Two patients had PD within 3 months of CR, one in the bladder/pelvis and the other in bone. One patient had PD in the brain 18 months after CR, and one had PD in a regional lymph node after 41 months. **Conclusions:** Patients with advanced, unresectable melanoma can have durable CR, even after discontinuing therapy. OS and CR rates in our large dataset are similar to published trials yet follow-up time for some pts exceeds that reported in clinical trials. The incidence of disease progression after CR to nivo + ipi is low after 3 months. The need for ongoing systemic and intracranial surveillance requires further study

9553 Poster Session (Board #380), Mon, 1:15 PM-4:45 PM

Distinct patterns of response and toxicity (tox) by sites of metastases (mets) in patients (pts) treated with ipilimumab combined with PD-1 antibodies (ipi +PD1). *First Author: Ines Esteves Domingues Pires Da Silva, Melanoma Institute Australia, Sydney, Australia*

Background: Combined ipilimumab and nivolumab has the highest response rate (RR), progression-free survival (PFS) and overall survival (OS) for any immunotherapy in metastatic melanoma (MM), but the pattern of response and tox is variable. We sought to examine the association between site and size of mets with the pattern of response and tox in pts treated with ipi+PD1. **Methods:** MM pts treated with first line ipi+PD1 (nivolumab or pembrolizumab) had all mets > 5 mm (brain > 1 mm, lymph nodes > 15 mm in short axis) on CT/MRI measured. Lesional response was determined by RECIST. Demographics, disease characteristics, tox and outcomes were examined. **Results:** 140 pts were studied with 819 mets (median 5/pt); median (med) follow-up 12.9 months (mo). Mets with complete response (CR) were significantly smaller than non-CR mets (med 13 vs 17 mm, $p < 0.0001$) and the rate of patient CR decreased as number of mets increased within a pt, with no CR if > 8 mets ($p < 0.0001$). Med tumour regression was -64%, higher in subcutis (-90%, $p < 0.01$), soft tissue [ST] (-87%, $p < 0.01$), gastrointestinal [GI] (-82%, $p = 0.04$) and lung (-71%, $p = 0.03$), and lower in liver (-7%, $p = 0.06$) and spleen (0%, $p = 0.03$). The highest RR was in lung, GI and ST mets (69%), while splenic mets had the lowest RR (33%). GI mets had the fastest time to response (2.7mo) and liver the slowest (8.2mo). In multivariate analysis, pts with lung mets had superior RR (OR 2.75, $p = 0.02$) and PFS (HR 0.47, $p = 0.03$) and pts with liver mets had inferior RR (OR 0.33, $p = 0.02$) and PFS (HR 3.08, $p < 0.01$), while OS was poorer in pts with liver (HR 4.38, $p = 0.01$) or brain mets (HR 2.82, $p = 0.06$). Pts with lung mets had more rash (31% vs 9%, $p = 0.05$), while pts with liver and GI mets had less rash (6% vs 33%, $p = 0.02$) or thyroiditis (0 vs 14%, $p = 0.02$) compared with pts without these mets. Disease burden and number of metastases did not associate with tox. **Conclusions:** Metastases in different anatomical locations display distinct response patterns with combination immunotherapy, with inferior responses in liver mets and shorter survival in patients with liver mets, similar to that seen with PD1 monotherapy. Patterns of metastasis may influence toxicity.

9554 Poster Session (Board #381), Mon, 1:15 PM-4:45 PM

Off treatment survival (OTS) in patients (pts) with advanced melanoma after anti-PD1 therapy. *First Author: Shelly Ann Christiansen, Georgetown Lombardi Comprehensive Cancer Center, Washington, DC*

Background: Anti-PD1 alone and combined with anti-CTLA4 therapy has improved survival in pts with advanced melanoma. Optimal treatment duration has not been defined and it is unclear if survival is compromised when pts discontinue (DC) therapy. **Methods:** A single institution review of pts with advanced melanoma treated with nivolumab or pembrolizumab monotherapy (anti-PD1) or nivolumab plus ipilimumab (nivo-ipi) was performed. Response rate (RR; provider assessed), reason for treatment DC and survival were analyzed. Outcomes in pts after treatment DC with CT scan response, PET/CT and/or biopsy of residual disease was assessed. OTS in pts with disease control was defined from time of last anti-PD1 dose to time of subsequent systemic therapy or death. **Results:** Of 96 pts, 44 received anti-PD1 and 52 received nivo-ipi. Median age 64 yrs, 62% male, 95% ECOG 0-1, 73% stage M1c, 37% BRAF mutant, 39% elevated LDH, and 28% brain metastasis. Overall RR was 34% for anti-PD1 and 63% for nivo-ipi. Another 25% and 6% of pts had stable disease, respectively. Median overall survival (OS) was not reached, although survival was significantly greater with nivo-ipi ($P = 0.007$). At 24 months, 80% of nivo-ipi pts were alive vs 51% anti-PD1 pts. 41 pts with disease control DC treatment for toxicity (n = 21) or pt/provider choice (n = 20). Of the latter, 17 pts DC treatment after one year for partial/complete response on CT scan (n = 4), negative PET/CT scan (n = 9), and positive PET/CT with negative biopsy (n = 4). 3 pts DC treatment after 2 years for positive PET/CT and negative biopsy. Median OTS was not reached for either group (91% and 77% were event free at 18 months); median follow up was 13.5 and 27.5 months, respectively. In the pt/provider choice group, 1 pt had progressive disease (PD) managed surgically and 1 pt died from non-melanoma causes; none received further systemic treatment. In the toxicity group, 4 pts had PD requiring further systemic therapy. **Conclusions:** In our experience, superior OS was seen with nivo-ipi over anti-PD-1 alone. OTS appears durable in pts with disease control if treatment DC due to toxicity or pt/provider decision. PET/CT and biopsy may be an effective strategy for safe DC of therapy after 1 year. Further prospective study is warranted.

9555 Poster Session (Board #382), Mon, 1:15 PM-4:45 PM

Impact of simultaneous radiotherapy in melanoma patients treated with pembrolizumab in the French early access program. *First Author: Philippe Saiag, General & Oncology Dermatology, CHU Ambroise Paré APHP & University of Versailles, Boulogne-Billancourt, France*

Background: Information on the use of radiotherapy in anti-PD-1 monoclonal antibody-treated melanoma pts is limited although some data support a synergistic effect. **Methods:** We investigated the influence of simultaneous radiotherapy in a multicenter ambispective cohort of advanced melanoma patients initiating pembrolizumab between May 2014-sept 2015 (CCTIRS, #15.640). Palliative or curative intent of radiotherapy was recorded. Overall (OS) and progression-free (PFS) survivals were analyzed using Kaplan-Meier survival analysis and Log rank tests were used to compare curves. **Results:** 663 pts (151 pts with brain metastases) were included in 40 French centers, with 125 pts (19%) receiving simultaneous radiotherapy (43 pts with $\geq$1 brain metastasis, 82 without). No significant difference in baseline LDH level, ECOG performance status, N of metastatic sites, previous treatment lines or post-progression therapies was observed between pts who did or did not receive radiation. As compared to pts without brain metastases, radiotherapy was performed in brain metastases pts closer to initiation of pembrolizumab (median 1.1 m vs 3.7 m, p = 0.009) and more frequently with a curative intent (72% vs 37%, $p < 0.001$). Globally, OS was longer in radiated vs non-radiated pts (median 18.9 m vs 12.5 m, HR:0.78, 95%CI: 0.57-0.96). This benefit was mainly driven by the pts with brain metastases (OS: median 26.0 m vs 6.0 m, HR:0.35, 95%CI:0.22-0.56, $p < 0.001$)(PFS: 6.4 m vs 2.5 m, HR:0.54, 95%CI:0.36-0.81, $p < 0.002$). No significant difference was seen for OS in radiated pts without brain metastasis, who were mainly radiated later and for palliative reasons and had shorter PFS (2.8 vs 3.4 m, HR 1.32, $P < 0.03$). **Conclusions:** Simultaneous radiotherapy may enhance efficacy of anti-PD1 therapy, particularly when initiated early and in brain metastases pts. Controlled studies are needed. Clinical trial information: 15.640.

9556 Poster Session (Board #383), Mon, 1:15 PM-4:45 PM

Survivorship experience for patients (pts) with metastatic melanoma (MM) on long-term targeted therapy (TT). *First Author: Chloe Chia Hoey Khoo, Peter MacCallum Cancer Centre, Melbourne, Australia*

Background: TT has improved survival for pts with MM. The lived experience for long-term responders remains under-studied. We characterised pt issues using a cross-sectional survey. **Methods:** Eligible pts had MM, aged > 18, $\geq$ 6 months post initiation of TT, and had a complete response. A 72-item survey including items from validated measures and custom questions covering physical and psychological effects, impact on lifestyle, access to information, satisfaction with care, and availability of support was administered. Impact of treatment duration ($\leq 12 / > 12$ months) on pt experience was assessed. **Results:** 36/42 (86%) pts responded from Aug-Dec 2017: median age 59 (range 30-84); 18 (50%) male; 21 (58%) had M1c disease; 34 (94%) were receiving TT as 1st line therapy. The majority (31, 86%) were still on treatment; most (22, 74%) had been on treatment for > 12 months. Long-term toxicities including fatigue (33, 92%), dry/itchy skin (25, 69%) and arthralgias (23, 64%) were common. Typical acute toxicities, such as fevers, rashes and gastrointestinal toxicities, were minimal. Psychological morbidity was high, including fear of cancer recurrence (31, 86%), concern regarding long-term toxicities (30, 83%), anxiety awaiting results (29, 81%), concern regarding ongoing sun exposure (28, 78%) and fear of death (26, 72%). The prevalence of both physical and psychological issues was higher among pts on treatment > 12 months, and persisted in 5 (14%) who ceased treatment. Patients reported difficulties with finances (19, 53%), undertaking recreational activities (23, 64%), and performing domestic tasks (14, 39%). Most would value screening for skin cancers (35, 97%), for other cancers (34, 94%), and a survivorship care plan (SCP) to guide management (34, 94%). **Conclusions:** Physical, psychological and functional issues exist in long-term responders to TT. These issues may increase with increasing duration on treatment. Pts may benefit from ongoing toxicity management, tailored psychological support and an SCP.

9557 Poster Session (Board #384), Mon, 1:15 PM-4:45 PM

Phase 1 study of cemiplimab, a human monoclonal anti-PD-1, in patients with unresectable locally advanced or metastatic cutaneous squamous cell carcinoma (CSCC): Final efficacy and safety data. *First Author: Taofeek Kunle Owonikoko, Emory University, Atlanta, GA*

Background: Initial analysis of expansion cohorts (ECs) patients in a phase 1 study showed that cemiplimab (REGN2810) demonstrated a positive risk/benefit profile and produced antitumor activity in patients (pts) with advanced CSCC. We now report mature final data from the CSCC ECs of the phase 1 study (NCT02383212). **Methods:** Pts with distantly metastatic and locally advanced CSCC were enrolled in EC 7 and 8, respectively. All pts received cemiplimab 3 mg/kg by intravenous infusion over 30 minutes every 2 weeks for up to 48 weeks. Tumor measurements were performed every 8 weeks according to RECIST 1.1 to determine overall response rate (ORR; complete response [CR] + partial response [PR]). The data cutoff date was Oct 02, 2017. Tumor response was assessed by an independent central review committee. **Results:** A total of 26 pts were enrolled (21 M/ 5 F; 10 in EC 7, 16 in EC 8; median age: 72.5 years [range, 55–88]; ECOG performance status 1 in 16 pts and 0 in 10 pts). Median duration of cemiplimab exposure was 36.0 weeks. The most common treatment-related adverse event (TRAE) of any grade was fatigue (26.9%). The following $\geq$Grade 3 TRAEs occurred once: asthenia, maculopapular rash, increased alanine aminotransferase, increased aspartate aminotransferase, adrenal insufficiency, and myalgia. ORR was 50.0% (95% CI: 29.9–70.1); 0 CR and 13 PRs. Disease control rate (DCR; ORR + stable disease [SD] + non-CR + non-progressive disease [PD]) was 76.9% (95% CI: 56.4–91.0); 6 SD and 1 non-CR/non-PD. Durable DCR (SD/non-CR/non-PD or response for $\geq$105 days) was 65.4% (95% CI: 44.3–82.8). 3 pts were not evaluable for response. The median duration of response has not been reached; however, for pts with PR, the duration of response exceeded 6 months in 7 pts and 12 months in 2 pts. Median time to response was 2.3 months (range, 1.7–7.3). Median duration of follow-up was 11.0 months (range: 1.1–17.0). **Conclusions:** In this study, cemiplimab demonstrated a positive risk/benefit profile and produced substantial antitumor activity as well as durable responses in pts with advanced CSCC. Clinical trial information: NCT02383212.

9558 Poster Session (Board #385), Mon, 1:15 PM-4:45 PM

Chemoimmunotherapy combination after PD-1 inhibitor failure to improve clinical outcomes in metastatic melanoma patients. *First Author: Jesus Vera Aguilera, Mayo Clinic, Rochester, MN*

Background: Clinical management of metastatic melanoma (MM) after PD-1 blockade failure remains a challenge and lacks a standard of care. Chemo-immunotherapy (CIT) combinations have demonstrated favorable efficacy and safety profiles in lung cancer patients (pts). Our pre-clinical study has shown that in MM pts who have failed PD-1 blockade, the addition of chemotherapy can reshape a subset of tumor-reactive CD8+ T cells, resulting in enhanced anti-tumor immune responses. We conducted a retrospective study comparing the clinical outcomes of CIT with immunotherapy or chemotherapy alone after PD-1 blockade failure. **Methods:** We retrospectively reviewed MM pts seen at Mayo Clinic, Rochester between Jan, 2012 and Jun, 2017 who had failed anti-PD1 therapy. We identified 48 pts who received subsequent CIT (carboplatin/paclitaxel n = 22; temazolomide n = 1, nab-paclitaxel n = 1), or immune checkpoint inhibitors (ICI) or chemotherapy alone. The overall survival (OS), objective response rate (ORR), time-to-next therapy (TTNT), and toxicities were assessed between these groups. **Results:** Among the 48 pts, 24 received CIT after disease progression on PD-1 blockade. At median follow up of 3.9 years, pts who received CIT had a median OS of 5 years (95% CI: 2-NR) versus 1.8 years (95% CI: 0.9-2; p = 0.002) for those who received either ICI (n = 9) or chemotherapy alone (n = 15), with ORR of 61% versus 17% (p = 0.001), respectively. The median TTNT was 8 months (95% CI: 6-15) for CIT cohort versus 3.4 months (95% CI: 2.8-4; p = 0.004) for those who received ICI or chemotherapy alone. **Conclusions:** In MM pts who have failed anti-PD-1 therapy, the chemo-immunotherapy combination showed favorable clinical outcomes and acceptable toxicity profile. This regimen should be considered for MM pts in this setting who have limited treatment options.

9559 Poster Session (Board #386), Mon, 1:15 PM-4:45 PM

Analysis of the kinetics and effects of vemurafenib (V) + cobimetinib (C) on intratumoral and host immunity in patients (pts) with BRAFV600 mutant melanoma (BRAFmM): Implications for combination with immunotherapy. *First Author: Suthee Rapisuwon, Georgetown University, Lombardi Comprehensive Cancer Center, Washington, DC*

Background: Prior studies in pts with BRAFmM have shown increased density of tumor infiltrating lymphocytes (TIL) at 2 weeks (wks) with BRAF +/- MEK inhibition(i), but did not fully characterize kinetics or functional state of the TIL. To better assess the impact of BRAFi +/- MEKi on the tumor microenvironment, we conducted a study to evaluate serial tumor biopsies (Bx) and blood through the first 4 wks of V+/-C therapy (Tx). **Methods:** Subjects with Bx-accessible BRAFmM received either V alone or V+C Tx. Staging CT scans were performed at baseline, wks 6, 12 and q12 weeks until PD or study withdrawal. Tumor Bx and heparinized blood samples were obtained at baseline, day (d) 8, 15, and 29. Bx samples were formalin-fixed paraffin-embedded (FFPE), frozen in OCT, and processed for TIL. PBMC and plasma were isolated from blood. FFPE slides were analyzed by quantitative immunofluorescence (QIF), NanoString 770 Immune Panel and TCRseq (Adaptive). Frozen tumors were analyzed for single cell (sc)RNAseq. TIL and PBMC were analyzed by flow cytometry. **Results:** 5 pts (4M/1F) with BRAFmM were enrolled (3 received V and 2 V+C). All had initial tumor response (2 CR, 3 PR) and subsequent PD. No unusual or G4-5 toxicities were observed. In 4 of 5 tumors, $CD8^+$ and $CD4^+$ TIL increased by d8 or d15 by QIF and NanoString, waning thereafter. %$CD4^+$ cells expressing $CD45RO^+$ decreased over time suggesting a dominance of naïve T cells in new infiltrates. No specific change in %$CD8^+$ TIL expression of $CD45RO^+$ was seen. NanoString showed no significant change in FoxP3, arginase or TGFB1 expression and no change in IFNG, granzyme B or Caspase 3. Other analyses are in process. **Conclusions:** BRAFi +/- MEKi leads to tumor T cell infiltration by d8 that peaks at d15. $CD4^+$ cells are increasingly antigen-inexperienced, while CD8 cells do not change. CD8 infiltrates are not accompanied by inflammatory or apoptotic response. Immune cell influx is not required for tumor response. The data suggest that T cell influx is not related to the generation of new anti-tumor immunity and that BRAF/MEKi Rx may, at best, augment an existing immune response rather than priming a new one. Clinical trial information: NCT01813214.

9560 Poster Session (Board #387), Mon, 1:15 PM-4:45 PM

Safety and preliminary activity data from a single center phase II study of triplet combination of nivolumab (N) with dabrafenib (D) and trametinib (T) [trident] in patients (Pts) with BRAF-mutated metastatic melanoma (MM). *First Author: Hussein Abdul-Hassan Tawbi, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Targeted therapies and immunotherapies (IMTs) have each improved survival for pts with BRAF V600 mutated MM, however many still progress and ultimately die from this disease. New combinatorial approaches targeting known mechanisms of resistance are needed. Preclinical data demonstrates that BRAF inhibition (BRAFi) in BRAF-mutated tumors is associated with increased T cell tumor infiltration and enhanced responses with combined BRAFi and PD-1 blockade in murine models, supporting the rationale for a clinical combinatorial approach. We hypothesize that N + DT is safe and will demonstrate clinical activity in BRAF-mutated pts with MM. **Methods:** We are conducting a phase II study (NCT02910700) of NDT in pts with BRAF-mutated unresectable stage III or IV MM. Prior PD-1 therapy is allowed but prior BRAFi/MEKi treatment is excluded. Pts with brain metastases are allowed if untreated and asymptomatic or mildly symptomatic/requiring stable or decreasing steroids (up to 4 mg PO dexamethasone). Pts receive 3mg/kg Q2wks of N, 150mg BID of D and 2mg QD of T, all starting on Day 1 q28 days. This study is continuously monitored for safety and futility. The primary endpoint of the study is objective response rate (ORR). **Results:** 6 pts were enrolled onto the safety run-in phase of the study and no DLTs were experienced. The study continues to accrue; 14 pts have been treated with NDT to date. 3 pts discontinued therapy due to toxicity (gr 3 immune-mediated hepatitis at 12 wks, and immune-mediated nephritis after 8 and 10 mos of therapy, respectively). 11 pts have been assessed for response 10 have achieved a PR (ORR 91%), and 1 experienced PD. 6 of the 10 pts achieving PR received prior IMT, as did the pt experiencing PD. This study is currently being amended to allow a formalized evaluation of a separate cohort of pts with untreated brain metastases (n = 24). **Conclusions:** Treatment with NDT is well-tolerated at full doses and shows preliminary clinical activity. The combination warrants further evaluation in pts who have received prior immunotherapy and in patients with brain metastases. Clinical trial information: NCT02910700.

9561 Poster Session (Board #388), Mon, 1:15 PM-4:45 PM

Tumor mutational burden, clinical features, and outcomes to PD-1 mono- and combination therapy in patients with cutaneous and unknown primary melanoma. *First Author: Alexander Noor Shoushtari, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Tumor mutational burden (TMB) in cutaneous and unknown primary (CUP) melanomas is associated with benefit to PD-1 monotherapy (mono), but the impact of TMB on nivolumab plus ipilimumab (combo) is not well established. Few TMB analyses have included standard clinical features in a multivariate analysis (MVA). **Methods:** All patients (pts) with CUP melanoma who underwent 340+ gene sequencing at Memorial Sloan Kettering Cancer Center and received PD-1 mono or combo as initial checkpoint inhibitor were analyzed. Somatic TMB/megabase (Mb), AJCC 8 stage, ECOG performance status (PS), sites of metastases (mets), lactate dehydrogenase (LDH) elevation, and neutrophil:lymphocyte ratio (NLR) > 4.73 were included in a Cox proportional hazards model and MVA built using backward selection. Overall survival (OS) and time to treatment failure (TTF), the interval until next therapy, clinical progression, or death, were calculated from PD-1 start. **Results:** 154 pts received PD-1 mono; median follow up was 11 months. 125 pts received combo; median follow up was 19 months. Pts receiving combo vs PD-1 mono were younger (median age 62 vs 71, $p < 0.001$) and had higher rate of elevated LDH (34% vs 18%, $p = 0.04$) and stage M1c/d (66% vs 41%). TMB did not vary by combo vs PD-1 mono (median 15.1 vs 18.4 mut/Mb, $p = 0.21$). Stage was associated with TTF and OS for PD-1 mono and combo (all $p < 0.03$). On MVA for PD-1 mono, TMB (hazard ratio [HR] 0.98; $p = 0.005$) and NLR > 4.73 (HR 2.16; $p = 0.002$) were associated with TTF; PS (ECOG 2+ vs 0, HR 9.86, $p < 0.001$; 1 vs 0, HR 2.59, $p = 0.03$) and LDH (HR 3.16, $p = 0.005$) were associated with poorer OS. TMB was not associated with TTF or OS for combo. On MVA for combo, brain (HR 2.64, $p = 0.004$) and bone mets (HR 2.28, $p = 0.008$) were associated with TTF; PS (ECOG 2+ vs 0, HR 5.37, $p = 0.009$), NLR > 4.73 (HR 2.27, $p = 0.037$), and bone mets (HR 2.86; $p = 0.014$) were associated with OS. **Conclusions:** For patients with cutaneous and unknown primary melanomas, TMB is associated with improved TTF in PD-1 mono but not combo. Performance status, NLR, and bone mets, but not TMB, are associated with OS in PD-1 combo. Models assessing clinical utility of TMB should also include established prognostic features.

9562 Poster Session (Board #389), Mon, 1:15 PM-4:45 PM

Association of body mass index (BMI) with overall survival (OS) in metastatic melanoma (MM) patients (pts) treated with combined anti-CTLA4 + anti-PD1. *First Author: Jennifer Leigh McQuade, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Obesity has recently been associated with improved outcomes in male, but not female, MM pts treated with single-agent anti-CTLA4 and with single-agent anti-PD1 immunotherapy. However, the association between BMI, sex, and outcomes in MM pts treated with combined anti-CTLA4 + anti-PD1 is unknown. **Methods:** We examined the association of WHO BMI category at treatment initiation with outcomes in an international, multi-institutional cohort of MM pts treated with anti-CTLA4 + anti-PD1. Kaplan-Meier analysis was used to estimate progression free survival (PFS) and OS. Associations between BMI, PFS, and OS were assessed in Cox proportional hazard models adjusted for age, sex, AJCC 8 stage, LDH, and performance status. **Results:** The cohort included 413 pts from 4 institutions. Median age was 57; 67% were male, 56% had ECOG PS > 0, 31% had elevated LDH, 46% had $BRAF^{V600}$ mutation. Clinical stage was 9% III, 12% M1a, 20% M1b, 40% M1c, 19% M1d. 75% of pts were overweight/obese (BMI$\geq$25), including 83% of males and 58% of females. In multivariable (MV) models, BMI was not associated with PFS (BMI$\geq$25 vs. BMI $<$ 25 HR 1.0, 95% CI 0.7-1.4) or OS (HR 1.0, 95% CI 0.6-1.7) in the full cohort. On sex-stratified MV analysis, BMI$\geq$25 was associated with shorter OS in females (HR 2.6, 95% CI 1.1-5.8); no significant association was detected in males (BMI$\geq$25 vs. BMI $<$ 25 HR 0.7, 95% CI 0.4-1.3; $p_{interaction} = 0.03$). BMI was not associated with PFS in either sex. Pts with higher BMI were more likely to have immune related adverse events (irAEs) leading to treatment discontinuation ($p = 0.03$); this association did not differ by sex. **Conclusions:** Higher BMI is associated with shorter OS in female MM pts treated with combined anti-CTLA4 + anti-PD1 immunotherapy. There was a significant interaction between BMI and sex, consistent with analyses of other cohorts. However, unlike observations in cohorts of MM pts treated with anti-PD1 or anti-CTLA alone, higher BMI was not associated with improved PFS or OS in males with combined anti-PD1 + anti-CTLA4. Rates of irAEs were higher in patients with higher BMI. Further studies should examine the basis for the observed associations.

9563 Poster Session (Board #390), Mon, 1:15 PM-4:45 PM

HORIZON: A French descriptive cohort of 663 patients treated for melanoma with pembrolizumab with a focus on the mucosal subgroup (n=59). *First Author: Caroline Dutriaux, Hôpital Saint-André,CHU Bordeaux, Bordeaux, France*

Background: Advanced mucosal melanoma is a rare subgroup of tumors for which few data on immune therapeutic approaches is available as they are rarely or not included in pivotal trials. Pembrolizumab, a monoclonal anti-PD1 antibody, has been approved in France as a first-line treatment of patients with advanced melanoma since October 2015. Although it has been shown to significantly improve OS and PFS of cutaneous melanoma, we have few data on its efficacy in mucosal melanoma. **Methods:** Horizon is a real-life setting descriptive cohort analysis of patients treated with pembrolizumab from June 2014 to September 2015 in the context of the French national early access program, at the dose of 2 mg/kg/3 weeks. Here are presented the results of the second interim analysis (data cut-off January 7th, 2017) in the mucosal melanoma subpopulation. **Results:** A total of 663 patients were included with a median follow-up of 12.95 months (95%CI: [11.15-16.16]). Among those patients, 59 (8,9%) had a primary mucosal melanoma. Twenty-two (37,3%) had no prior therapy. The median OS was 7.54 months (95%CI: [5.25-10.52]) versus 16.75 months (95%CI: [13.15-18.89]) in the non-mucosal melanoma population ($p < .0001$). The median PFS was 2.69 months (95%CI: [2.26-3.05]) versus 3.41 months (95%CI: [3.02-4.03]) in the non-mucosal group ($p < .0001$). The ORR was 11.9% (31.5% in the no- mucosal group), the DCR was 18.6% (44.2% in the non-mucosal group), and the median DR was 7.64 months (not reached in the non-mucosal group). Withdrawal of pembrolizumab was necessary for 47 patients (79,7%); the main reason for discontinuation was disease progression (68,1%), far ahead toxicity (14,9%) or complete remission (6,38%). Immune related adverse events were consistent with previous reports on pembrolizumab. **Conclusions:** Pembrolizumab provides objective activity in some mucosal melanoma patients, although less than that observed in the non-mucosal population. Anti-PD1 should be considered as a relevant treatment option for these patients. Nevertheless, further studies are warranted to describe underlying resistance mechanisms involved in order to improve management of this rare subgroup.

9564 Poster Session (Board #391), Mon, 1:15 PM-4:45 PM

Immune checkpoint inhibition (ICI) in advanced cutaneous squamous cell carcinoma (cSCC): Clinical response and correlative biomarker analysis. *First Author: Jong Chul Park, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: ICI has shown major benefit in cutaneous malignancies including melanoma and Merkel cell carcinoma. Efficacy data in cSCC is, however, limited. Here we report our institutional experience of anti-PD-1 therapy in patients (pts) with advanced cSCC, and biomarker analysis. **Methods:** We conducted a retrospective analysis of cSCC pts treated with nivolumab or pembrolizumab at Massachusetts General Hospital. NGS and IHC for PD-L1 expression and immune cell composition were performed, and correlation with response was analyzed. **Results:** 13 cSCC pts treated with ICI were identified, 7 of whom had predisposing conditions: CLL or other lymphoma (n = 3), xeroderma pigmentosum (n = 2), and Marjolin's ulcer (n = 2). 8 pts were treated with pembrolizumab and 5 with nivolumab. 9 pts (69%) had prior cytotoxic chemotherapy or cetuximab. At median follow-up of 16.5 months, 7 pts (62%) achieved objective responses with 2 complete responses. 4 pts had stable disease over 6 months and 2 had primary resistance. 12-month progression-free survival (PFS) and overall survival (OS) was 68.4 % and 83.3%, respectively. Median PFS and OS were not reached. Grade ≥ 3 adverse events were observed in 3 pts (23%), including 1 treatment-related death (myocarditis). Pre-treatment tissues were available for 11 pts. CD4, CD8 T cells and Tregs were present in variable frequencies and showed no association with response. PD-L1 expression in either tumor (TC) or immune cells (IC) was observed in most pts (78%). Mean TC and IC PD-L1 expression in responders vs nonresponders was 11.5 vs 0% and 5 vs 5%, respectively. TC but not IC PD-L1 expression correlated with response (cut-off 1%, $p = 0.04$). TP53, PIK3CA, DKN2A, and TERT promoter alterations were common. Tumor mutation burden analysis is underway, and its correlation to response will be analyzed. **Conclusions:** Our single institution "real-world" experience with anti-PD-1 therapy in advanced cSCC shows promising activity, including in pts who would not be eligible for clinical trial enrollment. PD-L1 expression was common and TC expression correlated with response. Further molecular analysis to identify potential predictive biomarkers is ongoing.

9566 Poster Session (Board #393), Mon, 1:15 PM-4:45 PM

Treatment of metastatic uveal melanoma (mUM) directed by a comprehensive molecular tumour analysis program (CMTA). *First Author: Serge Leyvraz, Charité Comprehensive Cancer Center, Berlin, Germany*

Background: There is a lack of active treatment against mUM. Such "hard-to-treat" tumour might benefit from treatment decisions driven by a complete genomic and transcriptomic analysis program. **Methods:** From 1.3.2016 to 1.12.2017, mUM were included in the prospective TREAT20Plus study and were subjected to a CMTA including WGS, WES, RNAseq, cell culture and systems biological/pharmacodynamic modelling. Treatment recommendations were made by a molecular tumour board. **Results:** Twenty six patients (12 F, 14M). Age: 61 (32-80). PS: 0 (0-2). Metastases: 4 (1-10). Abnormal LDH: 19. Pre-treatment: 1 (0-5) and type: iv chemotherapy: 11, checkpoint-inhibitors (-i): 7, intra-hepatic: 13, vaccine: 1. Insufficient material in 3 patients. The mutation burden was low: 32 (15-449). The treatment recommendations (TRec) were based on the different mutations or activation profiles: A) MEK-i. for mutations of *GNAQ*: 11, *GNA11*: 13. B) a MET-i. for MET overexpression: 17. ALK-i. for the oncogenic ALK^{ATI} isoform: 3. C) CDK4/6-i. for CDKN2A loss: 1. D) checkpoint-i. for mutation burden > 100: 3. E) For the other alterations no off-label treatment was available: mutation of *BAP1:* 8 or *SF3B1: 10,* overexpression of *MYC*: 14, *BCL2*: 24, *CCND2*: 16, *ERBB3*: 5 , biallelic loss of TNFAIP3: 1. Among novel non-recurring gene-fusions: inactivating gene fusion affecting MITF: 1. In 1 patient repeated biopsies at time of recurrence after MEK-i disclosed biallelic loss of *CDKN2A*. The pharmacodynamic modeling confirmed TREc in 10 and helped with the decision in 8 patients. A treatment was initiated in 15 patients: Trametinib: 6, Cabozantinib: 3, Crizotinib: 6, Palbociclib: 1. A treatment was not initiated for 8 patients: 4 too early, 4 rapid progression. Among the 12 evaluable patients the antitumor response was: minor response: 2, stable disease: 4, progressive disease: 5, too early: 1. Median PFS of the treated patients: 5,5 months. **Conclusions:** Precision medicine in mUM is clinically feasible. It leads to a better understanding of the biology of the tumour and of the potential therapeutic targets. Its clinical efficacy is limited by the non-availability of drugs as single agent or in combination. Clinical trial information: EA4/063/13.

9567 Poster Session (Board #394), Mon, 1:15 PM-4:45 PM

Adverse events of special interest in the phase 3 COLUMBUS study. *First Author: Helen Gogas, First Department of Medicine, Laiko General Hospital, National and Kapodistrian University of Athens School of Medicine, Athens, Greece*

Background: Combination BRAF/MEK inhibitor (BRAFi/MEKi) therapy is standard of care for *BRAF*V600-mutant metastatic melanoma. In COLUMBUS Part 1, encorafenib 450 mg once daily (QD) + binimetinib (BINI) 45 mg twice daily (BID) (COMBO450) reduced risk of progression or death vs encorafenib 300 mg QD (ENCO300) or vemurafenib 960 mg BID (VEM) in patients (pts) with advanced *BRAFV600*-mutant melanoma. Adverse events of special interest (AESIs) including pyrexia, serous retinopathy, photosensitivity, and rash are reported here. **Methods:** Pts were randomized 1:1:1 to receive COMBO450, ENCO300, or VEM. Pts had standard physical and laboratory assessments, and regular dermatologic, cardiac, and ophthalmologic evaluations. AESIs comprised known effects of available BRAFi and/or MEKi. **Results:** Safety was evaluated in 192, 192, and 186 pts in the COMBO450, ENCO300 and VEM arms, respectively. Median duration of exposure to treatment was 51 weeks for each component in the COMBO450 arm, 31 weeks in the ENCO300 arm, and 27 weeks in the VEM arm. Pyrexia incidence with COMBO450 was low (grade 1/2: 14%; grade 3: 4%) and led to treatment discontinuation in 1% of pts and to dose modification in 4%. Photosensitivity was infrequent with COMBO450 (grade 1/2: 4%; grade 3: 1%), required dose modification in 1% of cases, and did not lead to treatment discontinuation. Rash occurred in 22% of pts with COMBO450 (grade 1/2: 21%, grade 3: 1%, grade 4: 1%), led to discontinuation in 0.5%, and to dose modification in 2%. Serous retinopathy (grade 1/2: 17%; grade 3: 3%) and left ventricular dysfunction (grade 1/2: 6%; grade 3: 2%) with COMBO450 did not lead to discontinuation and were generally reversible (in 89% and 93% of pts, respectively). **Conclusions:** Common BRAFi/MEKi toxicities were generally manageable and reversible and were infrequently associated with treatment discontinuation. Pyrexia and photosensitivity were uncommon with COMBO450. The observed safety profile suggests COMBO450 may provide a meaningfully differentiated treatment option for patients with *BRAF*V600-mutant melanoma. SPONSOR: Array BioPharma Inc. Clinical trial information: NCT01909453.

9568 Poster Session (Board #395), Mon, 1:15 PM-4:45 PM

Multi-spatial whole-lesion molecular heterogeneity of an immunotherapy-resistant metastatic melanoma. *First Author: Akash Mitra, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Genomic and immune intratumor heterogeneity (ITH) can be a major reason for therapy failure in patients undergoing checkpoint blockade immunotherapy. Here, we report comprehensive molecular and immune analysis of a sequential anti-CTLA-4- and anti-PD-1-resistant metastatic lesion, sampled and reconstructed in 3D, combined with a longitudinal view of a pre-immunotherapy lesion. **Methods:** We performed 3D reconstruction of a metastasis obtained at palliative surgery from a patient progressing on sequential anti-CTLA-4 and anti-PD-1 therapy utilizing genomic (gene expression, methylation, whole exome sequencing and neoantigen prediction) and immune (immunohistochemistry, RNA- and DNA-based T cell receptor sequencing) profiling of 67 spatially distinct regions. **Results:** Limited point-mutation heterogeneity was found in melanoma driver genes however, copy number alteration analysis revealed changes over time and space with gain of chromosome 7 and 13, and loss of chromosome 10 in spatially-distinct regions. Differences in immune signatures were observed across regions of the tumor with pockets of immune activation and suppression. TCR profiling revealed dominance of three T cell clonotypes distributed across the tumor, highlighting spatial patterns in tumor immunogenicity and T cell response. Neoantigen prediction and expression indicated the persistence of a neoantigen detectable prior to anti-CTLA-4 therapy enriched in different regions of the post-anti-PD-1 tumor. Gene expression correlated with the distribution and dominance of a specific T cell subclone. **Conclusions:** 3D-reconstruction of a sequential immune checkpoint blockade treated progressing tumor shows marked spatially-distinct genomic and immune ITH in the setting of a relatively homogenous somatic gene mutation landscape. As immune markers move into the mainstream for use as biomarkers, the use of single biopsies to inform treatment choice may be confounding. These data further impress the need for comprehensive, integrated molecular phenotyping approaches to unravel immunotherapy response and resistance in metastatic melanoma.

9569 Poster Session (Board #396), Mon, 1:15 PM-4:45 PM

Immune checkpoint inhibitor (ICI) treatment in advanced melanoma (aMel) patients (pts) with renal or hepatic dysfunction (dysf): Real-world patient characteristics and outcomes. *First Author: Susan Spillane, Division of Cancer Epidemiology and Genetics, National Cancer Institute, Rockville, MD*

Background: ICIs were approved for first line (1L) therapy in aMel. However, pts with renal or hepatic dysf are often excluded from clinical trials; little is known about usage or outcomes for these pts. **Methods:** We retrospectively analyzed de-identified real-world data aggregated by Flatiron Health from US community oncology practices. Pts had confirmed aMel, a documented order/administration of an ICI as 1L therapy from 1/1/11 to 12/1/17 and ≥1 hepatic or renal lab value up to 30 days before 1L start. Renal [serum creatinine (cr)] and hepatic [total bilirubin (Tbili), aspartate aminotransferase (AST), and alanine aminotransferase (ALT)] function labs were graded by Common Terminology Criteria for Adverse Events v4.03. Dysf was defined as grade 2+. Categorical variables were assessed using Chi-square test; continuous variables with Kruskal-Wallis test; therapy duration and OS with log-rank test. **Results:** 1475 pts with relevant data were identified (Table). **Conclusions:** In this real-world aMel cohort, <3% of ICI-treated pts had baseline hepatic or renal dysf. Relative to pts with normal organ function, pts with baseline renal dysf were more often male and were more likely to be older. Although only hepatic dysf was significantly associated with shorter ICI duration, both renal and hepatic dysf pts had significantly shorter median OS. The OS findings may reflect competing risk from underlying comorbidities, practice patterns, tolerance (renal dysf), toxicity and/or ICI efficacy in the setting of organ dysf. Additional research is needed to better understand ICI treatment for real-world pts with baseline renal or hepatic dysf.

Characterization and spatial localization of the tumor immune microenvironment in metastatic uveal melanoma. *First Author: Kimberly Mayumi Komatsubara, Columbia University Medical Center, New York, NY*

Background: Uveal melanoma (UM) is a rare subset of melanoma that is resistant to immune checkpoint blockade. High density of macrophages (Mϕ) and TILs is associated with poor prognosis in primary UM but little is known about the tumor microenvironment (TME) in metastatic UM (MUM). Here we performed quantitative spatial analysis using multiplex immunohistochemistry (mIHC) to characterize the TME in MUM, compare the TME of MUM to metastatic cutaneous melanoma (MCM), and identify potential mechanisms of MUM resistance to immunotherapy. **Methods:** We identified pts with untreated metastatic melanoma with clinical follow-up and available pre-treatment tissue who consented to an IRB-approved protocol. 5μm slides were stained using Opal mIHC for DAPI, CD3, CD8, CD68, HLA-DR, Ki67, and SOX10. Tumor areas were pre-selected by a dermatopathologist, visualized using Vectra and analyzed for density and spatial localization using inForm software. **Results:** 6 MUM and 8 MCM cases were evaluable at the time of this analysis. CD3+ and CD8+ T-cell density is similar between MUM and MCM, however, there is a trend towards a higher density of proliferating cytotoxic T lymphocytes (CTL) (CD8+Ki67+) in MCM ($p = 0.05$). Interestingly, CD68+ Mϕ density is lower in MUM compared to MCM ($p = 0.03$). Both CD68+HLA-DR+ Mϕ (activated) and CD68+HLA-DR- Mϕ (inactivated) density is lower in MUM. Using nearest neighbor spatial analysis, CD8+ CTLs are significantly farther from activated Mϕ (CD68+HLA-DR+) ($p = 0.01$), but not from inactivated Mϕ (CD68+HLA-DR-) in MUM compared to MCM. **Conclusions:** Unlike primary UM, our sample of untreated MUM is not characterized by a high Mϕ density. Fewer Mϕ are present in untreated MUM compared to MCM and activated Mϕ are located farther from CTLs in UM. Density of CTLs is similar in MUM and MCM, although proliferating CTL are more numerous in MCM. These preliminary results suggest that Mϕ may play a less prominent role in innate resistance to immunotherapy in MUM. Gene expression analysis and further classification of Mϕ type is ongoing. Additional cases are ongoing analysis and will be reported.

9571 Poster Session (Board #398), Mon, 1:15 PM-4:45 PM

Factors predicting the use of immunotherapy for patients with advanced melanoma. *First Author: Richard Wayne Joseph, Mayo Clinic, Jacksonville, FL*

Background: Both pembrolizumab (PEMBRO) and the combination of ipilimumab and nivolumab (IPI+NIVO) are approved by the US FDA for treatment of advanced (unresectable or metastatic) melanoma. Clinical trials have demonstrated different benefit-risk profiles associated with each that may impact selection in the real-world. We performed a retrospective chart review of patients with advanced melanoma to understand patient characteristics associated with PEMBRO vs IPI+NIVO treatment selection. **Methods:** A retrospective, chart-review study was conducted in the US; 12 oncologists from 12 US academic centers and affiliated satellite clinics were recruited to contribute patients ≥18 years of age with advanced melanoma receiving PEMBRO or IPI+NIVO in any line between Jan 1, 2016 – Dec 30, 2017. Demographics and baseline disease characteristics were compared between cohorts in univariate analysis. A mixed-effects logistic regression model with site of treatment specified as a random effect was created to predict PEMBRO vs IPI+NIVO selection using parameters identified in univariate analysis. **Results:** 400 patients were included, 200 each PEMBRO and IPI+NIVO. There were no significant differences in mean age, race, gender, family income, education level, insurance status, comorbidity index, site of metastasis, and line of therapy between the cohorts. However, the PEMBRO cohort had poorer Eastern Cooperative Group (ECOG) status at treatment start 70.5% ECOG 0 or 1 vs 88.0% ($p < 0.001$), were more likely to be PD-L1 positive (76.9% vs 63.1%, $p = 0.011$), and less likely to harbor a BRAF mutation (34.8% vs 49.7%, $p = 0.003$). In regression, PEMBRO was favored over IPI-NIVO in ECOG 2-3 patients vs 0-1 (OR 6.6, 95%CI 3.0, 14.7), and PD-L1 expression positive (OR 4.5, 95%CI 1.9, 10.4). Those with BRAF wild-type were more likely to receive PEMBRO (OR 2.2, 95%CI 1.4, 3.6) than IPI+NIVO. **Conclusions:** In the real-world, patient factors are significantly associated with treatment selection in advanced melanoma. PEMBRO appears to be selected more often than IPI+NIVO in patients with poorer ECOG performance status, PD-L1 positive tumors, BRAF wild-type tumors. Any real-world comparison of outcomes between treatments should take this into consideration.

9572 Poster Session (Board #399), Mon, 1:15 PM-4:45 PM

Perilesional edema and blood vessel characteristics in brain metastases and implications for treatment with immune therapy. *First Author: Thuy Tran, Yale-New Haven Smilow Hospital, New Haven, CT*

Background: Little is known about tumor-associated vasogenic edema in brain metastasis, yet it is the cause of significant morbidity and mortality. Our purpose was to better characterize edema and vessel leakage in humans treated with anti-PD1 and in pre-clinical models. We hypothesized that the etiology of tumor edema is multifactorial and not dependent on tumor volume mass effect alone. **Methods:** We analyzed tumor and edema volume in 18 non-small cell lung (NSCLC) and 18 melanoma patients with untreated brain metastasis treated with pembrolizumab. Cerebral melanoma tumors were stained with anti-CD34 to determine vessel density and the association with vascular leak. We employed an *in vitro* model of the blood-brain barrier using short term cultures from melanoma brain and extracranial metastases to determine tight junction resistance. **Results:** While larger tumors tended to have more edema, the correlation was weak (R^2= 0.30). Edema:tumor volume ratios are similar in NSCLC and melanoma brain metastasis and were not associated with response (P> 0.50), progression-free (P= 0.22), or overall survival (P= 0.17). Patients responding to pembrolizumab had concurrent shrinkage of edema volume (R^2= 0.81). Vessel density by CD34+ cell staining on brain metastasis samples was not correlated with perilesional edema on imaging. Melanoma brain metastasis cells in culture were able to cause decreases in tight junction resistance in an *in vitro* system, whereas cell cultures from extracerebral samples did not. **Conclusions:** Additional factors aside from tumor mass effect cause perilesional edema. Edema itself should not deter physicians from using PD-1 inhibitors; pembrolizumab-sensitive tumors tend to have decreases in both tumor volume and edema on treatment. Factors other than vessel density result in endovascular leak, and should be further studied. Moreover, melanoma cells themselves can cause vessel leakiness in an experimental system void of immune cells, suggesting they secrete properties that affect tight junctions, which might be harnessed for pharmacologic targeting.

9573 Poster Session (Board #400), Mon, 1:15 PM-4:45 PM

Effects of sonidegib dose reduction or delay in locally advanced basal cell carcinoma: 42-month data from BOLT. *First Author: Karl D. Lewis, University of Colorado Comprehensive Cancer Center, Aurora, CO*

Background: Sonidegib is a hedgehog pathway inhibitor (HPI) approved for the treatment of locally advanced basal cell carcinoma (laBCC) not amenable to curative surgery or radiotherapy. Patients treated with sonidegib may require dose reductions and/or interruptions to manage adverse events, and the impact of these adjustments on the long-term efficacy is unknown. **Methods:** BOLT was a randomized, double-blind, multicenter phase 2 study (NCT01327053). Patients with advanced BCC not amenable to curative surgery/radiotherapy and naive to HPI treatment were randomized 1:2 to sonidegib 200 mg or 800 mg QD, respectively. Data were analyzed at 6, 12, 18, 30, and 42 months. Patients receiving 800 mg were allowed two dose reductions (to 400 mg and 200 mg QD, respectively) for an adverse event (AE) related to sonidegib; among patients in the 200-mg arm, a delay was instituted until the AE resolved to ≤ grade 1. The primary endpoint was objective response rate (ORR) per central review; ORR by investigator review was analyzed as a secondary endpoint. We compared ORR in laBCC patients with (≥1) and without dose reduction/delay at the 42-month follow-up. **Results:** ORRs remained consistent with prior follow-up analyses. The frequency of dose reduction/delay was lower in the 200 mg (18%) vs. 800 mg (38%) arm (Table). Importantly, dose reduction/delay did not compromise efficacy. ORRs by investigator assessment were consistently higher than by central review. **Conclusions:** These data support long-term efficacy of sonidegib at the approved dose of 200 mg daily, and also suggest that dose reductions and/or treatment delays are possible without negatively impacting efficacy. Clinical trial information: NCT01327053.

ORR in sonidegib-treated patients by dose reduction/delay (central and investigator review).

Mutational and immune gene expression profiling at relapse in patients (pts) treated with adjuvant dabrafenib plus trametinib (D + T) or placebo (pbo) in the COMBI-AD trial. *First Author: Reinhard Dummer, University Hospital Zürich Skin Cancer Center, Zürich, Switzerland*

Background: In the COMBI-AD trial, adjuvant D + T resulted in a significant relapse-free survival benefit (HR, 0.47 [95% CI, 0.39-0.58]; $P < .001$) vs pbo in pts with resected stage III *BRAF* V600E/K–mutant melanoma. At a median follow-up of 2.8 y, 37% of pts in the D + T arm and 57% in the pbo arm had relapsed. Resistance mechanisms are largely unknown in the adjuvant setting. We report mutational and immune gene expression profiling at relapse in COMBI-AD. **Methods:** COMBI-AD (NCT01682083) randomized pts with resected stage III *BRAF* V600E/K–mutant melanoma to receive D + T or pbo. DNA and RNA were extracted from the same relapse sample. Mutational landscape and immune gene expression signature were examined by sequencing 570 genes (mean depth ≈ 500×) and gene expression profiling using a customized NanoString panel. Plasma samples were subjected to ctDNA profiling (73 genes). **Results:** At relapse, 66 tissue samples (D + T, n = 24 [n = 4 relapsed on treatment]; pbo, n = 42) were collected (20 distant, 43 local/regional, 3 secondary primary melanoma). Paired baseline samples were available in most cases (n = 57). A *BRAF* V600E/K mutation was detected in all relapse samples except in 1 secondary primary melanoma. The genomic landscape was as expected for melanoma: the most common non–*BRAF* V600 genetic aberrations were *CDKN2A* (38%), *CDKN2B* (24%), *PTEN* (23%), *TP53* (18%), and *ARID2* (14%), and median tumor mutation burden (TMB) was ≈ 10 SNVs/Mb. No substantial differences in mutation frequency, TMB, or *BRAF* copy number were noted in relapse vs baseline samples or between treatment arms. Putative genetic resistance mechanisms in the MAPK (eg, *MAP2K1*, *NRAS* mutations) and non-MAPK (eg, PI3K pathway mutations) pathways were found in a small subset of relapse samples from pts treated with D + T. No significant differences in T-cell–specific/immune gene expression signatures were observed between arms. **Conclusions:** Although mutations in MAPK and non-MAPK pathways were found in a few relapse samples, no uniform adaptations were observed, suggesting that resistance to adjuvant D + T is caused by various genetic/epigenetic mechanisms. Clinical trial information: NCT01682083.

9575 Poster Session (Board #402), Mon, 1:15 PM-4:45 PM

Gut microbiome and immunotherapy response in melanoma patients. *First Author: Brandilyn Peters, NYU School of Medicine, New York, NY*

Background: Treatment of melanoma with checkpoint blockade immunotherapy brings potential for long-term freedom from progression. However, responses to immunotherapy are heterogeneous, and improving outcomes remains a critical need. We explored whether gut microbiota may modulate response to immunotherapy. **Methods:** Stool was collected from 26 stage 3-4 melanoma patients at NYU Langone Health, prior to immunotherapy (Ipi, Nivo, Ipi+Nivo, or Pembro). We conducted 16S rRNA gene sequencing on Illumina MiSeq, followed by the QIIME2 Deblur workflow to characterize taxonomic composition. We examined bacterial community α- and β-diversity, and taxon abundance, in relation to time to disease progression, using survival methods and adjusting for age and sex. **Results:** During follow-up (range: 3-18 months), 12 patients progressed. Higher community diversity was marginally associated with lower risk of progression (Shannon index HR = 0.40; 95% CI = 0.14-1.17; p = 0.09). Overall community composition was also marginally associated with time to progression, according to the non-phylogenetic Jensen-Shannon Divergence (MiRKAT-S p = 0.07 with 1000 permutations), but not according to the phylogenetic weighted UniFrac distance (p = 0.26). Centered log ratio-transformed abundance of several bacterial taxa was related to risk of progression ($p < 0.05$), though small sample size limited detection of associations after false discovery rate adjustment (all $q > 0.44$). An operational taxonomic unit (OTU) within *Faecalibacterium prausnitzii* was associated with significant risk reduction (HR = 0.71; 95% CI = 0.57-0.88; p = 0.002), resulting in significance at higher taxonomic levels (*Faecalibacterium* genus and *F. prausnitzii* species, p = 0.02). Additionally, genus *Desulfovibrio* (HR = 1.24; 95% CI = 1.04-1.49; p = 0.02) and an OTU in *Ruminococcus gnavus* (HR = 1.49; 95% CI = 1.12-2.00; p = 0.007) were associated with increased progression risk. **Conclusions:** We observed that gut microbiome is associated with response to immunotherapy, suggestive that microbiome manipulation may improve immunotherapy outcomes. Forthcoming shotgun metagenome and metatranscriptome sequencing of these samples will further elucidate species and functions related to response.

Validation of a prognostic 53-immune-gene panel in stage II/III melanoma. *First Author: Margaret Borgardus, Columbia University College of Physicians and Surgeons, New York, NY*

Background: Patients with resected stage II/III melanoma are at high risk of systemic metastasis and prognostic indices to stratify these patients for adjuvant immunotherapy. We previously defined and validated a 53-immune-gene panel predictive of non-progression (AUC = 0.787), recurrence free survival (RFS, $p < 0.001$) and disease specific survival ($p = 0.024$). Here, we present a second validation of the prognostic ability of this immune-gene panel in an independent cohort of 81 patients with stage II/III primary melanoma. **Methods:** Dermatopathology reports for 1349 melanoma patients seen at Columbia University Medical Center between 2001 and 2014 were queried to identify 81 patients with stage II-III primary melanoma with FFPE tissue and at least 24 months of clinical follow-up available. Presence of tumor was confirmed by a dermatopathologist, RNA was extracted from tissue, and expression of the 53-immune-gene panel was assessed using NanoString. Data was processed using nSolver software and prediction score calculated. **Results:** 81 patients with stage II-III primary melanoma were analyzed, of whom 61 were alive or had no evidence of disease at death and 20 died from melanoma. Of the 81 patients, 69 had progression data available, 22 patients had progression of disease, while 47 had non-progression. Prediction scores correlated with non-progression (AUC = 0.722). In the complete 81 patient cohort, the signature correlated with disease specific survival ($p = 0.008$) and overall survival ($p = 0.0007$). Over the course of follow up 36 patients died. Using median score as a cutoff, hazard ratio for death in the high risk group was 2.8 (95% CI 1.3-6.0). **Conclusions:** We validate in a second retrospective population the prognostic ability of our previously-identified 53-immune-gene panel in patients with stage II/III primary melanoma. The 53-gene panel may constitute a powerful clinical tool to aid in predicting disease course in melanoma and may allow for stratification of patients for adjuvant immunotherapy, facilitating rapid acquisition of significant survival statistics in clinical trials. Prospective retrospective (PRA) validation of the signature in samples collected as part of the E1697 trial of adjuvant interferon is planned.

9577 Poster Session (Board #404), Mon, 1:15 PM-4:45 PM

A multi-gene risk signature for improved identification of cutaneous squamous cell carcinoma (cSCC) patients with a high risk of recurrence. *First Author: Chrysalyne Schmults, Brigham & Women's Hospital, Boston, MA*

Background: cSCC is rivaled only by basal cell carcinoma as the most common cancer in the U.S. Though most cases are cured by excision, a subset recur and become incurable with number of deaths approximating melanoma (Karia et al., *JAAD*, 2012). Identifying the subset at risk of recurrence is critical for development of clinical trials in cSCC which has no FDA-approved treatments and very few phase II trials. Therefore, we set out to develop a gene expression-based biomarker associated with disease recurrence/metastasis in cSCC. **Methods:** According to an IRB approved multicenter protocol, 230 primary cSCC tumors were analyzed for mRNA expression of 73 candidate genes reported to be associated with cSCC metastasis. After quality filtering, 63 genes and 212 samples were included in the predictive model construction. Multiple machine learning algorithm approaches were applied with 75% of the specimens used for training and the remaining 25% used for validation. **Results:** Six genes demonstrated consistent expression across all samples tested and were used as controls to normalize expression values of the remaining genes. Eighteen genes were differentially expressed between recurrent and non-recurrent cases. Evaluation of the genes with multiple predictive modeling methods identified an optimal model that was 71% sensitive, 90% specific, had a 50% positive predictive value (PPV), and a 96% negative predictive value (NPV) for recurrence. **Conclusions:** This study developed a predictive model for risk of recurrence with a much higher PPV than staging criteria developed by Brigham and Women's Hospital and the American Joint Committee on Cancer (50% vs. approximately 24% and 18% respectively) while maintaining a high NPV (Karia et al., *JCO* 2014; Karia et al., *JAMA Dermatology*, 2017). Clinical application of such a prognostic test with a robust PPV (50% risk of recurrence) will enable identification of cSCC patients who may be appropriate for therapeutic intervention beyond surgical clearance (e.g. nodal staging and/or adjuvant radiation) and enrollment in clinical trials evaluating contemporary therapies.

9578 Poster Session (Board #405), Mon, 1:15 PM-4:45 PM

Time to treatment failure (TTF) as a potential clinical endpoint in real-world evidence (RWE) studies of melanoma. *First Author: Rajeshwari Sridhara, U.S. Food and Drug Administration, Silver Spring, MD*

Background: Time to treatment failure (TTF) has been suggested as a practical clinical endpoint for studies of oncologic agents using real-world evidence (RWE). However, TTF is rarely studied as an endpoint in the clinical trial setting; thus, little is known about its association with commonly used endpoints such as progression-free survival (PFS) or overall survival (OS). **Methods:** All studies submitted to CDER as part of a marketing application between 2010 and 2016 for treatment of patients with advanced melanoma were considered. 11 phase 3, randomized, and active-controlled trials were included in this analysis; 3 studies had 3 arms, resulting in a total of 25 randomized arms. Therapeutic agents were categorized as chemotherapy (CT), single agent PD-1 inhibitors (PD1), all immunotherapy (IT), and targeted therapy (TT). Patient-level association between TTF and PFS or OS was determined using correlation coefficients (corr) for each trial and for each therapeutic category. Additionally, to determine associations of trial-level comparative efficacy measures, pair-wise analyses were performed of hazard ratios (HR) for TTF, PFS, and OS using a weighted linear regression model. **Results:** 6021 patients from 11 clinical trials were included in the analysis. Patient-level corr for each trial ranged from 0.62 to 0.93 for TTF and PFS and from 0.53 to 0.82 for TTF and OS. Corr between TTF and PFS, and TTF and OS by therapeutic category are listed in the Table below. Trial-level associations between TTF HR & PFS HR and TTF HR & OS HR in all patients were poor. However, in TT these associations were much stronger (TTF & PFS: $R^2 = 0.56$ and TTF & OS: $R^2 = 0.80$). **Conclusions:** Though these analyses indicate a clear association of TTF & PFS for all categories, the association of TTF & OS may only exist for a few therapeutic categories. Extension of this work to other disease types and therapeutic categories would benefit the discussion of clinical endpoints for RWE.

Therapeutic Category	N	mTTF	mPFS	mOS	Corr of TTF & PFS	Corr of TTF & OS
All patients	6021	5.1	5.1	18.7	0.80	0.60
CT	786	2.3	2.1	11.2	0.65	0.35
PD1	1354	8.4	6.2	28.2	0.86	0.67
IT	2937	3.2	3.5	18.7	0.79	0.58
TT	2298	7.5	7.4	19.8	0.79	0.72

9579 Poster Session (Board #406), Mon, 1:15 PM-4:45 PM

Blood-based multiplex kinase activity profiling as a predictive marker for clinical response to checkpoint blockade in advanced melanoma. *First Author: Daan Hurkmans, Erasmus Medical Center, Rotterdam, Netherlands*

Background: Prediction of clinical responses to checkpoint inhibitor therapies is urgently needed. Notably, a significant proportion of patients does not benefit from the treatment, agents are costly and may cause serious toxicity. The kinase activity of peripheral blood cells (PBMCs) may reflect biological mechanisms underlying response to immunotherapy. We hypothesized that kinase activity profiles from PBMCs may constitute a predictive marker for clinical response to CTLA4 and/or PD1 blockade immunotherapy in patients with advanced melanoma. **Methods:** In a multicenter effort, data were prospectively collected from 6 cohorts of anti-CTLA4- or anti-PD1-treated advanced melanoma patients (n = 138). Kinase activity profiles were generated by analyzing phosphorylation signatures of PBMC lysates on a peptide micro-array. The PamChip (PamGene, Netherlands) microarray comprises 144 different peptides derived from protein phosphorylation sites that are substrates for protein tyrosine kinases. Performance of the predictive model (PLS-DA) was estimated using cross-validation and described by correct classification rate (CCR). Analyses were based on binary grouping of best overall response (RECIST v1.1; CR/PR/SD vs PD) and early/late progression using PFS data (cut-off 140 days). **Results:** Predictive signatures were discovered for anti-CTLA4 in cohort 1 (anti-CTLA4; n = 10; CCR = 100%; 95%CI 69-100%) and confirmed in cohort 2 (anti-CTLA4; n = 28; CCR = 82%; 95%CI 63-94%), as well as for anti-PD1 in cohort 3 (anti-PD1; n = 17; CCR = 76%; 95%CI 50-93%), which was confirmed in cohort 4 (anti-PD1; n = 29; CCR = 72%; 95%CI 53-87%), cohort 5 (anti-PD1; n = 38; CCR = 75%; 95%CI 57-87%), and cohort 6 (anti-PD1; n = 16; non-evaluable due to the low number of responders). **Conclusions:** In advanced melanoma patients, kinase activity profiles of baseline PBMCs samples can predict the likelihood of response to anti-PD1 or anti-CTLA4 therapy. This assay may serve as a rapid and fast predictive liquid biomarker to stratify patients prior to treatment. Involvement of receptor tyrosine kinases underlying the mechanism are being further elucidated and a larger validation study is underway.

9580 Poster Session (Board #407), Mon, 1:15 PM-4:45 PM

Quantitative multiplex immunofluorescence (qmIF) and genomic evaluation of tumor microenvironment (TME) to identify candidate biomarkers in stage II/III melanoma. *First Author: Robyn Denise Gartrell, Columbia University Medical Center, New York, NY*

Background: Biomarkers are needed to risk stratify for adjuvant trials in early stage melanoma. Features of the immune infiltrate within the TME are hypothesized to be prognostic, but quantification methods are not standardized for clinical practice. Expression profiling of stage II/III melanoma shows that Th1 genes have prognostic value. Combination of genomic and qmIF analyses of the TME may identify prognostic immune biomarkers. **Methods:** We performed qmIF analysis on 104 primary melanoma tumors (stage II-III) diagnosed at Columbia University Medical Center from 2000-2012. Tissue was stained for DAPI (nuclei), CD3 (T cell), CD8 (cytotoxic T cell (CTL)), CD68 (Mj), SOX10 (tumor), HLA-DR (activation) and Ki67 (proliferation). Phenotyping was performed with inForm software. High/low density cut-offs were defined by Classification and Regression Tree Analysis (CART) and Receiver Operating Characteristic (ROC) curves. For 64 patients (pts), with known of cause of death, KM curves were calculated. mRNA expression analysis for 63 immune genes (NanoString) was performed on 44 of 64 pts for whom sufficient tissue was available. **Results:** On qmIF, we find that high CTL and low Mj infiltration, particularly when located in the stroma, correlates with disease specific survival (DSS) ($p = 0.004$ and $p < 0.001$, respectively). Of greatest significance, when combined, low stromal CTL/Mj ratio correlates with death from melanoma using ROC (AUC = 0.724, $p = 0.026$). By AUC cutoff, low CTL/Mj ratio predicts poor DSS ($p = 0.003$) and overall survival (OS) ($p = 0.008$). On multivariable cox analysis, low CTL/Mj was independently associated with DSS ($p = 0.002$) and OS ($p = 0.020$). Genomic analysis identified increased expression of CXCL9, CXCR3, CCL5 and CD37 in non-recurrent pts ($p < 0.050$ after bonferoni correction) which did not correlate with CTL/Mj ratio. **Conclusions:** Multiparameter phenotyping of stage II/III melanoma pts shows that stromal CTL/Mj ratio strongly correlates with survival. mRNA analysis shows that high Th1 gene expression correlates with non-recurrence. Combination of qmIF and mRNA analysis may be useful in stratifying pts to receive immunotherapy.

9581 Poster Session (Board #408), Mon, 1:15 PM-4:45 PM

Phylogenetic analysis of longitudinal melanoma samples to reveal convergent evolution and markers of immunotherapy resistance. *First Author: David Liu, Dana-Farber Cancer Institute, Boston, MA*

Background: Immune checkpoint inhibitors (ICI) have revolutionized treatment in metastatic melanoma (MM), but progression occurs in the majority of patients (pts), and the evolution of resistance to immunotherapy in individual pts is not well characterized. **Methods:** Matched longitudinal tumor and germline samples from MM pts treated with ICI underwent whole exome sequencing (WES), bulk RNAseq, bisulfite sequencing, and multiplex immunofluorescence (IF) staining. Single nucleotide variants, small insertions and deletions, copy number alterations, tumor purity and ploidy, and tumor heterogeneity were inferred using standardized analytical pipelines. Phylogenetic analysis was conducted and validated using independent Bayesian clustering approaches. **Results:** 23 longitudinal tumor samples from a pt with delayed complete response to sequential ipilimumab and nivolumab were sequenced and analyzed. Samples spanned a three year time frame, from pre-treatment primary (n = 1), palliatively resected on-treatment lesions (n = 20), and escape lesions (n = 2, small bowel and brain) which appeared after a 2 year disease-free interval. Mutational load was similar (~500 somatic mutations per tumor) with 400 shared mutations, including driver mutations in *IDH1*, *MAP2K1*, *CTNNB1,* and *ARID2*. Phylogenetic analysis identified 5 melanoma lineages arising out of a common ancestor, with multiple spatially separated lineages co-existing in time. The escape lesions arose out of a lineage characterized by 15q arm loss (including *B2M*), with further acquisition of a genome doubling event as well as biallelic *CDKN2A* loss compared to earlier tumors within the lineage. Interestingly, biallelic *PTEN* loss was found across lineages and in 12/13 tumors after day 39 of therapy compared to 4/10 tumors prior ($p = 0.02$, Fisher's Exact), suggesting convergent evolution. Further analysis of tumor epigenetics, transcriptomics, functional proteomics, and IF is ongoing. **Conclusions:** Our results suggest that multiple mechanisms of immunotherapy resistance develop within the same pt. More broadly, phylogenetic analyses of longitudinal tumor samples may shed light on the clinical evolution of resistance.

9582 Poster Session (Board #409), Mon, 1:15 PM-4:45 PM

Impact of a gene expression profiling risk score and web-based melanoma outcome calculator on the precision of AJCC-based prognostic assessment. *First Author: Georg Brunner, NeraCare GmbH, Cologne, Germany*

Background: AJCC staging of primary cutaneous melanoma (CM), based on clinico-pathological criteria, is limited in its ability to provide a precise prognosis for all patients. To improve risk assessment, a prognostic eight-gene expression profiling (GEP) risk score was identified in CMs and adjacent stroma, predicting clinical outcome, independently of and synergistically with AJCC staging. For the same purpose, a web-based melanoma outcome calculator (MOC) was developed (www.CancerMath.net). This study evaluated single and combined prognostic performance of both tools in complementing AJCC-based prediction of melanoma-specific survival (MSS). **Methods:** Five-yr MSS probabilities were prognosticated by multivariate Cox models, including GEP score + AJCC parameters or MOC parameters. To assess prognostic improvement, the models were compared to each other and to a reference model based on AJCC parameters only (Breslow, ulceration, node status). Data analyses (n=529 CMs, AJCC stages IA-IIIC, median follow-up 65 months) had been pre-specified. **Results:** *GEP score and MOC both improved precision of 5-yr MSS prediction by AJCC* (sensitivity + specificity increased by GEP: 14%, $p<0.001$; by MOC: 11%, $p<0.001$, by GEP + MOC: 15%, $p<0.001$). Combining GEP score and MOC improved precision of 5-yr MSS prognosis by MOC alone (sensitivity + specificity increased by 3%, $p=0.006$). Kaplan-Meier estimates clearly indicated that precision of AJCC-based MSS prediction can be corrected by both tools ($p<0.001$ by logrank test), independently and synergistically (Table 1). **Conclusions:** GEP score (based on 125 CMs) and MOC (based on > 92.000 CMs) are independent and equivalent prognostic tools, which improve the precision of AJCC-based MSS prediction. Correction was highest when the tools were combined. GEP score is a prognostic parameter that complements AJCC staging as well as MOC.

Correction of AJCC-based 5-yr MSS prediction by the prognostic tools (kaplan-meier estimates).

Entire sample cohort		75%
Increase in MSS	GEP low risk	+6%
	MOC low risk	+6%
	GEP low risk + MOC low risk	**+10%**
Decrease in MSS	GEP high risk	-10%
	MOC high risk	-6%
	GEP high risk + MOC high risk	**-15%**

9583 Poster Session (Board #410), Mon, 1:15 PM-4:45 PM

Performance of a 31-gene expression profile melanoma test in clinically relevant clinicopathologic subgroups. *First Author: Brian Gastman, Cleveland Clinic, Cleveland, OH*

Background: Accurate assessment of risk for recurrence and metastasis and early identification of low-burden metastatic disease is of utmost importance for cutaneous melanoma (CM) patient care. Although CM staging has improved with the development of new inflection points to define risk, additional information for risk assessment is critical, particularly considering advances in effective adjuvant therapy. A 31-gene expression profile (GEP) test accurately predicts risk of recurrence and metastasis, classifying CM as Class 1 (1A lowest risk) or Class 2 (2B highest risk). Herein, we analyze its utility for risk stratification beyond traditional staging factors in clinically-relevant subgroups of CM patients. **Methods:** Using an IRB-approved protocol, CM specimens and clinical data were collected from 16 centers. 690 samples met the inclusion criteria of stage I-III disease with at least 5 years follow up or an event. Low-risk patients (stage I-IIA) by national guidelines and the subpopulation of patients with microscopic nodal disease (stage IIIA), were selected to test the association of clinical factors and GEP with patient outcomes. **Results:** GEP Class was a significant predictor of recurrence, distant metastasis, and melanoma-specific survival independent of thickness, ulceration, node-status, and mitotic rate using multivariate Cox regression ($p < 0.05$ all endpoints), and the only significant factor for stage I-IIA cases. Stage I-IIA patients with a GEP Class 2B test result had 5-year recurrence free survival (RFS), distant metastasis free survival (DMFS), and melanoma-specific survival (MSS) rates of 61, 76, and 86% compared with 96, 97, and 100% for Class 1A patients ($n = 393$ $p < 0.0001$). Stage IIIA patients also exhibit statistically significant RFS, DMFS, and MSS when comparing GEP-test class results ($n = 75$ $p < 0.05$ all endpoints). **Conclusions:** GEP class is a robust and independent predictor of metastasis risk that adds prognostic information to clinically-relevant subpopulations. Accordingly, GEP results add benefit to traditional staging factors and thus can be incorporated in clinical decision-making regarding follow-up, surveillance, and may inform adjuvant therapy decisions.

9584 Poster Session (Board #411), Mon, 1:15 PM-4:45 PM

Mutation burden in conjunction with MAPK-pathway mutation status as a prognostic biomarker of overall melanoma survival. *First Author: John Cadley, New York University Langone Health, New York, NY*

Background: The high tumor mutation burden (TMB) in melanoma triggers the increased presentation of neoantigens, which are required to elicit an immune response. As a result, TMB has been proposed as a potential biomarker of immunotherapy treatment (IT). It is highly plausible that immunogenicity is also likely to play a role in melanoma progression. Thus, we explored whether the TMB and neoantigen burden (NB) impact melanoma overall survival (OS), independent of IT treatment. **Methods:** Excluding all patients treated with IT, we used 356 metastatic melanomas from The Cancer Genome Atlas (TCGA), and designed discovery (N = 240 patients) and validation sets (N = 116 patients) by random sampling. For all samples, we calculated total TMB as the number of non-synonymous mutations detected in each sample. We have also calculated NB as a function of specific mutations and HLA-type. Using total TMB and NB separately, we assessed their impact on OS using Kaplan-Meier survival analysis. Finally, we repeated this analysis restricted to a subset of patients with MAPK-pathway mutations (N = 260). **Results:** We found that total TMB predicts better OS in both the discovery and validation sets (p = 2e-04, p = 5e-04, respectively). Patients with fewer than 125 mutations showed significantly worse survival, and this result was replicated by repeated sampling. Restricting the analysis to the patients with a mutation in the MAPK-pathway (BRAF or NRAS), using the same mutation cutoff, we demonstrated a significantly stronger association between total TMB and OS (p = 4e-07). As our final analysis, we determined that NB and total TMB are highly correlated (r^2 = 0.977), and a NB of fewer than 50 neoantigens associated with worse OS (p = 9e-07). **Conclusions:** We have shown that lower total TMB and NB is strongly associated with worse OS in melanoma patients. When restricted to tumors containing MAPK-pathway mutations, we found even greater significance, demonstrating the interdependence of specific mutation status (BRAF- or NRAS-positive), total TMB, and OS. Importantly, this result indicates the potential utility of TMB as a biomarker of melanoma prognosis, outside of the context of IT.

9585 Poster Session (Board #412), Mon, 1:15 PM-4:45 PM

Immune gene profiling of pretreatment tumor samples in "real-world" advanced melanoma patients treated with anti-PD-1 and/or anti-CTLA-4. *First Author: Elisa A. Rozeman, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: The immune checkpoint inhibitors (CI) anti-CTLA-4 (ipilimumab [IPI]) and anti-PD-1 (pembrolizumab [PEM] and nivolumab [NIVO]) have improved survival in advanced melanoma patients (pts). Because of the range of upcoming new CI combinations, there is a need for biomarkers identifying pts who benefit from anti-PD-1 monotherapy. The NanoString T cell Inflammation Signature (TIS) is an 18-gene signature including IFN-γ responsive genes related to antigen presentation, chemokine expression, cytotoxic activity and adaptive immune resistance that are reflective of a pre-existing, but suppressed, adaptive immune response in the tumor. TIS was associated with positive treatment outcomes to PEM in advanced stage melanoma and other solid tumors (Ayers, JCI 2017). Here, we evaluate the TIS and other immune-related signatures in pre-treatment tumor samples obtained from "real world" pts treated with anti-PD-1 and/or IPI. **Methods:** RNA isolated from formalin fixed, paraffin embedded pre-treatment tumor samples from pts receiving either IPI, NIVO or PEM outside clinical trials at the Netherlands Cancer Institute were profiled with NanoString PanCancer gene expression panels. RNA samples from 97 pts treated with anti-PD-1 and 55 pts treated with IPI were profiled. Response to therapy was defined as an immune related CR or PR. **Results:** RNA profiling was of sufficient quality in 93 pts treated with anti-PD-1 (NIVO n = 17, PEM n = 76) and 51 pts treated with IPI. There was no significant difference in TIS between the different origins of the tumor samples. The TIS was associated with response in pts treated with IPI (p = 0.002) and first-line anti-PD-1 (p = 0.012). Pretreatment with IPI and/or targeted therapy abolished this significant association of the TIS and response to anti-PD-1 (p = 0.52), which also holds true for other signatures analyzed. **Conclusions:** Immune gene profiling by TIS is a valuable tool for response prediction in "real world" advanced melanoma pts treated with IPI and first-line anti-PD-1. Interestingly, this association was lost in pts treated with anti-PD-1 after targeted therapy or IPI. Validation of our observations in an independent cohort is required.

Surveillance for melanoma (MEL): Results of a database study of stage I-III MEL. *First Author: Corey Rearick, University of Pittsburgh School of Medicine, Pittsburgh, PA*

Background: Optimal surveillance for MEL recurrence is elusive. While consensus guidelines agree on surveillance imaging for high-risk MEL, there is no consensus regarding optimal modality for surveillance and routine imaging surveillance is not recommended for stage IA-IIA MEL. We examined the utility of surveillance in stage I-III MEL. **Methods:** Patients (pts) at the University of Pittsburgh's Melanoma Program 1991-2011 were queried using a clinical database. Eligible pts had stage I-III MEL and underwent routine surveillance with clinical examination, chest x-rays (CXR). Minimum follow-up was 9 months (mos). CXR positivity was determined by primary review of attending radiologist report. Pt documentation was queried for information pertaining to relapse, details of advanced imaging, pathology and treatment. Primary endpoints were the incidence of pulmonary (pulm) and extra-pulm metastases. **Results:** 324 pts with 2,700 CXRs were identified, of whom 114 (35%) had stage I, 63 (20%) stage II, and 147 (45%) stage III MEL. Median duration of screening was 46 mos. During this period, pulm mets were identified in 11%, 25% and 26% of stage I, II and III MEL respectively. Of these, CXR was initially diagnostic in 85%, 81%, and 92% respectively. Incidence of extra-pulm mets was 8%, 24% and 29% for stage I-III MEL, in whom diagnosis was made on advanced imaging ordered to evaluate examination findings and/or pt symptoms. **Conclusions:** Incidence of pulm and extra-pulm mets in MEL increases by stage, and CXR reliably detects pulm mets, although a higher incidence of non-pulm mets in stage II-III pts diminishes the value of CXR for relapses overall. Our data suggests that routine CXR surveillance detects few relapses in high-risk stage II-III pts.

Melanoma mets by site/stage.

		Pulm (N/%)				
	Skin/LN (N/%)	Isolated	Total	Extra-pulm (N/%)	Any site (N/%)	Multiple sites (N/%)
Stage I	3 (3%)	2 (2%)	13 (11%)	9 (8%)	16 (14%)	4 (4%)
Stage II	7 (11%)	5 (8%)	16 (25%)	15 (24%)	23 (37%)	10 (16%)
Stage III	19 (13%)	19 (13%)	38 (26%)	42 (29%)	58 (39%)	25 (17%)
All Pts	29 (9%)	26 (8%)	67 (21%)	66 (20%)	97 (30%)	39 (12%)

Comprehensive genomic profiling of metastatic cutaneous adnexal carcinomas to reveal multiple routes to targeted and immunotherapies. *First Author: Nicolas Girard, Institut Curie, Paris, France*

Background: Carcinomas that arise from the skin adnexae (Cutaneous Adnexal Carcinomas, CAC) may progress to refractory, metastatic disease. We queried whether comprehensive genomic profiling (CGP) of CAC could reveal genomic alterations (GA) that could guide the use of targeted and immune checkpoint inhibitor (ICPI) therapies. **Methods:** A total of 103 relapsed/refractory and metastatic CAC underwent CGP using 50 ng of DNA and a hybrid-capture, adaptor ligation-based next-generation sequencing assay to a median coverage depth of > 600X. Results were analyzed for all classes of GA and tumor mutational burden (TMB) was determined on up to 1.2 Mb of sequenced DNA; microsatellite instability (MSI) determined by principal components analysis of optimal homopolymer loci. **Results:** The 103 CAC included 56 (54%) sweat duct (SWCAC), 21 (20%) sebaceous (SBCAC), 5 (4%) hair shaft/follicle (HRCAC) and 20 (19%) not otherwise specified (NOS) samples (Table). The CAC subtypes had similar median age and male preponderance, except for HRCAC (Table). The CAC had a mean GA/tumor of 5.47 (range 4.33 to 6.90). In CAC overall, potentially targetable GA were in *PTEN*, *ERBB2*, *BRCA2*, *PTCH1*, *NF1* and *BRAF*. More than 20% of CAC had TMB of > 20 mut/Mb, indicating high potential for immunotherapies. Potential ICPI resistance-associated GA included *STK11* inactivating GA (4%) and *MDM2* amplification (2%). MSI-High status was found in 2% of CAC overall, and limited to the SBCAC cohort. **Conclusions:** CAC are a rare and heterogeneous group of epithelial malignancies for which CGP can uncover multiple routes to targeted therapies. The prevalence of high TMB predicts that ICPI could play a role in relapsed and refractory disease.

	All CAC (n = 103)	Sweat Duct (n = 56)	Sebaceous Gland (n = 21)	Hair Shaft (n = 6)	NOS (n = 20)

9588 Poster Session (Board #415), Mon, 1:15 PM-4:45 PM

Genetic aberrations in the CDK4 pathway and association with innate resistance to PD-1 blockade in acral melanoma. *First Author: Jiayi Yu, Department of Renal Cancer and Melanoma, Peking University Cancer Hospital & Institute, Collaborative Innovation Center for Cancer Medicine, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Beijing, China*

Background: PD-1 checkpoint blockade immunotherapy induces long durable responses in patients with advanced melanoma. However, only a minor subset of acral melanoma patients could gain benefit from it. In this study, we aim to explore factors that may influence innate sensitivity or resistance to anti-PD-1 therapy and screen drugable targets with potential to be combined with anti-PD-1 antibody monotherapy in acral melanoma. **Methods:** Whole exome sequencing (WES) and RNAseq analyses were performed in 13 biopsies from baseline lesions of advanced melanoma patients who were treated with anti-PD-1 antibody (JS001, Shanghai Junshi Biosciences, China). The copy number variations (CNV) of candidate genes were identified by TaqMan Copy Number Assay in an independent cohort. The effect of CDK4/6 inhibitors combined with anti-PD-1 antibody monotherapy was evaluated by PD-1 humanized mouse (C57BL/6-hPD-1) and patient-derived xenograft (PDX) models. **Results:** WES revealed parallel CNV amplifications in both the CR+PR and PD cohorts, such as 4q22.1, 10q23.32, 15q26.3, 22q13.1. However, several significant CNV amplifications notably only occurred in the PD cohort, such as 1q23.1, 5p15.33, 7p22.3, 11q13.3, 12q14.1, which harbor *Cdk4, Ccnd1, CARD11* and *mTOR* genes. The association between *Cdk4* or/and *Ccnd1* amplification with innate resistance to anti-PD-1 therapy was validated in 46 acral melanoma patients ($P < 0.01$). The CDK4/6 inhibitor treatment increased PD-L1 protein levels in primary acral melanoma cell line and PDX model. Moreover, CDK4/6 inhibitor augments the response to PD-1 blockade in PD-1 humanized mouse (C57BL/6-hPD-1) and PDX models. Tumor growth curves for each treatment group demonstrate the improved efficacy of combining PD-1 blockade with the CDK4/6 inhibitor ($P < 0.05$). **Conclusions:** In summary, we discovered the genetic aberrations in the CDK4 pathways were associated with innate resistance to anti-PD-1 therapy in patients with advanced acral melanoma. Moreover, our study provides evidence for the testing of CDK4/6 inhibitors combined with anti-PD-1 antibody monotherapy in acral melanoma.

9589 Poster Session (Board #416), Mon, 1:15 PM-4:45 PM

Phase III randomized, multicenter trial comparing high-dose IFN-a2b with temozolomide plus cisplatin as adjuvant therapy for resected mucosal melanoma. *First Author: Bin Lian, Peking University Cancer Hospital and Institute, Beijing, China*

Background: Mucosal melanoma is rare and associated with extremely poor prognosis. Standard adjuvant therapy for mucosal melanoma has not been established. Based on the result of phase 2 trial which compared temozolomide-based chemotherapy, high-dose IFN-a2b (HDI) and observation, we compared HDI with temozolomide plus cisplatin as adjuvant therapy for resected mucosal melanoma in this phase 3 trial. **Methods:** In this multicenter, randomized, controlled, phase 3 trial, 204 patients of mucosal melanoma with stageI-III after completely resected were randomized 1:1 into two groups from Feb 2014 to Jun 2016: HDI group (101 patients, treated with i.v. 15×10^6U/m^2/d IFN-a2b on days 1 to 5 each week for 4 weeks, followed by s.c. 9×10^6U IFN-a2b three times per week for 48 weeks), and chemotherapy group (103 patients, per os 200 mg/m^2/d temozolomide on days 1 to 5 plus i.v. 75 mg/m^2 cisplatin divided into 3 days, which was repeated every 3 weeks for six cycles). The primary end point was relapse-free survival (RFS), Secondary end points included distant metastasis-free survival (DMFS), overall survival (OS), and safety. **Results:** At a median follow-up of 23.7 months, the median RFS was 15.53 months (95% CI, 11.37-19.69m) in the chemotherapy group, as compared with 9.47 months (95% CI, 8.49-10.45m) in the HDI group (HR for relapse, 0.56; 95% CI, 0.40 to 0.77; $P < 0.001$). The median DMFS was 16.80 months (95% CI, 9.35-24.25m) in the chemotherapy group, as compared with 9.57 months (95% CI, 7.46-11.67m) in the HDI group (HR for metastasis, 0.53; 95% CI, 0.38 to 0.74; $P < 0.001$). Estimated median OS for chemotherapy group and HDI group was 41.20, 35.73 months ($P = 0.083$). Toxicities were generally mild to moderate in two groups. **Conclusions:** Adjuvant chemotherapy with temozolomide plus cisplatin resulted in a significantly lower risk of relapse and metastasis in resected mucosal melanoma than high-dose IFN-a2b and was not associated with seriously toxic effects. Clinical trial information: BCHMMAT001.

9590 Poster Session (Board #417), Mon, 1:15 PM-4:45 PM

Effect on health-related quality of life (HRQOL) of adjuvant treatment (tx) with dabrafenib plus trametinib (D + T) in patients (pts) with resected stage III *BRAF*-mutant melanoma. *First Author: Dirk Schadendorf, University Hospital Essen, Essen, Germany*

Background: Adjuvant tx of resected stage III *BRAF*-mutant melanoma with D + T significantly reduced risk of recurrence vs placebo (pbo). In the COMBI-AD study, 1-y tx with D + T resulted in improvements in relapse-free survival, distant metastasis–free survival, freedom from relapse, and overall survival. The effect of D + T on HRQOL in the adjuvant setting is reported here. **Methods:** COMBI-AD (NCT01682083) was a randomized, double-blind, phase 3 study evaluating pts with resected stage III *BRAF* V600E/K–mutant melanoma. Pts were randomized 1:1 to receive D 150 mg twice daily plus T 2 mg once daily or matching pbo for 12 mo. HRQOL assessment using the EuroQol-5D (EQ-5D-3L) questionnaire and visual analogue scale (VAS) was an exploratory endpoint. A mixed-model, repeated-measures analysis was used to assess differences in mean scores. **Results:** A total of 870 pts were randomized (D + T, n = 438; pbo, n = 432). Although pts available for assessment declined during study primarily due to consent withdrawal, missed scheduled visits, and deaths, completion rates among available pts were high (98% at baseline [BL], ≥ 90% throughout the 12-mo tx period, and ≥ 75% at assessments after 12 mo). Pts in both arms had similar BL VAS values (D + T, 79.0; Pbo, 80.4 [0-100 scale]). During tx (3- to 12-mo assessments), VAS scores remained similar to BL, with no clinically meaningful differences observed between arms (adjusted mean change from BL at 12 mo: D + T, 0.14; pbo, −0.02). In the D + T arm, no clinically meaningful or statistically significant difference in VAS was reported between pts who did and did not experience pyrexia ($P > .1$). During follow-up (15-48 mo), VAS scores were similar between arms, with no significant or clinically meaningful differences reported. At relapse, a statistically significant reduction in VAS score was observed in both arms (mean difference [pre- vs postrecurrence], D + T, −6.02, $P = .003$; pbo, −6.84, $P < .001$). **Conclusions:** In the absence of disease-related symptoms in the adjuvant setting, these results demonstrate that D + T do not negatively impact HRQOL during tx or in long-term follow-up and further emphasize the importance to pt HRQOL of preventing relapse. Clinical trial information: NCT01682083.

9591 Poster Session (Board #418), Mon, 1:15 PM-4:45 PM

Dabrafenib plus trametinib (D + T) as adjuvant treatment of resected *BRAF*-mutant stage III melanoma: Findings from the COMBI-AD trial analyzed based on AJCC 8 classification. *First Author: James M. G. Larkin, Royal Marsden NHS Foundation Trust, London, United Kingdom*

Background: The COMBI-AD trial demonstrated that adjuvant treatment with D + T in patients (pts) with resected stage III *BRAF*-mutant melanoma significantly reduced the risk of melanoma recurrence vs placebo (pbo). Pts were stratified based on the AJCC 7 disease stage classification. We present efficacy results from COMBI-AD based on the updated AJCC 8 staging classification. **Methods:** COMBI-AD (NCT01682083) is a randomized, double-blind, pbo-controlled, phase 3 study evaluating pts with stage III *BRAF* V600E/K–mutant melanoma without prior anticancer therapy. Pts were randomized 1:1 within 12 weeks of complete resection to receive D 150 mg twice daily plus T 2 mg once daily or matching pbos for 12 months. The primary endpoint was relapse-free survival (RFS). Pts were stratified by disease stage (stages IIIA, IIIB, and IIIC) based on AJCC 7 criteria. This post hoc subgroup analysis evaluated RFS in pts by disease stage based on AJCC 8 (stages IIIA, IIIB, IIIC, and IIID). **Results:** 870 pts were randomized (D + T, n = 438; pbo, n = 432). Pts were recategorized per AJCC 8 into stages IIIA (D + T, n = 50; pbo, n = 39), IIIB (D + T, n = 145; pbo, n = 154), IIIC (D + T, n = 217; pbo, n = 214), and IIID (D + T, n = 22; pbo, n = 17). RFS benefit with D + T over pbo was observed regardless of disease stage (stage IIIA: HR, 0.46 [95% CI, 0.17-1.21]; stage IIIB: HR, 0.46 [95% CI, 0.33-0.65]; stage IIIC: HR, 0.49 [95% CI, 0.38-0.64]), with the largest benefit observed in higher-risk stage IIID pts (HR, 0.34 [95% CI, 0.15-0.80]). When stage IIIB and IIIC subgroups were combined, the HR for RFS (D + T vs pbo) was the same (0.48) regardless of the AJCC classification used. Three-year RFS rates favored pts in the D + T vs pbo arm across all disease stages: IIIA, 83% vs 70%; IIIB, 63% vs 43%; IIIC, 52% vs 33%; and IIID, 40% vs 18%. RFS rates were similar in D + T and pbo arms in pts with stages IIIA, IIIB, and IIIC disease whether classified by AJCC 7 or 8. **Conclusions:** The RFS benefit observed with D + T vs pbo in pts with resected *BRAF* V600E/K–mutant melanoma was similar across all stages and was maintained when reclassified by AJCC 8 compared with the original AJCC 7 classification. Clinical trial information: NCT01682083.

9592 Poster Session (Board #419), Mon, 1:15 PM-4:45 PM

Liver-directed treatment for patients with uveal melanoma hepatic metastasis: A retrospective analysis of overall survival. *First Author: Rino S Seedor, Sidney Kimmel Medical College of Thomas Jefferson University, Philadelphia, PA*

Background: Despite successful treatment of primary uveal melanomas, up to 50% of patients subsequently develop systemic metastasis, with the liver involved in up to 90% of patients. At our institution, recognition of the poor prognosis associated with liver metastasis has led to the use of various liver-directed treatment modalities including transarterial chemoembolization (TACE) with BCNU, drug-eluting beads with doxorubicin (DEBDOX), immunoembolization (IE) with GM-CSF, and radioembolization with Yttrium 90 radioactive microspheres. The purpose of this study is to compare overall survival between uveal melanoma patients with hepatic metastasis before and after the shift of initial treatment from systemic to liver-directed approaches. **Methods:** A retrospective single-institution chart review was performed on consecutive series of uveal melanoma patients with hepatic metastasis who were treated at Thomas Jefferson University between 1971–1993 (Cohort 1, n = 98) and 2000–2017 (Cohort 2, n = 634). The following data was collected from medical records: primary tumor stage and genetic abnormalities, primary eye treatment, date to hepatic and extra-hepatic metastasis, types of liver-directed and systemic treatments utilized, and date of death. Time from development of hepatic metastasis to death (OS-Liver) and time from initial treatment of primary uveal melanoma to death (OS-Eye) in individual cohorts were measured and analyzed. **Results:** 81% of cohort 1 patients received systemic chemotherapy as their initial treatment for liver metastasis, while 91% of cohort 2 patients (n = 574) initially received liver-directed treatments including IE (n = 296), BCNU TACE (n = 147), DEBDOX (n = 45), radioembolization (n = 37), and other liver-directed treatments (n = 49). OS-Liver in cohort 1 and cohort 2 was 4.8 months and 16.4 months, respectively ($P < 0.001$). More importantly, OS-Eye in cohort 2 (5.1 years) is much longer than that of cohort 1 (3.3 years) ($P < 0.001$). **Conclusions:** Liver-directed treatments provided significant survival benefit for uveal melanoma patients with hepatic metastasis.

9593 Poster Session (Board #420), Mon, 1:15 PM-4:45 PM

Indirect treatment comparison of nivolumab versus placebo as an adjuvant therapy for resected melanoma. *First Author: Alexander Noor Shoushtari, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: There are no randomized trials of nivolumab and placebo as adjuvant therapy in patients with resected melanoma. This study uses pooled data from CheckMate 238 and EORTC 18071 to evaluate the number of patients needed to treat (NNT) based on recurrence-free survival (RFS) for nivolumab vs. placebo and nivolumab vs. ipilimumab over 12 and 18 months. **Methods:** Patients with stage IIIB or IIIC cutaneous melanoma from the two trials were pooled using propensity score weighting. The following characteristics were adjusted for: age, gender, race, ECOG, time from resection, disease stage, presence of tumor ulceration, lymph node involvement (microscopic vs. macroscopic), baseline LDH, and pretreatment events. The NNTs to achieve one additional recurrence-free survivor for nivolumab compared to placebo and ipilimumab were calculated as the reciprocal of the difference of the weighted RFS rates between treatments at month 12 and month 18. **Results:** After adjustment, baseline characteristics were balanced between the two trials. 1,286 patients with stage IIIB and IIIC cutaneous melanoma treated with nivolumab (N = 277), ipilimumab (N = 644), and placebo (N = 365) were included in the study. After weighting, the RFS rates of nivolumab, ipilimumab, and placebo were 74.2%, 61.9%, and 48.7% at 12 months and 70.7%, 54.1%, and 41.8% at 18 months, respectively. At month 12, NNT to achieve one additional recurrence-free survivor of nivolumab vs. placebo was 3.9 (95% CI: 3.0, 5.6) and nivolumab vs. ipilimumab was 8.1 (95% CI: 5.2, 18.7). At month 18, NNT to achieve one additional recurrence-free survivor decreased for both nivolumab vs. placebo (3.5; 2.7, 4.7) and nivolumab vs. ipilimumab (6.0; 4.2, 10.8). **Conclusions:** In patients with resected stage IIIB and IIIC cutaneous melanoma, adjuvant nivolumab was associated with the highest RFS rates compared to placebo and ipilimumab. To prevent one recurrence/death at 12 months, 4 patients would need to be treated with nivolumab instead of observation. With longer follow-up, the number needed to be treated to prevent one recurrence/death decreased, suggesting the magnitude of the clinical benefit may become more prominent over time. Clinical trial information: NCT02388906 and NCT00636168.

9594 Poster Session (Board #421), Mon, 1:15 PM-4:45 PM

Assessing the value of nivolumab (NIVO) versus placebo (PBO) and ipilimumab (IPI) as adjuvant therapy for resected melanoma. *First Author: Morganna Louise Freeman, The Angeles Clinic and Research Institute, Los Angeles, CA*

Background: Healthcare value frameworks consider the clinical benefits in the context of cost when assessing the value of cancer therapies. Here, we assess the cost per recurrence-free life month (RFLM) and associated drug and medical services costs using pooled data from CheckMate 238 and EORTC 18071 for NIVO compared to PBO and IPI as adjuvant therapies in patients with resected melanoma. **Methods:** Patients with stage IIIB or IIIC cutaneous melanoma were pooled using propensity score weighting, adjusting for baseline characteristics. For each treatment, RFLMs within 12 and 18 months were calculated as the area under the weighted Kaplan-Meier curve of RFS. Drug acquisition costs and medical service costs were calculated. No drug costs were considered for PBO. Cost per RFLM was calculated by dividing costs per patient by mean duration of RFLMs. **Results:** 1,286 patients were included in the analysis. After adjustment, baseline characteristics were balanced between the two trials. Overall, the mean duration of RFLM was highest for NIVO vs. both IPI and PBO. NIVO had lower mean drug cost vs. IPI, and lower mean medical cost vs. both PBO and IPI, attributed to lower hospitalizations. **Conclusions:** In patients with resected stage IIIB and IIIC cutaneous melanoma, adjuvant NIVO provides lower medical cost per RFLM due to longer recurrence-free periods and savings in medical costs compared to PBO and IPI over 1 year. The value of RFLM with NIVO continues to evolve over time compared to IPI and PBO, with improvement in drug costs per RFLM over 18 months compared to IPI. Longer term follow-up and consideration of subsequent therapies will further characterize the cost-effectiveness of adjuvant NIVO.

Outcome measures	NIVO 3 mg/kg n = 277	IPI 10 mg/kg n = 644	PBO n = 365
Mean duration of RFLMs			
Within 12 mo	10.2	9.3	8.1
Within 18 mo	14.5	12.8	10.8
Mean drug cost			
Within 12 mo	$133,213	$488,048	$0
Within 18 mo	$133,229	$538,193	$0
Mean medical costs (within 12 mo)	$4,494	$12,585	$5,411
Hospitalization	$3,960	$11,738	$4,986
Emergency room	$14	$25	$3
Outpatient	$514	$813	$420
Home health care	$6	$9	$2
Mean drug cost per RFLM			
Within 12 mo	$13,091	$52,577	$0
Within 18 mo	$9,192	$40,371	$0
Mean medical cost RFLM (within 12 mo)	$442	$1,356	$664

TPS9595 Poster Session (Board #422a), Mon, 1:15 PM-4:45 PM

A phase 2, multicenter study to assess the efficacy and safety of autologous tumor-infiltrating lymphocytes (LN-144) for the treatment of patients with metastatic melanoma. *First Author: Amod Sarnaik, Moffitt Cancer Center, Tampa, FL*

Background: Adoptive cell therapy utilizing tumor-infiltrating lymphocytes (TIL) is recognized as an effective treatment in metastatic melanoma and other solid tumors elliciting durable and complete responses, even in heavily pretreated patients. Despite recent approvals of multiple checkpoint-directed therapies there remains an unmet need to improve therapeutic outcomes in patients with metastatic melanoma post checkpoint therapy. The C-144-01 study is evaluating TIL therapy with LN-144 in metastatic melanoma patients who have progressed on prior checkpoint-targeted therapy. C-144-01 is a phase 2 multicenter, open-label study enrolling patients in the US and Europe. LN-144 is manufactured at centralized GMP facilities providing either a non-cryopreserved (Gen 1), or a second generation cryopreserved (Gen 2) TIL infusion product. The Gen 2 process reduces manufacturing time for LN-144 to 22 days, allowing for dramatic efficiencies in scheduling, distribution and delivery needed for commercial use. **Methods:** Three treatment cohorts are being evaluated: Cohort 1 (N = 30) patients receive a single dose of Gen 1 LN-144; Cohort 2 (N = 30) patients receive a single dose of Gen 2 LN-144; and up to 10 eligible patients from either Cohort 1 or Cohort 2 may enroll in Cohort 3 for re-treatment with a second dose of LN-144. For patients in all cohorts, TIL for LN-144 manufacturing are extracted from surgically-resected tumors. LN-144 infusion is preceded by a non-myeloablative lymphodepletion regimen of Cy/Flu, and followed by up to 6 infusions of IV IL-2. Patients $\geq$ 18 years of age must have confirmed stage IIIc/IV met. melanoma and have progressed following $\geq$1 line of prior systemic therapy including an immune checkpoint inhibitor and BRAF-targeted therapy (if BRAF mutation-positive). Other major eligibility criteria include: minimum of 2 tumor lesions; adequate organ function; ECOG PS of 0 or 1. The primary endpoint is the evaluation of efficacy of LN-144 using ORR per RECIST 1.1; secondary endpoints are CR rate, DOR, DCR, PFS, OS, and safety. Key exploratory objectives include tumor response per irRECIST, immune correlates of response, and HRQoL. Clinical trial information: NCT02360579.

TPS9596 Poster Session (Board #422b), Mon, 1:15 PM-4:45 PM

Phase I/II study of the PI3Kβ inhibitor GSK2636771 in combination with pembrolizumab (P) in patients (pts) with PD-1 refractory metastatic melanoma (MM) and PTEN loss. *First Author: Hussein Abdul-Hassan Tawbi, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Immune checkpoint blockade (ICB) improves overall survival and provides long-term disease control in 35-40% of pts with MM. However, more than a third of pts experience no clinical benefit (de novo resistance) and many progress even after achieving an initial response (acquired resistance). Our group has demonstrated that increased activation of phosphatidylinositol 3-kinase (PI3K) pathway, most commonly through loss of the tumor suppressor gene PTEN, plays a critical role in resistance to ICB. PTEN loss occurs in up to 30% of MM pts and correlates with decreased T cell infiltration and inferior outcomes to ICB. In preclinical models, we showed that loss of PTEN inhibits T cell mediated tumor killing and decreases T cell trafficking into tumors, and that selective inhibition of the PI3Kβ-subunit with GSK2636771 was superior to pan-PI3K inhibitors and significantly increased the activity of ICB, and the number of infiltrating CD4+ and CD8+ T cells. We therefore hypothesized that PI3Kβi will reverse resistance to ICB in MM with PTEN-loss. To test this hypothesis, we are conducting a Phase I/II study of the PI3Kβ inhibitor GSK2636771 in combination with P in pts with PD-1 refractory MM and PTEN loss. **Methods:** The primary objective of the Phase I portion is to determine the safety and Maximum-Tolerated Dose (MTD) and/or the Recommended Phase II Dose (RP2D) of GSK2636771 in combination with P in pts with PD-1 refractory disease and PTEN loss. Pts will be treated with P given at 200 mg IV q 3-wk cycle. GSK2636771 will be given orally starting at a dose level of 300 mg PO qd for 21 days and escalated to a maximum dose of 400 mg PO qd using a "3+3" design. The Phase II portion will enroll a total of 35 pts at the MTD/RP2D. Continuous monitoring for both toxicity and futility will be assessed. The primary objective of the Phase II portion is to determine the safety, tolerability, and efficacy of the combination as defined by Objective Response Rate (ORR) by RECIST 1.1 in MM with PTEN loss. Secondary Objectives include the PKs of GSK2636771 and correlation with ORR and pharmacodynamic effects in tumor tissue as measured by pathway inhibition and T cell trafficking into tumors. Clinical trial information: NCT03131908.

TPS9597 Poster Session (Board #423a), Mon, 1:15 PM-4:45 PM

Combining ipilimumab (ipi) and nivolumab (nivo) in advanced melanoma following progression on a PD-1 inhibitor (SWOG S1616). *First Author: Ari M. Vanderwalde, Division of Hematology/Oncology, The University of Tennessee Health Science Center, West Cancer Center, Germantown, TN*

Background: We hypothesize that patients with advanced melanoma who progress on anti-PD-1 therapy upfront may respond to the addition of the CTLA-4 inhibitor ipi to continue PD-1 inhibition (with nivo), and that responses would occur at a rate higher than would be expected from switching to ipi alone. We surmise that this would occur because melanomas primarily refractory to PD-1 antibodies may not have a sufficient pre-existing T cell infiltrate, which can be corrected by adding treatment with ipi, as CTLA-4 blockade increases new intratumoral T cell infiltration. **Methods:** This is a Phase 2, prospective open-label study of ipi +/- nivo in patients with advanced melanoma refractory to a PD-1 inhibitor. The primary endpoint of the study is progression free survival. Secondary objectives include the difference in T-cell infiltrate in biopsies of patients with response and no-response to therapy; objective response rate; overall survival; and toxicity. Key eligibility criteria include unresectable melanoma; disease progression while on prior PD-1 agents or after stopping with no intervening therapy; no confirmed partial or complete response to prior anti-PD1 agents; no prior receipt of CTLA-4 inhibitor; Zubrod performance status 0-2; no active brain metastases; no history of autoimmune pneumonitis or colitis requiring steroids or interruption of therapy; and adequate organ function. Prior receipt of BRAF/MEK inhibitors is permitted. Subjects are randomized 1:3 to ipi 3mg/kg q3wk x4 doses or ipi with nivo 1mg/kg q3wk x4 doses followed by nivo 240mg q2wk (21 planned on ipi; 63 on ipi+nivo). Tumor biopsy and blood for correlative studies are taken prior to enrollment and at Day 28-35 on study. Tumor assessments are performed every 12 weeks for 1 year and treatment is continued while clinical benefit persists with a final survival follow-up at 2 years. The combination will be considered superior to single-agent ipi if PFS is doubled from 3 to 6 months with one-sided alpha of 0.1 and power of 0.9. As of January 2018, 5 of 84 planned subjects have enrolled. Clinical trial information: NCT03033576.

TPS9598 Poster Session (Board #423b), Mon, 1:15 PM-4:45 PM

A phase II study of study of bevacizumab (BEV) in combination with atezolizumab (ATEZO) in pts (pts) with untreated melanoma brain metastases (BEAT-MBM). *First Author: Gustavo Schvartsman, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Immunotherapy (IO) has significantly improved survival for many pts with metastatic melanoma. However, the majority of trials excluded pts with MBM. Recently, combination of nivolumab and ipilimumab (IPI) showed objective response rate (ORR) of up to 55%, but pts with symptomatic disease still do poorly and usually are not candidates for IO due use of high dose steroids. Additionally, there is a concern for increased perilesional edema, which can lead to neurologic symptoms. BEV has widely been used as a "steroid-sparing agent" with remarkable success in controlling intracranial edema. Moreover, studies have implicated elevated angiogenic markers as predictors of poor outcome with IO by limiting effector T-cell trafficking and activity. Clinically, BEV has been shown to improve the outcome of IO and has indeed increased expression of favorable chemokines in the tumor microenvironment, improving ORR when added to IPI. Moreover, the combination of BEV and ATEZO, a PD-L1 inhibitor, produced remarkable responses in renal cell carcinoma. We therefore hypothesized that combining BEV and ATEZO will be more effective and have an improved toxicity profile in MBM. **Methods:** This phase II study will evaluate the intracranial safety and efficacy of BEV + ATEZO by ORR (iRANO criteria) in pts with untreated or progressive MBM who have not been exposed to PD-1/PD-L1 inhibitors. We will accrue 40 pts, divided in two cohorts: cohort A (25 asymptomatic pts); and cohort B (15 pts that are either mildly symptomatic, or asymptomatic, but requiring a low dose of systemic steroids (no higher than 4 mg/day of PO dexamethasone or equivalent). BEV will be given at 15 mg/kg and ATEZO at 1200 mg flat dose, both IV every 3 weeks until progression or death. Efficacy will be assessed by MRI of the brain and systemic imaging every 2 cycles. Continuous monitoring for toxicity and futility will be performed and assumes an ORR of 45% (96% power to detect a 25% difference from historical control of 20%). Effects of BEV + ATEZOL on correlative immune markers will be studied. This study is open for enrollment. Clinical trial information: NCT03175432.

TPS9599 Poster Session (Board #424a), Mon, 1:15 PM-4:45 PM

A randomized phase II study of anti-PD1 antibody [MK-3475 (Pembrolizumab)] alone versus anti-PD1 antibody plus stereotactic body radiation therapy in advanced merkel cell carcinoma (Alliance A091605). *First Author: Jason J. Luke, University of Chicago Comprehensive Cancer Center, Chicago, IL*

Background: Merkel cell carcinoma (MCC) is a rare cutaneous malignancy associated with ultraviolet light exposure, advanced age and infection with the Merkel cell polyomavirus (MCP). Historically, median survival in the metastatic setting was approximately 9.6 months with radiation and platinum- based chemotherapy as the foundations of treatment. More recently, outcomes have been markedly improved with the development of PD1/L1 antibodies. Durable response rates have been observed ranging from 30-50%, depending on line of therapy, that are independent of PDL1 or MCP status, mutation burden or tumor-infiltrating lymphocytes. A large preclinical literature and some clinical observations support the hypothesis that radiation may augment the systemic efficacy of immunotherapy (abscopal effect) through increased antigen presentation, T-cell priming, and interferon gamma associated signaling. No clinical studies to date have directly tested this hypothesis. **Methods:** This is an NCTN supported (Alliance for Clinical Trials in Oncology, SWOG and NRG Oncology) open-label phase II study comparing pembrolizumab with pembrolizumab plus stereotactic body radiation therapy to a single lesion in advanced MCC. The study randomizes patients 1:1 with eligibility including no prior therapy in the metastatic setting, ≥2 sites of RECIST measurable disease, ECOG performance status 0-2 and no autoimmunity or immunosuppression. The primary endpoint is progression-free survival in non-irradiated lesions (abscopal), with secondary endpoints evaluating response rate, overall survival and toxicity. Translational biospecimens, including archival tumor tissue (for PDL1, TMB, gene expression profiling and other analyses), serum and peripheral blood mononuclear cells and fecal microbiome samples, are being collected for analysis. The study is open to accrual via the Cancer Trials Support Unit (CTSU) of NCI to any NCTN group member site. Recruitment is on-going (target 96 patients). Clinical trial information: NCT03304639.

TPS9600 Poster Session (Board #424b), Mon, 1:15 PM-4:45 PM

A randomized phase III study of duration of anti-PD-1 therapy in metastatic melanoma (STOP-GAP): Canadian Clinical Trials Group study (CCTG) ME.13. *First Author: Tara D. Baetz, Division of Medical Oncology, Queen's University, Kingston, ON, Canada*

Background: Efficacy of the anti-PD -1 agents has been demonstrated in metastatic melanoma in phase I-III trials. During the development of these trials there was no optimal duration of treatment identified. Trials stopped therapy due to unacceptable side effects, investigator's choice, at a specific time point typically at 24 months of therapy or at disease progression. Clinical reports suggest that stopping treatment early due to toxicity may not adversely impact efficacy. In addition, there is evidence that retreatment with immunotherapy may be clinically effective. Unnecessary long term therapy may result in a higher risk of toxicity, diminished quality of life (QoL) and will impact the cost-effectiveness of the therapy. We hypothesize that treatment to maximum tumour response will result in non-inferior overall survival with better QoL, less toxicity and lower cost than continuous therapy. **Methods:** This is a large, simple randomized phase III trial evaluating the duration of anti-PD-1 therapy in metastatic/unresectable melanoma. Consenting patients must be eligible to receive anti- PD-1 inhibitor as standard of care. Patients are randomized 1:1 to either standard 24 months of therapy in the absence of disease progression versus treatment until maximum tumour response (MTR) with retreatment at the time of progression. MTR is determined by at least two radiologic measurements three months apart. Eligibility criteria are broad to reflect a "real world" patient population. Data collection is streamlined to focus on key endpoints. The primary endpoint is overall survival. Secondary endpoints are PFS, response rate, adverse event rate, health related QoL and economic analysis. Patients are stratified based on line of therapy, stage of disease, BRAF status, LDH level, prior use of adjuvant therapy, anti-PD -1 inhibitor selected and the presence of CNS metastases. The trial will enroll 550 patients with 275 in each arm. It is expected that accrual will last 5.5 years. Currently 78 patients have been enrolled. Clinical trial information: NCT02821013..

TPS9601 Poster Session (Board #425a), Mon, 1:15 PM-4:45 PM

Trial in progress: A phase 2 study of intratumor pil-12 plus electroporation in combination with intravenous pembrolizumab in patients with stage III/IV mealanoma progressing on either pembrolizumab or nivolumab treatment (PISCES). *First Author: Robert Hans Ingemar Andtbacka, Huntsman Cancer Institute at the University of Utah, Salt Lake City, UT*

Background: Immunotherapy and targeted therapies have significantly changed the treatment landscape for advanced melanoma over the past few years. However, despite the addition of these new therapeutic strategies, a lack of response or disease progression continues to occur in a significant fraction of patients (~60%). Pembrolizumab (anti-PD-1 antibody) for the treatment of advanced melanoma confers a 33% objective response rate (ORR). Intratumoral plasmid IL-12 (tavokinogene telseplasmid; tavo) with electroporation (IT-tavo-EP) is a gene-based immunotherapeutic approach that forces localized expression of the proinflammatory cytokine IL-12, which converts both treated and untreated lesions from poorly immunogenic/low T-cell infiltrating tumors unlikely to respond to anti-PD-1 therapy into highly inflamed immunologically active lesions. The purpose of this study is to evaluate the tolerability and efficacy of pembrolizumab plus IT-tavo-EP in Stage III/IV melanoma patients who have progressed or are progressing on approved checkpoint inhibitors, and to assess the immunomodulatory effects of therapy **Methods:** OMS-I103 (PISCES) is a phase 2, multicenter, open-label trial of IT-tavo-EP with pembrolizumab in patients with stage III/IV melanoma who are progressing on either pembrolizumab or nivolumab. The primary objective is best ORR by RECIST v1.1 at 24 weeks determined by independent reviewers. A Simon 2-stage minimax design is employed. In Stage 1, up to 23 eligible patients will be enrolled and treated with IT-tavo-EP to the accessible lesions on Days 1, 5 and 8 every 6 weeks with IV pembrolizumab (200 mg) on Day 1 of each 3-week cycle for 24 weeks. If the predesignated threshold is reached in Stage 1, ($N > 3$ /23) enrollment for Stage 2 will include an additional 25 patients (total of 48 patients). The study is enrolling in the US and Australia. Clinical trial information: NCT03132675.

TPS9602 Poster Session (Board #425b), Mon, 1:15 PM-4:45 PM

Multicenter phase I/IIa study using T cell receptor gene therapy in metastatic melanoma. *First Author: Maartje W. Rohaan, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Since the introduction of targeted therapy and checkpoint inhibitors, the historically poor prognosis of patients with unresectable stage IIIc/IV melanoma has greatly improved, with now known 2-year survival rates of 46-64%. However, a substantial group of patients, for example those with metastatic uveal melanoma, have poor response rates upon these therapies with no alternative approved therapy yet available. Adoptive transfer of T cell receptor (TCR) gene modified T cells is a modality to create a large pool of tumor reactive T cells. Responses of clinical significance have been seen in preclinical and clinical trials when targeting the melanocyte differentiation antigens gp100 and MART-1. The primary aim of our study is to explore the feasibility, safety and objective response rate of the adoptive transfer of autologous T cells modified with a MART-1 specific TCR, preceded by non-myeloablative (NMA) chemotherapy. **Methods:** In this phase I/IIa study, a total of 25 patients $\geq$ 18 years of age, with irresectable stage IIIc/IV melanoma (cutaneous, melanoma of unknown primary, mucosal and uveal melanoma) who have failed previous standard treatments, are HLA-A2 positive and have MART-1 and MHC class I expressing tumors, will be included. Patients will undergo leukapheresis to isolate autologous T cells, which will be transduced with a retroviral vector encoding the 1D3HMCys MART-1 TCR and expanded *ex vivo*. Patients will receive NMA chemotherapy and a single intravenous infusion with MART-1 TCR transduced T cells in a dose escalating regimen after evaluation of toxicity and efficacy. Primary endpoints are the feasibility of MART-1 specific TCR therapy in terms of delivery of this sequence of treatment in metastatic melanoma patients, safety according to CTCAE 4.0 and objective response rate according to RECIST 1.1. Secondary endpoints are the 1-year progression free survival, median overall survival and the efficacy of induction of tumor specific T cell responses measured in peripheral blood and tumor biopsies. Enrollment started in March 2012 in The Netherlands Cancer Institute and will be continued in a 2-stage Simon design. Clinical trial information: NCT02654821.

TPS9603 Poster Session (Board #426a), Mon, 1:15 PM-4:45 PM

Reversing resistance to PD-1 blockade by combination of talimogene laherparepvec (T-VEC) with pembrolizumab (pembro) in advanced melanoma patients following progression on a prior PD-1 inhibitor: SWOG S1607 (NCT#02965716). *First Author: Siwen Hu-Lieskovan, UCLA's Jonsson Comprehensive Cancer Center, Los Angeles, CA*

Background: A significant number of patients do not respond to PD-1/L1 blockade because there are no pre-existing tumor antigen-specific T-cells in their tumors ready to attack the cancer. We hypothesize that this lack of sufficient immune activation can be addressed by a combination therapy with an immune activating oncolytic virus such as T-VEC. Intralesional administration of T-VEC, a modified herpes simplex virus type-1, can selectively replicate in tumor tissue and stimulate a local and systemic antitumor immune response. **Methods:** This is a Phase 2 study of T-VEC plus pembro in patients with advanced melanoma whose disease progressed after prior therapy with a PD-1/L1 inhibitor. The primary endpoint is durable response rate. Secondary objectives include objective response rate in the injected, non-visceral non-injected and visceral lesions, progression free survival, overall survival and toxicity. Translational objectives include difference in T-cell infiltrate in responding vs non-responding tumors. Key eligibility criteria include unresectable melanoma; anti-PD-1/L1 based therapy must be the immediate previous line of treatment within 56 days prior to registration; no confirmed partial or complete response to prior anti-PD1 agents; Zubrod performance status 0-2; no active brain metastases; no history of autoimmune disease or toxicity requiring steroids; and adequate organ function. Subjects in cohort A must have at least one measurable visceral lesion; in cohort B subjects must not have visceral lesion. Subjects will receive intratumoral injection of T-VEC 1 million PFU/ml for cycle 1 followed by 100 million PFU/ml from cycle 2 to 36 (one cycle equals 21 days). Pembro 200mg IV will be given every 21 days. Tumor biopsy and research blood are taken at baseline and while on treatment at Day 28 (both injected and non-injected lesions). Tumor assessments are performed every 12 weeks, and treatment is continued while clinical benefit persists for up to 2 years. A total of 36 subjects will be enrolled in cohort A and 25 subjects in cohort B, with a Simon 2 stage design. Clinical trial information: NCT02965716.

TPS9604 Poster Session (Board #426b), Mon, 1:15 PM-4:45 PM

Determining optimal sequencing of anti-PD-1 and BRAF-targeted therapy: A phase II randomised study of neoadjuvant pembrolizumab with/without dabrafenib and trametinib (D+T) in BRAF V600 mutant resectable stage IIIb/c/d melanoma (NeoTrio trial). *First Author: Maria Gonzalez, Melanoma Institute Australia, North Sydney, Australia*

Background: BRAF targeted and CTLA-4/PD-1 immunotherapies have high response rates and improve survival for patients (pts) with metastatic melanoma, however, most still die of this disease. It is hypothesised the activated cytotoxic T cell infiltrate that occurs early during treatment with BRAF/MEK inhibitors is potentiated by adding checkpoint inhibitors, resulting in improved response and survival. While trials combining BRAF/MEK inhibitors and anti-PD-1/L1 antibodies are underway in the metastatic setting, the neo-adjuvant (neo-adj) setting provides an opportunity to test different treatment schedules in small cohorts of pts. Tissue and blood biomarkers can be drawn at several timepoints and correlated to clinical and pathological endpoints to explore mechanisms of response, biomarkers of efficacy, and to select the best schedules to take forward to larger-scale trials. **Methods:** Eligible pts with BRAF V600 mut, stage IIIB/C/D, resectable and measurable (RECIST 1.1) melanoma are evenly assigned to 3 cohorts (n = 60). All pts undergo complete macroscopic resection (RES) at wk 12 and receive neo-adj therapy for 12 wks preceding RES, followed by 40 wks of adjuvant (adj) therapy. Cohort 1 receive sequential therapy with D+T for 2 wks, then 4 pembrolizumab (pembro) doses until wk 12, and 3 wkly pembro after RES. Cohort 2 receive concurrent D+T and 3 wkly pembro before and after RES. Cohort 3 receive 3 wkly pembro for the entire treatment course. Pembro is given at a flat dose of 200mg. Ultrasound of known disease areas is undertaken during the neo-adj period. CT and FDG PET/CT are used to measure response and exclude progression in the neo-adj phase, and to monitor for recurrence during adj and post treatment phases. Blood and tumour samples are collected at baseline, wk 1, 4 and 12. The primary endpoint is the complete pathological response rate at RES following 12 wks of therapy. Secondary endpoints include RECIST response, metabolic response, OS, RFS, safety/tolerability, surgical outcomes, quality of life, and biomarker analysis. First patient enrolled 29Nov2017. Clinical trial information: NCT02858921.

TPS9605 Poster Session (Board #427a), Mon, 1:15 PM-4:45 PM

ADAM trial: A multicenter, randomized, double-blinded, placebo-controlled, phase 3 trial of adjuvant avelumab (anti-PD-L1 antibody) in merkel cell carcinoma patients with clinically detected lymph node metastases; NCT03271372. *First Author: Shailender Bhatia, University of Washington Fred Hutchinson Cancer Center, Seattle, WA*

Background: Merkel cell carcinoma (MCC) is a rare and aggressive skin cancer. MCC with clinically detected lymph node (LN) metastases is associated with high risk of systemic recurrence despite initial surgical therapy and/or radiation therapy (RT). Adjuvant cytotoxic chemotherapy is not associated with overall survival benefit in stage III MCC and there is a strong unmet need for effective adjuvant systemic therapy. Clinical investigation of PD-1/PD-L1 blockade in patients with metastatic MCC is associated with remarkable improvement in clinical outcomes with response rates > 50% in a chemotherapy-naïve setting. This notable benefit from PD-1 blockade in stage IV MCC, along with the recent success with adjuvant PD-1 blockade in stage III melanoma, together provide strong rationale for investigating avelumab, an anti-PD-L1 antibody, for adjuvant systemic therapy in MCC patients with high risk of recurrence. **Methods:** The ADAM (Adjuvant Avelumab in Merkel) trial is an investigator-sponsored, phase 3, multi-center, double-blinded and placebo-controlled study. We plan to enroll 100 MCC patients with clinically or radiologically detected LN metastases treated definitively with surgery (with or without adjuvant RT). Patients will be randomized (1:1) to receive either avelumab or placebo administered IV at a dose of 10mg/kg every 15 days for the first 4 months, then once monthly for the next 4 months, and then once every 4 months. Treatment will end 2 years after starting the study drug, or upon recurrence of disease, unacceptable toxicity, or study withdrawal. The primary endpoint is relapse-free survival. Secondary endpoints include overall survival, disease-specific survival, distant metastasis-free survival, and safety and tolerability. Exploratory endpoints include tissue and blood-based biomarkers and AMERK (Anti-Merkel polyomavirus) serology as a recurrence predictor in a prospective, multi-center setting. The ADAM trial represents the first-ever phase 3 trial in MCC and is a major academic collaboration across several US cancer centers. Clinical trial information: NCT03271372.

TPS9606 Poster Session (Board #427b), Mon, 1:15 PM-4:45 PM

Multicenter phase 2 study to identify the optimal neo-adjuvant combination scheme of ipilimumab (IPI) and nivolumab (NIVO) (OpACIN-neo). *First Author: Elisa A. Rozeman, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: The outcome of high risk stage III melanoma patients (pts) is poor, with a 5 year overall survival (OS) rate of < 50%. Adjuvant (adj) high dose IPI significantly improves 5 year progression free survival (PFS) and OS and adj NIVO improves the median PFS even more. In stage IV pts, the combination of IPI and NIVO improves response rates (RR) and PFS compared to monotherapy, but at cost of higher toxicity. Neo-adjuvant (neoadj) treatment may be a favorable approach as immune checkpoint inhibition (ICI) is of greatest value at the moment of TCR triggering and therefore dependent on the amount of antigen. The phase Ib OpACIN study compared neoadj versus adj IPI plus NIVO. The pathological RR (pRR) was 80% in the neoadj arm, and to date after a median follow-up of 24 months, none of the responders has relapsed, while 4/10 pts have relapsed in the adj arm. Moreover, pts in the neoadj arm expanded more tumor-resident TCR clones than adj treated pts. Neoadj IPI+NIVO was feasible, but toxicity was high with 90% grade 3/4 immuun-related adverse events (irAE) in both arms. This raises the question whether neoadj IPI plus NIVO can be alternatively scheduled to reduce toxicity but preserve efficacy. **Methods:** The aim of the multi-center phase 2 OpACIN-neo trial is to identify an optimal neoadj combination scheme of IPI and NIVO. 90 pts with resectable stage III melanoma will be randomized 1:1:1 between three different combination schemes of IPI and NIVO (Arm A: 2x IPI 3mg/kg plus NIVO 1mg/kg q3wks, Arm B: 2x IPI 1mg/kg plus NIVO 3mg/kg q3wks, Arm C: 2x IPI 3mg/kg q3wks directly followed by 2x NIVO 3mg/kg q2wks). All pts will undergo surgery at week 6. Primary endpoints are rate of grade 3 and 4 irAEs, pRR, and radiologic RR according to RECIST 1.1. Major inclusion criteria are: ≥1 measurable lymph node metastases (according to RECIST 1.1) that can be biopsied, no history of in-transit metastases in the last 6 months, and naïve for ICI. Baseline biopsies and blood samples (week 0, 6, 12) will be taken. An interim analysis was planned after 13 pts had been accrued to each arm (according to the Simon stage-2 design). Pre-specified activity goals for the first stage of accrual were met; until now 56 of 90 pts have been enrolled. Clinical trial information: NCT02977052.

TPS9607 Poster Session (Board #428a), Mon, 1:15 PM-4:45 PM

Confirmatory trial of non-amputative digit preservation surgery in subungual melanoma: JCOG1602 (J-NAIL study). *First Author: Yasuhiro Nakamura, Department of Skin Oncology/Dermatology, Saitama Medical University International Medical Center, Saitama, Japan*

Background: Subungual melanomas (SUMs) are rare, comprising only 2–3% of all cutaneous melanomas in the Caucasian population and 8.7–20% of all cutaneous melanomas in the Asian and African populations. The excision margin for SUM remains controversial, and although amputations at various bone levels have been proposed, more proximal amputation levels have not improved prognoses. In addition, the prognosis for patients with SUM does not depend on the amputation level, but rather on the time from initial diagnosis to surgery. Furthermore, non-amputative digit-preservation surgery has been performed for SUMs in situ and < = 0.5 mm-thick. A recent study has indicated that not all patients with invasive SUMs histologically showed invasion to the underlying distal phalanx, and digit-preservation surgery can be applied to such patients without compromising prognosis. This trial is designed to investigate the efficacy and safety of digit preservation surgery in SUMs without bone invasion. **Methods:** Eligible patients are less than 80 years old, with stage I, II, or III SUM without evidence of tumor invasion to the underlying distal phalanx on preoperative radiograph. Eligible patients receive digit preservation surgery. Sentinel node biopsy is performed for patients without regional lymph node enlargement. Regional lymph node dissection is performed for patients with regional lymph node enlargement. The primary endpoint is major relapse-free survival (major RFS), which do not include local recurrence as an event; and the secondary endpoints are overall survival, digit-preservation survival, relapse-free survival, local relapse-free survival, partial relapse-free survival, and incidence of adverse events. We anticipate that the expected 5-year major RFS of historical control of amputation surgery is 77%, and that of non-amputative digit preservation surgery will decrease the major RFS by less than 10%. The planned sample size is 85 patients to provide power of 70% and on-sided alpha of 10%. Planned accrual period is 5.5 years and a follow-up period is 5 years. The trial began in November 2017 and two patients have been enrolled as of January 2018. Clinical trial information: UMIN000029997.

TPS9608 Poster Session (Board #428b), Mon, 1:15 PM-4:45 PM

SWOG S1512: A phase II and pilot trial of pembrolizumab in patients with resectable or unresectable desmoplastic melanoma (DM). *First Author: Kari Lynn Kendra, The Ohio State University Comprehensive Cancer Center, Columbus, OH*

Background: DM is characterized by high collagenous stroma and a high mutational burden. A retrospective review demonstrated a 70% RR to anti-PD1 -in 60 patients with metastatic melanoma. Surgery for locally advanced DM often results in large resections in exposed areas of the body. Determining the capability of reducing the tumor size and surgical defects is of clinical interest. Evaluating the correlation of T cell infiltrate, TCR clonality, and the impact of pre-existing adaptive immune response with clinical response is of potential predictive interest. **Methods:** This prospective study evaluates neoadjuvant pembrolizumab in patients with resectable DM (phase 2) and pembrolizumab in patients with unresectable DM (pilot). The primary endpoint of cohort A (resectable DM) is pathologic complete response rate (pCR). Secondary endpoints: ORR at 9 weeks, OS at 9 weeks, and toxicity. The primary endpoint of cohort B (unresectable DM) is CR. Secondary endpoints: PFS and OS. Translational objectives for both cohorts: evaluate the association between mutational load (whole exome sequencing) and pCR, examine relationships between T-cell infiltration and response, and assess the difference in TCR clonality in responders and non-responders. Key eligibility criteria include no prior systemic therapy and adequate organ function. In addition (cohort A) patients must have resectable disease. Cohort A: pembrolizumab 200 mg IV q 3wk x 3, followed by resection. Cohort B: pembrolizumab 200 mg IV q3wk. Blood for correlative studies: prior to initiation of pembrolizumab. For both cohorts, biopsies will occur pre-treatment, prior to C2, and at the time of resection (cohort a). Tumor assessments are performed at baseline and at week 9. Cohort B: tumor assessments continue every 9 weeks. Cohort A: if >5 patients demonstrate a pCR, further study is warranted (alpha of 4.6%, power of 90.2%). Cohort B: ≥ 3 patients demonstrating a CR warrants further study (true CR is 5%, power is 82%). As of January 2018, accrual = 5. Funding: NIH/NCI grant awards U10CA180888 and U10CA180819; and in part by Merck, Sharpe & Dohme, Corp. Clinical trial information: NCT02775851.

10000 **Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

Omega-3 fatty acid use for obese breast cancer patients with aromatase inhibitor-related arthralgia (SWOG S0927). *First Author: Sherry Shen, Columbia University Medical Center, New York, NY*

Background: Although aromatase inhibitors (AIs) prolong survival in postmenopausal women with breast cancer (BC), AI arthralgia can lead to discontinuation. Obese patients have higher rates of AI arthralgia than non-obese patients. Omega-3 fatty acid (O3-FA) treatment for AI arthralgia has produced mixed results. We performed an exploratory analysis to evaluate whether the effects of O3-FAs are associated with body mass index (BMI). **Methods:** SWOG S0927 was a randomized placebo-controlled trial of O3-FA use for AI arthralgia. Post-menopausal women with stage I–III BC taking an AI were randomized to 24 weeks of O3-FAs or placebo. Brief Pain Inventory (BPI) pain scores and serum were assessed at baseline, 6, 12, and 24 weeks. Global change in joint pain was assessed with scores ranging from -3 for "very much worse" to +3 for "very much better" than baseline. **Results:** Among the 249 participants, 139 had BMI $<$ 30 (56%) and 110 had BMI $\geq$30 (44%). Patients with BMI $\geq$30 had higher rates of diabetes (19% vs. 8%, p= 0.009) and hypertension (53% vs. 31%, p= 0.0005), were more likely to have $\geq$2 cardiovascular risk factors (33% vs. 17%, p= 0.009), and had lower HDL levels (49.9 vs. 60.3, $p<$ 0.0001). O3-FA use was associated with significantly reduced triglyceride levels at 12 weeks compared with placebo in patients with BMI $\geq$30 (-22.42 vs. +1.59, p= 0.03), but not in those with BMI $<$ 30 (p= 0.12, interaction p= 0.09). Among patients with BMI $\geq$30, O3-FA use was associated with a 2.89-point decrease in BPI worst pain score after 24 weeks compared to a 1.49-point decrease with placebo use (p= 0.02), whereas there was no significant difference between O3-FAs and placebo in those with BMI $<$ 30 (p= 0.40, interaction p= 0.05). Trends were similar using global change in joint pain for O3-FA use compared to placebo (BMI $\geq$30, +0.98 vs. +0.48 respectively, p= 0.05; BMI $<$ 30, +0.57 vs. +0.50 respectively, p= 0.80), though the interaction was not statistically significant (p= 0.22). **Conclusions:** In BC patients with BMI $\geq$30, O3-FA use was associated with significantly reduced AI arthralgia and significantly lower triglyceride levels compared to placebo. If confirmed, O3-FA use may lead to improved AI adherence in this subset of BC patients. Clinical trial information: NCT01385137.

The effect of acupuncture versus cognitive behavior therapy on insomnia in cancer survivors: A randomized clinical trial. *First Author: Jun J. Mao, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Insomnia is a common and debilitating disorder experienced by up to 60% of cancer survivors. We evaluated the effectiveness of acupuncture versus cognitive behavior therapy for insomnia (CBT-I). **Methods:** We conducted a randomized clinical trial of acupuncture vs. CBT-I among 160 post-treatment cancer survivors with clinically diagnosed insomnia disorder. Acupuncture involved stimulating body points with needles. CBT-I included sleep restriction, stimulus control, cognitive restructuring, relaxation training, and education. The intervention duration was eight weeks (primary end point) with a follow up assessment at 20 weeks. Insomnia severity, measured by the Insomnia Severity Index, was the primary outcome. **Results:** The mean age of participants was 61.5 years, 57% (n = 91) were women, and 29.4% (n = 47) were non-white. At the end of treatment, acupuncture reduced insomnia severity by 8.3 points (95% CI 7.3-9.4), compared to 10.9 points (95% CI 9.8-12.0) for CBT-I, with CBT-I being the more effective treatment overall (2.6, 95% CI 1.1 – 4.1, P = 0.0007). Patients with mild insomnia were significantly more likely to respond to CBT-I than acupuncture (85% vs. 18%, p $<$ 0.0001); however, patients with moderate to severe insomnia had similar response rates to CBT-I and acupuncture (75% vs. 66%, p = 0.26). Both groups had few mild adverse events and maintained improvements up to 20 weeks. Both groups also had similar improvement in quality of life in physical health (p = 0.46) and mental health (p = 0.44) during the study. **Conclusions:** While both acupuncture and CBT-I resulted in clinically meaningful and durable effects among cancer survivors with insomnia, CBT-I was more effective, especially among patients with mild insomnia symptoms. Patients and oncology clinicians can use these findings to inform their choice of insomnia treatment. Clinical trial information: NCT02356575.

Improving communication with older patients with cancer using geriatric assessment (GA): A University of Rochester NCI Community Oncology Research Program (NCORP) cluster randomized controlled trial (CRCT). *First Author: Supriya Gupta Mohile, University of Rochester Medical Center, Rochester, NY*

The full, final text of this abstract will be available at abstracts.asco.org at 2:00 p.m. ET on Friday, June 1, 2018, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2018, issue of the *Journal of Clinical Oncology*. On site at the Meeting, this abstract will be printed in the Sunday edition of *ASCO Daily News*.

10004 **Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

Symptom burden in hospitalized patients with curable and incurable cancers. *First Author: Richard Newcomb, Massachusetts General Hospital, Boston, MA*

Background: Inpatient supportive care interventions are targeted to patients with advanced solid tumors due to perceived higher symptom burden. Yet, few studies have characterized symptom prevalence in hospitalized patients with curable cancers. We aimed to describe and compare symptom burden and palliative care utilization in hospitalized patients with curable and incurable cancers to determine the allocation of such supportive care resources. **Methods:** We conducted a single center study of 1549 patients (238 curable hematologic, 239 curable solid, 123 incurable hematologic, 949 incurable solid cancers) who experienced an unplanned hospitalization between 9/14-4/17. On admission, we assessed patients' physical symptoms (Edmonton Symptom Assessment System) and psychological distress (Patient Health Questionnaire-4 and Primary Care PTSD Screen). **Results:** The median number of moderate to severe symptoms reported by patients with curable hematologic, curable solid, incurable hematologic, and incurable solid cancers were 5 [3-6], 5 [3-7], 5 [4-6], and 6[4-7], respectively. Most patients reported moderate to severe fatigue (83.6%, 82.9%, 81.3%, 86.9%). Table 1 depicts rates of psychological distress. In adjusted analyses patients with incurable solid cancers reported higher symptom burden (β = 7.6, P $<$ 0.01), depression (β = 0.4, P = 0.01), and anxiety (β = 0.3, P = 0.03) symptoms, but no difference in PTSD symptoms. Among patients in top quartile of symptom burden, palliative care was consulted in 16.2%, 7.9%, 23.8%, and 49.6% (P $<$ 0.01) of patients with curable hematologic, curable solid, incurable hematologic, and incurable solid cancers, respectively. **Conclusions:** Hospitalized patients with solid and hematologic cancers experience substantial physical and psychological symptoms regardless of the curability of their illness. Palliative care is rarely consulted for highly symptomatic patients with curable cancers. Inpatient supportive care interventions should target the needs of all highly symptomatic patients with cancer.

Symptoms	Curable Hematologic	Curable Solid	Incurable Hematologic	Incurable Solid
Depression	15.2%	14.2%	21.4%	18.1%
Anxiety	11.8%	13.4%	15.0%	19.3%
PTSD	13.1%	13.0%	13.2%	13.3%

10005 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Randomized trial of a symptom monitoring intervention for hospitalized patients with cancer. *First Author: Charn-Xin Fuh, Massachusetts General Hospital, Boston, MA*

Background: Hospitalized patients with cancer experience a high symptom burden, which is associated with poor health outcomes and increased healthcare utilization. We conducted a pilot randomized trial to assess the feasibility and preliminary efficacy of a symptom monitoring intervention to improve symptom management in hospitalized patients with advanced cancer. **Methods:** We randomly assigned patients with advanced cancer and unplanned hospitalizations who were admitted to the oncology service to a symptom monitoring intervention or usual care. Patients in both arms daily self-reported their symptoms (Edmonton Symptom Assessment System and Patient Health Questionnaire-4) via tablet computers. Patients assigned to the intervention had their symptom reports presented graphically with alerts for moderate/severe symptoms during daily team rounds. We defined the intervention as feasible if participants completed > 75% of their daily symptom assessments. We also observed daily team rounds to determine how often clinicians discussed and developed a plan to address patients' symptoms. We used regression models to assess intervention effects on patients' symptoms throughout their hospital stay and readmission risk. **Results:** From 10/26/16-6/30/17, we randomized 150 patients (81.1% enrollment rate; median age = 64.0 [22.7-92.8]; 40.7% female). The most common cancers were gastrointestinal (36.7%) and lung (22.0%). Patients completed 89.4% of their daily symptom assessments. Clinicians discussed 60.4% of the symptom reports and developed a plan during rounds to address patients' symptoms 20.8% of the time. Compared with usual care, patients assigned to the intervention had a greater proportion of days with lower psychological distress (B = 0.12, P = .008). Intervention patients experienced improvements in their average symptom scores for drowsiness (B = -0.54, P = .033) and dyspnea (B = -0.43, P = 0.009). Intervention patients had lower risk of readmissions (hazard ratio = 0.68, P = .221), although this difference was not significant. **Conclusions:** This symptom monitoring intervention is feasible and demonstrates encouraging preliminary efficacy for improving patients' symptoms and risk for readmissions. Clinical trial information: NCT02891993.

10006 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Does timing of palliative care consults impact end-of-life health services utilization in pancreatic cancer patients? *First Author: Nizar Bhulani, University of Texas Southwestern Medical Center, Dallas, TX*

Background: Early palliative care consult can influence end of life health care utilization in controlled clinical trials. However, the effect in large scale, real world setting is not known. We explored the effect of early vs. late palliative care consult on end of life health care utilization in Medicare patients with pancreatic cancer. **Methods:** Pancreatic cancer patients diagnosed between 2000 - 2009 with palliative consults were identified using the Surveillance, Epidemiology, and End Results (SEER)-Medicare linked database. Early palliative care was defined as a consult received in the first 4 weeks of diagnosis. Patients older than 66 years, with survival more than 3 months and known date of death were included. Trend of palliative care consults and health services utilization was studied for patients with early vs late palliative care consults. Statistical analyses were performed with SAS version 9.4 (SAS Institute, Inc., Cary, NC). **Results:** Out of the 1966 patients with palliative care consults, 840 (43%) received early palliative care. On univariate analysis, age, sex, state of residence and stage at diagnosis were associated with early palliative care consult ($p < 0.001$). On multivariate analysis, patients with early palliative care consults were more likely to be women, older than 85 years and have stage 4 disease. Race and state of residence were not associated with early vs late palliative care consult. Patients with early palliative care had lower number of visits to the ED (2.4 vs. 3.0 $p < 0.001$) and lower cost of ED care ($3043 vs. $4117, $p < 0.001$). Early palliative care patients were admitted less frequently to the ICU compared to late palliative care patients (0.68 vs. 0.94, $p < 0.001$) and the duration of Intensive care unit stay was shorter (3.0 days vs 3.7 days, p 0.04). Cost of ICU care was not statistically different between both the groups. **Conclusions:** In this claims analysis of elderly pancreatic cancer patients, those with early palliative care had lower health care utilization as measured by ED and ICU stay. This provides real world evidence to support oncology societies' recommendations for early integration of palliative care.

10007 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Patient (Pt) and oncologist (MD) discordance in goals of care in end of life (EOL) decision making. *First Author: Sara L Douglas, Case Western Reserve University-Nursing and Case Comprehensive Cancer Center, Cleveland, OH*

Background: Providing EOL care that is in accordance with Pt goals of care is an essential component of quality care. Because discordance between the attitudes of Pt and physician can undermine optimal EOL care, identification of disagreements regarding goals of care is important, particularly in the context of advanced disease. **Methods:** This was a longitudinal design study. Adult Pts with Stage IV gastrointestinal (GI) or lung cancer were eligible. Each Pt and MD were surveyed at study enrollment and every 3 months for 15 months or until the Pt died. The primary variables of interest were the Pt and MD identified goals of care and what the MD believed to be the Pt's goal of care, using a visual analog scale (VAS). Scores on the VAS ranged from 0 (comfort, quality of life) to 100 (survival, length of life). Discordance was defined as an absolute difference > 40 on the VAS. **Results:** Between January 2015 and July 2017, 378 Pts were enrolled. Refusal rate was 27.5%; attrition rate 8.1%. 168 Pts (44%) died and their results are presented. Mean age was 64 years (range = 36-88 years); 66% had GI and 34% had lung cancer. Mean time from enrollment to death was 6.5 months (range = 3 - 15 months). At the last assessment prior to Pt death, 32% of the Pt-MD pairs had discordant goals (> 40 points different). In 60% of these cases, the Pt had more survival focused goals while in 40% of cases the MD had more survival focused goals. Also, 77% of Pt-MD pairs with discord at enrollment still had discord at the last assessment before death ($p < .001$). In comparing what the MD believed to be the Pt's goal of care with the Pt's actual goal of care at death, there was discord in 27% of the pairs. The correlation between MDs' own identified goals for Pts and what MDs identified as the Pts' goals was large ($r = .71$, $p < .001$). **Conclusions:** These data suggest that communication between Pts and MDs is suboptimal regarding goals of care at the EOL. Interventions to improve the explicit discussion of mutual goals of care over time between MDs and Pts are needed in order to ensure that patients receive EOL care consistent with their goals.

10008 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Understanding factors contributing to geographic variations in end-of-life expenditures. *First Author: Nancy Lynn Keating, Harvard Medical School, Boston, MA*

Background: Health care spending at the end of life varies across geographic areas and yet is not associated with improved outcomes. The factors underlying these variations are poorly understood. We assessed the extent to which geographic variation in end-of-life spending for advanced-stage cancer patients is explained by differences in patient sociodemographic factors, clinical factors, patient beliefs, physician beliefs, and availability of services. **Methods:** Using data from the prospective, multi-regional CanCORS study, we studied 1132 patients with advanced-stage lung and colorectal cancer diagnosed in 2003-2005 who died before 2013. We linked patient and physician survey data, medical record data, and Medicare data, and we characterized Medicare spending in the last 30 days of life. After assessing differences in patient factors/beliefs, physician beliefs, and availability of services across areas that differed based on Dartmouth Atlas measures of intensity of end-of-life spending, we used mixed effects linear regression with random area effects to assess the area-level variance in spending in the last 30 days of life in our cohort and the proportion of that variance explained with sequentially adding groups of explanatory variables. **Results:** The mean (SD) expenditures in the last 30 days of life were $13,664 ($17,563). Physicians in higher-spending areas reported less knowledge and comfort caring for dying patients and less positive attitudes about hospice (all $P < .05$). Higher-spending areas had more physicians, a lower percentage of primary care providers, and fewer hospices/10,000 persons. Physician beliefs and availability of services each explained 45-60% of the variation in end-of-life expenditures; area-level patient beliefs did not contribute to area-level variations. **Conclusions:** Physicians' beliefs and area-level availability of services but not patients' beliefs were important factors explaining geographic variations in intensity of end-of-life spending for patients with advanced-stage cancer. Physician training and strategic allocation of services may have potential for decreasing unwarranted variation in care at the end of life for patients with advanced-stage cancers.

10009 Clinical Science Symposium, Mon, 1:15 PM-2:45 PM

Patient-defined goals and preferences among older adults with cancer starting chemotherapy (CT). *First Author: Enrique Soto Perez De Celis, City of Hope, Duarte, CA*

Background: Older adults with cancer facing decisions with competing health outcomes may favor maintaining quality of life (QOL), independence, or cognition over prolonging survival. The goal of this study was to elicit preferences among outcomes from older adults starting CT. **Methods:** This is a secondary analysis of an ongoing prospective study aimed at identifying and addressing vulnerabilities in older adults (age ≥65) starting CT (NCT02517034). Patients completed 3 tools assessing preferences in health outcomes: 1) *Health Outcomes Tool:* rates the relative importance of 4 outcomes (survival, function, freedom from pain, and freedom from symptoms) using a visual analog scale (VAS); 2) *Now vs. Later Tool:* rates the relative importance of QOL at 3 times: today,1 year (y) in the future , and 5y in the future using a VAS; and 3) *Attitude Scale:* rates subjects' agreement with statements related to outcomes. We measured the proportion of patients reporting other outcomes being "as important" or "more important" than survival and studied their characteristics. **Results:** 121 patients (median age 71y, 47% male, 72% Stage IV, 31% gastrointestinal cancer) were included. 52% had poor physical function, 50% needed help with instrumental activities of daily living (e.g. cooking or transportation), and 73% had poor social support. On the *Health Outcomes Tool*, 44% rated other outcomes as more important than survival. On the *Now vs. Later* tool, 59% considered current QOL more/as important as QOL at 1y, and 58% considered current QOL more/as important as QOL at 5y. On the Attitude Scale, 58% agreed/strongly agreed with: "*I would rather live a shorter life than lose my ability to take care of myself*"; and 81% agreed/strongly agreed with: "I*t is more important to me to maintain my thinking ability than to live as long as possible*". Patients with good physical function and/or good social support were more likely to consider survival as the most important outcome, regardless of stage. **Conclusions:** Half of older patients rated other outcomes (particularly cognitive ability) as being more important than survival. Eliciting which outcomes are the most important for older patients can help define treatment goals and improve shared decision-making.

10010 Clinical Science Symposium, Mon, 1:15 PM-2:45 PM

Quality of life (QoL) in older patients (pts) with cancer and prognostic factors for QoL decline. *First Author: Lore Decoster, UZ Brussel, Brussels, Belgium*

Background: QoL is an important outcome parameter for older pts with cancer. This study aims to investigate baseline QoL and its evolution during treatment in older pts with cancer and to determine prognostic factors for QoL decline. **Methods:** A prospective Belgian multicentre (n = 22) study was performed. Pts ≥70 years with a malignant tumor and abnormal G8 screening tool (≤14/17) underwent geriatric assessment (GA) and baseline QoL evaluation using the European Organization for Research and Treatment Quality of Life Questionnaire core 30 (EORTC QLQ-C30) Global Health Status Scale, with follow up at 2-3 months. QoL change was defined as the difference between follow-up and baseline QoL score and categorized in three groups: decline (< -10), improvement (> 10) and no change (≥-10 and ≤10). Uni- and multivariate regression was performed to determine factors associated with baseline QoL and with QoL decline (level of significance at p = 0.05). **Results:** 3673 pts with abnormal G8 and QoL data available at both time points were included in the present analysis. In multivariate analysis, baseline QOL was significantly worse with decreasing age, poor ECOG-PS (≥2 vs 0/1), higher stage (reference stage I) and abnormal geriatric domains such as functional status by instrumental activities of daily living, pain, fatigue, mental status and nutritional status. Pts with tumors of the digestive system, gynaecological system and thorax presented statistically lower baseline QoL compared to pts with breast cancer, (reference group) (p = 0.030; p = 0.017 and p = 0.017 respectively). During the course of treatment (n = 2972), an improvement in QoL was observed in 1037 pts (35%) and a decline in 838 pts (28.2%). In multivariate analysis, stage, baseline pain and fatigue, malnutrition and absence of comorbidities were prognostic for QoL decline **Conclusions:** Our study demonstrates that QoL improves in 1/3 of older pts with cancer during treatment, indicating that these pts can benefit from cancer treatment. On the other hand, QoL declines in 1/4 of older pts during cancer treatment and we identified prognostic factors for QoL decline in these pts. Directed interventions against pain, fatigue and malnutrition may subsequently improve QoL for these pts.

10011 Clinical Science Symposium, Mon, 1:15 PM-2:45 PM

Relationship between preoperative geriatric frailty and need for postoperative intensive care unit admission and subsequent short- and long-term mortality. *First Author: Armin Shahrokni, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The relationship between age-related impairments in geriatric surgical patients and the need for postoperative intensive care unit (ICU) admission and subsequent outcomes is largely unknown. **Methods:** Since 2015, Memorial Hospital surgical services have referred cancer patients age 75+ to the Geriatrics Service for preoperative evaluation including the eRFA (Shahrokni et al., JNCCN, Feb 2017). The eRFA has 13 items: the Karnofsky Performance Scale, basic and instrumental activities of daily living, Timed Up and Go test, history of falls, social activity level, social support, distress level, depression, cognitive impairment, polypharmacy, weight loss, and number of comorbid conditions. In order to develop a scoring system , we performed a univariate & multivariate analysis of the correlation between these variables, the frequency of ICU admission, and the likelihood of 12-month mortality among ICU survivors. **Results:** 1164 patients (median age 79) were evaluated prior to surgery after which 53 patients (4.6%) were admitted to the ICU. Five eRFA factors were associated with ICU admission: > 4 comorbid conditions, weight loss > 10 pounds, polypharmacy, limited social activity, and high distress level. The median number per patient of these 5 impairments in our cohort was 2. In a univariate analysis, frail patients (> 2 of 5 impairments) were more likely to be admitted to the ICU than fit patients (≤2 of 5 impairments (OR = 3.42, p < 0.001). The correlation persisted after adjusting for age, gender, ASA performance status, duration of surgery, and preoperative albumin level (OR = 2.87, p = 0.013). The one year mortality of patients not needing ICU care was 1.8% for fit patients and 5.7% for frail patients. The one year mortality of patients needing ICU care was 9.4% for fit patients and 20.4% for frail patients. **Conclusions:** Frail patients are at higher risk for postoperative ICU stay compared to fit patients. 1 out of 5 frail patients age 75+ dies within 1 year after ICU stay. Future studies should assess the effectiveness of interventions aimed to improve the long-term outcomes of geriatric ICU survivors.

10012 Clinical Science Symposium, Mon, 1:15 PM-2:45 PM

Randomized trial of a pharmacy intervention for older adults with cancer. *First Author: Margaret Ruddy, Massachusetts General Hospital, Boston, MA*

Background: Oncology clinicians often struggle with managing medications and vaccinations in older adults with cancer. We sought to demonstrate the feasibility and preliminary efficacy of integrating pharmacists into the care of older adults with cancer to enhance medication management and administration of appropriate vaccinations. **Methods:** We enrolled patients age ≥65 years with breast, gastrointestinal (GI), or lung cancer receiving first-line chemotherapy and randomly assigned them to the pharmacy intervention or usual care. Patients assigned to the intervention met with a pharmacist during their second or third chemotherapy infusion. The pharmacist performed medication reconciliation, obtained vaccination history and made recommendations to the care team. We obtained information about patients' medications and vaccinations via patient-report and from the electronic health record (EHR) at baseline and week 4. We determined the number of discrepant medications, defined as the difference between patient-report and the EHR; and categorized medications as potentially inappropriate, based on Beers Criteria as determined by non-intervention pharmacists blinded to group assignment. We defined the intervention as feasible if > 75% of patients enrolled in the study and attended the visit with the pharmacist. **Results:** From 1/17/17-10/27/17, we randomized 60 patients (median age = 71.5 years [range 65.1-91.5]; 32 [53.3%] female; 39 [65.0%] retired; cancer types: 27 [45.0%] GI, 21 [35.0%] lung, and 12 [20.0%] breast). We enrolled 80.1% of patients approached, and 96.6% of patients assigned to the intervention attended the pharmacist visit. At week 4, patients assigned to the intervention had higher vaccination rates for pneumonia (67.9% vs 40.0%, P = .040) and influenza (67.9% vs 23.3%, P = .001). Compared with usual care, intervention patients had fewer discrepant (5.8 vs 8.3, P = .081) and potentially inappropriate (3.5 vs 4.8, P = .069) medications at week 4, although the differences were not statistically significant. **Conclusions:** Integrating pharmacists into the care of older adults with cancer is feasible with encouraging preliminary efficacy for enhancing medication management and improving patients' vaccination rates. Clinical trial information: NCT02871115.

10013 Poster Discussion Session; Displayed in Poster Session (Board #1), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Impact of cancer on employment and finances in young adult (YA) survivors. *First Author: Tyler Garrett Ketterl, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: YA survivors face challenges unique from those survivors of childhood cancer or older adults. The potential impact of cancer or its treatment upon employment and financial burden in YAs are not fully known. **Methods:** Eligibility included diagnosis of malignancy between ages 18-39, 1-5 years from diagnosis and ≥1 year from therapy completion. Participants were randomly selected from tumor registries of 7 participating sites and asked to complete an online patient reported outcomes survey. Diagnostic/treatment data were abstracted from medical records. **Results:** Subjects included 872 survivors, 72.3% female, grouped into 4 diagnostic categories: breast (n = 209), thyroid (n = 104), lymphoma (n = 91), and other (n = 332) including brain tumors. Most survivors (736, 84.4%) reported working for pay at some time between diagnosis and survey completion and 517 (70.2%) reported a physical component to their job and that their cancer/treatment interfered with their ability to perform the physical (58.6%) or mental (54.2%) job tasks required. Males were more likely to be working for pay any time after diagnosis (OR1.6, 95% CI 1.0-2.5, p = 0.05). Survivors treated with surgery alone were less likely to have impairments limiting their ability to perform physical (OR 0.5 95% CI 0.3-0.7, $p < 0.005$) or mental tasks (OR 0.4, 95% CI of 0.3-0.5, $p < 0.005$) at work compared to those treated with chemotherapy +/- radiation. 56.6% reported taking extended paid or unpaid time off from work, or made a change in their hours, duties or employment status and 95.6% of those reported this was related to their cancer/treatment. Unpaid time off from work was taken by 286 survivors (38.9%) with 107 (37.4%) of those taking > 6 months unpaid time off. Survivors in the "other diagnosis" category were significantly more likely to have taken unpaid time off work (OR of 1.5, 95% CI 1.0-2.2, p = 0.015). Nearly 1/3 of all survivors reported that they/their family borrowed money or went into debt because of cancer/treatment; 47.2% with debt borrowed > $10,000 and 13 (4.9%) reported bankruptcy. **Conclusions:** In YA survivors, cancer/treatment has a significant impact on the physical and mental activities of their jobs and many report ongoing work limitations > 1 year from therapy completion.

Predictors of long-term follow-up care (LTFU) among survivors of adolescent and young adult (AYA) cancers: A population-based study in the IMPACT cohort. *First Author: Dalia Kagramanov, The Hospital for Sick Children, Toronto, ON, Canada*

Background: AYA cancer survivors are at elevated risk for developing therapy-related adverse health outcomes and require life-long risk-adapted health care. We determined the location and providers of LTFU care received by a population-based cohort of survivors and explored the demographic, disease and treatment factors that predict care received. **Methods:** We conducted a retrospective study using multiple linked administrative health databases in Ontario, Canada. Five-year AYA cancer survivors were identified from the IMPACT cohort, which consists of all AYA who were 15-20.9 years of age at diagnosis of one of six specified cancers in Ontario between 1992-2010. We defined four models of care: specialized survivor clinic; general oncology clinic; primary care physician; no regular care. Specialized survivor clinic attendance was only available to those treated at a paediatric cancer centre. Separate Poisson regression models determined attendance rates, adjusting for demographic, disease and treatment characteristics. **Results:** The cohort consisted of 1574 survivors (1066 treated at adult centres; 508 treated at paediatric centres). Median follow-up from five-year survival was 8.7 years (95% CI, 4.3-13.9 years). Over their follow-up, the highest level of care accessed by survivors was: survivor clinic (16.7%), oncology clinic (47.3%), PCP (9.3%), no regular care (26.7%). Among those eligible for the specialized survivor clinics, greater attendance was observed in females, those younger at diagnosis, living closer to a clinic, and those treated with Bone-Marrow Transplant. Specialized clinic attendance decreased by 19% with every 2-years of follow up. In contrast, the risk of receiving no regular care among all survivors was highest in males and increased by 20% with every 2-years of follow-up. **Conclusions:** Despite the need for risk-based care, most eligible AYA survivors do not attend specialized clinics, and almost one-third receives no regular care, with lack of care increasing over time. Strategies are needed to ensure that the maximum number of survivors receive life-long risk-based care.

10015 Poster Discussion Session; Displayed in Poster Session (Board #3), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Risk of chronic comorbidities in survivors of adolescent and young adult cancer (AYA). *First Author: Chun Chao, Kaiser Permanente Southern California, Pasadena, CA*

Background: Data needed to develop age-appropriate survivorship care guidelines for AYA cancer are lacking. Using a retrospective cohort design, we described risk of chronic comorbidities in AYA cancer survivors. **Methods:** 6,778 two-year survivors of cancers diagnosed at age 15-39y at Kaiser Permanente Southern California between 2000-2012 were included. A non-cancer comparison group (N = 87,737) was matched to cancer survivors (1:13) on age, sex and calendar year. New onset of comorbidities listed in Table 1 was ascertained using ICD-9 diagnosis codes, laboratory values, medication prescription and cause of death in the electronic health records through end of 2014. Incidence rate and incidence rate ratio (IRR) from Poisson regression adjusting for age, sex, race/ethnicity were derived for each comorbidity. Within cancer survivors, multivariable Poisson regression was used to evaluate the associations between chemotherapy exposures (mutually adjusted) and risk of selected comorbidities. **Results:** Median age at cancer diagnosis was 33y; 35% were male; 42% were non-Hispanic white. The most common cancer types were thyroid (16%), breast (16%) and melanoma (10%). Comparison with non-cancer subjects: see Table 1. Within cancer survivors: chemotherapy exposure was associated with multiple comorbidities. The largest IRR was found for methotrexate use and avascular necrosis (AN) (IRR = 15.5); followed by ifosfamide and chronic kidney disease (IRR = 8.3); and bleomycin and pulmonary fibrosis (IRR = 4.7). **Conclusions:** These data provide basis for identifying high-risk individuals for population-based targeted surveillance.

IRR for cancer survivors in reference to non-cancer comparisons.

	IRR	95% Confidence Interval	
Heart Failure	2.6	1.8	3.8
Coronary Artery Disease	1.6	1.1	2.3
Stroke	3.2	2.4	4.3
Dyslipidemia	1.3	1.2	1.4
Hypertension	1.4	1.2	1.5
Premature Ovarian Failure	2.9	1.6	5.3
Diabetes	1.5	1.3	1.7
Thyroid Disorders	2.1	1.8	2.4
Hearing Loss	1.7	1.3	2.1
Vision Loss	1.4	0.7	2.5

Scrambler therapy for established chemotherapy-induced neuropathy: A randomized phase II trial. *First Author: Charles L. Loprinzi, Mayo Clinic, Department of Oncology, Rochester, MN*

Background: Pilot data support that Scrambler therapy may benefit patients with Chemotherapy-induced peripheral neuropathy (CIPN). **Methods:** Patients with CIPN for at least 3 months were eligible if the patient had finished previous neurotoxic chemotherapy. They needed to have CIPN-related tingling or pain of at least 4/10 during the week prior to registration. Patients were randomized to receive Scrambler therapy versus TENS (trans-electrical nerve stimulation), for 2 weeks. Patient- reported outcomes were utilized, including the EORTC CIPN 20 instrument, the Subject Global Impression of Change (GIC) scale, and a number of 0-10 numerical analog scales regarding applicable symptoms. After each treatment day, and weekly for 8 more weeks, patients were asked whether they would recommend their therapy to others. The primary chosen endpoint was the percentage of patients who achieved more than 50% reduction in pain or tingling scores (based on which item was selected most problematic at baseline for each patient), from baseline values, after 2 weeks of therapy. The proportion of patients with ≥50% reduction in symptom scores were estimated and compared using the chi-square test. The areas under the curves (AUC) were compared using the t-test. **Results:** 50 patients were randomized, 25 per arm. Data are provided in the Table. P values are provided, understanding that this is not a well-powered phase III trial. **Conclusions:** These results support that Scrambler therapy decreases CIPN symptoms, to a moderate degree. Further exploration of this approach is indicated. Clinical trial information: NCT01290224.

Item (higher scores are better)	Scrambler	TENS	P-value
≥50% reduction in selected pain/tingling scores, at 14 days	40%	20%	0.06
≥50% reduction in pain scores, at 14 days	56%	28%	0.04
≥50% reduction in tingling scores, 14 days	48%	24%	0.08
14 day AUC pain reduction from baseline	25	16	0.08
14 day AUC tingling reduction from baseline	24	13	0.08
14 day AUC GIC neuropathy symptoms rating	17	5	0.001
14 day AUC GIC pain rating	13	4	0.004
14 day AUC GIC overall QOL rating	14	4	0.006
10 week AUC pain reduction from baseline	11	13	0.72
10 week AUC GIC neuropathy symptoms rating	7	3	0.09
10 week AUC GIC pain rating	5	2	0.16
10 week recommendation of therapy to other patients (mean)	82%	39%	0.0001

Randomized, double-blind, phase III trial of monosialotetrahexosylganglioside versus placebo in GI cancer patients with oxaliplatin induced peripheral neurotoxicity (TJMUCH-GI-001). *First Author: Zhou Likun, Tianjin Medical University Cancer Institute and Hospital, National Clinical Research Center for Cancer Tianjin's Clinical Research Center for Cancer, Key Laboratory of Cancer Prevention and Therapy Tianjin Medical University, Tianjin, China*

Background: Neurotoxicity is the most common dose-limiting toxicity of oxaliplatin. There is no treatment for cumulative sensory neuropathy. This trial is designed to study the efficacy of Monosialotetrahexosylganglioside (GM1) in GI cancer patients with oxaliplatin-induced peripheral neurotoxicity (OIPN). **Methods:** In this single center (TJMUCH),double-blind, phase III trial, patients were randomized in a 1:1 ratio to receive GM1 or placebo. Patients with OIPN persisting during or after oxaliplatin-based chemotherapy were eligible. The patients who remained on oxaliplatin after enrollment, received concurrent placebo or GM1 x 7 days with each chemotherapy cycle. The patients who stopped taking oxaliplatin, were treated with placebo or GM1 x 14 days every 3 weeks. GM1 was dosed at 60mg daily for every 3-week or 40mg daily for every 2-week schedule. Trial was continued until visual analogy score (VAS) decreased by ≥30% or stayed unchanged after two more treatments beyond completion of oxaliplatin. The primary endpoint was reduction of modified EORTC QLQ-CIPN20(MCIPN20) score by ≥30%. Secondary endpoints were improvement of VAS by ≥30%, CTCAE grade by≥1. Patients who received ≥1 treatment cycle were included in the analysis. Chi-square tests were used for statistical analysis. **Results:** From May 2015 to Dec 2017, 73 patients were enrolled in GM1 and 72 in placebo arm. 39 (53%) patients in GM1 and 10 (14%) in placebo arm achieve ≥30% reduction in MCIPN20 (RR = 3.85, 95% CI, 2.08-7.11, P < 0.0001). 36 (49%) patients in GM1 and 16 (22%) in placebo arm had ≥30% improvement of VAS (RR = 2.22, 95% CI,1.36-3.623, P = 0.001). The median treatment cycles of GM1 was 2 (range,1-7). Majority of patients in both arms (89% in GM1 and 83% in placebo) continued receiving oxaliplatin on the trial. There were no significant differences in CTCAE and acute neurotoxicity grading between the two arms. There was no ≥G3 GM1 related adverse events. **Conclusion:** GM1 effectively reduces OIPN in GI cancer patients. The observed clinical benefit is independent of oxaliplatin discontinuation. Trial: NCT02486198 (Drug was afforded by Qilu Pharmaceutical Co., Ltd, China). Clinical trial information: NCT02486198.

Pretreatment physical activity to predict short- and long-term chemotherapy-induced peripheral neuropathy (CIPN) in a nationwide longitudinal study of paclitaxel for breast cancer. *First Author: Ian Kleckner, University of Rochester Medical Center, Rochester, NY*

Background: CIPN is a dose-limiting toxicity with no established treatments and limited knowledge of risk factors. Exercise during chemotherapy may mitigate CIPN, but it is unknown whether pre-treatment physical activity protects against CIPN. This secondary analysis examines whether physical activity before paclitaxel predicts short- and long-term CIPN symptom severity. **Methods:** 200 women with non-metastatic breast cancer (52±10 years) receiving paclitaxel with curative intent rated their CIPN (0-10 severity of numbness/tingling in the past week) three times—within 1 week pre-paclitaxel, and within 1 month and 6 months post-paclitaxel. We used linear regression to test whether pre-paclitaxel patient-reported physical activity (Aerobic Center Longitudinal Study) predicted CIPN symptoms (either within 1 month or 6-months post-paclitaxel) controlling for pre-paclitaxel neuropathy, age, BMI, diabetes (yes/no), and cumulative paclitaxel dose. **Results:** CIPN symptom severity increased significantly from pre- to post-paclitaxel (+3.6 units; $p < 0.001$) and from pre- to 6-month follow-up (+2.08; $p < 0.0001$). This is a high level of development of CIPN considering that a 0.5-unit change is clinically significant. Each additional 15 min/day of physical activity pre-paclitaxel was associated significantly less severe CIPN symptoms at post-paclitaxel (-0.5; $p = 0.0002$) and 6 months follow-up (-0.25; $p = 0.09$). Each additional 10 years of age was associated with significantly more severe CIPN symptoms at post-paclitaxel (+0.8, $p < 0.0001$) and 6-month follow-up (+0.9; $p < 0.0001$) controlling for pre-paclitaxel neuropathy, physical activity, BMI, diabetes, and paclitaxel dose. **Conclusions:** Breast cancer patients who are more physically active pre-paclitaxel experience less severe CIPN immediately and 6 months post-paclitaxel. Physical activity may be especially important for older patients because CIPN severity increases with age. Clinicians prescribing paclitaxel should ask patients about pre-treatment physical activity levels because it may lead to greater treatment tolerability.

Efficacy and safety of additional olanzapine to ondansetron and dexamethasone for prevention of chemotherapy-induced nausea and vomiting: A randomized, double-blind, placebo-controlled, crossover study. *First Author: Veerisa Vimolchalao, Division of Oncology, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand*

Background: Currently, the antiemetic regimen consisting of dexamethasone, palonosetron plus a NK-1 antagonist or olanzapine is recommended in prevention of chemotherapy induced nausea and vomiting (CINV) for highly emetogenic chemotherapy (HEC). However, palonosetron and NK-1 antagonists are costly and not accessible for all Thai patients. We sought to evaluate efficacy and safety of the additional olanzapine to ondansetron and dexamethasone for CINV prevention in patients receiving HEC. **Methods:** We randomly assigned chemotherapy-naïve patients receiving either anthracycline-cyclophosphamide or high dose cisplatin (≥50 mg/m^2) regimen, to receive olanzapine or placebo in addition to ondansetron and dexamethasone. All subjects were crossed over to another arm on second-cycle chemotherapy. The primary endpoint was complete response (CR) rate defined as no vomiting and no use of rescue drugs. **Results:** At first cycle, CR was 69% among the 32 patients receiving olanzapine and 25% among the 32 patients receiving placebo, $p < 0.001$. CR was significantly better with olanzapine than with placebo in acute phase (0-24 h) (75% vs. 31%, $p < 0.001$) and delayed phase (24-120 h) (69% vs. 43%, $p = 0.038$). In analysis after two crossover antiemetic regimens, CR was improved in olanzapine group compared to placebo group in acute phase (72% vs. 33%, $p < 0.001$), delayed phase (67% vs. 38%, $p < 0.001$) and overall period (67% vs. 25, $p < 0.001$). In crossover analysis using visual analog score (VAS), the patients with olanzapine had lower mean VAS in nausea (1.28 vs. 3.05, $p < 0.001$) and fatigue (3.5 vs. 4.58, $p < 0.001$) but higher mean VAS in appetite (2.5 vs. 1.55, $p = 0.003$) and sleepiness (3.26 vs. 2.2, $p < 0.001$). There were no grade 3 and 4 antiemetic-drug-related toxicities. Mean QT interval change did not different between two groups (-4.30 ms vs. -1.86 ms, $p = 0.69$). The olanzapine combination was preferable to placebo in 52 of 60 patients ($p < 0.001$). **Conclusions:** Without the NK-1 antagonists, the additional olanzapine to ondansetron and dexamethasone significantly improved CINV prevention and was safe in patients receiving HEC.

Treating anorexia in people with advanced cancer. a randomised, double blind, controlled trial of megestrol acetate, dexamethasone or placebo. *First Author: David Christopher Currow, University of Technology Sydney, Sydney, Australia*

Background: This multi-site, double blind, parallel arm, fixed dose phase III study compared megestrol acetate 480 mg/day, dexamethasone 4 mg/day and placebo for their net short-term effect on appetite and quality of life (QoL) in people with advanced cancer **Methods:** Inpatients or outpatients seeing a palliative care team with anorexia for ≥2 weeks with a score ≤4 on a 0-10 numeric rating scale (NRS; 0 = no appetite, 10 = best possible appetite) were recruited. Participants were randomised to receive megestrol 480 mg, dexamethasone 4 mg or placebo daily for up to 4 weeks. Primary response assessment occurred at day 7, and responders were defined as having more than a 25% improvement in NRS compared to baseline. **Results:** There were 190 people randomised (megestrol acetate n = 61; dexamethasone n = 67, placebo n = 62). At week 1 (primary endpoint), 79·3% of participants in the megestrol group, 65·5% in the dexamethasone group and 58·5% in the placebo group (p = 0·067) were responders. No differences in weight, performance status or quality of life were reported. Treatment emergent adverse events occurred in the majority of participants (90·4%), and included altered mood and insomnia. Hyperglycemia was more frequent in people on dexamethasone. **Conclusions:** Although there was little difference between treatment groups for the primary or secondary effectiveness endpoints, there was a consistent trend in secondary endpoints favouring megestrol acetate than dexamethasone or placebo. Subgroup analyses indicate megestrol acetate may be more effective in maintaining body weight for subjects whose appetite responded. Clinical trial information: ACTRN12608000405314.

Retrospective cohort study comparing hydration protocols with or without mannitol in patients treated with cisplatin (HYDRA study). *First Author: Nathalie LeTarte, Centre Hospitalier de l'Université de Montréal (CHUM), Montreal, QC, Canada*

Background: Various hydration protocols have been used to mitigate acute kidney injury (AKI) induced by cisplatin. The use of mannitol remains controversial however recent studies suggested that mannitol has a protective effect against cisplatin-induced nephrotoxicity. **Methods:** This is a retrospective observational study including patients who received at least one dose of cisplatin between September 2010 and December 2016 at the Centre Hospitalier de l'Université de Montréal. After approval by our IRB, we compared the risk of all grade AKI between hydration protocols with or without mannitol (12.5 g if cisplatin < 75 mg/m^2 or 25 g if cisplatin ≥ 75 mg/m^2). Patients received a total of 3 or 4 L of fluids (D5/0.45 NS or NS) according to the cisplatin dose. AKI was evaluated by comparing baseline serum creatinine (SCr) to the highest SCr levels between each cycle. **Results:** Of 1932 patients identified, 1821 were included in this study of which 658 received mannitol whilst 1163 received hydration alone. The risk of all grade AKI was significantly lower in the mannitol group for patients with lymphoma, gynecologic, upper gastrointestinal and urinary tract malignancies. No difference was seen for head and neck, lung, germ cell and others cancer (see table I). In the subgroup of patients receiving cisplatin < 75 mg/m^2, mannitol reduced all grade AKI for head and neck (HR 0.37 [95% CI 0.2 – 0.8]), lung (HR 0.56 [95% CI 0.3 – 0.98], upper GI (HR 0.15 [95% CI 0.1 – 0.5]) and urinary tract cancer (HR 0.14 [95% CI 0.1 – 0.5]). **Conclusions:** Hydration protocols containing mannitol were associated with a significantly lower risk of all grade AKI compared to hydration alone. Therebefore, mannitol should be added to hydration protocol with cisplatin especially those with doses < 75 mg/m^2.

All grade AKI for mannitol vs non-mannitol hydration.

Malignancies	Hazard Ratio [95% CI]	p value
Head and Neck (N = 543)	0.99 [0.7–1.5]	p = 0.99
Lung (N = 456)	0.73 [0.5–1.1]	p = 0.096
Gynecologic (N = 333)	0.50 [0.3–0.94]	p = 0.033
Upper GI (N = 128)	0.32 [0.1–0.8]	p = 0.009
Urinary tract (N = 80)	0.29 [0.1–0.7]	p = 0.005
Lymphoma (N = 63)	0.33 [0.2–0.8]	p = 0.008
Germ cell cancer (N = 69)	1.15 [0.3–4.4]	p = 0.836
Other (N = 149)	1.29 [0.6–2.7]	p = 0.508

Survival of advanced cancer patients (ACP) receiving early inpatient palliative care (PC) compared to standard oncologic care (SOC) without palliative care. *First Author: Fay J. Hlubocky, University of Chicago Medicine, Chicago, IL*

Background: Palliative care has been described as significantly enhancing ACP quality of life, symptom control, and reducing healthcare costs. Increasing evidence has shown improved outcomes for hospitalized ACP including discharge status, transitions to end-of-life care, and overall morality. **Methods:** An ACP cohort receiving either PC or SOC between Jan 2015-Dec 2015 were retrospectively analyzed for potential predictors associated with discharge and death. Demographics, diagnosis, discharge status, and survival from the time of discharge were compared between groups. Univariate and multivariate analyses were performed (e.g. log-rank survival and Cox proportional hazards regression). **Results:** Of a total of 810 patient encounters, 468 were admitted to PC and 342 to SOC. In comparison with SOC, PC were more likely to be: younger (61.1±13.2 v. 62.5±13.0, p = 0.02); AA (48% v. 36%, p = 0.0045); female (50% v. 40%, p = 0.005); shorter length of inpatient stay(5.7± 4.9 v. 6.2±6.5, p = 0.01). Compared with SOC, ACP receiving PC were more likely to be discharged to: home (55% v.45%, p = 0.01); healthcare facilities (e.g. skilled nursing, inpatient rehabilitation) (36.1% v. 20%, p = 0.04); and hospice (home and inpatient) (7.7% v 5.8%, p = 0.02). PC had overall greater median survival from the time of discharge (106.8±99.95 v. 73.8±61.93, p = 0.03) compared to SOC. PC were less likely to die during admission compared to SOC (4.7% v. 6.8%, p = 0.01) and 1.2 times more likely to be discharged home (p < 0.0001). Home discharge was associated with longer survival (ratio = 0.34; 95%CI, p = 0.002). For PC, multivariate logistic regression revealed younger age (< 50) (p < 0.001); female gender (p = 0.004); and AA ethnicity (p = 0.003) was associated with home discharge. Primary cancer diagnosis (p = 0.0001) and disease severity (p = 0.0034) were independently associated with greater likelihood of death. **Conclusions:** Results from this simultaneous care program reveal a unique model of care such that early inpatient PC benefits younger and underserved ACP with distinct clinical characteristics and survival, with improved outcomes, compared to those receiving SOC.

10023 Poster Discussion Session; Displayed in Poster Session (Board #11), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Association between phase angle and survival in patients with advanced cancer admitted to an acute palliative care unit (APCU). *First Author: David Hui, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Many complex healthcare decisions in the last weeks and days of life are dependent on accurate prediction of survival. Phase angle, a novel measure of cellular function, has been found to be prognostic in patients with months of survival; however, its utility has not been examined in patients with weeks/days of survival. We determined the association between phase angle and survival in advanced cancer patients admitted to an APCU. **Methods:** In this prospective cohort study, we assessed phase angle with bioelectric impedance analysis in consecutive patients with advanced cancer admitted to our APCU. Survival analysis was conducted using the Kaplan Meier method, log rank test and multivariate Cox regression analysis, adjusting for established prognostic factors including the Palliative Prognostic Score and delirium. We identified the optimal phase angle cutoff using the Contal and O'Quigley method. Subgroup analysis was conducted in patients without peripheral edema. **Results:** Among 204 patients, the median overall survival was 10 days (95% confidence interval 8-11 days). 74 (36%) did not have edema. The median phase angle was 3.7° for the entire cohort and 3.9° for the no edema cohort. In univariate analysis, a low phase angle was associated with decreased survival for the entire cohort (≤3° vs. > 3°, median survival 7 vs. 10 days; P = 0.045) and for the no edema cohort (5 vs. 18 days; P < 0.001). In multivariate Cox regression analysis adjusting for known prognostic factors, phase angle was not significant for the entire cohort but remained significant in the no edema cohort (hazard ratio 2.46, 95% confidence interval [CI] 1.14, 5.31; P < 0.001). Specifically, phase angle ≤3° had an accuracy of 86% (95% CI 77%-93%) for 3 day survival among patients without edema, with a sensitivity of 50%, specificity of 90%, positive predictive value of 30%, negative predictive value of 95% and positive likelihood ratio of 5.2. **Conclusions:** We identified phase angle as a novel, independent prognostic factor even among patients with a short survival. Phase angle ≤3° was predictive of impending death within 3 days. Our findings suggest that phase angle may be best used among patients without edema.

Comprehensive evaluation of place of death for patients with hematological malignancies, 1999-2015. *First Author: Fumiko Ladd Chino, Duke University Radiation Oncology, Durham, NC*

Background: Patients with hematologic malignancies (HM) are more likely to receive aggressive care at the end of life than patients with solid tumors, and less often utilize hospice care. However, most prior research in this area is Medicare-based (only patients ≥65), or limited to hospice reporting, thus more comprehensive US-based analyses are needed. **Methods:** CDC WONDER contains death certificate data for all US counties and is maintained by the National Center for Health Statistics. Place and year of death was obtained for all HM deaths from 1999- 2015, as well as sociodemographic information. Place of death was dichotomized to death at home or hospice facility, vs other location. Data from 2015 was used to test for disparities in place of death associated with sociodemographic variables or primary cancer on univariate (UVA) and multivariate (MVA) logistic regression. **Results:** In the study period, there were 951,435 deaths due to HM. 26.1% of HM deaths were in those aged < 65. HM inpatient deaths decreased from 54.6% in 1999 to 38.2% in 2015, while home (25.9 to 32.7%) and hospice facility deaths (0 to 12.1%) increased (p < 0.001). On MVA of all cancers, including solid tumors, patients with HM had the lowest odds of home or hospice facility death (OR 0.56, 95% CI 0.55-.057). Compared to any other cancer type, in 2015 patients with HM were 65% more likely to die in the hospital (38.2% HM vs 23.2% non-HM) and 25% less likely to die at home (32.7% HM vs 43.6% non-HM) (both p < 0.001). On MVA of HM cancers, older age (40-64: OR 1.57, 95%CI 1.35-1.82 and 65+: OR 2.29, 95%CI 1.97-2.65), being married (OR 1.44, 95%CI 1.44-1.73) and having myeloma (OR 1.32, 95%CI 1.25-1.39) were associated with death in home or hospice facility, while being black (OR 0.71, 95%CI 0.66-0.77), Asian (OR 0.55, 95%CI 0.48-0.64) or Hispanic (OR 0.83, 95% CI 0.76-0.90) or having a chronic leukemia (OR 0.81, 95%CI 0.76-0.87) had decreased odds of dying at home or hospice. **Conclusions:** Despite a 30% decrease in hospital deaths over time, patients with HM remain more likely than solid tumor patients to die in the hospital, and disparities exist along age, racial, and ethnic lines. Continued efforts are needed to improve the provision of quality end-of-life care in hematology.

10025 Poster Session (Board #13), Mon, 1:15 PM-4:45 PM

Hospice use among Medicare fee-for-service (FFS) or managed-care organization (MCO) enrollees with leukemia and myeloma. *First Author: Adam J. Olszewski, The Warren Alpert Medical School of Brown University, Providence, RI*

Background: Hospice services are "carved out" of Medicare MCO contracts and covered by FFS Medicare. This financially incentivizes MCOs to enroll their patients (pts) in hospice early, and may affect survival outcomes. We compared the use of hospice at the end of life (EOL) and associated overall survival (OS) among MCO and FFS Medicare beneficiaries with hematologic cancers, who are known to underuse hospice and need effective strategies to improve their EOL care. **Methods:** From the linked Surveillance, Epidemiology, and End Results-Medicare database, we selected pts with acute myeloid leukemia (AML), chronic lymphocytic leukemia (CLL), or myeloma who died in 2007-2011. We identified their MCO/FFS status before death, hospice use at EOL, and disenrollment from hospice before death. We compared binary outcomes in multivariable robust Poisson models, reporting relative risk (RR) adjusted for multiple sociodemographic characteristics. OS from diagnosis was compared in Cox models, reporting adjusted hazard ratios (HR) with 95% confidence intervals (CI). **Results:** Among 24,118 pts (median age 78 y, 43% women), 25% were enrolled in a MCO at EOL. MCO enrollees were 17% more likely to use hospice than pts with FFS Medicare (RR, 1.17; 95%CI, 1.14-1.21), consistent across histologies (Table). They were also less likely to use hospice services for < 3 days (RR, 0.82; 0.75-0.89). We found no difference in adjusted OS (HR, 0.98; 0.95-1.01), or in the rate of early hospice disenrollment (RR, 1.07; 0.91-1.27) between MCO and FFS enrollees. **Conclusions:** Compared with FFS enrollees, MCO enrollees with leukemia or myeloma use hospice more frequently and for longer, without any decrease in survival. Enhanced care coordination in MCO may contribute to more meaningful use of hospice among pts with these cancers, suggesting a novel strategy for improving quality of care at EOL in hematology.

	AML	CLL	Myeloma
N	7,347	6,847	9,924
Hospice at EOL, MCO / FFS	54% / 47%	50% / 45%	55% / 48%
RR (95%CI)	1.18 (1.12-1.24)	1.15 (1.08-1.22)	1.18 (1.12-1.23)
< 3 days on hospice, MCO / FFS	19% / 25%	18% / 20%	17% / 21%

10026 Poster Session (Board #14), Mon, 1:15 PM-4:45 PM

Aligning goals of care with aggressiveness at end of life (EOL). *First Author: Sara L Douglas, Case Western Reserve University-Nursing and Case Comprehensive Cancer Center, Cleveland, OH*

Background: Aggressiveness of care at EOL should be aligned with the patient's (Pt) goals of care that ideally are established in collaboration with the oncologist (MD). This is particularly important for Pts with advanced disease. **Methods:** A longitudinal study was conducted. Adult Pts with Stage IV gastrointestinal (GI) or lung cancer were eligible. Each Pt and MD were surveyed at study enrollment and every 3 months for 15 months or until the Pt died. The primary variables of interest were the Pt and MD identified goals of care using a visual analog scale (VAS). Scores on the VAS ranged from 0 (comfort, quality of life) to 100 (survival, length of life). Individual scores > = 70 indicated a strong preference for prolonging survival and presumably a willingness to undergo aggressive interventions. Scores < = 30 indicated a strong preference for comfort care and presumably a willingness to forgo aggressive interventions. Aggressiveness of care was assessed using standard indicators (e.g. > 1 hospitalization in last 30 days of life, hospice stay < 3 days, etc.). **Results:** Between January 2015 and July 2017, 378 Pts were enrolled. Refusal rate was 27.5%; attrition rate 8.1%. 168 Pts (44%) died and their results are presented. Mean age was 64 years (range = 36-88 years); 66% had GI and 34% had lung cancer. Mean time from enrollment to death was 6.5 months (range = 3-15 months). As seen in Table 1, when there was strong agreement between Pt and MD on goals (either survival or comfort) the patient received levels of aggressiveness of care that were reflective of the goals. For example, when Pt and MD agreed on the goal of survival, 90% received at least 1 indicator of aggressive treatment. **Conclusions:** These data confirm the importance of aligning Pt and MD goals of care. When there are differences in goals, regardless of whether the Pt or MD identified comfort as the priority, Pts are at risk for receiving care that is not congruent with their preferences and goals of care.

	Survival Pt > MD	Survival MD > Pt	Survival Agreement	Comfort Pt > MD	Comfort MD > Pt	Comfort Agreement
% of Subjects (n = 168)	17.3%	11.3%	5.95%	19.6%	23.8%	12.5%
Hospice LOS: Md	12.5	15	2	12	13	20.5
No Aggressive Tx (%)	75%	63%	10%	66%	64%	81%

10027 Poster Session (Board #15), Mon, 1:15 PM-4:45 PM

Impact of palliative care consults on racial disparity in do-not resuscitation (DNR) orders at an urban safety net hospital. *First Author: Nizar Bhulani, University of Texas Southwestern Medical Center, Dallas, TX*

Background: Previous studies have suggested that racial disparities exist for DNR orders in cancer patients. We examined racial differences in DNR orders for pancreatic cancer patients in an urban setting safety net hospital with a high proportion of black patient population. **Methods:** Retrospective analysis was conducted of pancreatic cancer patient records seen at the Parkland Health and Hospital System, Dallas between 1/1999 - 9/2016. Cancer cases and receipt of palliative care were identified from prospectively maintained registries. Demographics, cancer characteristics, DNR order, were abstracted. All statistical analysis was done using IBM SPSS version 24. **Results:** A total of 455 pancreatic cancer patients were included; mean age was 61 years, 227 (50%) were female, 228 (50%) were white and 202 (44%) were black, 277 (61%) received a palliative care, and 29 (6.4%) had at least one ICU admission. There was no statistically significant difference in palliative care consults between whites and black patients. Do-Not-Resuscitate (DNR) order was placed for 140 (30.8%) patients within 60 days of death. DNR status was significantly associated with cancer stage, admission to the ICU and receiving a palliative care consult ($p < 0.001$). There was no difference in the rate of DNR order between white and black patients, 29.7% (68/229) white patients and 32.2% (65/202) black patients ($p = 0.71$). Additionally, age, sex, cancer site or histology were not associated with DNR order. **Conclusions:** In this single institution study of pancreatic cancer patients there was no racial disparity in DNR orders. This can be explained by a high rate of palliative referrals (61%) and a safety net system which improves access to care. Additional studies are needed to understand determinants of DNR order use. Systems based changes, such as early integration of palliative care and increased access to health services can reduce racial disparities in DNR status of minority cancer patients.

10028 Poster Session (Board #16), Mon, 1:15 PM-4:45 PM

End of life care in gynaecological cancer patients: A population-based study of cancer deaths from the Swedish Register of Palliative Care. *First Author: Kristina Lindemann, Institute of Clinical Medicine, Faculty of Medicine, University of Oslo, Oslo, Norway*

Background: The quality of end of life care for gynecological cancer patients in Europe is unknown. Patient age may affect of end of life care. **Methods:** Patients who died expectably from gynaecological cancer between 2013 and 2015 were identified in the population-based Swedish Register of Palliative Care (N = 2,970). We investigated if age-dependent differences were present with respect to twelve indicators of palliative care quality. Patients were categorized in five predefined age groups. Odds ratios (OR) with 95% confidence intervals (CIs), adjusted for type of end-of-life care unit where appropriate, were calculated using logistic regression, with the oldest group (≥85 years) as reference. **Results:** Age-dependent differences in implementation rate were present for three out of 12 end-of-life care quality indicators, some of which were progressively less well met with each increment in age group. Compared to elderly cancer patients, younger patients (40-59 years) were more often informed about imminent death, (OR, 2.29; 95% CI, 1.41-3.71; p = 0.001). They were also more likely to be cared for by a specialised palliative care service (OR, 5.02; 95% CI, 3.78-6.65;p < 0.001). There was no difference between age groups in the assessed for the presence and severity of pain, injections prescribed as needed against pain, nausea, anxiety or death rattle. However, younger patients were more likely to receive fluids via enteral tube or intravenously during last 24 hours of life (OR, 4.86; 95% CI, 3.174-7.445; p = 0.001). **Conclusions:** Elderly gynaecological cancer patients are at high risk to die without the care of specialized palliative care services. Still, also institutions outside specialized care seem to increasingly adhere to palliative care quality guidelines.

10029 Poster Session (Board #17), Mon, 1:15 PM-4:45 PM

Multicenter randomized controlled trial for advanced cancer patients receiving parenteral nutrition (PN) versus oral feeding (OF): Results of AlimK study. *First Author: Carole Bouleuc, Institut Curie, Paris, France*

Background: The decision to use PN in patients with advanced cancer is controversial. There is lack of high evidence level demonstrating its interest and safety in this population. In case of refractory cachexia, PN interest would be to improve health-related quality of life (HRQoL) and to reduce certain symptoms caused by food intake without significant toxicity. AlimK (NCT02151214) study was performed to address this gap. **Methods:** We planned a prospective multicenter randomized controlled parallel-group phase IV trial, with a Zelen single-consent design for randomization. Intervention arm received PN whereas control arm were pursuing OF alone. Primary objective assessed PN influence on HRQoL deterioration free survival (HRQFS) of one of the 3 targeted scores of the EORTC QLQ-C15-PAL: global HRQoL, physical functioning and fatigue. HRQFS was defined as a definitive deterioration of 10 points at least compared to the baseline score, or death. A p-value < 0.0166 was considered statistically significant (Bonferroni adjustment) to ensure an overall bilateral alpha risk of 5%. Key secondary endpoints included overall survival (OS) and safety. **Results:** Between 07/2012 and 03/2017, 148 cancer patients were enrolled in 13 French cancer centers. Informed consent was obtained for 111 patients: 48 (43%) in PN arm and 63 (57%) in OF arm. PN was refused by 8/48 (18%) patients. Among all patients, 98% were metastatic with life expectancy less than one year and 97 % were still on anticancer treatment. Patients were malnourished with median weight loss over 6 months of -8.20 (range -26.5; 10). There was a trend favoring HRQFS in the OF group for global HRQoL (HR = 1.31 95%CI, 0.88-1.94, p = 0.18), physical functioning (HR = 1.58, 95% CI, 1.06-2.35 p = 0,024) and fatigue (HR = 1.19, 95%CI, 0.80-1.77 p = 0.34). Median OS was 3.12 (95%CI 2.27-4.14) months in OF arm vs 1.97 (1.18-3.06) in PF arm. There was a higher total adverse events in PN arm (52%) than in OF arm (41%). **Conclusions:** In this study PN did not provide clinical benefit for advanced cancer patients with numerically reduced OS and increased toxicity. More data will be shown about tolerance of PN and influencing factors on HRQoL scores. Clinical trial information: NCT02151214.

10030 Poster Session (Board #18), Mon, 1:15 PM-4:45 PM

Impact of patient reported functional limitation on overall survival in older adults undergoing autologous hematopoietic cell transplant (AutoHCT). *First Author: Mariam T. Nawas, University of California San Francisco, San Francisco, CA*

Background: The optimal means of assessing fitness for AutoHCT in older adults with hematologic malignancies is unknown. Few studies have evaluated the impact of patient reported function on AutoHCT outcomes. **Methods:** Comprehensive geriatric assessment (GA) including the FACT-BMT quality of life tool was administered to 184 patients ≥50 years old (median 61, range 50-75) at a median of 21 days prior to AutoHCT (range 1-186 days). Associations between GA/QOL metrics and post-transplant outcomes were evaluated using Cox regression. **Results:** The indication for AutoHCT was multiple myeloma / amyloid in 139 patients (76%), lymphoma in 39 patients (21%) and acute leukemia in 6 patients (3%). Median progression-free survival (PFS) was 28 months, and median overall survival (OS) was not reached (median follow up time 23 months). Both PFS and OS were significantly associated with 5 GA components: limitation in instrumental activities of daily living (IADL), patient reported Karnofsky performance status (KPS), and FACT physical, functional and BMT subscale scores (Table). In multivariate analysis, each GA component was adjusted for known prognostic factors (age, provider reported KPS, disease status, comorbidity index). Three components – IADL limitation, patient reported KPS, and FACT-BMT physical subscale score – remained predictive of both PFS and OS. Age was not associated with PFS or OS. **Conclusions:** In patients ≥50 years old undergoing AutoHCT, limitation in any one of three patient reported measures of functional status is independently associated with inferior PFS and OS, even when adjusting for known prognostic factors. Importantly, chronologic age is not associated with outcomes in this population.

Measure		Univariate HR (p value)	Multivariate HR (p value)
Any IADL limitation	PFS	1.94 (0.003)	1.76 (0.02)
	OS	2.99 (0.003)	2.68 (0.02)
Patient reported KPS (per decile)	PFS	0.80 (0.004)	0.78 (0.01)
	OS	0.69 (0.004)	0.74 (0.06)
FACT physical score	PFS	0.94 (0.001)	0.96 (0.02)
	OS	0.91 (0.001)	0.93 (0.03)
FACT functional score	PFS	0.95 (0.02)	0.96 (NS)
	OS	0.91 (0.008)	0.94 (NS)
FACT BMT score	PFS	0.96 (0.02)	0.97 (NS)
	OS	0.93 (0.01)	0.96 (NS)

Randomized clinical trial of telephoned-based physical activity intervention in onco-geriatric patients. *First Author: Haritz Arrieta, Department of Physiology, University of the Basque Country (UPV/EHU), Leioa, Bizkaia, Spain, Leioa (Bizkaia), Spain*

Background: Cancer in older patient favors the loose of physical function. Physical activity could be a key factor to diminish the age and cancer-related decline. **Methods:** We conducted a multicenter open-label 12-month randomized clinical trial with two parallel arms. Onco-geriatric patients with histological confirmation for lymphoma or carcinoma requiring curative treatment were included. Participants were randomly assigned to an intervention (IG) or usual care group (UCG). The IG received individualized phoned physical activity advice. Subjects in the UCG received a booklet with the current national recommendations in physical activity. **Results:** 301 participants were eligible and randomized. The loose of physical function measured by the Short Physical Performance Battery (SPPB) was experienced likewise in both the IG and the UCG at one year. However, after two years significantly less participants within the IG than the UCG declined in the SPPB score among breast cancer participants ($P = .006$), females ($P = .019$), and those with normal nutritional status ($P = .040$). Linear mixed models showed similar results in both the IG and the UCG in the SPPB, gait speed, the level of physical activity measured using the self-reported International Physical Activity Questionnaire, and verbal fluency at baseline and after three, six, twelve, eighteen and twenty four months (NS). Both the IG and the UCG showed similar results for falls, hospitalization, institutionalization, and death at one and two years (NS). **Conclusions:** Telephone-based physical activity intervention were not effective to reduce the functional decline at one year, but significant differences in favor of the IG were observed over two years among females with breast cancer and good nutrition subgroups. Clinical trial information: NCT01432067.

10032 Poster Session (Board #20), Mon, 1:15 PM-4:45 PM

The value of inflammatory markers in predicting overall survival in older adults with cancer. *First Author: Tomohiro F. Nishijima, New York University, New York, NY*

Background: The widely studied inflammatory markers, neutrophil lymphocyte ratio (NLR), platelet lymphocyte ratio (PLR) and lymphocyte monocyte ratio (LMR), are associated with survival outcomes in patients with various cancers. However, little is known about the value of these markers in older cancer patients, especially in relation to traditional prognostic factors, such as age and Karnofsky Performance Status (KPS), and a geriatric assessment (GA) derived scale that is predictive of overall survival (OS) [Nishijima, J Geriatr Oncol. in press]. **Methods:** Our sample includes 144 patients age ≥ 65 years with solid tumor (Carolina Senior Registry NCT01137825) who completed a GA within 3 months of their date of diagnosis in 2010 - 2014 and had pretreatment CBC with differential. Patients were followed for death from any cause for a median of 2.5 years, during which 54 patients died. NLR was dichotomized at the upper limit of normal 3.5 [Forget, BMC Res Notes 2017] while PLR and LMR were dichotomized at the median. The 3-item GA-derived prognostic scale (score ranging 0-3) consisted of (1) "limitation in walking several blocks", (2) "limitation in shopping", and (3) "≥ 5% unintentional weight loss in 6 months". Univariable and multivariable Cox proportional hazards models evaluated whether NLR, PLR and LMR were independently predictive of OS. **Results:** Median age was 72 years, 53% had breast cancer, 27% had stage 4 cancer, 14% had KPS < 80, 11% received less intensive treatment than standard treatment for stage and 39% had NLR > 3.5. In the univariable survival analyses, higher NLR (hazard ratio (HR) = 5.08, 95% CI; 2.85-9.07, $p < 0.001$, 2-year OS; 43% vs 86%), higher PLR (HR = 2.10, 95% CI; 1.20-3.67, p = 0.009, 2-year OS; 60% vs 79%) and lower LMR (HR = 2.11, 95% CI; 1.21-3.66, p = 0.008, 2-year OS; 58% vs 80%) were associated with poor OS. Only NLR remained a significant predictor of OS (HR = 2.16, 95% CI; 1.10-4.25, p = 0.025) after accounting for cancer type, stage, age, KPS, treatment intensity and GA-derived prognostic scale. **Conclusions:** NLR > 3.5 was found to be predictive of poorer OS in older adults with cancer, independent of GA-derived prognostic scale and traditional prognostic factors; further validation in external datasets is warranted.

10033 Poster Session (Board #21), Mon, 1:15 PM-4:45 PM

Patient-reported psychosocial needs and psychological distress: the influence on survival in geriatric oncology patients. *First Author: Bonnie Leung, BC Cancer - Vancouver Centre, Vancouver, BC, Canada*

Background: Little is known about how psychosocial factors and distress affect geriatric oncology patients and their survival. The study goals were: review patient-reported needs from all cancer types; identify factors associated with increased risk for psychological distress, defined as moderate to severe anxiety (ANX) and depression (DEP); and determine whether ANX and DEP are independent prognostic variables for patients ≥65 years. **Methods:** All patients ≥65 years, referred to BC Cancer from 2011 – 2016 who completed the Psychosocial Screen for Cancer (PSSCAN-R) and the Canadian Problem Checklist (CPC) within 6 m of cancer diagnosis were included in the study. Baseline demographics and disease characteristics were collected retrospectively. Univariate analysis using the X^2 test were used to compare patient groups. OS was calculated using the Kaplan Meier method and compared using the log rank test. MVA conducted using Cox-regression analysis. **Results:** 26, 323 patients were included in the analysis. Baseline characteristics: female 50%; age 65-69 29%, 70-79 46%, ≥80 27%; GI 20%, Breast 18%, GU 16%, Lung 16%, Other 29%; M0 66%, M1 19%, MX 15%. Patients presenting with ANX and DEP were more likely to be female, be aged 65 to 69, have lung cancer and metastatic disease (p-values < 0.001). Patients reporting emotional, informational, physical, and social/family problems or needs were more likely to present with ANX and DEP ($p < 0.001$). Median OS ANX 34 m vs no symptoms 43 m ($p < 0.001$) and DEP 31m vs no symptoms 43m ($p < 0.001$). MVA including age, sex, M status, ANX, DEP showed all variables were statistically significant; increasing age HR 1.05, male vs female HR 1.11, M1 vs M0 HR 3.62, ANX vs no symptoms HR 1.30, DEP vs no symptoms HR 1.50. **Conclusions:** Geriatric oncology patients who are female, are aged 65-69, have metastatic disease or lung cancer are at risk for distress. ANX and DEP are independent prognostic variables, negatively impacting survival. This vulnerable cohort of geriatric oncology patients should receive psychological support and follow up to better improve survival.

10034 Poster Session (Board #22), Mon, 1:15 PM-4:45 PM

Is there a role for older-patient-specific cancer clinical trials? A pooled analysis of 2277 older patients in adjuvant breast cancer trials (Alliance A151715). *First Author: Dyda Dao, Mayo Clinic, Rochester, MN*

Background: Breast cancer incidence increases with age, but older patients tend to be underrepresented in clinical trials. To address this underrepresentation, this study examined the role of older-patient-specific trials – defined as those designed explicitly for older cancer patients. **Methods:** This study focused on patients 65 years of age or older (younger patients in age-unspecified trials were excluded). It included all Alliance phase III adjuvant breast cancer trials conducted from 1985-2012, encompassing older-patient-specific trials (CALGB 49907 and NCCTG 89-30-52; the latter was the only hormonal trial) and age-unspecified trials (CALGB 40101, NCCTG 9831, CALGB 9741, CALGB 9344, and CALGB 8541). Comparisons were based on trial type (older-patient-specific *versus* age-unspecified). **Results:** 2277 older patients were included (1014 from older-patient-specific trials; 1263 from age-unspecified trials). The cohort of older-patient-specific trials compared to the cohort of age-unspecified trials comprised a greater percentage of patients 75 year of age or older: 26% *versus* 6% ($p < 0.0001$) with a median age (range) of 72 years (65, 89) and 68 years (65, 84), respectively, ($p < 0.0001$). Median overall survival (OS) was comparable: 12.8 years (95% confidence interval (CI): 11.9-13.7 years) and 13.5 years (95% CI: 12.9-14.1 years) in older-patient-specific trials and age-unspecified trials, respectively. After adjusting for age, estrogen receptor status, tumor size, and positive lymph nodes, OS remained comparable (hazard ratio 0.9; 95% CI: 0.8-1.0; (referent: older-patient-specific trials; performance score excluded from the model due to missing data)). Similar conclusions were reached for recurrence-free survival. Older-patient-specific trials had lower grade 2-5 adverse event rates (68% versus 73%; $p = 0.03$). Sensitivity analyses with only chemotherapy trials (NCCTG 89-30-52 excluded) yielded similar findings. **Conclusions:** Older-patient-specific trials appear to help address the underrepresentation of older patients in cancer clinical trials. Support: UG1CA189823, U10CA180821, U10CA180882

10035 Poster Session (Board #23), Mon, 1:15 PM-4:45 PM

Geriatric comanagement and surgical outcomes of older cancer patients. *First Author: Armin Shahrokni, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Perioperative Geriatric Comanagement may improve surgical outcomes of older frail cancer patients. We present our 3 year experience with perioperative geriatric comanagement & the electronic Rapid Fitness Assessment (eRFA) at Memorial Hospital (MH). **Methods:** Since 2015, MH surgical services referred cancer patients age 75+ to the Geriatrics Service for preoperative evaluation including the eRFA (Shahrokni et al, JNCCN, Feb 2017). The eRFA score (0 to 13) is based on 1 point for impairments in the Karnofsky Performance scale score, dependency for basic and instrumental activities of daily living, Timed Up and Go test, history of fall, limited social activity, poor social support, presence of distress, depression, and cognitive impairment, polypharmacy, weight loss, and > 4 comorbid conditions. These patients were then co-managed by the geriatrics and surgical services while hospitalized. We compared the short- and long-term surgical outcomes of frail patients with fit patients. **Results:** 2291 patients (median age 79) had perioperative geriatric comanagement in 2015-17 with 1175 (51.3%) requiring hospitalization after surgery (average length of stay = 7days). The median eRFA score was 5 (IQR 3-8). 30 day minor & major surgical complications, emegrnecy room visit, readmission & mortality did not differ between frail patients (eRFA > 5) & fit patients (eRFA ≤5) in both the in- and out-patient surgical groups. Among patients requiring hospital stay, frailty was associated with a longer average length of stay (frail vs. fit; 7.7 vs. 6 days, $P < 0.001$). Frailty was associated with the higher likelihood of dying in 12 months after outpatient surgical procedure (OR = 5.27, $p < 0.001$) or inpatient surgical procedure (OR = 2.20, $p = 0.002$). **Conclusions:** Perioperative co-management by geriatricians & surgeons leads to similar short term outcomes between frail and fit patients. Future studies should assess the impact of prolonged geriatric comanagement on long-term outcomes of older cancer patients after surgery.

10036 Poster Session (Board #24), Mon, 1:15 PM-4:45 PM

Geriatric assessment to predict hospitalization frequency and long-term care utilization in older adult cancer survivors. *First Author: Grant Richard Williams, University of Alabama at Birmingham, Birmingham, AL*

Background: Geriatric assessments (GA) assess physiologic age in older adults; however, the association between GA identified impairments and long-term healthcare utilization in older cancer survivors remains unknown. Our objective was to evaluate whether a GA performed at cancer diagnosis was predictive of hospitalizations and long-term care [LTC] utilization in older adult cancer survivors. **Methods:** Older adults within the Carolina Senior Registry (NCT01137825) with GA performed between 3 months before and up to 6 months after diagnosis were included (n = 125). Patients with fee-for-service coverage were linked to Medicare claims. Hospitalizations and LTC utilization (skilled nursing or assisted living) were identified up to 5 years after their diagnosis, death, or 12/31/2013. GA risk measures (prefrail/frail status, impaired Instrumental Activities of Daily Living [IADL], limitations in climbing stairs, prolonged Timed Up and Go [TUG], > 5% unintended weight loss) were assessed in separate Poisson models estimating the relative risk (RR) for hospital and long-term care visits, controlling for person-time, age, and Charlson comorbidity score. **Results:** Participants median age of 74 years, majority female (80%), and white (89%). Most common malignancies were breast (64%) and lung cancer (8%); predominantly early stage disease (stage 0-III = 77%). During follow-up 41 (33%) participants were hospitalized and 20 (16%) received LTC. Prefrail/frail status (RR 2.5, $p < 0.001$), IADL impairment (RR 5.47, $p < 0.001$), and limitations in climbing stairs (RR 2.94, $p < 0.001$) were associated with increased hospitalizations. Prefrail/frail status (RR 1.86, $p < 0.007$), IADL impairment (RR 4.58, $p < 0.001$), presence of falls (RR 6.73, $p < 0.001$), prolonged TUG (RR 5.45, $p < 0.001$), and limitations in climbing stairs (RR 1.89, $p < 0.005$) were associated with LTC utilization. **Conclusions:** GA identified impairments were associated with increased hospitalizations and LTC utilization among older adults with cancer. GA-focused interventions, such as physical and occupational therapy, should be employed to potentially reduce long-term adverse health care utilization in this vulnerable population.

10037 Poster Session (Board #25), Mon, 1:15 PM-4:45 PM

Phase 2 randomized study of a walking intervention for radiation-related fatigue among older breast cancer patients receiving radiation. *First Author: Noam Avraham VanderWalde, Department of Radiation Oncology, University of Tennessee Health Science Center/West Cancer Center, Memphis, TN*

Background: This study's purpose is to determine if an exercise intervention can decrease fatigue in older women receiving radiotherapy (RT) for breast cancer. **Methods:** A phase 2 randomized study was conducted in women age $\geq$ 65 years with breast cancer receiving adjuvant RT. After informed consent, women were randomized to the intervention arm; the Walk with Ease (WWE) pamphlet, or the usual care arm (UC); a document describing the benefit of moderate exercise. Prior to RT patients completed an objective assessment of physical function using the Short Physical Performance Battery (SPPB), and questionnaires to assess fatigue, physical function, and other fatigue-related symptoms. All assessments were repeated at last week of radiotherapy and 1 month follow up. The primary outcome was change in fatigue as measured by the Total Disruption Index (TDI) of the Fatigue Symptom Index (FSI) over time. Secondary outcomes include change in level of activity (based on self-reported walking log), change in physical function as measured by the SPPB, and change in fatigue related symptoms. A Repeated Measures Mixed Linear Model was used to describe the change in outcomes over time. **Results:** Of the 54 patients accrued, 50 had complete data. Median age was 69 years (range 65-84). With the exception of hormone status, the baseline criteria were similar between study arms. Longitudinal modeling revealed no significant change over time in TDI between the two arms (p-value = 0.79). However, these models revealed that increasing walking over time was associated with lower levels of fatigue ($p = 0.04$). Number of minutes walking per week increased in both arms (45 min/wk baseline to 432 min/wk end of RT, $p < 0.01$) and physical function improved statistically over time in both arms ($p < 0.01$) and both remained improved at follow up (p-value = 0.01 and < 0.01 respectively). **Conclusions:** This study demonstrated no benefit in fatigue with the WWE program. However, women in both arms increased their walking and had improved physical function during and following RT. Increased walking was statistically associated with lower fatigue scores during and after radiotherapy in this older group of women with breast cancer. Clinical trial information: NCT02434367.

10038 Poster Session (Board #26), Mon, 1:15 PM-4:45 PM

Anti-PD1 antibodies in late elderly advanced melanoma patients: A retrospective multicentre study. *First Author: Francesco De Rosa, Immunotherapy, Cell Therapy and Biobank, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola (FC), Italy*

Background: advanced age is associated with comorbidities and impairment of the immune system: these aspects may influence efficacy and tolerability of immune checkpoint inhibitors. Limited data suggest that anti-PD1 antibodies in advanced melanoma are equally effective in patients (pts) aged over 65 years; however, the information on late elderly pts ($>$ 75 years) is still lacking, as comorbidities and logistic reasons often exclude them from clinical trials. **Methods:** we retrospectively reviewed clinical records of late elderly advanced melanoma pts treated in any line with an anti-PD1 agent (nivolumab or pembrolizumab) at our institutions to investigate efficacy and toxicity in a real practice setting. Clinical response was assessed according to RECIST criteria; toxicity was assessed according to CTCAE 4.0. Survival was estimated according to Kaplan-Meier method. **Results:** we identified 161 pts fulfilling inclusion criteria (68 M, 93 F). Median age was 79 (range 75-93); 110 pts (68%) had multiple comorbidities including history of other cancers (25 pts) and autoimmune/inflammatory disorders (13 pts). Eighty-eight pts received nivolumab, 73 pembrolizumab; basal LDH was elevated in 76 pts (47.2%). Fourteen pts (8.7%) obtained a complete response and 44 (27.3%) a partial response; additional 30 patients (18.6%) obtained a stable disease. Median overall survival was 8.71 months; normal LDH was significantly associated with better prognosis (14.45 vs 6.08 months; $P = 0.016$). Fifty-five pts have died; 48 of them because of progressive disease and the others for comorbidities. In our series treatment was well tolerated: only 5 pts had severe (G3-4) toxicity and no treatment-related death was reported. Adverse events were managed with corticosteroids and no pt needed additional immunosuppressive agents. **Conclusions:** anti-PD1 antibodies seem equally effective and well tolerated even in late elderly advanced melanoma pts, whose access to treatment should not be restricted solely because of advanced age.

10039 Poster Session (Board #27), Mon, 1:15 PM-4:45 PM

Examining progression free survival (PFS), overall survival (OS), and toxicities of palbociclib in a geriatric population. *First Author: Katherine Clifton, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: A recent FDA pooled analysis of patients treated with CDK4/6 inhibitors showed a trend towards improved PFS in the geriatric population, although this was not statistically significant. The study found more grade 3-4 events in the geriatric population, however the overall adverse event rate was low. The objective of this study was to analyze PFS, OS, dose reductions, dose delays and toxicity in a geriatric population receiving palbociclib as standard of care. **Methods:** Patients with metastatic breast cancer receiving palbociclib in any line of therapy were identified from a cohort of 845 pts at MDACC. Clinical, demographic, comorbidities, recurrence and survival data were collected. Dose delays, dose reductions, and toxicities were retrospectively extracted from the medical record. Data was analyzed using Fischer's exact test for categorized variables and T test/Wilcoxon rank-sum test for continuous variables. PFS and OS were analyzed using the Kaplan Meier method. **Results:** 605 pts who met eligibility criteria were included. Pts receiving palbociclib on clinical trial were excluded. 160 pts were $\geq$ 65 years-old and 92 pts were $\geq$ 70 years-old. Pts $\geq$ 70 had a significantly increased number of dose reductions ($p = 0.03$) and dose delays ($p = 0.02$) compared to the younger pts. Pts $\geq$ 70 had significantly lower baseline GFR ($p < 0.0001$) and higher Charleston Comorbidity index ($p < 0.0001$). There was no significant increase in toxicity rate, including neutropenic fever, infections, or hospitalizations, in the $\geq$ 70 cohort ($p = 0.3$). The $\geq$ 70 cohort had a significantly improved PFS as compared to the younger cohort ($p = 0.02$). This was also true when an age cut-off of $\geq$ 65 was used ($p = 0.009$). There was no difference in OS in either cohort (age $\geq$70 $p = 0.4$, age $\geq$ 65 $p = 0.9$). **Conclusions:** Palbociclib was well tolerated in the geriatric population. Interestingly, the geriatric population was found to have improved PFS. Palbociclib has been shown to restore senescence signaling. Further studies are warranted to investigate if palbociclib may work synergistically with already enhanced senescence pathways in the geriatric population.

10040 Poster Session (Board #28), Mon, 1:15 PM-4:45 PM

Impact of age on outcomes with PD-(L)1 blockade in patients (Pts) with non-small cell lung cancer (NSCLC). *First Author: Morgan Lichtenstein, Massachusetts General Hospital, Boston, MA*

Background: As the population ages, it has become increasingly important to understand the risks and benefits of novel agents among older adults with cancer. Immunotherapy (IO) has revolutionized the treatment of advanced NSCLC, but less is known about the activity of PD-(L)1 blockade in older adults ($\geq$70 years). In these pts, immunosenescence may theoretically blunt the effectiveness of anti-PD-(L)1 therapy and/or alter its toxicity profile. We sought to assess the impact of age on clinical outcomes and rates of IO-related toxicities in pts with advanced NSCLC treated with anti-PD-(L)1. **Methods:** We retrospectively evaluated all pts with NSCLC at our institution treated with IO between 1/2013 and 10/2017. To assess progression-free survival (PFS) and overall survival (OS) across age groups, we performed Kaplan-Meier and Cox regression models adjusted for sex, ECOG, comorbidity, stage at diagnosis (dx), time since dx with metastatic disease, and lines of treatment prior to IO. IO-related toxicities, steroid use, and hospitalizations were also compared. **Results:** Of 245 pts, 141 (58%) were $<$ 70 years and 104 (42%) were $\geq$70 years old. Compared with younger pts, older pts had higher comorbidity scores (6.9 vs 6.6, $p = 0.024$), worse ECOG scores (1.4 vs 1.2, $p = 0.011$), and lower stage at dx (stage 4: 50% vs 75%, $p < 0.001$). Older and younger pts had similar median PFS (2.6 vs 2.0 months, $p = 0.14$) with PD-(L)1 blockade; multivariable models demonstrated equivalent PFS across age groups (HR: 0.81, $p = 0.19$). Older pts had a worse median OS (8.6 vs 14 months, $p = 0.10$). After adjusting for key confounders, however, multivariable models demonstrated no significant difference in OS by age (HR = 1.4 $p = 0.070$). Overall, 102 (42%) pts experienced IO-toxicities with no significant difference by age (41% vs 44%, $p = 0.69$). Thyroiditis (17%), pneumonitis (10%), and dermatitis (9%) were most common. Toxicity-associated steroid use (26% vs 25%, $p = 1.0$) and IO-related hospitalizations (12% vs 10%, $p = 0.68$) did not differ between age groups. **Conclusions:** Older pts with NSCLC experienced similar toxicity and survival compared to younger pts receiving PD-(L)1 blockade, suggesting that IO may be a viable treatment option for the geriatric population.

10041 Poster Session (Board #29), Mon, 1:15 PM-4:45 PM

Predicting chemotherapy toxicity and death in older adults with colon cancer: Results of MOST (Massilia Oncologic Senior Tests) study. *First Author: Frédérique Retornaz, Centre Gérontologique de Marseille, Marseille, France*

Background: Older patients with colon cancer are more vulnerable to chemotherapy toxicity and early death. Establishing simple scores specific for colon cancer (cc) patients able to predict severe chemotoxicity or early death is needed to select the best appropriate treatment. **Methods:** This prospective multicenter study included cc patients aged ≥ 70 years receiving first-line adjuvant or metastatic chemotherapy. Five frailty markers (FM) : nutrition, physical activity, mobility, energy, grip strength), six domains of CGA (functional status, comorbidities, falls, nutrition, cognition, depression) and laboratory parameters were collected at admission. Logistic or Cox regression was used to examine at 500 days the association between FM, CGA, laboratory parameters and grade 3-4 toxicity or death, respectively. **Results:** 93 patients (mean age 78.8 years, range 70-90) received adjuvant (32, 34.4 %) or metastatic (61, 65.6 %) chemotherapy. During the first 500 days grade 3-4 toxicity occurred in 49 (53.3 %) and 23 (26.7 %) died. Multivariate logistic regression identified polychemotherapy, albuminemia < 32 g/L, abnormal grip strength and C-reactive protein > 11 mg/L (odds ratio: 6.85, 2.79, 2.40, 1.43, respectively) as independent predictors of toxicity. Cox regression identified metastasis, alkaline phosphatases > 100 IU/ml, age > 82 years, sex (female), and abnormal grip strength (hazard ratio: 7.99, 3.45, 3.31, 3.2, 1.18, respectively) as independent predictors of premature death. The predictive model for grade 3-4 toxicity combined (polychemotherapy x 3) + (albuminemia x 2) + (abnormal grip strength x 1.5) + C-reactive protein, cut-off > 3. The predictive model for premature death combined (metastasis x 5) + (age x 2.5) + alkaline phosphatases + sex + abnormal grip strength, cut-off > 6. Characteristics of both models are : Clinical trial information: NCT02148731. **Conclusions:** These two simple and efficient scores will help clinicians to better identify cc older patients with increased risk of toxicity and/or premature death.

Risk	AUC ROC curve (± SD)	95 % CI	*P*	Sensitivity (%)	Specificity (%)
Toxicity	0.747 ± 0.052	0.647-0.832	< 0.0001	71.4	72.1
Death	0.908 ± 0.032	0.826-0.960	< 0.0001	87.0	81.0

10042 Poster Session (Board #30), Mon, 1:15 PM-4:45 PM

Prevalence and clinical correlates of vulnerable status using the Vulnerable Elders Survey 13 (VES-13) in newly diagnosed adult non-Hodgkin lymphoma (NHL) patients: A LEO cross-sectional analysis. *First Author: Angelo Fama, Mayo Clinic, Rochester, MN*

Background: The VES-13 is a self-reported tool designed to identify people at risk of functional decline and death. We evaluated the prevalence of vulnerable (VUL) status in newly diagnosed NHL patients, overall, and by age, gender and clinical features. **Methods:** We used pre-treatment data from 1194 NHL patients consented 7/2015 to 7/2017 into the Lymphoma Epidemiology of Outcomes (LEO) cohort study (NCT02736357). Patients with a VES-13 score ≥3 were classified as VUL. χ^2 tests and unconditional logistic regression were used to identify correlates of VUL. **Results:** The median age was 62 years (range 18-94), 44% were ≥65 years, and 61% were male. Overall, 22% (268/1194) of the patients were classified as VUL, with a prevalence of 18% (117/666) for age < 65 years and 29% (151/528) for age ≥65 years. The prevalence of VUL status was higher in women vs men (26% vs 20%, p = 0.009), performance status ≥2 vs 0-1 (74% vs 19%, p < 0.0001), any B-symptoms (36% vs 19%, p < 0.0001), stage III-IV vs I-II (24% vs 20%, p = 0.11), ≥2 vs 0-1 comorbidities (41% vs 19%, p < 0.0001) and subtype (p = 0.0003, DLBCL 30%). All of these patterns were similar in analyses stratified on age 65 years. In a multivariable model, age (OR = 1.02 per year, 95% CI 1.01-1.04), female gender (OR = 1.6, 95% CI 1.2-2.2), PS ≥2 (OR = 8.1, 95% CI 4.5-14), B-symptoms (OR = 2.2, 95% CI 1.5-3.1), ≥2 comorbidities (OR = 2.5, 95% CI 1.7-3.8) and DLBCL subtype (OR = 2.0, 95% CI 1.3-3.1) were all predictors of VUL status. As physicians were unaware of the VES-13 score, we next evaluated VUL status by anthracycline (ATC) use as initial therapy (not accounting for dosing) in DLBCL cases. 89% of VUL patients (83/93) received an ATC compared to 90% of patients not classified as VUL (198/221; p = 0.93). **Conclusions:** Over 20% of newly diagnosed NHL patients were classified as VUL, including 18% < 65 years, highlighting the need for functional assessment of patients across a wider age spectrum. VUL status correlated with more adverse prognostic factors. The initial use of ATC not accounting for dosing/dose reduction in the treatment of DLBCL did not differ by VUL status. Future work will evaluate VES-13 with patient outcomes.

10043 Poster Session (Board #31), Mon, 1:15 PM-4:45 PM

Utilizing a practical tablet-based modified geriatric assessment in clinic for older adults with multiple myeloma (MM). *First Author: Nitya Nathwani, Judy and Bernard Briskin Center for Multiple Myeloma Research, Department of Hematology and Hematopoietic Cell Transplantation, Duarte, CA*

Background: More than 60% of patients diagnosed with MM are > 65 years old and at greater risk for treatment toxicity. Comprehensive geriatric assessment predicts toxicity and survival but is difficult to add to already stressed clinical workflow. We have previously demonstrated feasibility of a tablet-based modified geriatric assessment (mGA). Here, we provide a final report of impact on decision-making and treatment outcomes. **Methods:** In this multi site study, patients with MM > 65 years old completed a tablet-based mGA in clinic just prior to an oncology visit to discuss a treatment decision. Using the International Myeloma Working Group (IMWG) frailty model, a summary score, along with selected other GA and clinical data, was displayed to oncology providers at the beginning of the clinical visit. **Results:** 166 patients enrolled. Most were white (76%, n = 127) and male (56%, n = 93); mean age was 72 years (SD6.46; range 61-95). Based on IMWG criteria, patients were fit (39%, n = 64), intermediate fit (33%, n = 55) or frail (28%, n = 47), and 69% of providers agreed/strongly agreed that the mGA influenced the treatment recommendations for the patient. Treatments selected were more intensive for fit patients, while frail patients received lower intensity, with a reduced number of agents or a different route of administration (χ^2 = 20.81 (4), p < .0001). There was a significant association between fit status and transplant eligibility, with more fit patients being transplant eligible (χ^2 = 20.81 (6), p = .007). Outcome follow-up at 3 months on 144 patients indicated 39% (n = 56) of patients had a dose modification after the initial assessment and 18% (n = 26) discontinued therapy earlier than planned; 19.4% (n = 28) had a CTCAE grade 3-5 hematologic toxicity and 22% (n = 31) had a grade 3-5 non-hematologic toxicity, most commonly fatigue. Rates of toxicity were similar between patients considered fit, intermediate fit and frail. **Conclusions:** Results of a mGA presented to a provider at the point of care influenced treatment decisions. Most patients continued the prescribed therapy at 3 months, with relatively low rates of grade 3-5 toxicity. Further study is needed to compare outcomes with standard care. Clinical trial information: NCT03068637.

10044 Poster Session (Board #32), Mon, 1:15 PM-4:45 PM

Association between participation in religious activities and depression and anxiety in older patients with cancer. *First Author: Yu Cao, City of Hope, Duarte, CA*

Background: Older patients (pts) with cancer are at risk for depression and anxiety, which are often under-recognized. Participation in religious activities has been associated with better mental health in pts with cancer; however, data are conflicting and few studies focus on older pts. This study explores associations between participation in religious activities and depression and anxiety in older pts with cancer. **Methods:** This is a secondary analysis of a prospective study of pts age ≥ 65 with cancer. Prior to starting a new line of chemotherapy, pts self-reported if they felt depressed (yes/no on a 1-Question Yale Depression Screen) or anxious (score ≥ 6 on a 0-10 Likert Scale). Participation in public (e.g. church) and private (e.g. prayer) religious activities was measured via the Duke University Religion Index. High (≥ weekly public AND ≥ daily private), middle (≥ weekly public OR ≥ daily private), and low (< weekly public AND < daily private) religious participation groups were defined. Univariate and multivariate logistic regression analyses were conducted evaluating associations between participation in religious activities and depression and anxiety. **Results:** Of 458 pts (mean age 72 [range 65-91]; 57% female, 55% non-Hispanic white), with 31% GI, 19% breast, and 18% GU cancers, the majority (75%) had stage IV disease. Twenty-four percent (N = 110) reported anxiety, and 21% (N = 97) depression. Thirty-five percent (N = 161) reported ≥ weekly public, and 45% (N = 208) ≥ daily private religious activity. Both groups tended to report less anxiety (OR 0.66, p = 0.08; OR 0.68, p = 0.08, respectively); neither group was less likely to report depression (OR 0.79, p = 0.33; OR 1.05, p = 0.83, respectively). Combined, the high religious participation group (27.5%; N = 126) reported less anxiety on univariate (OR 0.59, 95% CI 0.35-0.99, p = 0.04) and multivariate (OR 0.51, 95% CI 0.28-0.92, p = 0.03) analyses, adjusting for age, gender, race, education, number of comorbidities, physical function, and social support, but not less depression (p = 0.46). **Conclusions:** Among older pts with cancer, participation in both public and private religious activities is associated with less anxiety, but not less depression.

10045 Poster Session (Board #33), Mon, 1:15 PM-4:45 PM

Prognostic benefit of taking statin and/or metformin in elderly patients with advanced non-small cell lung cancer: A nationwide population-based epidemiologic study. *First Author: Yun-Gyoo Lee, Division of Hematology/Oncology, Department of Internal Medicine, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea*

Background: Comorbidities including dyslipidemia, diabetes and coronary heart disease are frequently found in elderly patients with advanced non-small cell lung cancer (NSCLC). Taking statin and/or metformin attenuates chronic inflammations, and could affect cancer outcomes. We aimed to evaluate prognostic impact of taking statin and/or metformin on survival in elderly patients with advanced NSCLC. **Methods:** Patients ≥ 70 years with advanced NSCLC incident from 2007 to 2012 were identified using reimbursement claims from Korea's National Health Insurance Service Database, and exposures to statin and/or metformin were also documented. Cox proportional-hazards model and propensity score matched analysis were used to estimate the impact of drug exposures on overall survival (OS). **Results:** Excluding 976 treated by upfront anti-EGFR, 7298 receiving palliative chemotherapy were included: statin preparations were taken in 13.0%, metformin preparations in 13.8%, both in 3.5%, and neither in 76.6%, respectively. Median OS of statin + / metformin +, statin + / metformin –, statin - / metformin +, and statin - / metformin – users was 14.5, 12.9, 11.4 and 9.9 months respectively. By multivariate analyses, metformin was not statistically significantly associated with improved OS in statin non-user (HR 0.99; 95% CI 0.91-1.08; p= 0.819) and statin user (HR 0.99; 95% CI 0.85-1.16; p= 0.898) group. However, use of statin, regardless of metformin, was associated with improved OS (HR 0.80; 95% CI 0.74-0.86; $p< 0.001$). In propensity-matched cohort, survival benefit was noted not by use of metformin (HR 0.97; 95%CI 0.85-1.11; p= 0.661), but by use of statin (HR 0.83; 95%CI 0.73-0.95; p= 0.007). There was no significant effect modifier. **Conclusions:** We found that the about one-quarter of elderly NSCLC patients were taking statin and/or metformin. Exposures to statin could be the independent prognostic factor for better survival in elderly advanced NSCLC patients.

10046 Poster Session (Board #34), Mon, 1:15 PM-4:45 PM

The effect of a geriatric oncology (GO) evaluation on treatment (Tx) decisions for older patients (pts) with cancer in Mexico. *First Author: Haydee Cristina Verduzco-Aguirre, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Tlalpan, Ciudad De México, Mexico*

Background: GO evaluations may lead to improvements in the care of older adults with cancer, but their effect on Tx decisions in everyday clinical practice needs further research. Our goal was to describe the effect of GO evaluations on Tx decisions in the first GO clinic implemented in Mexico. **Methods:** The records of 173 pts aged ≥65 years (y) referred to our GO Clinic before active Tx initiation from 05/15 to 10/17 were reviewed. Pts were screened with a validated tool (G8; Soubeyran et al, 2011); those deemed vulnerable (score ≤14) underwent a full geriatric assessment; and Tx recommendations were sent to the treating oncologist. We measured the proportion of patients in which there was agreement between GO recommendations and final Tx decisions, and assessed whether agreement increased in cases in which the treating oncologist's notes mentioned the GO evaluation. **Results:** Median age was 79 y (range 64-97). 37% of pts had genitourinary and 32% gastrointestinal malignancies; 42% were stage IV. Proposed Tx before GO evaluation included palliative chemotherapy (CT) (32%), curative surgery/radiotherapy (31%), and neo/adjuvant CT (19%). A recommendation to administer standard Tx was made in 47% of cases, less intensive Tx in 32%, and best supportive care (BSC) in 20%. The treating oncologist's final Tx decision matched the GO recommendation for 81% of pts, and GO recommendations were mentioned in the treating oncologist's notes in 62% of cases. Agreement between the treating oncologist & GO clinic was higher when BSC was recommended (94%), followed by standard Tx (77%), and less intensive Tx (75%). Agreement between the treating oncologist & GO clinic was 84% when the GO evaluation was mentioned, compared to 75% when it wasn't (p = 0.16). In pts for which less intensive Tx was recommended (n = 56), agreement was 84% when the GO evaluation was mentioned, compared with 56% when it wasn't (p = 0.04). **Conclusions:** Agreement between GO recommendations and final Tx decisions was high, especially for cases in which BSC was recommended. Including GO evaluations in everyday clinical practice may provide useful information to guide oncologists caring for older pts, particularly when considering less intensive therapy.

10047 Poster Session (Board #35), Mon, 1:15 PM-4:45 PM

Inflamm-aging and the need to consider age in cytokine-patient-reported outcome (PRO) relationships: The case of acute myeloid leukemia (AML). *First Author: Shabbir M.H. Alibhai, University Health Network, Toronto, ON, Canada*

Background: Cancer-related fatigue (CRF) and poor quality of life (QOL) remain major problems in adults with AML during and after active treatment. Prior studies have linked cytokines to these PROs but have not examined age as a modifier. Ageing is associated with chronic inflammation which may alter the cytokine-PRO relationship. **Methods:** 213 patients age 18 or older who underwent intensive chemotherapy for AML were assessed at up to 4 time points (pre-treatment, 1 month, 6 months, 12 months). PROs were assessed with validated self-report questionnaires (FACT-F, EORTC QLQ-C30 global health) and blood was analyzed in duplicate for a panel of 32 cytokines using multiplexed protein immunoassays (Meso Scale Diagnostics). Log-transformed and centred cytokine values were regressed in models against CRF and QOL in separate models adjusting for age, gender, time, remission status, and haemoglobin. Models were stratified by age (< 60, 60+) and model and partial R^2 values were calculated. **Results:** 498 sets of cytokine measurements were available for analysis. For CRF, the model R^2 was 20.6%, with cytokines explaining 7.8% of the variance. For QOL, the model R^2 was 25.7%, and cytokines accounted for 7.8% of the variance. When stratified by age (< 60 versus 60+ years or older), the proportion of variance in CRF explained by the multivariable model and by cytokines collectively was greater in younger patients (34.1% for the entire model and 17.9% for cytokines) than older adults (21.7% and 14.4%, respectively). The interaction term was significant (p = 0.002). The three most influential cytokines were TNF-α, MCP-4, and IL-15 in younger adults and MIP-1a, TARC, and IL-7 in older adults. Similar differential results by age group were seen for global QOL (interaction term $p < 0.001$). **Conclusions:** Cytokines explain a significantly larger amount of variation in both CRF and QOL in younger patients with AML compared to older patients. Specific culprit cytokines also appear to be different. This suggests that cytokine-targeted therapies (drug or non-drug) may need to differ in younger versus older adults but requires verification in other tumour types.

10048 Poster Session (Board #36), Mon, 1:15 PM-4:45 PM

The impact of a positive cognitive impairment screen on conversations between patients, caregivers, and oncologists: A UR NCORP randomized study. *First Author: Allison Magnuson, University of Rochester Medical Center, Rochester, NY*

Background: The prevalence of CI and the utility of CI screening for community oncology practices are not well established. We used two tools to screen for CI in older patients (pts) enrolled onto a cluster randomized controlled trial and explored how CI screening influences conversations about cognition (CAC) between older pts, their caregivers, and oncologists. **Methods:** Pts aged ≥70 with advanced cancer were recruited (URCC 13070; PI: Mohile). CI screen, including Mini-Cog (MC) (normal/abnormal) and Blessed Orientation Memory Concentration Test (BOMC) (scored 0-28), were included in a Geriatric Assessment (GA). Practices were randomized to usual care (UC) vs GA intervention (GA summary provided to oncologists). Audio-recorded clinical encounters were transcribed by 2 blinded coders who coded CAC with a priori scheme as follows: cognition discussed (Y/N), type of concern, who initiated. MC and BOMC were compared and receiver operating characteristic (ROC) analyses identified BOMC score that best predicted abnormal MC. **Results:** Mean age was 77 (range 70-93); 2.2% screened positive by BOMC using standard score of ≥11 and 33.5% had abnormal MC. Pts with abnormal MC were more likely to have impaired activities of daily living (ADL) (34 vs 24%), Instrumental ADL (64 vs 52%), Timed Up and Go (47 vs 34%) and positive depression screen (28 vs 19%), ($p < 0.05$ for all). CAC occurred in 22% of encounters and were more common in the intervention arm (OR 4.64, 95%CI: 2.98- 7.21, $p < 0.001$). Differences in CACs were most notable for pts with abnormal MC (71% in intervention group vs 16% in UC, $p < 0.001$). Oncologists were more likely to be the initiator of CACs in the intervention arm (90% vs 57%, $p < 0.001$). The most common concerns were memory (54%) and comprehension (15%). A BOMC cutoff ≥4 was optimal for predicting abnormal MC (AUC = .73, sensitivity 59%, specificity 74%). **Conclusions:** In community oncology practices, 1/3 of older pts screen positive for CI and were more likely to have other GA impairments. Providing oncologists with results of a CI screen increases CACs. A lower BOMC cutoff predicted abnormal MC, consistent with studies in non-cancer pts where lower BOMC score predicted more mild CI.

10049 Poster Session (Board #37), Mon, 1:15 PM-4:45 PM

Development and temporal validation of a practical prognostic scoring system (ONCOGERIATRIC INDEX -OGI) based on the comprehensive geriatric assessment to predict early death in elderly cancer patients: A 892 patients cohort study. *First Author: Jurema Telles O Lima, IMIP - Instituto de Medicina Integral Professor Fernando Figueira, Recife, PE, Brazil*

Background: Recognizing prognostic factors is important when evaluating elderly people with cancer to decide the appropriate treatment. The Oncogeriatric Index (OGI) was developed to predict early death (in 6 months) among elderly people with cancer, based on the Karnofsky Performance Status Scale, the Mini Nutritional Assessment and the Charlson Comorbidity Index. OBJECTIVES: To temporarily validate the OGI.**Methods:** We used a prospective cohort of cancer patients aged 60 or + years for GA n 605 (2015-2017) [training set]; 2016–2017: n 291 [validation set]) was performed during a six-month follow-up. Epidemiologic data and CGA (using 12 scales) before oncologic treatment were collected. The outcome was ED (within first 180 days). Cox's proportional hazards model was used for the selection of prognostic factors. A prognostic score, the Onco Geriatric Index (OGI), was constituted of the number of abnormal CGA scales. Overall survival was estimated using the Kaplan–Meier method, and survival curves were compared using the log rank test. Predictive performance (calibration and discrimination) was determined. **Results:** There were 41 deaths among the 291 admitted patients. Patients who had three altered scales had 23.5 times higher risk of dying, adjusted for age, primary site of cancer and tumor staging (HR = 23.5, 95% CI 7.0-78.4, $p < 0.001$); those with two, 6.9 times (HR = 6.8, 95% CI 2.4-40.1, $p < 0.001$); and those with one, 3.1 fold (HR = 3.1, 95% CI 1.2-7.9, p = 0.020). The numbers of deaths predicted by the OGI were similar to those occurred, as well as a 6-month overlap of survival curves for each of the groups in the derivation and validation cohort, demonstrating that this prognostic model had an adequate predictive performance. **Conclusions:** Geriatric Index (OGI) is valid to evaluate elderly people with cancer in order to identify those at higher risk for early death.

10050 Poster Session (Board #38), Mon, 1:15 PM-4:45 PM

Diagnosing deficits in quality of life and providing tailored therapeutic options: Results of a randomized trial including 220 patients with colorectal cancer. *First Author: Monika Klinkhammer-Schalke, Tumor Center Regensburg, Institute of Quality Management and Health Services Research of the University of Regensburg, Regensburg, Germany*

Background: There have been increasing efforts to develop interventions that improve patients` quality of life (QoL) in routine cancer care. The Tumor Center Regensburg has designed and implemented an intervention consisting of the systematic diagnosis and tailored therapy of QoL. The efficacy of this intervention has been demonstrated in a randomized trial of patients with breast cancer. To generalize and strengthen the external validity of these findings, this intervention system was applied to a cohort of patients with colorectal cancer. **Methods:** In a 2-arm randomized controlled trial, 2x110 patients with primary colorectal cancer were recruited in four colorectal cancer centers and randomized into an intervention group (IG) or a control group (CG). QoL (EORTC QLQ-C30 and QLQ-CR29) was measured in both arms before clinical discharge and at the 3-, 6-, 12-, and 18-months routine follow-up. A network of local healthcare providers of QoL therapy was established that encompassed physiotherapy, psychotherapy, pain therapy, social support, nutrition, stoma care, and fitness. In the IG, the treating physician received printouts of QoL results (QoL profile including 15 scales). If a need for QoL therapy was diagnosed (cutoff < 50 points in scales of 0-100), specific QoL therapies were recommended. In the CG, QoL was also measured, but the treating physician neither received QoL profiles nor recommendations on QoL therapy. **Results:** At clinical discharge, a need for QoL therapy was diagnosed in 92% (96/104) of IG patients and in 85% (88/104) of CG patients. At 12 months (primary endpoint), the intervention had reduced the rate of patients with a need for QoL therapy to 50% (41/82) compared to 66% (57/87) in CG (χ^2-Test p = .041, number needed to treat (NNT) = 7). **Conclusions:** Patients with primary colorectal cancer benefited from the intervention with QoL diagnosis and therapy in terms of faster improvement of their QoL during the first year after surgery. The NNT was exactly the same as for patients with breast cancer, indicating high external validity of these results. Clinical trial information: NCT02321813.

10051 Poster Session (Board #39), Mon, 1:15 PM-4:45 PM

Patient and provider preferences for physician roles in breast cancer survivorship care. *First Author: Archana Radhakrishnan, University of Michigan, Ann Arbor, MI*

Background: Adoption of team-based models for cancer survivorship has lagged in part due to uncertainty around which physician—oncologist or primary care provider (PCP)—should lead which elements of delivery. We assessed patient, oncologist, and PCP preferences for who leads multiple aspects of survivorship after primary breast cancer treatment. **Methods:** SEER data from LA and Georgia was used to identify and survey women newly diagnosed with breast cancer between 2014-15 (N = 3672, 70% response rate). Participants identified their oncologist (N = 491) and PCP (N = 518) who were also surveyed (61.9% oncologist, 60.8% PCP response rates). Patients and providers were each asked their preference (oncologist- vs. PCP-led) for which physician should lead cancer-related (mammograms) and non-cancer related survivorship care (other cancer screenings, general preventive care and comorbidity management). Distributions of patient and provider preferences was tabulated for each of the four services. The level of overall agreement amongst all three (%) was then calculated for each service (N = 237 triads). **Results:** Agreement within patient-oncologist-PCP triads for physician role preferences (Table) was highest for follow-up mammograms (81% of triads, majority preferred oncologist-led care) and comorbidity management (81% of triads, majority preferred PCP-led care), and intermediate for general preventive care (62% of triads, majority preferred PCP-led care). Agreement was lowest for other cancer screenings (32% of triads): 95% of patients, 62% of oncologists, and 57% of PCPs preferred oncologists lead other cancer screenings. **Conclusions:** Breast cancer patients, oncologists, and PCPs largely agreed on who should lead follow-up mammograms and comorbidity management, but disagreed most on who should direct other cancer screenings during survivorship. Targeting efforts to clarify physician roles, especially for cancer vs. non-cancer related care, will be important to maximize the quality of team-based models of survivorship care.

N = 237 Triads	Follow-up mammograms	Other cancer screenings	General preventive care	Comorbidity management
Prefer oncologist-led (%)				
Patients	95	95	19	11
Oncologists	97	62	13	2
PCPs	89	57	10	6

E-cigarette use among patients of smoking-related cancers in the United States. *First Author: Oladimeji Akinboro, Boston University Medical Center, Boston, MA*

Background: The prevalence of e-cigarette use, and its impact on smoking cessation, among cancer survivors in the United States is unknown. We sought to estimate the prevalence of e-cigarette use, and examine its associations with cigarette smoking and quit attempts among survivors of smoking-related cancer survivors in the United States. **Methods:** We obtained data from the 2014-2016 annual cycles of the National Health Interview Survey. Our study sample comprised 2,561 adults with self-reported lifetime histories of at least one smoking-related cancer. We calculated the prevalence rates of e-cigarette use among survivors of smoking-related cancers. Using a multivariable logistic regression model, we examined independent associations of cigarette smoking history with e-cigarette use while adjusting for sociodemographic and other patient variables that were associated with e-cigarette use from the bivariate analyses. Survey weights were applied in estimating the population-based prevalence rates, odds ratios (OR), and 95% confidence intervals (CI). **Results:** The prevalence of e-cigarette use among survivors of smoking-related cancers was 3.31% (95% CI 2.39%, 4.56%). Those aged 18-44 years had the highest rates of e-cigarette use of any age group (7.26%; 95% CI 2.80%, 11.72%; p-value for age: < 0.001). No associations were seen between e-cigarrete use and gender, race, presence of other smoking-related comorbidities, or duration of survival. Current cigarette smokers were 31 times as likely as never smokers to use e-cigarettes (OR 31.48; 95% CI 4.54, 218.16). Among current smokers, no association was seen between e-cigarette use and either the number of quit attempts or smoking cessation counselling by health professional in the prior year. **Conclusions:** E-cigarette use was highest among current smokers and relatively young survivors of smoking related cancers. The lack of association between e-cigarette use and smoking quit attempts supports observations that e-cigarettes do not increase smoking quit rates. This is concerning, and highlights the need for further studies to define the impact of e-cigarette use on smoking cessation, and long-term outcomes of survivors of smoking-related cancers.

10053 Poster Session (Board #41), Mon, 1:15 PM-4:45 PM

Efficacy of haloperidol versus olanzapine for control of chemotherapy induced nausea and vomiting. *First Author: Soniya Dulal, National Academy of Medical Sciences (NAMS), Bir hospital, Kathmandu, Nepal*

Background: Prevention of chemotherapy induced nausea and vomiting (CINV) is an essential part of cancer care. In resource scarce countries like Nepal, determining anti-emetic combinations of highest value is of utmost importance. The purpose of the study was to compare the efficacy and toxicity of Olanzapine (OLN) (a higher cost drug) and Haloperidol (HAL) (a lower cost drug) in the prevention of CINV in patients (pts) receiving highly emetogenic chemotherapy (HEC) in a developing country. **Methods:** An IRB approved randomized phase II trial was performed in chemotherapy-naive pts receiving cisplatin $\geq$70 mg/m^2 or cyclophosphamide $\geq$ 500 mg/m^2 and doxorubicin $\geq$ 50 mg/m^2. Pts were randomized to receive OLN 10 mg orally on day 1 to 4 or HAL 1 mg orally on day 1 and 0.5 mg BID on days 2 to 4. Both groups received ondansetron (OND) 16 mg and dexamethasone (DEX) 12 mg intravenously on day 1. Use of additional antiemetics for CINV refractory to assigned treatment arm was permitted. From day 1 to day 5, pts recorded their nausea using the Edmonton Symptom Assessment Scale (ESAS). They also recorded their daily episodes of vomiting (number and when) and the use of additional antiemetics. The primary endpoint was complete nausea prevention (CNP) (ESAS - 0). The secondary endpoint was complete emesis prevention (CEP) without the use of additional antiemetics. **Results:** Sixty pts consented and were randomized, 30 in each arm. There was no difference in CNP during the overall period (day 1-5 post chemotherapy) between OLN and HAL (66.6% vs 70%; p = 0.78). In both the acute period (24 hours post chemotherapy) and delayed period (day 2-5 post chemotherapy) CNP was similar between OLN and HAL (acute - 83.3% vs. 80.0%; delayed - 66.6% vs. 73.3%). No difference was identified in the rate of CEP during the overall period (80% OLN vs. 76.6% HAL; p = 0.75) nor in the acute period (93.3% OLN vs. 90% HAL) or delayed period (83.3% OLN vs. 83.3% HAL). No difference in toxicities was noted between treatment arm. **Conclusions:** In this study, HAL was comparable to OLN in the control of CINV with no statistically significant difference in the primary and secondary endpoints suggesting it is the higher value option in pts receiving HEC in a resource scarce country.

10054 Poster Session (Board #42), Mon, 1:15 PM-4:45 PM

Pilot trial of epidermal growth factor (EGF) ointment for the patients with epidermal growth factor receptor (EGFR) inhibitor related skin side effects. *First Author: Sung Yong Oh, Department of Internal Medicine, Dong-A University College of Medicine, Busan, Korea, Republic of (South)*

Background: The efficacy of the EGFR inhibitors has been demonstrated in non-small cell lung cancer (NSCLC), pancreatic cancer (PC) and colorectal cancer (CRC). Dermatological reactions can cause significant physical and psycho-social discomfort to patients. In present study, we evaluated the efficacy of EGF ointment on EGFR inhibitor related skin side effects (ERSEs) **Methods:** this was placebo-controlled double blind, multicenter, phase III trial. The patients diagnosed as NSCLC, PC, or CRC who were treated with EGFR inhibitors (e.g. erlotinib, gefitinib, cetuximab). Only patients with Grade $\geq$2 ERSEs according to the NCI-CTCAE v. 4.03 were enrolled. The patients were randomized to 3 groups; A (placebo) group, B (1ppm concentration of EGF ointment), or C (20ppm of EGF ointment). The response to study drug was defined as follows: (1) Grade 2, 3, or 4 ERSEs downgraded to $\leq$Grade 1 or (2) Grade 3 or 4 ERSEs downgraded to Grade 2 and persisting for at least two weeks. The quality of life (QoL) was evaluated with SKINDEX-16. **Results:** Between Jun 2015 and Sep 2017, final efficacy evaluation included 80 patients. Palmar plantar erythrodysesthesia was main symptomatic ERSEs of PC, Rash/Acne was main symptomatic ERSEs of NSCLC and CRC. According to the definition of effectiveness, response to EGF study drug of A (placebo), B (1ppm), or C (20ppm) were 44.4%, 61.5%, and 77.8%, respectively (P= 0.0424). They had been observed linear correlation between different EGF concentration groups (P= 0.0119). The QoL results of the SKINDEX-16 were analyzed as an overall score and three domain scores (including symptoms, emotions and functioning), and reported as mean value. Mean $\pm$ standard deviation (SD) score change from baseline to maximum response of A (placebo), B (1ppm), or C (20ppm) were -5.16 $\pm$ 8.62, -11.74 $\pm$ 14.16, and -18.58 $\pm$ 17.70, respectively (P= 0.0078). Comparing with placebo group, emotions (P= 0.005) and functions (P= 0.044) score domains were much improved by EGF containing group. **Conclusions:** Based on the results, the EGF ointment is effective for ERSEs compared with placebo. The EGF ointment evenly improved all kinds of symptoms and QoL of patients with ERSEs. Clinical trial information: NCT02284139.

10055 Poster Session (Board #43), Mon, 1:15 PM-4:45 PM

Effect of comorbidities on outcomes in colorectal cancer (CRC) survivors. *First Author: Colleen A Cuthbert, University of Calgary, Calgary, AB, Canada*

Background: The effect of comorbidities on outcomes in cancer survivors has not been evaluated in detail, but this can inform survivorship care. We aimed to evaluate comorbid medical conditions, causes of death (COD), and the effect of these conditions on survival among CRC survivors in a Canadian province. **Methods:** A population-based cohort study using administrative data. Patients were diagnosed with stage I-III CRC from 2004 to 2015. ICD-10 codes were used to categorize COD. CRC patients were divided into 5 mutually exclusive comorbid groups: cardiovascular disease (CVD), diabetes (DM), both cardiovascular disease and diabetes (CVD+DM), other comorbidities (OC), and no comorbidities. Kaplan Meier and Cox proportional hazards models were used to evaluate survival, adjusting for age, cancer stage, and treatment. **Results:** We evaluated 12,265 patients. Median age 67.3(range 18-104) years, 56.2% men, 61.8% colon cancer, 38.8% stage III disease, and 36.8% Charlson comorbidity index $\geq$1. There were 1153 (9.4%), 1711(13.9)%, 515(4.2%), and 1141(9.3%) patients in the CVD, DM, CVD+DM and OC groups, respectively. Mean follow-up was 3.8 years. Median overall survival (mOS) was 8.6 (CI 8.3-8.9) years in the entire cohort. Among those who died (N = 3964), 51.2% and 39.3% were due to CRC and other causes, respectively. CVD was a common non-CRC COD (17.1%). In comparison to those with no comorbidities, patients with CVD+DM fared the worst (mOS 3.3 [2.8-3.7] years; adjusted HR for death, 2.27, 95% CI 2.0-2.6, p $<$ 0.001) (see Table). For stage III disease, the percentage receiving curative intent (surgery + adjuvant) treatment was different (p $<$ .001) across groups (31.7% in CVD+DM, 37.6% in CVD, 66.7% in DM, and 57.4% in OC). **Conclusions:** Specific comorbid medical conditions are associated with increased risk of death from CRC and non-CRC causes. Undertreatment was associated with comorbidity profile and may be a driver of worse CRC survival in these patients. Engagement of primary care and other specialty providers earlier in the survivorship trajectory is warranted.

Group	mOS	HR (95% CI)	P value
No comorbidities	10.8 yrs	referent	
CVD	4.2 yrs	1.98 (1.7-2.1)	$<$ .001
DM	7.3 yrs	1.33 (1.2-1.5)	$<$ .001
CVD+DM	3.3 yrs	2.27 (2.0-2.6)	$<$ .001
OC	6.0 yrs	1.61 (1.5-1.8)	$<$ .001

10056 Poster Session (Board #44), Mon, 1:15 PM-4:45 PM

Cardiometabolic risk in childhood cancer survivors: A Children's Oncology Group study. *First Author: Emma Lipshultz, Dana-Farber Cancer Institute, Boston, MA*

Background: Childhood cancer survivors (CCS) are at increased risk of cardiovascular (CV) disease. We assessed the burden of potentially modifiable cardiometabolic risk factors among young adult CCS vs population-matched controls. **Methods:** CCS who enrolled on Pediatric Oncology Group protocols 9404, 9425, 9426, and 9754 from 1996-2001 with acute lymphoblastic leukemia/lymphoma, Hodgkin lymphoma, and osteosarcoma were prospectively assessed for prevalence of obesity, hypertension, dyslipidemia, diabetes, and lifestyle habits (smoking, physical activity) in CCS vs an age-, sex-, and ethnicity-matched 2013 NHANES population. We then estimated Framingham and PDAY general CV risk scores for both groups, and for CCS we also estimated CV risk scores published by the Childhood Cancer Survivor Study (CCSS). **Results:** Compared with NHANES (n = 591), CCS (n = 109; 43% female, mean age 28y; 16y since diagnosis; mean doxorubicin dose 286 mg/m^2; 39% chest radiation, mean 23 Gy; 54% dexrazoxane exposed) had similar rates of obesity (26 vs 30%, p = .73), hypertension (35 vs 31% p = .46), hyperglycemia (12 vs 18%; p = .17), dyslipidemia (49 vs 46%; p = .55), and metabolic syndrome (ATP3 criteria: 12 vs 17%; p = .19). More CCS met Centers for Disease Control & Prevention's guidelines for physical activity (69 vs 45%; p $<$ .001) and fewer reported a history of smoking (27 vs 45%; p = .002). Results were similar among CCS recruited from sites with $>$ 50 vs $<$ 50% participation in this analysis. Because of lifestyle differences, Framingham and PDAY risk scores were generally higher for NHANES vs CCS. Applying the CCSS risk scores, 39% of CCS were at moderate risk of ischemic heart disease, and $>$ 95% at moderate or high risk for heart failure corresponding to a 9-12% predicted incidence of these conditions by age 50. **Conclusions:** Young adult CCS exhibited similar cardiometabolic profiles as NHANES. With more favorable lifestyle habits, CCS had lower predicted CV risk per general risk models but a high proportion had moderate or greater risk of CV disease predicted by the CCSS risk models. Further analyses are needed to determine the impact of dexrazoxane on CCS-specific CV risk. However, the favorable lifestyle habits of this cohort provide cause for optimism.

10057 Poster Session (Board #45), Mon, 1:15 PM-4:45 PM

Patient characteristics and long-term outcomes beyond the first 6 months after a diagnosis of cancer-associated thrombosis. *First Author: Robert Adam Schmidt, Department of Internal Medicine, University of British Columbia, Vancouver, BC, Canada*

Background: Cancer associated thrombosis (CAT) is a common complication of malignancies. However, little is known about the clinical course of CAT beyond the initial treatment period of 3 to 6 months. This information is important for clinicians and patients to inform their decision regarding duration of anticoagulation. **Methods:** Health records from 523 consecutive patients managed at the Vancouver General Hospital Thrombosis clinic for CAT (excluding catheter-related thrombosis) between 2013 and 2015 were reviewed; 327 were alive at 6 months post initial CAT diagnosis. Patient and cancer characteristics, objectively documented recurrent venous thromboembolism (rVTE), clinically relevant bleeding (CRB), and overall mortality of this "survivor" cohort over month 6 to 24 are described. **Results:** In the 6 month survivor cohort, patients were followed for a median of 605 days (range 1 to 730) and 85.9% had at least 24 months of follow-up or died. Patient characteristics at at 6 months are summarized (Table). Anticoagulation was continued in 68.8%, with a median duration of 93 days; 54.3% of patient-days were on anticoagulation. In the 6 to 24 months after the initial CAT diagnosis, there were 34 rVTE in 30 patients (9.2%; 95% CI 6.3 - 12.8) and 16 CRB in 14 (4.3%; 95% CI 2.4 – 7.1) patients, corresponding to 2.9 rVTE per 100 patient-days and 1.4 CRB per 100 patient-days of follow-up. Twenty-one (61.8%) rVTE events and 11 CRB episodes (68.8%) occurred on therapeutic anticoagulation. Over the 18 months, 141 (43.1%; 95%CI 37.7 – 48.7) patients died. Causes of death were cancer (80.9%), rVTE (1.4%), bleeding (2.8%), other (7.8%), and unknown (7.1%). Three fatal bleeds and 2 fatal rVTE occurred while on anticoagulation. **Conclusions:** Patients with CAT who are alive at 6 months after VTE diagnosis remain at high risk of rVTE, CRB and death.

Pharmacokinetic (PK) modeling of serum platinum to reveal extent of long-term exposure and associated comorbidities after cisplatin treatment. *First Author: Omar El Charif, The University of Chicago, Chicago, IL*

Background: Platinum (Pt) is detectable for years after cisplatin treatment completion, but few studies have examined the extent of long-term exposure to Pt and associated co-morbidities. **Methods:** Eligible testicular cancer survivors (TCS, n = 633) given 300 or 400 ± 15 mg/m^2 cisplatin underwent lab tests and extensive audiometry, and completed questionnaires at follow-up (median 5 y, range 1-35). Since subject-level PK parameters cannot be estimated in cross-sectional designs, we regressed log(Pt) on dose and follow-up time in the entire cohort. Each subject's PK trait was defined as the deviation from the average concentration-time curve (the residual). High values indicate Pt levels exceeding the expected value, i.e. slower elimination. The Pt reference interval (RI) used (central 95% of 147 non-Pt exposed patients) was 8-47 ng/L (JALM 2016; 1:2, 143). Linear regression at $\alpha = 0.05$ was used for associations with co-morbidities. Hearing loss was quantified as the geometric mean of thresholds: 4-12 kHz (JCO 2016; 34, 2712). Sensory neuropathy was self-reported using EORTC-CIPN20. Cardiovascular (CV) burden was defined as angina, angioplasty, stroke, DVT, PE, CAD, and/or MI $>$ 1 month after therapy. Serum Pt, LDL, HDL, and creatinine (used to estimate creatinine clearance [CrCl] with the Cockroft-Gault formula) were measured. **Results:** Only 35 TCS (5.6%) were within the RI (median follow-up for this group: 20 y, range: 10-35). The estimated time to reach RI upper limit was 18 and 21 y after 300 and 400 mg/m^2 cisplatin respectively (time to RI median: 46 and 57 y). The Pt PK phenotype was strongly negatively associated with CrCl ($p < 10^{-9}$), and positively associated with age ($p < 10^{-8}$), neuropathy ($p = 0.002$; age-adjusted $p = 0.04$), and HDL (age-adjusted $p < 0.001$). When adjusted for age, no associations were apparent with LDL, CV burden, or hearing loss. **Conclusions:** Circulating Pt persists for decades and may contribute to adverse outcomes. We previously showed that hearing loss, but not neuropathy, is associated with cumulative cisplatin dose. In conjunction with our findings here, this suggests differential kinetics of ototoxicity and neurotoxicity.

10059 Poster Session (Board #47), Mon, 1:15 PM-4:45 PM

Risk factors for the development of atrial fibrillation on ibrutinib treatment. *First Author: Robert William Lentz, Northwestern University Internal Medicine, Chicago, IL*

Background: Ibrutinib is a Bruton's tyrosine kinase inhibitor used for treating B-cell malignancies. The incidence of atrial fibrillation/flutter (AF) while on ibrutinib is reported to be 6-16%. The risk factors for incident AF while on ibrutinib are poorly defined. **Methods:** Charts were retrospectively reviewed to include patients treated with ibrutinib for any indication between July 2012 and July 2016. Those with existing AF were excluded. ECGs were manually reviewed to document AF. Patients were followed until incident AF, end of the medical record, end of ibrutinib treatment, or August 2017. Statistical analysis used chi-square and t-tests. **Results:** Of the 168 patients included, median age was 65.7 years, 70.2% were men, 68.5% were white, 60.7% had chronic lymphocytic leukemia, 13.1% had Waldenstrom macroglobulinemia, 11.3% had mantle cell lymphoma, and 14.9% had other cancer types. The incidence of AF was 11.9% after a median of 153 days of ibrutinib treatment. The median follow-up time for those without incident AF was 489 days. Age, coronary artery disease (CAD), heart failure (HF; systolic, diastolic, or either), and moderate/severe mitral regurgitation (M/S MR) were significantly different between patients with and without incident AF. Table 1 includes all evaluated parameters. Of those with HF or M/S MR, 45% and 100%, respectively, developed incident AF. **Conclusions:** In this large retrospective study, the incidence of AF on ibrutinib was higher in patients with older age, CAD, systolic or diastolic HF, and M/S MR. Every patient with M/S MR developed AF. Patients with these risk factors should be counseled on the risk of AF and monitored closely. An echocardiogram to evaluate for structural heart disease prior to initiating ibrutinib should be considered.

Risk factors for incident AF.

	No incident AF (n = 148)	Incident AF (n = 20)	p value
Body mass index, kg/m^2	27.9	28.3	0.758

A longitudinal assessment to evaluate the impact of higher body mass index on cancer-related fatigue in breast cancer patients receiving chemotherapy. *First Author: Julia Ellen Inglis, University of Rochester Medical Center, Rochester, NY*

Background: Obesity and weight gain post-chemotherapy leads to increases in all-cause mortality, inflammation, and decreased quality of life but little is known about how obesity contributes to cancer-related fatigue (CRF). Inflammation is also associated with cancer-related fatigue (CRF). We conducted a secondary analysis of a large prospective, nationwide study to assess the impact of obesity on CRF levels in breast cancer patients. **Methods:** Female breast cancer patients (N = 565, aged 53±10.61) completed the multidimensional fatigue symptom inventory (MFSI) and the symptom inventory (SI) to measure CRF symptoms at baseline pre-chemotherapy (T1), post-chemotherapy (T2), and six months post-chemotherapy (T3) as part of a longitudinal study for cognitive impairment. Height and weight were collected at T1 and subjects were categorized based on BMI: Obese (OB: ≥30.0 kg/m^2; n = 294), overweight (OV: 25.0-29.9 kg/m^2; n = 146) and normal weight (NW: 18.5-24.9 kg/m^2; n = 125). Multivariate regression models were used to evaluate the relationship of obesity level to CRF over time controlling for age, race, radiation history, hormonal therapy, cancer stage, exercise level and KPS score. **Results:** At T1, the obese had significantly higher CRF symptoms than normal weight subjects for both the MFSI (OB = 11.4 vs NW = 8.1; p = 0.03) and SI (OB = 3.5 vs NW = 2.9; p = 0.02). Significantly higher SI fatigue scores persisted at T2 for the obese (OB = 4.4 vs NW = 3.8; p = 0.02) with a trend towards significance for the overweight (OV = 4.4 vs NW = 3.8; p = 0.08) group. At T3, obese subjects still had significantly higher SI fatigue scores (OB = 3.8 vs NW = 3.2; p = 0.03). Over the course of the study, obese subjects maintained higher MFSI subscale scores for General, Mental, and Emotional subscales ($p < 0.05$). **Conclusions:** This nationwide multicenter study is one of the first to directly tie obesity to fatigue from pre-chemotherapy through six months post-chemotherapy. Recommendations for weight loss or weight maintenance should be considered to prevent CRF in obese breast cancer patients before and after chemotherapy. Funding: NCI UGCA189961, R25 CA102618

10062 Poster Session (Board #50), Mon, 1:15 PM-4:45 PM

Getting the most out of follow-up: A prospective study using the Measure of Ovarian Symptoms and Treatment concerns (MOST) symptom index to evaluate and track adverse effects (AEs) and detect symptoms of recurrence in patients with ovarian cancer (OC) following first line chemotherapy (1LT). *First Author: Michael Friedlander, Prince of Wales Hospital, Randwick, Australia*

Background: Patients with OC are followed clinically every 3 months (m) after 1LT with the aim of managing symptoms/late AEs and diagnosing recurrence. Studies report that clinicians are unaware of up to half the symptoms patients experience. We developed and validated the MOST in patients with recurrent OC. We hypothesized that patient self-reporting of symptoms could complement clinical follow-up by identifying patients who experience significant late effects and also detect abdominal symptoms of recurrence. **Methods:** Women with OC participating in a prospective study (OPAL) completed MOST every 3m after 1LT for up to 3 years. We analysed MOST subscales representing abdominal, (MOST-Abdo), chemotherapy-related (MOST-Chemo) and psychological (MOST_Psych) symptoms (scales range 0-100, higher scores = greater symptoms). **Results:** 812 patients who received ≥3 cycles and did not progress within 3m of completing 1LT were evaluable. MOST completion rate was 81%. MOST-Chemo revealed high symptom burden just before or < 7 days after the last cycle .Trajectory analyses showed that the symptoms improve significantly/resolve in many patients by 6 months. However, 40% reported persisting moderate symptoms and ~10% had severe symptoms to > 2 years. Patients who scored > 30/100 on MOST-Chemo at the end of chemotherapy were likely to have persistent symptoms and the ~10% who scored > 50/100 reported ongoing severe symptoms to > 2 years. Among ~400 women with recurrence detected during follow-up, the MOST-Abdo symptom scores increased 2-3 months before the clinical diagnosis of progression. **Conclusions:** MOST is a brief patient-reported symptom index that complements clinical surveillance after 1LT. It was well accepted with high compliance rates. It can quantify and track symptoms and AEs experienced post 1LT and can detect the re-emergence of abdominal symptoms associated with recurrence. MOST could help triage the subset of patients likely to experience ongoing moderate-severe symptoms following 1LT for appropriate interventions.

10063 Poster Session (Board #51), Mon, 1:15 PM-4:45 PM

Outcomes of immune-checkpoint inhibitor induced organ toxicities. *First Author: Hamzah Abu Sbeih, Department of Gastroenterology Hepatology and Nutrition, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Immune checkpoint inhibitors (ICPIs) are gaining more popularity as treatment for advanced cancers. However, immune-related adverse events (irAE) might limit their use. Immunosuppressants are commonly used to treat irAEs. We aimed to assess the impact of irAEs and their treatment on survival outcomes. **Methods:** We conducted a retrospective review of patients who received ICPIs between 2011 and 2017, who developed irAEs. Descriptive analyses were used to compare different groups. Kaplan-Meier curves and log rank tests were used to estimate overall survival durations. **Results:** A total of 427 patients were included in this analyses. IrAEs were observed in 202 patients; single irAE ($n = 126$), and multiple irAEs ($n = 76$). ICPI-related diarrhea/colitis was confirmed in 117 patients. Immunosuppressant treatment was needed mainly for grade 2 to 4 diarrhea (83.5%) or grade 2 to 3 colitis (62.0%). Ipilimumab treatment duration was shorter than other ICPIs ($P < 0.01$). Ipilimumab based regimens were associated with higher risk of irAEs (OR, 2.33; 95% CI, 1.31 – 4.16). Overall, patients developed irAEs had better overall survival than did patients with no irAEs regardless of immunosuppressant treatment ($P < 0.01$). Patients with mild irAEs who did not need immunosuppressant had better overall survival than did patients without irAEs ($P < 0.01$). Patients with 3 or more irAEs had better overall survival compared to patients with 2 or less irAEs ($P = 0.01$). Overall survival of patients who had irAEs that required immunosuppressant was comparable to patients who had irAE that did not require treatment ($P = 0.73$). Infliximab was associated with shorter duration of steroid use compared to steroid treatment only (2 months [SD, 8] vs. 4 months [SD, 4]). Steroid treatment for more than 30 days was associated with higher rate of infections compared to shorter duration ($P = 0.03$). **Conclusions:** IrAEs are associated with a favorable overall survival, regardless of immunosuppression treatment requirement. IrAEs involving multiple organs appeared to be beneficial for overall survival. Early infliximab use shortens the duration of steroid treatment which decreases the risk of steroid-related adverse events.

10064 Poster Session (Board #52), Mon, 1:15 PM-4:45 PM

Vaginal laser to improve symptomatic vulvovaginal atrophy and sexual function in breast cancer patients: Report from LAAVA pilot study. *First Author: Antonia Pearson, Medical Oncology Department, Royal North Shore Hospital, St Leonards, Australia*

Background: Vulvovaginal atrophy (VVA) is a commonly reported issue among breast cancer patients (pts), and its etiology is multifactorial. The use of systemic and topical estrogens to treat VVA has traditionally been discouraged in hormone positive breast cancer. Laser therapy has been reported to improve symptoms from VVA in women with menopause. We aimed to assess the symptomatic benefit and the impact on sexual function of this treatment in women with early breast cancer (EBC). **Methods:** We performed a single arm investigator initiated pilot study of female EBC pts with symptomatic VVA. 29 pts were recruited between February 2016 and August 2017. 3 pts were not enrolled; 2 had medical conditions that excluded them from treatment, 1 withdrew consent prior to commencing. Baseline demographic data was collected on all pts. A total of 3 vaginal fractional CO2 laser treatments were administered approximately 4 weeks apart for each pt. Questionnaires were completed at baseline, prior to each subsequent treatment and 4 weeks after completion of treatment. Our primary endpoint was symptomatic improvement of VVA (dryness, itch, burning, dysuria and dyspareunia) at 12 weeks on a 10cm visual analog scale (VAS). Our secondary endpoint was improvement in sexual function using the Female Sexual Function Index (FSFI) at 12 weeks. Statistical analysis was performed with a Wilcoxon Signed Rank test. **Results:** 26 pts were enrolled in our study with a median age of 55. All pts were post-menopausal. 25 pts had received anti-estrogen therapy as a part of their breast cancer treatment. All pts received the 3 pre-planned laser treatments, and questionnaire compliance was high (98%). There was significant improvement in VVA symptoms after treatment on a 10cm VAS (table 1) and in sexual function demonstrated on the FSFI ($p = < 0.001$). **Conclusions:** EBC pts had improvement in all 5 domains of VVA symptoms, as well as improvement in sexual function. Further randomized sham-controlled trials are needed to further assess this treatment.

Change in VVA symptoms on 10cm VAS score.

Variable	Mean absolute change	P value
Dryness	4.33	< 0.001
Itch	3.67	< 0.001
Burning	2.93	0.003
Dysuria	3.53	< 0.001
Dyspareunia	3.84	< 0.001

10065 Poster Session (Board #53), Mon, 1:15 PM-4:45 PM

Pregnancies during and following trastuzumab (T) and/or lapatinib (L) in patients (pts) with HER2-positive (HER2+) early breast cancer (EBC): Analysis from the NeoALTTO (BIG 1-06) and ALTTO (BIG 2-06) trials. *First Author: Matteo Lambertini, Institut Jules Bordet, Brussels, Belgium*

Background: Limited data exist on the safety of using targeted agents in pregnant cancer pts. So far, only retrospective studies assessed the prognosis of pts having a pregnancy after prior EBC with no data in HER2+ pts. We aimed to evaluate the outcome of pregnancies occuring during or following T and/or L and the prognostic effect of having a pregnancy in HER2+ EBC pts. **Methods:** NeoALTTO and ALTTO were randomized phase 3 trials in HER2+ EBC pts. In both trials, pregnancy information was prospectively collected. Pregnancy outcomes were compared between pts unintentionally exposed to T and/or L during gestation (exposed group) and those who got pregnant following T and/or L completion (not-exposed group). In the ALTTO trial, disease-free (DFS) and overall survival (OS) of pregnant pts were compared to those of pts ≤40 years without subsequent pregnancy with the Extended Cox Model With Time-Varying Covariates to account for guarantee-time bias. **Results:** Out of 455 and 8,381 pts included in NeoALTTO and ALTTO, 92 pts (7 in NeoALTTO and 85 in ALTTO) had a pregnancy at a median age of 33 years (range 23-40). Pregnancy outcomes are reported in the table No difference in DFS (HR 1.24; 95% CI 0.58-2.6) or OS (HR 0.53; 95% CI 0.13-2.17) was observed between young pts with (n = 85 pts) or without (n = 1,392 pts) a pregnancy. **Conclusions:** Despite fewer live births were described in the exposed group, unintentional exposure to T and/or L during gestation does not seem to affect newborns' outcomes upon treatment discontinuation. Having a pregnancy after HER2+ EBC does not appear to impact on DFS or OS. These data are of high relevance to counsel young EBC pts facing pregnancy-related issues. Clinical trial information: NCT00490139.

	Exposed Group n = 17 pts	Not-exposed Group n = 75 pts
Completed pregnancy	7 (41%)	52 (69%)
Induced abortion	10 (59%)	7 (9%)
Spontaneous abortion	0	10 (13%)
Ongoing/unknown	0	6 (8%)
Live births	7 (41%)	54 (72%)
Congenital anomalies	0	1 (2%)
Oligohydramnios	0	0
Gestational week at delivery (range)	38.5 (34-39)	39 (38-40)
Apgar score (range)	9 (9-9)	9 (9-10)
Newborn weight, g (range)	3,145 (2,880-3,776)	3,440 (3,016-3,710)
Newborn length, cm (range)	50 (49-52.5)	51 (49-52.5)

10066 Poster Session (Board #54), Mon, 1:15 PM-4:45 PM

Meta-analysis of the cardiac events in the adjuvant trastuzumab trials. *First Author: Evandro De Azambuja, Institut Jules Bordet, Brussels, Belgium*

Background: Cardiac dysfunction may occur in patients (pts) receiving adjuvant trastuzumab-based chemotherapy and long follow-up is required to better understand it. This meta-analysis of 3 adjuvant trials investigated the incidence, timing and risk factors for trastuzumab-associated cardiac events. **Methods:** We have conducted an individual patient level data meta-analysis of 3 phase III trials investigating the role of 1 year of trastuzumab (T): HERA, NSBAP B-31, and NCCTG 9831 (Alliance). Definitions of severe CHF (NYHA III or IV) and asymptomatic or mildly symptomatic (NYHA II) cardiac events were considered as per each study, as the precise definitions varied between studies. **Results:** A total of 7445 pts were included in the analysis with a median follow-up in excess of 10 years (119.2-137.2 months): 4017 were in the T arm and 3428 were in the control arm (observation). Nearly all pts (97.5%) in the T arms received anthracycline-based chemotherapy. Table 1 summarizes the incidence of cardiac events in pts treated with 1 year adjuvant T. In total, 452 pts experienced a cardiac event (11.3%). Most of the cardiac events occurred during T use (78.1%). Adjuvant T was completed by 76.2% of pts and 10.0% of pts discontinued T due to a cardiac event. Significant baseline risk factors for cardiac events were LVEF normal but $\leq$60%, hypertension, high BMI ($>$ 25), and age $\geq$60. **Conclusions:** 1-year of T increases the risk of cardiac events, though most are asymptomatic or mildly symptomatic LVEF drops. As cardiac events may lead to interruption in treatment, careful risk-factorr based patient selection, close follow-up and medical intervention (if necessary), are needed. Support: U10CA180868, -180822, UG1-189867, U24-196067; Genentech

Incidence of cardiac events in T treated patients CHF: cardiac heart failure.

	Trastuzumab Combined N = 4017	HERA N = 1682	NSABP B-31 N = 1055	N9831 N = 1280
Any cardiac event	452(11.3%)	92(5.5%)	205(19.4%)	155(12.1%)
Cardiac death	7(0.2%)	3(0.2%)	2(0.2%)	2(0.2%)
Severe CHF (NYHA class III/IV)	94(2.3%)	15(0.9%)	41(3.9%)	38(3.0%)
Asymptomatic or mildly symptomatic (NYHA class II)	351(8.7%)	74(4.4%)	162(15.4%)	115(9.0%)

Note: NSABP B-31 dataset considers an ITT population

10067 Poster Session (Board #55), Mon, 1:15 PM-4:45 PM

Impact of body mass index (BMI) and weight change after treatment in patients (pts) with HER2-positive (HER2+) early breast cancer (EBC): Secondary analysis of the ALTTO BIG 2-06 trial. *First Author: Samuel Martel, Centre Hospitalier Universitaire Sherbrook - Hopital Fleurimont, Sherbrooke, QC, Canada*

Background: Obesity is associated with worse outcomes in hormone receptor-positive (HR+) EBC. However, the association between obesity and prognosis in HER2+ EBC remains unclear. We aimed to determine the impact of BMI at diagnosis and weight change after treatment on the outcomes of HER2+ EBC pts. **Methods:** ALTTO was a phase 3 trial of HER2+ EBC pts. BMI was collected at baseline and at the 2-year visit. WHO BMI categories were used: underweight $<$ 18.5 kg/m^2, normal weight 18.5-24.9 kg/m^2, overweight 25-29.9 kg/m^2, and obese $\geq$30 kg/m^2. A change in weight from baseline of $\geq$5.0% and $\leq$5.0% was categorised as weight gain and weight loss, respectively. The impact of baseline BMI and weight change at the 2-year visit on disease-free survival (DFS), distant DFS (DDFS) and overall survival (OS) were investigated. Multivariate analyses adjusting for baseline pts and tumor characteristics were performed. The impact of weight change was assessed using a landmark analysis. **Results:** A total of 8,381 pts were included: 187 (2.2%), 3,797 (45.3%), 2,690 (32.1%), 1,707 (20.4%) were underweight, normal weight, overweight and obese at baseline, respectively. Compared to normal weight pts, being obese at diagnosis was associated with a significant worse DDFS (adjusted hazard ratio [aHR] 1.25; 95% CI 1.04-1.50) and OS (aHR 1.27; 95% CI 1.01-1.60), and a trend towards worse DFS (aHR 1.14; 95% confidence interval [CI] 0.97-1.32). Weight loss $\geq$5.0% at the 2-year visit was associated with poorer outcomes: DFS (aHR 1.34; 95% CI 1.05-1.71), DDFS (aHR 1.46; 95% CI 1.07-1.98) and OS (aHR 1.83; 95% CI 1.18-2.84). A similar trend, although not significant, was observed for weight gain $\geq$5.0%. Results were affected by hormone receptor status and menopausal status but not by anti-HER2 treatment. Grade 3-4 toxicities, pts with $\geq$1 serious adverse event and treatment discontinuation were more frequent in obese patients. **Conclusions:** In HER2+ EBC pts, obesity at baseline is a poor prognostic factor. Weight changes during treatment and follow-up impacts clinical outcomes: this calls for the need of dietary counselling and physical exercise in the context of survivorship programs. Clinical trial information: NCT00490139.

10068 Poster Session (Board #56), Mon, 1:15 PM-4:45 PM

An individual patient level data pooled analysis of T-DM1 cardiac safety in HER2-positive (HER2+) metastatic breast cancer (MBC) patients. *First Author: Noam Falbel Ponde, Centro Paulista de Oncologia, Sao Paulo, Brazil*

Background: T-DM1 is approved for the treatment of HER2+ MBC and is currently under investigation for use in the early setting. Cardiac dysfunction is a known side effect of trastuzumab, an anti-HER2 antibody that is a component of T-DM1. However, individual studies were not large enough to permit an adequate understanding of cardiac events (CEs) associated with T-DM1 use. We have conducted a pooled analysis of T-DM1 trials in the advanced setting to understand its incidence, clinical presentation as well as to establish possible risk factors. **Methods:** we have conducted an individual patient-level pooled analysis of trials testing T-DM1 in HER2+ MBC patients. CEs were defined either as: (1) congestive heart failure (CHF) of any grade or grade 3/4 LVEF drop (symptomatic CHF); (2) cardiac ischemia, (3) cardiac arrhythmia, (4) grade 1/2 LVEF drop. Logistic regression was used to assess possible risk factors (age, prior heart disease, prior hypertension, prior diabetes, prior anthracycline use, concomitant pertuzumab, among others) for CEs. **Results:** 7 trials with 1961 patients exposed to T-DM1 were obtained. Of these, 1544 received T-DM1 and 417 T-DM1 + Pertuzumab. Median age of patients was 53 years (25-89) and median LVEF at baseline was 63%. 63% of patients had received anthracyclines previously. Symptomatic CHF was reported in 0.7%, cardiac ischemia in 0.1%, cardiac arrhythmia in 0.7% and grade 1/2 LVEF drop in 2%, resulting in a total CE rate of 3.4% (95% CI, 2.6% to 4.3%). No cardiac deaths or cardiac event grade 4 were reported, and only one in five CEs was of grade 3. Multivariate analysis showed patient's age (odds 5% increase per one-year increase, $p < 0.001$) and concomitant pertuzumab use (odds ratio 2.1 {95% CI, 1.2 to 3.5}, p 0.007) as significant risk factors for CEs. Further analysis will be presented at the conference. **Conclusions:** The incidence of CEs in patients receiving T-DM1 was low and most events were not symptomatic. As is the case for trastuzumab, the most common presentation was LVEF drop. Elderly patients receiving T-DM1 should be carefully evaluated for cardiac safety during treatment.

10069 Poster Session (Board #57), Mon, 1:15 PM-4:45 PM

Risk of solid cancer after treatment for testicular germ cell cancer in the platinum era. *First Author: Michael Schaapveld, Department of Psychosocial Oncology and Epidemiology, The Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Testicular cancer (TC) treatment has been associated with increased risks of subsequent malignant neoplasms (SMNs). It is unknown whether changes in TC treatment over time have affected SMN risk. **Methods:** Solid SMN risk was evaluated in a multicenter cohort, comprising 5,848 one-year survivors treated for TC before age 50 years, between 1976-2007. SMN incidence was compared with cancer incidence in the general population. Cumulative incidences were estimated and treatment-specific risks were assessed using multivariable regression in a case-cohort design. **Results:** After a median follow-up of 14.1 years (interquartile range: 9.3-20.1 years) 350 solid SMNs were observed, translating into a 1.8-fold (95% Confidence Interval (95%CI):1.6-2.0) increased risk compared to the general population. Solid SMN risk was increased both in seminoma (180 SMNs) and non-seminoma (170 SMNs) patients (Standardized Incidence Ratios of 1.5, 95%CI:1.3-1.8 and 2.2, 95%CI:1.9-2.6, respectively). Non-seminoma patients experienced increased risk of SMNs of the thyroid, lung, stomach, pancreas, colon, bladder and of melanoma and soft tissue sarcoma, whereas seminoma patients experienced increased risk of SMNs of the small intestine, pancreas, and urinary bladder. Cumulative solid SMN incidence was 10.3% (95%CI:9.0%-11.6%) at 25 years of follow-up. In multivariable analysis, platinum-based chemotherapy was associated with increased risk of solid SMNs (Hazard ratio (HR) 2.40, 95%CI:1.58-3.62), colorectal SMNs (HR:3.85, 95%CI:1.67-8.92) and non-colorectal gastrointestinal SMNs (HR:5.00, 95%CI:2.28-10.95). With each additional cycle of platinum-containing chemotherapy, the HRs of solid SMNs and gastrointestinal SMNs increased with 22% (95%CI:16-48%) and 53% (95%CI: 34-74%), respectively. The HR of infradiaphragmatic SMNs increased with 6% per Gray of radiation dose administered (95%CI: 5-7%, $P < 0.001$). **Conclusions:** Both radiotherapy and platinum-containing chemotherapy are associated with a dose-depended increased solid SMN risk, specifically with gastrointestinal SMNs.

10070 Poster Session (Board #58), Mon, 1:15 PM-4:45 PM

Independent prognostic value of the EORTC QLQ-C30 summary score on all-cause mortality: Results from the population-based PROFILES registry. *First Author: Olga Husson, Institute of Cancer Research, Sutton, United Kingdom*

Background: Health-related quality of life (HRQoL) has been shown to be a prognostic factor for cancer survival in randomized clinical trials. It is questioned whether this association also holds in the "real world" and which HRQoL scores as measured by the EORTC QLQ-C30 are the best prognosticators. The aims of the present observational, population-based study were to: (1) investigate the association of HRQoL with all-cause mortality; and (2) determine which QLQ-C30 scores (the summary score covering all HRQoL domains, the global QoL or the physical functioning scale) exhibits the strongest association with all-cause mortality. **Methods:** Between 2008 and 2015, cancer patients (colon, rectum, melanoma, basal/squamous cell, endometrial, ovarian, prostate, thyroid, Hodgkin, non-Hodgkin lymphoma, chronic lymphocytic leukemia, multiple myeloma) were invited to participate in PROFILES ('Patient Reported Outcomes Following Initial treatment and Long term Evaluation of Survivorship') disease-specific registry studies (response 69%). In this secondary analysis on a collated patient sample with complete data (n = 6895) multivariate Cox proportional hazard regression models were used to analyze the association between the QLQ-C30 scores and all-cause mortality. **Results:** In the overall regression model including sociodemographic and clinical variables, the QLQ-C30 summary score was associated significantly with all-cause mortality (HR = 0.77; 95%CI = 0.72-0.82; $p < 0.01$). In stratified analyses, significant associations between the summary score and all-cause mortality were found for colon, rectal, prostate cancer, non-Hodgkin lymphoma, chronic lymphocytic leukemia and multiple myeloma only. The summary score had a stronger association with all-cause mortality than the global QoL (HR = 0.82; 95%CI = 0.78-0.85; $p < 0.01$) and the physical functioning scales (HR = 0.81; 95%CI = 0.78-0.84; $p < 0.01$). **Conclusions:** Our results indicate that, in a population-based setting, HRQoL, as assessed by the summary score of the QLQ-C30, has prognostic value for a number of cancer patient populations above and beyond that provided by clinical and sociodemographic variables.

10071 Poster Session (Board #59), Mon, 1:15 PM-4:45 PM

Prevalence and predictors of decreased cardiorespiratory fitness among cancer patients. *First Author: Jesse Pittard Caron, Brigham and Women's Hospital Heart and Vascular Center, Boston, MA*

Background: Exercise limitation is prevalent among cancer (CA) patients (pts). Predictors of decreased cardiorespiratory fitness (CRF) in CA pts require investigation. **Methods:** Single-center retrospective study of 1,632 CA pts (mean age 64 ± 12 years; 58% male, 45% prostate CA; 27% breast CA, 15% Hodgkin lymphoma, 13% head and neck CA) referred for exercise treadmill testing (ETT) a median of 6.8 (3.1, 12.4) years after a CA diagnosis. CRF was determined by peak metabolic equivalents (METs) achieved during ETT. Decreased CRF was defined as failure to achieve > 8 METs. Multivariable logistic regression models assessed associations of CA therapies with decreased CRF. **Results:** 36.6 % of CA pts had decreased CRF. Any chemotherapy, supra-diaphragmatic radiation therapy (RT), and the combination, were independently associated with a significantly higher likelihood of decreased CRF in an age- and sex-adjusted model (Table). These factors remained significant and anthracycline exposure was associated with a 53% increased risk of decreased CRF in the larger multivariable model. **Conclusions: :** Decreased CRF is prevalent among CA pts. Exposure to chemotherapy and/or supra-diaphragmatic RT predispose to decreased CRF in this cancer cohort. Interventions to improve CRF should be considered for select CA pts, especially those treated with chemotherapy and/or supra-diaphragmatic RT.

	Age- and sex-adjusted OR (95% CI), p value	Adjusted* OR (95% CI), p value
Any chemotherapy (n = 478, 29%)	1.75 (1.33, 2.29), p < 0.0001	1.84 (1.35, 2.52), p = 0.0001
Anthracycline chemotherapy (n = 267, 16%)	1.36 (0.96, 1.92), p = 0.08	1.53 (1.04, 2.27), p = 0.032
Supra-diaphragmatic RT (n = 703, 43%)	1.52 (1.16, 1.98), p = 0.001	1.56 (1.14, 2.11), p = 0.005
Combination of any chemotherapy and supra-diaphragmatic RT (n = 386, 24%)	1.92 (1.43, 2.57), p < 0.0001	1.99 (1.42, 2.81), p < 0.0001

*Adjusted for age, sex, low body mass index, obesity, diabetes mellitus, congestive heart failure, ischemic heart disease, hypertension, smoking history, atrioventricular nodal blocking agents, abnormal heart rate recovery, abnormal blood pressure response to exercise, chronotropic incompetence, positive ETT result, and interval from diagnosis to ETT

10072 Poster Session (Board #60), Mon, 1:15 PM-4:45 PM

Cardioprotective effect and safety of dexrazoxane in all breast cancer stages in patients treated with anthracyclines with or without trastuzumab: A systematic review and meta-analysis. *First Author: Ariane Macedo, Federal University of Minas Gerais, Belo Horizonte, Brazil*

Background: Anthracyclines continue to rank among the most effective agents in Breast Cancer (BC) treatment, but its use is limited by a dose-dependent cardiotoxicity. Clinical studies have suggested that dexrazoxane (DZR) could reduce this toxicity, however it is unclear whether the effect is maintained during an adjuvant treatment followed by trastuzumab(TTZ). DZR is frequently used in the metastatic setting, when higher anthracycline cumulative doses are needed, but is often omitted in adjuvancy. We aimed to analyse whether DZR is cardioprotective in all BC stages in patients receiving anthracycline-based chemotherapy followed or not by trastuzumab. **Methods:** We performed a systematic review and meta-analysis. The review was registreded in PROSPERO database. We searched data from 1990 to august 2017 in Cochrane Central Register of Controlled Trials, google scholar, MEDLINE/pubmed, LILACS, web of science, articles references and ASCO proceedings. Studies assessing congestive heart failure or cardiac event (cardiac function alterations without cardiac symptoms or hospitalization for cardiac reasons) as primary endpoints were included. Secondary outcomes were potential adverse effects of DZR on response (complete or partial, overall and progression free survivals). Two reviewers independently performed the studies selection, risk of bias assessment and data extraction. Meta-analysis was done using random effect model for estimation of treatment effect. Heterogeneity was assessed by visual inspection of forest plots and by Q test. **Results:** Nine studies were identified, including 1545 patients. DZR reduced heart failure incidence (RR 0.182, CI95%: 0.080-0.413, $p < 0.0001$) and cardiac events (RR 0.262, CI95%:0.169-0.407, $p < 0.0001$), without impact on response rate or survival. In a subgroup analysis of studies using TTZ after anthracycline, the overall benefit and safety of DZR was maintained. **Conclusions:** DZR delayed and reduced anthracycline induced cardiac toxicity, with or without trastuzumab. These findings may have significant implications for clinical practice

10073 Poster Session (Board #61), Mon, 1:15 PM-4:45 PM

Symptom burden and employment status in breast cancer (BC) survivors. *First Author: Ines Maria Vaz Duarte Luis, Dana-Farber Cancer Institute, Boston, MA*

Background: At time of BC diagnosis, a large proportion of patients (pts) work. However, long term effects of BC and BC treatment are likely to impact employment status in follow up. **Methods:** The ECOG ACRIN protocol E5103 was a phase III trial that randomized BC pts to receive adjuvant doxorubicin, cyclophosphamide, and paclitaxel with either bevacizumab or placebo. Telephone based surveys were administered to all pts enrolled between 01/Jan/10 and 08/Jun/10 as part of a Decision-Making/QOL component. Symptom burden was evaluated using the Memorial symptom assessment scale's (MSAS) global distress index (GDI), psychological and physical scores. Employment status was defined as 1) full time, 2) unemployed, disabled, medical leave 3) other (part time, homemaker, retired and other/unk). Results presented here are part of the 18 months (m) post enrollment follow up. **Results:** Of 519 pts who had not withdrawn at a time point prior to 18 m, pt reported outcomes (PRO) were available from 460 (88.6%). At enrollment (at least 1 m from primary surgery), 38% of pts were working full time and 19% were unemployed, disabled or on medical leave. At 18 m, 42% of pts were working full time, but 13% were unemployed, disabled or on medical leave. Pts who were unemployed, disabled or on medical leave reported significantly worse symptom burden -Table. **Conclusions:** Among pts enrolled in a randomized controlled trial and treated with contemporary adjuvant BC chemotherapy, persistent symptomatology was associated with negative employment outcome. Future strategies are needed to support BC survivors at risk of difficulties in job reintegration. Clinical trial information: NCT00433511.

Employment by MSAS symptom burden* at 18 m.

10074 Poster Session (Board #62), Mon, 1:15 PM-4:45 PM

Ultra-low doses of TX-004HR to improve symptoms of vulvar and vaginal atrophy (VVA) while maintaining serum levels of estradiol within the normal postmenopausal range. *First Author: Shari Beth Goldfarb, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: More than 60% of postmenopausal breast cancer (BC) patients have symptoms of dyspareunia and vaginal dryness that often result from endocrine therapy, and are challenging to treat. Local vaginal estrogens are proven safe and effective for VVA treatment, but a major concern of BC patients is the potential risk of systemic absorption and adverse breast effects; and it is contraindicated by the FDA to be used in this population. TX-004HR, an investigational, vaginal, softgel capsule of soluble 17β-estradiol (E2), is being developed to treat menopausal VVA. Serum E2 levels following TX-004HR treatment, which significantly reduced moderate-to-severe dyspareunia and vaginal dryness, were determined and compared with that of the normal postmenopausal range. **Methods:** A 12-wk, randomized, placebo-controlled, phase 3, safety/efficacy study (REJOICE) was conducted in menopausal women with VVA. TX-004HR (4 or 10 μg) was administered daily for 14 d, then twice weekly for 10 wks. Serum E2 levels using validated GC/MS/MS and pharmacokinetics (PK) were determined in 17-19 subjects/group on days 1 and 14 of daily dosing and day 84 of twice-weekly maintenance dosing. **Results:** The day 1, 0-h, mean±SD, serum E2 level was 4.05±2.69 pg/mL (95th percentile 8.49 pg/mL). The mean 24-h average levels on day 1 for the placebo, 4 μg, and 10 μg groups were 4.86±3.22, 3.92±1.46, and 5.76±3.13 pg/mL, respectively. Day 14 mean serum levels were lower than those on day 1; 4.34±2.77, 3.63±1.78, and 4.59±2.27 pg/mL, respectively. No accumulation of E2 was observed on day 14. On day 84 (maintenance phase), serum E2 levels were 4.36, 4.25, and 4.79 pg/mL, respectively. Primary efficacy and safety endpoints had been met for both doses. Changes in E2 levels from baseline to day 14 and day 84 were similar. **Conclusions:** TX-004HR (4 or 10 μg) improved VVA symptomatology, while maintaining serum E2 levels within the normal postmenopausal range. Although not yet studied in BC patients, further study in this population, especially in those taking aromatase inhibitors, is warranted. Clinical trial information: NCT02253173.

10075 Poster Session (Board #63), Mon, 1:15 PM-4:45 PM

Cancer survivorship, financial wellbeing and food insecurity in the U.S. *First Author: Zhiyuan Zheng, American Cancer Society, Atlanta, GA*

Background: Cancer is associated with increased out-of-pocket spending for medical care and limitations in the ability to work, frequently lasting many years after diagnosis. Few studies have addressed other non-medical financial consequences of cancer. This study examines general financial wellbeing and food insecurity for cancer survivors. **Methods:** Using the National Health Interview Survey (2013-2016), we identified cancer survivors (18-64: n = 4340; 65+: n = 6014) and those without a cancer history (18-64: n = 99,958; 65+: n = 27,642). Financial wellbeing measures included worry about standard of living, monthly bills, housing costs, and credit card payments. Financial food insecurity measures included food running out, food not lasting, and eating unbalanced meals. Additionally, skipping meals, eating less, hungry, losing weight, and not eating for an entire day were examined among those who reported any food insecurity. Predicted margins were generated to examine the burden associated with a cancer history, controlling for demographic characteristics, health insurance, income, and comorbidities, stratified by age (non-elderly: 18-64; elderly: 65+). **Results:** In the non-elderly population, cancer survivors consistently reported higher worry about standard of living (45% vs 41%), monthly bills (35% vs 31%), housing costs (28% vs 25%), and credit card payments (14% vs 13%) than those without a cancer history. Moreover, a cancer history was associated with increased food insecurity, i.e. food running out (18% vs 15%), food not lasting (16% vs 13%), and eating unbalanced meals (13% vs 11%). Among those with food insecurity, a cancer history was associated higher likelihood of skipping meals (41% vs 36%), eating less (42% vs 38%), and not eating for an entire day (22% vs 18%, all $p < .05$). In the elderly population, cancer survivors (n = 6014) are comparable to those without a cancer history, with 28% reported any financial wellbeing and 10% reported any food insecurity. **Conclusions:** Non-elderly cancer survivors experience poor financial wellbeing and food insecurity, which go beyond medical financial hardships. Future efforts should assess the relationships between various aspects of adverse financial consequences due to cancer.

10076 Poster Session (Board #64), Mon, 1:15 PM-4:45 PM

Oncology patients referred for cognitive training in a military treatment facility: Demographics, symptom reporting and cognitive functioning for CNS and non CNS cancers. *First Author: Katherine Sullivan, Walter Reed National Military Medical Center, Bethesda, MD*

Background: The Brain Fitness Center (BFC) at Walter Reed National Military Medical Center (WRNMMC) offers computer-based cognitive training, biofeedback, and brain-health classes. Originally designed for service members with traumatic brain injury, the BFC is experiencing an increase in patients with oncology-related cognitive complaints, prompting the need to better understand symptom reporting and objective cognitive functioning in this population. The goal of this analysis is to gain a better understanding of this patient population and compare the presenting symptoms and concerns of cancer patients with and without a history of central nervous system (CNS) involvement. **Methods:** Retrospective review and analysis of six validated symptom self-report questionnaires and objective cognitive functioning assessed by the Automated Neuropsychological Assessment Metrics (ANAM). Participants were 97 Military medical beneficiaries with cancer-related treatments referred to the BFC. Data are derived from an IRB-approved retrospective analysis protocol and were compared with published norms. **Results:** The average age of the study sample at time of referral was 47.3 years (SD 13.3; 49% men, 51% women), with 49% classified as CNS cancer (primary or metastatic disease) and 51% as non CNS cancer. Questionnaire results indicated moderate resilience, low adverse headache impact on daily function, reduced satisfaction with life, mild-to-moderate self-reported functional and neurobehavioral concerns, and subclinical posttraumatic stress symptoms. Average cognitive processing efficiency was poorer than demographically-matched controls (> 1 SD below average) and was inversely associated with self-reported symptom concerns (r -.273 to -.339, $p < .05$). There were no differences between the CNS and non CNS groups on symptom reporting or objective cognitive performance ($p > .05$). **Conclusions:** CNS and non CNS oncology patients produce comparable symptoms and cognitive scores and demonstrate less cognitive efficiency than sex, military service, and age- matched normative groups. Limitations and clinical implications are discussed.

10077 Poster Session (Board #65), Mon, 1:15 PM-4:45 PM

Self-reported functional assessment by patients receiving different prostate cancer strategies: Five-year results from the VICAN large prospective cohort. *First Author: G Raldine Pignot, Institut Paoli-Calmettes, Marseille, France*

Background: Several treatment options are available for prostate cancer (PC) with different functional side effects. The aim of our study was to assess the long-term consequences of the therapeutic strategies on continence, sexual function and quality of life (QOL) for men with a diagnosis of PC from the 5-year VICAN survey. **Methods:** The VICAN survey consisted in a French representative sample of 4174 5-years cancer survivors. Self-reported data were collected through telephone interviews. The questionnaire aimed to document the living conditions and quality-of-life (using the SF-12 questionnaire) of cancer survivors, including treatments' side-effects. **Results:** 447 out of 4174 survivors had PC, median age 71 [57-86] years. Strategies included: radical prostatectomy alone (RP) (42.8%) or with salvage radiotherapy (RP+RT) (7.5%), radiotherapy alone (RT) (17.5%) or in association with hormonal therapy (RT+HT) (11.6%), surveillance (17.4%), and hormonotherapy alone (HT) (3.2%). A total of 51.5% of patients had urinary leakage (sometimes 36.2%, often 12.3%, or very often 3.0%), with a significant impact on physical and mental QOL, and perceived discrimination ($p = 0.049$, $p = 0.020$, and $p = 0.025$, respectively). Patients treated with RP had significantly more urinary leakage than other strategies (59.0% versus 36.6% for RT, and 47.3% for RT+HT, $p = 0.026$). Among 380 pts assessable for sexual function, 56.0% reported dysfunction, with a significant difference to the detriment of RP+RT (74.1% versus 63.5% for RP, 48.6% for RT, 58.2% for RT+HT, 43.4% for HT and 37.8% for surveillance, $p = 0.004$). More significant decrease in the number of sexual intercourse (70.6%) and libido (74.6%) were reported in case of HT ($p = 0.035$), with a significant impact on depressive symptoms, physical and mental QOL ($p = 0.002$, $p < 0.001$, and $p = 0.002$). **Conclusions:** Self-assessed functional outcomes 5 years after PC diagnosis remain poor, specifically for continence after RP and sexual dysfunction after HT, with a significant impact on QOL. Implementation of new long-term management strategies for these patients is required to improve their urinary, sexual function and QOL.

10078 Poster Session (Board #66), Mon, 1:15 PM-4:45 PM

Cumulative burden of severe chronic health conditions (CHC) and health related quality of life (HRQoL) among adult survivors of childhood cancer: A report from the St. Jude Lifetime Cohort study (SJLIFE). *First Author: Nickhill Bhakta, St. Jude Children's Research Hospital, Memphis, TN*

Background: Childhood cancer survivors have high cumulative burden of severe and life-threatening CHC. The impact of CHC burden on self-reported HRQoL, however, has not been extensively assessed. **Methods:** Participants included 2666 survivors (mean age at study 34 years [range 18-66]) enrolled in the SJLIFE cohort; eligibility: survived ≥10 years and ≥18 years of age. Survivors were clinically assessed for the presence of a severe/life-threatening condition for 78 CHC using the SJLIFE modified CTCAE. HRQoL was assessed with the Short Form 36 and categorized into suboptimal (< -0.5 SD) or optimal (≥ -0.5 SD) based on the physical and mental component summaries (PCS, MCS). A latent class analysis approach was used to generate CHC classes, identify socio-demographic and exposure determinants and estimate associations with HRQoL. **Results:** Unique HRQoL profiles corresponded with the three CHC latent classes identified: optimal PCS and MCS (81% of survivors), suboptimal PCS/optimal MCS (4%) and suboptimal PCS & MCS (15%). Component scores and the prevalence of a subset of CHCs by HRQoL profiles are presented in the Table. Survivors who received ≥30Gy cranial radiation were more likely to have suboptimal PCS/MCS while those who received ≥250mg/m^2 anthracyclines clustered in the suboptimal PCS/optimal MCS class ($p < 0.01$, respectively). **Conclusions:** Despite a high cumulative burden of CHC, most adult survivors of childhood cancer report a HRQoL similar to the general population. Results suggest that most survivors adjust well to the excess disease burden, but also identified profiles of subgroups with suboptimal HRQoL who may benefit from targeted interventions.

Hypogonadism and effects on quality of life in previously treated germ cell tumor survivors: A single-centre, non-randomized, prospective observational study. *First Author: Nabin Khanal, Indiana University School of Medicine, Indianapolis, IN*

Background: Prior studies have shown that around 12% to 16% Germ Cell Tumour (GCT) survivors can have subnormal serum testosterone level as well as up to 15% reported decreased health related Quality of life (QOL). It is important to identify the correlation of hypogonadism with QOL scores in survivors of GCT. **Methods:** This is a single-centre, non-randomized, prospective observational study in GCT survivors 18-50 yrs of age previously treated with Surgery and Chemotherapy or Surgery alone. Total testosterone was measured at baseline, 3, and 6 months. Patients completed a validated QOL questionnaire at baseline, 3, and 6 months. Patients could get supplemental testosterone as standard of care. Mean QOL scores were compared between two treatment groups and within each group between survivors with hypogonadism (serum testosterone level < 300 ng/dL) versus without (> 300 ng/dL). A two-sided independent-groups t test was used to compare means. **Results:** We evaluated 199 GCT survivors. At baseline, the prevalence of hypogonadism was 48.2% overall, 51.45% in Chemo + Surgery group (C) and 44.7 % in surgery alone (CN) (p = 0.39). Overall, there was no statistically significant difference in QOL scores between two groups, except the C group exhibited greater Aging Male Symptoms (AMS) on the AMS scale score than the CN group, at baseline and 6 months. However, compared to patients with testosterone ≥ 300, patients with hypogonadism reported more fatigue (p = .04), poor sleep quality (p = .02) and worse general health (p = .006) at baseline. There was no statistically significant difference in depression (p = .33), or sexual functioning (satisfaction, p = .44; interest, p = .56; ability to have an erection, p = .23). There were no statistical differences in QOL between testosterone groups at 3 months or 6 months; however, sample sizes were small for participants who were measured on the testosterone at 3 months and 6 months. **Conclusions:** GCT survivors treated with chemo exhibited greater Aging Male Symptoms compared to chemo naive group. Hypogonadism was associated with sleep disturbance, worse energy and lower general health QOL scores at baseline.

10080 Poster Session (Board #68), Mon, 1:15 PM-4:45 PM

Unmet need for clinician engagement about financial toxicity after diagnosis of breast cancer. *First Author: Reshma Jagsi, University of Michigan Health System, Ann Arbor, MI*

Background: Little is known about whether growing awareness of the financial toxicity of cancer diagnosis and treatment has led to increased clinician engagement nor the status of current patients' needs. **Methods:** In 2013-15, we surveyed women with early-stage breast cancer, identified through population-based sampling from two SEER regions (Los Angeles and Georgia), and their physicians. We describe responses about experiences with financial toxicity and its management received from 73% of surgeons (n = 370), 61% of medical oncologists (n = 306), 67% of radiation oncologists (n = 169), and 68% of patients (n = 2502). **Results:** Half (50.9%) of responding medical oncologists reported that someone in their practice often or always discusses the financial burden of cancer with patients, as did 15.6% of surgeons and 43.2% of radiation oncologists. Among patients, 17% spent ≥10% of household income on out-of-pocket medical expenses and 7% spent ≥10% of household income on out-of-pocket nonmedical expenses. Debt from treatment was reported by 27.1% of whites, 58.9% of blacks, 33.5% of Latinas, and 28.8% of Asians. Privations were common: 21.5% of whites and 22.5% of Asians had to cut down spending on food, as did 45.2% of blacks and 35.8% of Latinas. Few whites (1.4%) or Asians (1.0%) lost their home, but 4.7% of blacks and 6.0% of Latinas did. Many patients desired to talk to healthcare providers about the financial impact of breast cancer: 15.2% of whites, 31.1% of blacks, 30.3% of Latinas, and 25.4% of Asians. Unmet patient needs for engagement with doctors about financial concerns were common. Of the 945 women who expressed worrying at least somewhat about finances, 679 (72.8%) indicated that cancer doctors and their staff did not help at least somewhat. Of the 523 women who expressed a desire to talk to healthcare providers about the impact of breast cancer on employment or finances, 283 (55.4%) reported that they had not had a relevant discussion. **Conclusions:** Improved clinician assessment and communication regarding financial toxicity are necessary. Even physicians who perceive that they are routinely offering necessary services may fail to meet patient needs. Cure at the cost of financial ruin falls short of physicians' duties.

10081 Poster Session (Board #69), Mon, 1:15 PM-4:45 PM

The hidden burden of anxiety and depression in ovarian cancer: A prospective longitudinal study from diagnosis. *First Author: Penelope M Webb, QIMR Berghofer Medical Research Institute, Brisbane, Australia*

Background: Women with ovarian cancer (OC) report high rates of anxiety (A) and depression (D), but most studies have used a cross-sectional design at a single time-point, not considered prior history and not included women who are symptom-free due to medication. Our goals were to quantify the total burden of A/D among women newly diagnosed with OC; the proportions who experienced symptoms only after their OC diagnosis and those with persistent symptoms; and determine use of appropriate medication/services by those affected. **Methods:** The OPAL (Ovarian Cancer Prognosis & Lifestyle) Study is a prospective study of Australian women diagnosed with OC from 2012-15. At baseline, they were asked if they had ever been diagnosed with A or D and if they took medication for this in the year before their OC diagnosis. At follow-up (3, 6, 9, 12, 24, 36 & 48 months after diagnosis) they complete the Hospital Anxiety and Depression Scale (HADS) and are asked about current medication use. **Results:** Of 893 women with ≥1 follow-up questionnaire, 373 (42%) reported clinical levels of anxiety (HADS > 10, 18%) and/or depression (15%) and/or use of anxiolytic or antidepressant medications (A/D meds) (18%) on at least one occasion during the first 3 years after diagnosis. An additional 166 women (19%) reported subclinical A or D (HADS 8-10). Of those with clinical A/D or taking A/D meds, 159 (42%) reported this at ≥3 time-points, 218 (58%) reported no prior history of A or D and 274 (73%) reported no use of A/D meds in the year prior to diagnosis. When women reported clinical levels of A or D, only 45% reported taking medication (37%) and/or seeing a psychiatrist or psychologist (19%). Among those not already on A/D medication at diagnosis, a prior history and low levels of optimism were the strongest predictors of A/D onset. **Conclusions:** More than 40% of women with OC experienced clinical levels of A or D during treatment or the first 3 years of follow-up. For 42% of those affected this was their first experience of distress and > 50% did not receive appropriate medication or psychological support. The hidden burden of anxiety and depression in this population is much greater than previously reported but is amenable to effective intervention if recognized.

10082 Poster Session (Board #70), Mon, 1:15 PM-4:45 PM

Sustained long-term benefits of a psycho-educational intervention targeting fear of cancer recurrence in people at high risk of developing another melanoma: A randomised controlled trial. *First Author: Mbathio Dieng, NHMRC Clinical Trials Centre, The University of Sydney, Sydney, Australia*

Background: People with melanoma want and need effective treatments for managing and living with fear of cancer recurrence (FCR). This study reports the long-term efficacy of a psycho-educational intervention designed to reduce FCR in people at high risk of developing another primary melanoma compared to usual care. **Methods:** Adults previously diagnosed with stage 0, I or II melanoma were randomly allocated to the intervention (n= 80) or control (usual care) arm (n= 84). Of 164 participants, 87% completed the 12-month assessment. Outcomes for 8 participants (5%) who completed the 6-month but not the 12-month assessment were imputed using model-based multiple imputation; thus, 151 participants are reported in the analysis. The intervention comprised a 76-page psycho-educational resource and three individually-tailored, telephone-based sessions with a psychologist, scheduled at specific time-points around participants' dermatological appointments. The intervention effect at 12-months was estimated by intention-to-treat analysis of the mean change in FCR score using a linear mixed model and as a FCR severity sub-score $\geq$13 vs $<$ 13 using logistic regression adjusted for repeated measures. **Results:** The intervention group had significantly lower FCR at 12 months; the between-group mean difference was -1.41 for FCR severity (95% CI -2.6 to -0.2; p= 0.02), and -1.32 for FCR triggers (95% CI -2.6 to -0.02; p= 0.04). The odds ratio for FCR severity $\geq$13 (54% intervention, 63% control) was 0.59 (95% CI 0.30 to 1.14, p= 0.12). There were no differences in secondary outcomes including anxiety, depression, or health-related quality of life. **Conclusions:** This psycho-educational intervention had a sustained effect in reducing fear of cancer recurrence over the longer-term. This novel intervention has no adverse effects and its benefits persist long after the last psychology session, supporting implementation as part of routine clinical care in melanoma. Clinical trial information: ACTRN12613000304730.

10083 Poster Session (Board #71), Mon, 1:15 PM-4:45 PM

PCPs knowledge and self-efficacy for caring for breast and colon cancer survivors. *First Author: Niharika Dixit, University of California San Francisco/ZSFG, San Francisco, CA*

Background: The role of primary care providers (PCPs) in caring for cancer survivors is critical, as care shifts from active cancer treatment to managing late and long-term effects of treatment and health maintenance. Safety net providers often need to provide cancer survivorship care in limited resource settings. This study assessed PCPs' knowledge, attitudes, and self-efficacy related to caring for breast and colon cancer survivors in a public hospital setting. **Methods:** A modified National Cancer Institute Survey of Physician Attitudes Regarding the Care of Cancer Survivors was sent electronically to 220 PCPs in 12 primary care clinics in the San Francisco Health Network affiliated with Zuckerberg San Francisco General Hospital. The response rate was 50% (110/220). **Results:** About half of PCPs strongly/somewhat agreed (vs. strongly/somewhat disagreed) that PCPs have the knowledge needed to provide follow-up care related to breast (49%) and colon cancer (53%). Providers were more likely to report feeling somewhat/very confident (vs. not at all confident) in providing appropriate surveillance testing to detect recurrent colon than breast cancer (73.6% vs. 65.3%). Most providers (92%) correctly reported recommended frequency of mammography, however, frequency of blood tests and other imaging surveillance were not as well recognized for breast or colon cancer. Recognition of long-term side effects of chemotherapy drugs was low (highest = 44% for Adriamycin). Lack of knowledge (76.3%) and unclear delineation of roles between PCP and oncologists (70.7%) were the most commonly reported barriers to providing high quality cancer survivorship care. Only 33% of providers reported receiving any survivorship training on late and long-term effects of treatment. The most preferred model for survivorship care was shared care (40.2%) and least preferred was one in which PCPs have primary responsibility (47.6%). **Conclusions:** PCPs feel they lack the appropriate knowledge, training, and confidence to assume primary responsibility for the care of breast and colon cancer survivors. A shared care model was most preferred, indicating an opportunity to improve survivorship care through effective oncologist-PCP-patient partnerships.

10084 Poster Session (Board #72), Mon, 1:15 PM-4:45 PM

Cannabis use in hematopoietic transplantation survivors. *First Author: Elizabeth Trice Loggers, Seattle Cancer Care Alliance, Seattle, WA*

Background: Approximately 20% of cancer patients report cannabis use (CU) within the last month despite limited data regarding its risks/benefits. CU among hematopoietic transplantation survivors (HTS) is of interest given the high symptom burden, infectious risk and research regarding cannabidiol in graft versus host disease prevention. **Methods:** From January 1 to June 1, 2017, a 15-question module addressing CU was included in a self-administered, annual survey of all adult HTS at Fred Hutchinson Cancer Research Center (Seattle, WA). Analysis included descriptive statistics and logistic regression. **Results:** Responders (n = 697, 32%) were more likely to be older, white and female than non-responders (all $p < 0.001$). Among responders, 329 (47%) considered CU and 124 (18%) reported CU. Reasons for considering CU included: physical symptoms (86%), emotional concerns (50%), recreation (45%) and to treat cancer (22%). While HTS aged 18-39 were 4-fold more likely to consider CU than those $>$ 65 years (odds ratio 4.04, 95% confidence interval 2.25-7.27, $p < 0.0001$), age was not associated with CU. Instead, white race, perception of benefits of CU, CU for cancer treatment, and communication/receipt of information from clinicians, naturopaths or cannabis dispensers or peers was associated with CU (see Table 1). CU was not associated with the legal status of cannabis in the HTS's state/province. **Conclusions:** While most HTS use cannabis to address physical and emotional concerns, nearly a quarter use it with the hope of improving their cancer outcomes. Whereas the perceived benefits of, and communication regarding, cannabis may play a significant role in use, age and legality likely do not.

Factors associated with cannabis use (n = 329).

Randomized trial of a text messaging intervention for symptom distress in BCa patients undergoing chemotherapy. *First Author: Kuang-Yi Wen, Fox Chase Cancer Center, Temple University Health System, Philadelphia, PA, Philadelphia, PA*

Background: Chemotherapy is often associated with treatment side-effects that negatively affect HRQOL. The aim of this study was to examine the feasibility and preliminary efficacy of a novel mobile text messaging (TXT) intervention to help breast cancer (BCa) patients coping with chemotherapy. **Methods:** Through an iterative patient-centered formative evaluation process, we developed an automatic bidirectional theory-guided and evidence-informed TXT intervention that sent two daily proactive messages addressing education, symptom management and support with options for patients to request more texts. In a RCT study, 100 BCa patients undergoing chemotherapy were assigned to either the TXT group or a control group that received an ACS chemotherapy booklet. Measures were administered at baseline, 1-month, 2-month, 3-month and 4-month. A satisfaction interview was conducted following the intervention. Acceptability and feasibility were examined. Primary outcomes were symptom distress and HRQOL. Secondary outcomes were depressive symptoms, self-efficacy and doctor-patient communication. **Results:** The majority of the sample was white (70%) with a mean age of 59 years. Both study groups reported significant increase in symptom distress and decline in HQROL from baseline to follow-ups. Symptom distress was found significantly lower and HRQOL was higher in the intervention group at month 1 and month 3 than the control (p-value $\leq$ 0.05). Intervention group reported significant improvement in self-efficacy and doctor-patient communication (p-value $\leq$ 0.05). No difference was found in depressive symptoms between two groups. Regarding acceptability, 70% of eligible participants consented and 90% of the TXT group participants were satisfied with the intervention. Intervention participants texted back to the system a total of 2388 times requesting additional texts with a mean range of 3-58 requests. **Conclusions:** Feasibility, satisfaction, and preliminary efficacy of a TXT intervention to promote better outcomes for BCa patients undergoing chemotherapy were established. Further research is needed to develop additional tailoring and personalization per participants' feedback.

10086 Poster Session (Board #74), Mon, 1:15 PM-4:45 PM

Trust in doctors and non-doctor sources for health and medical information. *First Author: Leo Chen, University of British Columbia, Vancouver, BC, Canada*

Background: Patients today have unprecedented access to health and medical information (HMI) from a diverse range of sources. This access helps inform patients, but it may also misinform and adversely affect patients' trust in doctors (TD). In this study, TD is compared with trust in 8 other sources of HMI. **Methods:** This study examines the Health Information National Trends Survey (HINTS-5) data published July 2017 by the National Cancer Institute. A nationally representative sample was generated from 3,295 Americans, and analyses included the 1873 who sought cancer information. Trust was ranked 1 (not at all) to 4 (a lot). Trust in family (F), news (N), radio (R), internet (I), TV, government (G), charities (C), and religious sources (RS) were independently compared to TD. Logistic regression was used to evaluate associations between demographic characteristics and viewing non-doctor sources as equal or superior to TD (EOSTD) for HMI. **Results:** Post-survey weighting, 75.6% of the sample trusted doctors "a lot", followed by trust in G (32.1%), I (15.4%), and C (8.3%). 60.4% viewed at least one non-doctor source as EOSTD. Earning $75,000 or more was inversely associated with viewing F (OR 0.89, p = 0.009), N (OR 0.91, p = 0.027), T (OR 0.84, p = 0.004), C (OR 0.83, p = 0.003), and R (OR 0.88, p = 0.004) as EOSTD for HMI compared to earning < $20,000. Compared to not completing high school, some college (OR 0.82, p = 0.029), college (OR 0.80, p = 0.011), or postgraduate education (OR 0.80, p = 0.011) reduced OR for viewing TV as EOSTD. Compared to being White, being Non-Hispanic increased viewing I as EOSTD, while being Black (OR 1.14, p = 0.007) or Non-Hispanic (OR 1.27, p = 0.034) increased viewing TV as EOSTD. Being female was associated with viewing F as EOSTD (OR 1.04, p = 0.040). **Conclusions:** Doctors are the most trusted HMI source, but most respondents viewed at least one non-doctor source as EOSTD. Patients should be reminded that alternative sources are not equivalent to doctors for HMI.

10087 Poster Session (Board #75), Mon, 1:15 PM-4:45 PM

Gender differences and trends in suicide risk among cancer survivors. *First Author: Nosayaba Osazuwa-Peters, Saint Louis University School of Medicine, St. Louis, MO*

Background: Cancer survivors have higher risks of dying from suicide compared with noncancer patients as well as the general United States population. This risk may differ based on gender and may be increasing due to the concomitant increase in the number of cancer survivors in the United States. This study aimed at describing the differences and identifying suicide risk trends based on gender. **Methods:** We queried the Surveillance, Epidemiology and End Results 18 database from 2000-2014 for all cancer deaths confirmed as suicide. Mortality rates from suicide was estimated for the 20 most common cancers in the United States, including lung, pancreatic, and head and neck cancers, three sites with leading suicide rates. Multivariate Poisson regression estimated mortality rate ratios (RRs) and 95% confidence intervals (CIs), stratified by sex (when applicable), and adjusting for site, race, marital status, age, year and stage of diagnosis. **Results:** There were 4,769 suicides observed among 4,427,272 cancer survivors from 2000-2014, yielding an incidence rate of 23.6 suicides per 100,000 person-years. Of these, 84.1% were suicides among male cancer survivors. Males cancer survivors were almost six times more likely to die from suicide compared with females (aRR = 5.62, 95% CI:5.17, 6.11). For males, increasing age (ref: 20-39 years) was associated with increasing risk of suicide: 40-59 years (aRR = 1.50, 95% CI: 1.22, 1.84), 60-69 years (aRR = 1.85, 95% CI: 1.50, 2.28), 70+ years (aRR = 2.52, 95% CI: 2.04, 3.11). It was the reverse in female survivors, where 60-69 (aRR = 0.71, 95% CI 0.61, 0.82) and 70+ year olds (aRR = 0.49, 95% CI 0.42, 0.57) were less likely than 20-39 years to commit suicide. Finally, compared with 2000-2004, female survivors diagnosed in 2010-2014 were 32% (aRR = 1.32, 95% CI: 1.19, 1.47) more likely to commit suicide, whereas male survivors were only 12% (aRR = 1.12, 95% CI 1.02, 1.23) more likely to commit suicide in the same period. **Conclusions:** There are significant male vs. female differences in suicide risks among cancer survivors, and there may have been an increased risk of suicide among women of reproductive age, and in the last decade. Survivors of cancer need surveillance to optimize survivorship and decrease suicide risks.

10089 Poster Session (Board #77), Mon, 1:15 PM-4:45 PM

Exercise counseling in integrative oncology: Patient characteristics and effects on self-reported symptoms. *First Author: Gabriel Lopez, University of Texas, MD Anderson Cancer Center, Houston, TX*

Background: Physical activity and exercise have shown benefits for cancer prevention and contribute to improved treatment related outcomes. We reviewed the characteristics of cancer patients referred for physical therapist-led exercise counseling at a comprehensive cancer center and its effects on self-reported symptoms. **Methods:** Patients presenting for an exercise counseling consultation and follow up encounter at an Integrative Medicine Center outpatient clinic from Feb 2016 to May 2017 completed the Edmonton Symptom Assessment Scale (ESAS; 0-10 scale, 10 most severe) pre/post-encounter; a PROMIS 10 global health assessment was also completed within 30 days of each encounter. Exercise counseling was provided by a physical therapist. ESAS individual items and subscales of Physical Distress (PHS), Psychological Distress (PSS), and Global Distress (GDS) were analyzed. We used paired t-tests with a p-value correction (i.e., p < .001) to examine symptoms before and after each encounter. **Results:** Data were available for 367 participants; 68 (18.5%) had at least one follow up encounter at 56.1 days (mean). Most were female (77.7%), caucasian (66.2%) with breast (43%), gastrointestinal (15.8%), or gynecologic (6.8%) cancer. Highest and most frequently reported (%) symptom scores at baseline included poor sleep (63.2%; 3.55), fatigue (59.9%; 3.19), and poor well-being (62.4%; 3.17). Pre/post change for one encounter was statistically and clinically significant for the ESAS GDS subscale (-3.36, SD 6.54, p < 0.001). ESAS change (n = 40) between baseline and first follow up within 60 days was statistically and clinically significant for improvement in fatigue (-1.35, p = 0.006), GDS (-4.55, p = 0.008), and PHS (-3.15, p = 0.016). PROMIS10 scores (n = 321) at baseline included global health 31.34. For the follow up group (n = 67), significant improvements were observed for mental health (p = 0.015) and global health (p = 0.024), not physical health (p = 0.07). **Conclusions:** Patients presenting for an exercise consultation had a moderate symptom burden with global health scores lower than the population mean, with improvements observed in global distress, physical distress, and fatigue after one encounter.

10090 Poster Session (Board #78), Mon, 1:15 PM-4:45 PM

Randomized controlled trial of percutaneous transesophageal gastrotubing for symptom palliation in patients with malignant gastrointestinal obstruction. *First Author: Miyuki Sone, National Cancer Center Hospital, Tokyo, Japan*

Background: Malignant gastrointestinal obstruction occurs in approximately 10-16% of end-stage cancer patients. Nasogastric tubing (NGT) is a standard palliative treatment; however, NGT causes nasopharyngeal discomfort, pain, skin ulcer, and difficulties in the appearance care such as shaving or makeup. Percutaneous transesophageal gastrotubing (PTEG) was developed as an image-guided, minimally invasive tube placement directly accessing to the cervical esophagus under local anesthesia. As the previous phase II study of PTEG (JIVROSG-0205) demonstrated high technical success (100%) and clinical efficacy (91%), we hypothesized that patients receiving PTEG would have higher quality of life (QOL) than NGT. The aim of this multicenter, open-label, randomized controlled trial (JIVROSG-0805) was to evaluate the efficacy of PTEG. **Methods:** Patients with symptomatic malignant gastrointestinal obstruction were randomly assigned (1:1) to receive PTEG or NGT. The primary endpoint was symptomatic scores of four elements (nasopharyngeal discomfort, satisfaction with appearance, restriction of daily life, and sleep disturbance) evaluated with area under the curve (AUC) during 2 weeks after the treatments. Secondary endpoints included change in global health-related QOL (EQ-5D, SF-8) and incidence of adverse events evaluated with CTCAE v.3.0. **Results:** From October 2009 to January 2015, 40 patients were enrolled (PTEG: 20; NGT: 20). Symptomatic scores were evaluable in 39 patients (PTEG: 19; NGT: 20) and the safety was evaluable in all patients. The AUC of the symptomatic scores of the PTEG group (mean: 149.6; 90% CI: 125.2, 173.9) was significantly higher than that of NGT group (mean: 44.9; 90% CI: 21.2, 68.7) ($p<$ 0.0001). Differences in EQ-5D (mean: 3.5; 90% CI: 1.6, 5.3; $p<$ 0.036) and SF-8 (mean: 220.7; 90% CI: 113.3, 328.1; $p<$ 0.0020) between two groups were statistically significant. There was no procedure-related complication in both groups. **Conclusions:** This analysis demonstrated the statistical superiority of the PTEG compared to the NGT. PTEG was effective in reduction of the distressing symptoms caused by NGT. Clinical trial information: UMIN000003565.

10091 Poster Session (Board #79), Mon, 1:15 PM-4:45 PM

PG2 injection, a novel botanical drug approved for improving cancer-related fatigue among advanced cancer patients under standard palliative care: A double blind, multi-center, randomized phase IV study. *First Author: Cheng-Hsu Wang, Chang Gung Memorial Hospital, Keelung, Taiwan*

Background: Cancer-related fatigue (CRF) is one of the most frequent and debilitating symptoms in 60% to 90% of patients with advanced cancer. The fatigue experienced by cancer patients can not only deteriorate patient quality of life, but also affect treatment efficacy and survival rate. PG2 injection developed by PhytoHealth Co., Taiwan with Astragulus Polysaccharides as API is the only drug approved by Taiwan Food and Drug Administration (TFDA) for relieving CRF in patients with advanced cancer. To further explore the effect of PG2 injection at lower dose, we recruited more patients in the current study and observe the effect of PG2 injection in 2 doses. **Methods:** Patients with advanced cancer receiving standard palliative care (SPC) with moderate to severe CRF (Score of the Brief Fatigue Inventory-Taiwan (BFI-T)≥4) were enrolled. Patients were randomized at a 1:1 ratio into two arms of PG2 injection treatment: 500mg dose or 250mg dose (both were prepared in 500ml saline and injected 3 times per week for 4 weeks) for two cycles. Fatigue improvement response rates (FIRR) were analyzed at the end of the first cycle to determine the efficacy of the two PG2 doses. Improvement of BFI-T score for more than 10% is considered as effective for relieving CRF. **Results:** Three hundred and ten patients were enrolled in this study. Two hundred and fourteen patients were included in the ITT population, including 111 subjects in high dose group and 103 subjects in low dose group. Results showed that improvement in fatigue scores by at least 10%, 20%, 30%, and 40% was observed in 65.07%, 46.60%, 34.95%, and 26.61% of subjects receiving 250 mg PG2 injection after one treatment cycle when compared to the baseline; in 500 mg group, fatigue score improvement by at least 10%, 20%, 30%, and 40% was observed in 65.77%, 51.35%, 34.23%, and 18.92% of subjects after one PG2 treatment cycle when compared to the baseline. **Conclusions:** This study demonstrates that more than 60% of subjects showed at least 10% improvement in fatigue score when compared to baseline after both 250mg and500mg PG2 treatments. Clinical trial information: NCT01720550. Clinical trial information: NCT01720550.

10092 Poster Session (Board #80), Mon, 1:15 PM-4:45 PM

Prophylactic treatment for acneiform rash caused by EGFR inhibitors: Prospective randomized double-blind trial comparing daily topical chloramphenicol 3% plus prednisolone 0.5% vs chloramphenicol 3% vs aqua cream. *First Author: Salomon M. Stemmer, Davidoff Cancer Center, Rabin Medical Center-Beilinson Hospital, Petah Tikva, Israel*

Background: Epidermal growth factor receptor inhibitors (EGFR-I), which are indicated for various tumor types, are associated with acneiform rash on the face/torso in approximately 90% of patients. This rash adversely impact patients' quality-of-life and may result in dose reductions/delays and treatment discontinuation. **Methods:** This randomized double blind trial investigated chloramphenicol 3% + prednisolone 0.5% (Threolone) vs chloramphenicol 3% vs aqua cream as prophylactic treatment for acneiform rash caused by EGFR-I. Adult cancer patients treated with EGFR-I (cetuximab, panitumumab, erlotinib, or gefitinib) were randomized to treatment with the 3 above mentioned options and were instructed to administer the assigned topical treatment to their face daily for 3 weeks and every 2 days for another week. The severity of the rash was assessed using the Common Terminology Criteria for Adverse Events (CTCAE) v4.0 as well as the number of facial lesions. Severe rash was defined as grade≥3 by the CTCAE criteria or ≥10 facial lesions. The rash was assessed on Days 0, 14, and 28. **Results:** Overall, 69 patients were randomized (21 chloramphenicol 3% + prednisolone 0.5%, 23 chloramphenicol 3%, and 25 aqua cream). The arms were similar with respect to demographics and tumor types. Number of facial lesions and CTCAE grade were highly correlated (r = 0.9). According to the number of facial lesions, chloramphenicol + prednisolone but not chloramphenicol alone was significantly more effective than aqua cream (Table). **Conclusions:** Topical chloramphenicol 3% + prednisolone 0.5% may be an effective prophylactic treatment for EGFR-I-associated acneiform rash. Clinical trial information: NCT01256437.

Proportion of patients with protocol specified severe acneiform rash.

		Day 14		Day 28		Day 14 or 28	
Study arm	N	Severity by CTCAE, %	Severity by NOL, %	Severity by CTCAE, %	Severity by NOL, %	Severity by CTCAE, %	Severity by NOL, %
Chloramphenicol 3% + prednisolone 0.5%	21	0	14[a]	0	6[a]	0	19[a]
Chloramphenicol 3%	23	5	40	5	16	5	39
Aqua cream	25	20	48	5	43	20	52

[a] $P < 0.05$ vs aqua cream treatment. All other 2-way comparisons were non-significant. NOL: number of lesions

10093 Poster Session (Board #81), Mon, 1:15 PM-4:45 PM

Adapalene gel 0.1% vs. placebo as prophylaxis for anti-EGFR-induced acne-like rash: A randomized left-right comparative evaluation (APPEARANCE). *First Author: Motoko Tachihara, Divisions of Respiratory Medicine, Department of Internal Medicine, Kobe University Graduate School of Medicine, Kobe, Japan*

Background: Anti-EGFR drugs frequently cause acne-like rash. Adapalene (ADP), a topical retinoid used as first-line therapy for acne, is efficacious against acne-like rash induced by anti-EGFR drugs. To evaluate the prophylactic efficacy of ADP, we conducted a randomized, placebo (PLC)-controlled, evaluator-blinded, left-right comparative trial. **Methods:** Non-small cell lung, colorectal, or head and neck cancer patients scheduled to receive EGFR monoclonal antibodies (MABs) or tyrosine kinase inhibitors (TKIs) were randomly assigned to once daily ADP application on one side of the face, with PLC on the other side. All patients had topical moisturizer co-applied to both sides of the face, and received oral minocycline. The primary endpoint was the difference in total facial lesion count of acne-like rash at 4 weeks. A sample size of 26 has 80% power to detect a mean of paired differences of 15 with an estimated standard deviation of differences of 25 and a significance level of 0.05. Secondary endpoints included global skin assessment and ≥ grade 2 acne-like rash (MASCC scale) at 4 weeks. Two blinded dermatologists independently evaluated the endpoints from photographs. **Results:** From Feb 2016 to May 2017, 36 patients were enrolled, but 10 discontinued mainly because of poor adherence. Of the remaining 26 evaluable patients, 13 each received EGFR MABs or TKIs. Although the total lesion count did not differ with ADP treatment compared with PLC at baseline (0.6 vs 0.9), ADP treatment was unexpectedly associated with greater lesion count than PLC, although the difference was not statistically significant (12.6 vs 9.8, p = 0.1127). All 4 patients with a difference > 10 in lesion count between face sides had a greater lesion count on the ADP-treated side. No significant differences were observed in global skin assessment or incidence of ≥ grade 2 acne-like rash between ADP- and PLC-treated sides. The most common adverse event other than acne-like rash was dry skin, but the incidence did not differ between ADP- and PLC-treated sides (57% vs. 54%). **Conclusions:** Based on our findings, ADP is not recommended for the prevention of acne-like rash induced by anti-EGFR drugs. Clinical trial information: 000016692.

10094 Poster Session (Board #82), Mon, 1:15 PM-4:45 PM

Patient reported outcomes (PRO) results for prophylactic effect of dexamethasone on regorafenib-related fatigue and/or malaise: a randomized, placebo-controlled, double-blind clinical study in patients with unresectable metastatic colorectal cancer: KSCC1402/HGCSG1402. *First Author: Mototsugu Shimokawa, Clinical Research Institute, National Kyushu Cancer Center, Fukuoka, Japan*

Background: KSCC1402/HGCSG1402 is a phase II, randomized, double-blind, placebo (PLC)-controlled study evaluating the prophylactic effects of oral dexamethasone (DEX) on regorafenib-related fatigue and malaise for patient (pts) with metastatic colorectal cancer. The primary endpoint was incidence of fatigue or malaise (CTCAE ver. 4, all grades) during the protocol period. Here we report intervention related PROs. **Methods:** PROs were assessed at baseline, on every once a week thereafter until 4 weeks, using the Brief Fatigue Inventory (BFI), the European Quality of Life 5 Dimensions-3 Level (EQ-5D-3L), Functional Assessment of Cancer Therapy-General (FACT-G) and Functional Assessment of Cancer Therapy-Colorectal (FACT-C). QOL scores were compared using a mixed-effects models for repeated measures (MMRM), adjusting for baseline score and the stratified randomization (the presence/absence of fatigue and/or malaise and sex). **Results:** Between October 2014 and December 2015, 74 pts were enrolled and randomized (DEX group: 37, PLC group: 37). BFI score, EQ-5D-3L score, FACT-G total score and FACT-C total score were improved at each point in DEX group. Least-squares mean difference from PLC group for baseline-to-week 4 changes were -0.68 (95% confidence interval (CI), -1.56 to 0.20; p = 0.1289), 0.02 (95%CI, -0.04 to 0.09; p = 0.4930), 3.9 (95%CI, -0.8 to 8.5; p = 0.0996) and 5.3 (95%CI, -0.6 to 11.2; p = 0.0775), respectively. **Conclusions:** Among pts who remained on treatment and for whom PROs data were available, dexamethasone had a clinical meaningful improvement at each of the post-baseline timepoints for FACT-G and FACT-C in comparison with those who received PLC, although the relatively small sample size. Clinical trial information: NCT02288078.

10095 Poster Session (Board #83), Mon, 1:15 PM-4:45 PM

Cryocompression for enhanced limb hypothermia in preventing paclitaxel-induced peripheral neuropathy. *First Author: Raghav Sundar, National University Health System, Singapore, Singapore*

Background: Severe peripheral neuropathy is a common dose-limiting toxicity of paclitaxel chemotherapy, with no effective treatment. We have previously described the role of continuous-flow hypothermia in reducing neurotoxicity caused by paclitaxel. We hypothesized that cryocompression (addition of pressure to hypothermia) may enhance depth of cooling and improve efficacy. **Methods:** A proof-of-concept study was conducted in cancer patients receiving taxane chemotherapy. Each subject underwent four-limb cryocompression with each chemotherapy infusion (3 hours) for a maximum of 12 cycles. Cryocompression was administered at 16°C and cyclic pressure (5-15 mmHg). Skin surface temperature and tolerance scores were recorded. Neuropathy was assessed using nerve conduction studies (NCS) conducted before (NCS_{pre}), after completion (NCS_{post}) and 3-months post chemotherapy (NCS_{3m}). **Results:** In total, thirteen patients underwent 142 cycles of cryocompression concomitant with chemotherapy. Mean skin temperature reduction of 3.8 ± 1.7°C was achieved and was well tolerated. Only 1 out of 13 patients required an intra-cycle temperature increase, with no early termination of cryocompression in any subject. NCS analysis showed significant preservation of motor amplitudes at NCS_{3m} compared to baseline (common peroneal nerve below fibula head stimulation: 12.7 ± 25.6 %; $p = 0.013$; tibial nerve abductor hallucis stimulation: 8.8 ± 22.9%; $p = 0.005$). Sensory nerve amplitudes showed a reduction at NCS_{post} compared to baseline but continued to be preserved at NCS_{3m} (% change from baseline: (NCS_{post}) -28.1 ± 21.9 %; (NCS_{3m}) -26.7 ± 19.0 %). Crycompression did not significantly affect taxane-induced changes in nerve velocities. **Conclusions:** Cryocompression is well tolerated and results in preservation of neuron function, as measured by gold-standard NCS. When compared to our previously reported continuous-flow hypothermia (21°C) cohort, cryocompression permitted delivery of lower temperatures with similar tolerability, potentially leading to improved efficacy in neurotoxicity amelioration. Larger studies investigating cryocompression are ongoing. Clinical trial information: NCT03299582.

10096 Poster Session (Board #84), Mon, 1:15 PM-4:45 PM

Effects of mindfulness meditation on quality of life in adults with advanced cancer and family caregivers: A randomized pilot. *First Author: Shelley A. Johns, Indiana University School of Medicine, Indianapolis, IN*

Background: Patients with advanced cancer often avoid emotionally sensitive discussions with family caregivers (FCGs) about their end-of-life (EOL) treatment preferences. Avoidance of these advance care planning (ACP) discussions inhibits EOL preparations and may reduce quality of life (QoL) for both patients and FCGs. Most ACP interventions fail to address emotional barriers that hinder timely ACP. Mindfulness training facilitates emotional regulation and adaptive coping, and was tested in this randomized pilot. **Methods:** Eligible patients had a: (1) locally-advanced solid malignancy; (2) life expectancy < 12 months as rated by their oncologist; (3) score of ≥ 7 on cancer-related cognitive avoidance (Mini-MAC); and (4) FCG willing to enroll. Patient-FCG dyads (n = 55) were randomly assigned to a 6-session mindfulness meditation class with communication training or usual care. Primary endpoints were feasibility, retention, QoL, and ACP confidence (patients only). Outcomes were assessed at baseline and 6- and 10-weeks using intent-to-treat analysis. **Results:** Of 133 patients who screened eligible, 41% enrolled. Dyadic retention was 84% through 10 weeks. Most patients (85%) had stage IV cancer, with breast (29%) and GI (27%) cancers being most prevalent. The majority of patients and FCGs were female (60-62%), white (94-95%), and college educated (63-64%). Mindfulness patients reported a large and significant improvement in existential QoL (d = 0.82, p = 0.009) at 6 weeks compared to controls; however, the magnitude of improvement was not sustained at 10 weeks (d = 0.24, p = 0.43). Mindfulness FCGs reported a significant *within-group* improvement in QoL at 10 weeks (d = 0.45, p = 0.03); however, *between-group* comparisons were not significant at any time point. A non-significant improvement in ACP confidence favoring mindfulness patients over controls at 6 weeks became significant at 10 weeks (d = 0.67, p = 0.03). **Conclusions:** Within limits of a small pilot, results suggest that mindfulness training is feasible and potentially beneficial for improving QoL and ACP confidence in dyads coping with advanced cancer. A full-scale efficacy trial with a more diverse sample is planned. Clinical trial information: NCT03257007.

10097 Poster Session (Board #85), Mon, 1:15 PM-4:45 PM

REZOLVE (ANZGOG-1101): A phase 2 trial of intraperitoneal (IP) bevacizumab (bev) for recurrent ascites in advanced, chemotherapy-resistant, epithelial ovarian cancer (CR-EOC). *First Author: Katrin Marie Sjoquist, NHMRC Clinical Trials Centre, The University of Sydney, Sydney, Australia*

Background: We sought to determine the safety and activity of IP bev for recurrent malignant ascites requiring repeated paracenteses, a major problem for women with CR-EOC. **Methods:** Eligible women had CR-EOC and symptomatic, malignant ascites that recurred within 28 days of their last paracentesis (P-1). Participants had IP bev 5mg/kg instilled at the end of their first therapeutic paracentesis on study (P0). Additional doses of IP bev were allowed at each subsequent paracentesis (P1, P2 etc) if the interval from the last dose was 42 days or more. The primary objective was to determine the proportion alive and free of repeat paracentesis at 42 days. Safety and quality of life were secondary outcomes. Serial samples of blood and ascites were collected for translational studies. The hypothesis was that IP bev would be worthy of further study if the proportion alive and free of repeat paracentesis at 42 days was 54% or more, but not if it was 20% or less. **Results:** We recruited 24 participants with a median age of 67 years (range 38 – 86), median of 4.5 lines of prior systemic treatment (range 1 – 12), and ECOG performance status of 0-1 in 9, and 2-3 in 15. The numbers of doses of IP bev administered were 1 in 13 participants, 2 in 5, 3 in 2, 4 in 1, and 5 in 1. The proportion free of paracentesis at 42 days using competing risk analysis was 77% (95% CI 58 to 92). Median time from P0 to P1 or death (puncture-free survival) was 48 days (range 8 to 248 days). Median Paracentesis free interval (P0 to P1 or death) was 4.29 (95% CI 2.4 to 5.8) times higher following first dose of IP bevacizumab compared with the time between paracenteses prior to study entry (P-1 to P0). Grade 3-4 AEs (number of participants, regardless of attribution) included abdominal pain (4), distension (4), small bowel obstruction (3), nausea (2), fatigue (2), and grade 3 bowel perforation (1). **Conclusions:** IP bev was safe, active, and warrants further study as a palliative intervention for recurrent ascites in CR-EOC. Clinical trial information: 12611000801910.

10098 Poster Session (Board #86), Mon, 1:15 PM-4:45 PM

Celiac plexus radiosurgery: A new palliative modality for upper gastrointestinal malignancies—Final results of a proof-of-concept clinical trial. *First Author: Yaacov Richard Lawrence, Sheba Medical Center, Ramat Gan, Israel*

Background: Many patients with upper-abdominal malignancies suffer from severe lower back pain radiating to the epigastrium, caused by infiltration of the celiac plexus. The celiac plexus is a network of nociceptive nerves, located along the aorta. Contemporary approaches (opioids, celiac plexus chemical neurolysis, systemic chemotherapy) are often inadequate. The celiac plexus has not previously been targeted using radiation. We hypothesized that ablative radiation targeted to the celiac plexus would alleviate pain. **Methods:** We conducted a single arm prospective clinical trial. Eligible patients had celiac-pain $> 4/10$ on Numerical Rating Scale (NRS), ECOG ≤ 3, no previous abdominal RT, and were evaluable if they completed treatment per protocol with at least one post-treatment visit. The celiac plexus was irradiated from D12 to L2. Radiation was given as either five fractions of 9 Gy or a single-fraction 25 Gy. The primary endpoint was NRS pain 3 weeks post-treatment. Secondary endpoints were toxicity, pain at 6w, analgesic use, and pain interference with daily activities as evaluated by 'Brief Pain Inventory' before and after radiation. **Results:** 21 patients were evaluable: 2 received fractionated treatment, 19 received 25Gy single fraction. The median age of the study population was 63 yr with a median ECOG of 1, 86% had pancreatic cancer. Patients were a median of 8 months out from diagnosis, and had received a median of one systemic treatment. Toxicity was limited to grade 1-2. All patients reported decreased celiac pain: median baseline pain was 6/10 (IQR 5-7.7), was reduced to 2.3/10 (IQR 0.9-3.9) ($p < 0.0005$) at 3w, and to 1.8/10 (IQR 0-3.2) ($p < 0.0005$) at 6w post-treatment. Seven patients reported their celiac pain had been eliminated entirely. Median morphine consumption decreased (NS). Improvement was seen in multiple quality of life measures, includ. total wellbeing (p = 0.0001), daily activity (p = 0.005) and sleep quality (p = 0.002). **Conclusions:** Celiac plexus radiosurgery alleviates pain, and improves quality of life among patients with advanced upper-GI cancer. An international multi-center phase II trial is accruing. Clinical trial information: NCT02356406.

10099 Poster Session (Board #87), Mon, 1:15 PM-4:45 PM

Relationships between immune cell profiles and frailty in patients with breast cancer from pre- to post- chemotherapy: A University of Rochester NCI community oncology research program prospective, longitudinal study. *First Author: Nikesha Gilmore, University of Rochester Medical Center, Rochester, NY*

Background: Frailty is an important factor for oncologists in determining risk of chemotherapy toxicity, especially for older adults. While inflammation has been associated with survival, its relationship with developing frailty is not understood. In this secondary analysis we sought to determine whether changes in immune cell profiles are predictive of frailty after chemotherapy. **Methods:** Patients (pts) had stage I-IIIc breast cancer (n = 583, mean age 53; range 22-81) scheduled to receive adjuvant/neoadjuvant chemotherapy. Frailty was assessed by a modified Fried score (0-4) using self-reported measures of weakness, exhaustion, physical activity and walking speed. Absolute counts of immune cell types as well as neutrophil:lymphocyte ratio (NLR) and lymphocyte:monocyte ratio (LMR) were calculated at pre-chemotherapy (PrC; $\leq$7 days of first cycle) and post-chemotherapy (PoC; $\leq$ 1 month of last cycle). Separate linear regressions were used to evaluate the associations between PrC cell counts and ratios with PoC frailty, controlling for relevant covariates and baseline frailty. Additional analyses examined the associations of changes in cell counts and ratios with changes in frailty (PoC minus PrC). **Results:** Chemotherapy significantly increased pts mean frailty score (PrC = 1.28, PoC = 2.0; $p < 0.001$). Higher PrC LMR was significantly associated with higher PoC frailty ($\beta = 0.20$; $p = 0.035$). Lower PrC NLR was marginally associated with higher PoC frailty ($\beta = -0.158$; $p = 0.078$). In both models higher baseline frailty and older age were significantly predictive of PoC frailty. From PrC to PoC, greater lymphocyte decrease ($\beta = -0.27$; $p = 0.036$) and NLR increase ($\beta = 0.18$; $p = 0.015$) were predictive of increased frailty change score. LMR decrease ($\beta = -0.17$; $p = 0.058$) was also marginally associated with increased frailty score. **Conclusions:** Baseline LMR and lymphocyte decline were both predictive of PoC frailty. Immune cell counts may help clinicians identify pts at risk of frailty PoC. Future research is needed to further elucidate inflammation-related mechanisms of frailty in cancer patients.

10100 Poster Session (Board #88), Mon, 1:15 PM-4:45 PM

Effect of pre-treatment sleep disturbance on radiation therapy (RT)-induced pain in 676 women with breast cancer. *First Author: Anita Roselyn Peoples, University of Rochester Medical Center, Rochester, NY*

Background: Pain is a debilitating side effect that remains poorly controlled in ~50% of cancer patients. Data from the general population has shown a strong bi-directional relationship between sleep disturbance and pain; however, little is known about this relationship in cancer patients. The present secondary analyses examine the effect of pre-RT moderate-severe cancer-related sleep disturbance (CRSD) on subsequent RT-induced pain. **Methods:** Analyses were performed on 676 female breast cancer patients (mean age 58) scheduled to receive RT from a previously completed multicenter, phase II RCT examining the efficacy of oral curcumin on radiation dermatitis. The trial was conducted at 21 community oncology practices throughout the U.S. affiliated with the URCC NCORP Research Base. CRSD and total pain as well as the subdomains: sensory pain (SP), affective pain (AP), and perceived pain intensity (PPI) were assessed at pre-RT (baseline) and post-RT by the modified MD Anderson Symptom Inventory and the short-form McGill Pain Questionnaire, respectively. Patients were dichotomized into 2 groups: those with moderate-severe CRSD at baseline (N = 101) vs. those with mild or no CRSD (control; N = 575). **Results:** Spearman rank correlations showed that changes in CRSD from baseline to post-RT were significantly correlated with concurrent changes in total pain, SP, AP, and PPI ($r = 0.21$–0.38; all p's < 0.001). Generalized linear estimating equations, after controlling for baseline pain and other covariates (baseline fatigue and distress, age, sleep medications, anti-anxiety/depression medications, prescription pain medications, and depression or anxiety disorder), showed that patients with moderate-severe CRSD at baseline had significantly higher mean values of post-RT total pain (by 39%; $p = 0.033$), SP (by 41%; $p = 0.046$), and AP (by 55%; $p = 0.035$) than the control group, but not for PPI ($p = 0.066$). **Conclusions:** These findings suggest that moderate-severe disturbed sleep prior to RT is an important predictor of pain at post-RT in breast cancer patients. Further research is needed to confirm these findings. *NCI UG1CA189961, NCATS TL1 TR002000.* Clinical trial information: NCT01246973.

10101 Poster Session (Board #89), Mon, 1:15 PM-4:45 PM

Risk stratification using patient-reported outcomes (PROs) in patients (pts) with advanced cancer. *First Author: Shiven B. Patel, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT*

Background: Performance status is often used to stratify cancer pts for treatment and to guide supportive care resources. This retrospective study was conducted to evaluate whether PROs have prognostic value, independent of physician assessment of functional status. **Methods:** Pts treated at Huntsman Cancer Institute were assessed using the NCI PROMIS-Ca bank from May 2016. Physical function, fatigue, depression, anxiety, and pain scores were collected via iPad in pts with metastatic NSCLC, CRC, and breast cancer. A single PRO score at the time of metastatic disease for each pt was merged with outcome data using the Flatiron Health database, processed with technology-enabled abstraction and supplemented with third-party death information. Associations between PROs, PROs and overall (OS), and PROs and hospital-free survival (HFS) were assessed. **Results:** The five PRO domains were interrelated with moderate-strong correlation coefficients (0.40-0.79). Physical function score was worse for NSCLC than both CRC ($p < 0.001$) and breast cancer ($p < 0.001$), while both anxiety and depression were worse for NSCLC than CRC ($p = 0.003$ and $p = 0.042$, respectively). All individual PRO domains and a summary score were strongly associated with outcomes. Physical function and fatigue provided the greatest discrimination. The correlation of PROs with 12-month survival (table) and HFS were statistically significant. **Conclusions:** PRO scores, independent of physician interpretation, are prognostic for OS and HFS. These findings have substantial implications for patient care, treatment planning, clinical research, and financial modeling.

Kaplan-Meier estimates of 12 month survival by tertile by PRO.

	Probability of Survival to 12 months			
	Low Tertile	Middle Tertile	High Tertile	Log-rank P-Value
Physical Function	0.57 (0.46-0.71)	0.70 (0.61-0.81)	0.83 (0.73-0.94)	< 0.001
Pain Interference	0.72 (0.61-0.85)	0.81 (0.72-0.90)	0.54 (0.42-0.68)	< 0.001
Fatigue	0.82 (0.72-0.94)	0.69 (0.60-0.79)	0.57 (0.45-0.72)	< 0.001
Anxiety	0.73 (0.63-0.86)	0.73 (0.64-0.83)	0.67 (0.56-0.79)	0.014
Depression	0.81 (0.71-0.91)	0.70 (0.60-0.81)	0.62 (0.51-0.75)	0.002
Composite	0.77 (0.66-0.90)	0.75 (0.66-0.86)	0.59 (0.48-0.72)	< 0.001

10102 Poster Session (Board #90), Mon, 1:15 PM-4:45 PM

A multi-center, randomized, double-blinded, placebo-controlled trial of additive effect of duloxetine for neuropathic cancer pain refractory to opioids and gabapentinoids: JORTC- PAL08 (DIRECT study). *First Author: Eriko Satomi, Department of Palliative Medicine,National Cancer Center Hospital, Tokyo, Japan*

Background: Management of cancer patients experiencing neuropathic pain (NP) refractory to opioids remains an important challenge. Gabapentinoids are one of the most widely used therapies for NP. However, duloxetine is also used for NP. We have evaluated the efficacy of addition of duloxetine for neuropathic cancer pain refractory to opioids and gabapentinoids. **Methods:** Multicenter, randomized, double-blind, placebo-controlled trial. Patients with any cancer NP, currently being administered opioids, non-responsive or intolerant to gabapentinoids were eligible. Patients with chemotherapy-induced peripheral neuropathies were excluded. Patients were administrated 20 mg to 40 mg of duloxetine or placebo for 10 days. The primary endpoint was the average pain intensity (Brief Pain Inventory (BPI) item 5) at Day 10, the main analysis was *t* test (significance level one side 5%), Complete Case (CC) analysis was performed to handle missing primary data and Baseline Observation Carried Forward (BOCF) analysis was performed for sensitivity analysis. **Results:** 70 patients were registered at 12 sites in Japan. BPI item 5 at Day 10 was i) average of Group D (Duloxetine) 4.03 [90% CI 3.33, 4.74], Group P (Placebo) 4.88 [4.37, 5.38] ($p = .053$) (CC analysis); ii) Group D 4.06 [3.37, 4.74], Group P 4.91 [4.41, 5.41] ($p = .048$) (BOCF analysis). Point estimate of the difference of average values between the two groups was -0.84 [-1.71, 0.02] (CC analysis) and -0.85 [-1.69, -0.01] (BOCF analysis). Compared to Day 0, the improvement rate of 50% or more at Day 10 was 32.4% in Group D and 3.0% in Group P ($p = .002$). **Conclusions:** The minimum important difference (MID) with clinical significance in cancer pain is said to be 1 point in 11 stages of the Numerical Rating Scales (NRS), and our results were close to the MID (-0.84; CC analysis). Moreover, sensitivity analysis and secondary analysis show significant improvement in Group D. Overall, duloxetine is clinically effective for NP. Clinical trial information: UMIN000017647.

10103 Poster Session (Board #91), Mon, 1:15 PM-4:45 PM

Evaluation of a mobile application to prepare and engage cancer patients prior to a palliative care (PC) visit: Results of a randomized, controlled trial. *First Author: Arif Kamal, Duke Cancer Institute, Durham, NC*

Background: Despite the growth in guidelines and evidence supporting routine PC for patients with advanced cancer, up to 40% of patients referred and given an appointment never show up. This high "no show" rate stems from patients harboring misconceptions about PC (e.g. confusing with hospice care) and not knowing its value. No tool to educate patients on the value of PC and prepare them for an upcoming visit has been tested. **Methods:** We conducted a randomized, controlled trial of PCforMe, a web-based mobile education and engagement tool, from December 2016 through February 2018. Patients were randomly assigned prior to a new PC clinic appointment to either PCforMe or an active control on a tablet device. The active control included three popular websites about PC developed by major specialty societies. We collected demographics and assessed system usability scores, patient preparedness (PEPPI), change in knowledge about PC, and change in no-show rate. **Results:** 78 patients were enrolled. Mean age was 61 (range 20-83) with 56% with less than a Bachelors education. The mean usability score was 77, putting PCforMe usability in the 90th percentile of mobile health tools. Scores on the single-item "I know what questions to ask" improved significantly ($p < 0.002$) after using PCforMe. Similar improvements were not seen in the control arms. Scores on the knowledge survey improved more in the intervention arm ($p < 0.05$). No show rates for new visits during the course of the trial decreased by 35%. **Conclusions:** Even among an elderly population with advanced cancer, a novel, mobile tool to prepare and engage cancer patients prior to a PC appointment is highly usable. The tool led to greater sense of readiness and familiarity with PC and reductions in the no-show rate to palliative care clinic. Larger, multi-site trials are needed to further test this novel tool.

10104 Poster Session (Board #92), Mon, 1:15 PM-4:45 PM

Racial disparities in palliative and hospice care beliefs of lung cancer patients. *First Author: Aditya Varnam Shreenivas, Icahn School of Medicine at Mount Sinai, Newyork, NY*

Background: Minority patients with lung cancer often have higher rates of morbidity and mortality. Recent data shows that early integration of palliative care with standard oncologic care for advanced lung cancer patients is associated with better quality of life and potential survival. Little is known about racial disparities in palliative and hospice care beliefs and the influence of these factors on the utilization of palliative care and hospice. **Methods:** We performed a prospective cohort study of patients diagnosed with advanced lung cancer (stage III and IV). At baseline (within 3 months of diagnosis), patients completed a validated survey assessing palliative and hospice beliefs as well as care preferences. Multivariate methods were used to compare differences in these beliefs among minority (Black and Hispanic) and non-minority patients. Responses to questions on beliefs were scored on a scale of 1-5, with 1 standing for strongly agree and 5 for strongly disagree. Using ANOVA, mean score differences between minorities and non-minorities were assessed. **Results:** We enrolled 97 of 160 eligible patients (61%). To date, baseline surveys have been completed on 61 patients. Of those, 38 (62.3%) were minorities and 23 (37.7%) were non-minorities. There were no significant differences in baseline demographics. In terms of palliative care beliefs, minorities reported feeling more hopeful ($p = .008$) and more secure ($p = .03$) with palliative care referral. Minorities were more likely to believe that they cannot afford hospice ($p = .002$), that hospice is not as good as the hospital for cancer care ($p = .02$), were less likely to believe that hospice care can be provided at home ($p = .04$) or that hospice can help with physical, psychological , social and spiritual needs ($p = .04$). Additionally, more minorities compared to non-minorities preferred palliative care to hospice ($p = 0.007$). **Conclusions:** Minority patients with advanced lung cancer are more likely to prefer palliative care than hospice and hold false beliefs about hospice. Having adequate palliative and hospice care for minorities is necessary to ensure health equity among patients with lung cancer. Future studies will be performed to see how these beliefs effect the use of these services.

10105 Poster Session (Board #93), Mon, 1:15 PM-4:45 PM

Patterns and determinants of pain and emotional distress in older adults with cancer: A population based study. *First Author: Amy J. Davidoff, Yale School of Public Health, New Haven, CT*

Background: There is increasing concern about the adequacy of symptom management among older adults with cancer. We examined patterns and predictors of pain and emotional distress after a cancer diagnosis. **Methods:** Using the linked SEER-Medicare Health Outcomes Survey database, we selected participants from 2007-2012, within 5 years of cancer diagnosis. We used survey responses describing activity limits due to pain and emotional distress within the past 30 days to construct study outcomes. We undertook bivariate analyses and estimated multivariable logistic regression to determine the association of pain and emotional distress with cancer type, stage at diagnosis, years since diagnosis, demographics, socioeconomic status (educational attainment and area poverty rates) and chronic conditions. **Results:** Among 9481 respondents, prostate (31%) and breast (19%) cancers were most prevalent. Activity limits due to pain were reported by 22%, with highest rates among adults with lung cancer (37%), stage 4 diagnosis (34%), depression (53%) and heart failure (44%), minorities, and patients with lower socioeconomic status. The odds of reporting pain were increased for lung (ref = breast; adjusted odds ratio (aOR):1.5; 95% confidence interval (CI) 1.2-1.9); stage 2-4 (stage 4 aOR: 1.75; CI 1.36-2.25); and chronic conditions; and were decreased for prostate (aOR: .70; CI .54-.92) or colorectal cancers and higher socioeconomic status. Limitations due to emotional distress were reported by 14%, with the highest rates among patients with lung (27%), stage 4 (24%), prior depression (50%), Crohn's disease (33%), heart failure (30%), and lower socioeconomic status. The odds of emotional distress were higher with increasing age (80+ years, aOR: 2.1; CI 1.7-2.6), Hispanic ethnicity, prior depression (aOR: 7.9; CI 6.7-9.1), stroke, COPD, stage 3-4 diagnosis, and reduced for prostate cancer or lymphoma, initial surgery, and year 2 post diagnosis (ref=year 5). **Conclusions:** Despite an increased focus on symptom management, pain and emotional distress remain prevalent among older adults with cancer. Efforts to identify and target unmet supportive care needs are necessary to further improve quality of life.

10106 Poster Session (Board #94), Mon, 1:15 PM-4:45 PM

Impact of oncologist outpatient productivity on prevalence of goals of care discussions. *First Author: Sofya Pintova, Mount Sinai Medical Center, Brooklyn, NY*

Background: Oncologists report that time required to conduct goals of care (GoC) discussions impede its practice, yet, little data is available to support this widely held belief. We studied the impact of oncologists' productivity on their ability to have meaningful GoC discussions. **Methods:** At community, academic, municipal and rural hospitals, we recruited & randomized solid tumor oncologists & their newly diagnosed advanced cancer patients with < 2 year prognosis to participate in a RCT, testing a coaching model of communication skills training. Patients were surveyed after the post-imaging visit where GoC discussion was expected. We measured quality of GoC discussions by patients' rating how well their physician talked about goals. We measured productivity by work revenue value units (wRVUs) per hour for each day the oncologist saw the study patient post-imaging. Analyses were done with Kruskal-Wallis and Wilcoxon tests. **Results:** We enrolled 22 oncologists and 221 productivity days were assessed. The highest median productivity was observed in the Community hospital. In all four sites participating in this study, no significant difference in productivity was observed between visit days where quality GoC discussion took place vs no quality GoC discussion occurred. A multivariate analysis controlling for intervention group, hospital, patient and oncologist characteristics, found no relationship between productivity and conduct of high quality GoC discussion. **Conclusions:** The prevalence of high quality GoC discussion reported by advanced cancer patients was high among the four institutions in this study. Despite concerns about time constraints, productivity was similar regardless of whether or not a quality GoC discussion took place . Clinical trial information: NCT02374255.

Hospital N = 221	Prevalence of High Quality GoC Discussion	Productivity Median	Productivity Quality GoC Discussion Occurred (+)	Productivity No Quality GoC Discussion Occurred (-)	p value
Community	77%	4.3 (1.7-9.9)	4.3 (1.7-9.9)	3.8 (2.7-6.0)	0.69
Academic	80%	3.6 (0.4-7.5)	3.6 (0.9-6.4)	3.8 (2.3-7.5)	0.45
Municipal	70%	3.0 (0.7-6.1)	2.9 (0.7-6.1)	3.1 (3.0-3.2)	0.62
Rural	62%	2.9 (1.4-6.0)	3.0 (1.7-6.0)	2.9 (1.4-4.1)	0.48
	$p = 0.1$	$p < 0.001$

Length of time to conduct goals of care visits. *First Author: Sofya Pintova, Mount Sinai Medical Center, Brooklyn, NY*

Background: Oncologists report that time to conduct a goals of care (GoC) discussion is a barrier. We studied the relationship of GoC discussion and visit times at different type hospitals. **Methods:** At community, academic, municipal and rural hospitals, we recruited & randomized solid tumor oncologists & their newly diagnosed advanced cancer patients with < 2 year prognosis to participate in a RCT, testing a coaching model of communication skills training. Patients were surveyed after post-imaging visits. These visits were audiotaped and median encounter time recorded. We define GoC discussions as patient report that their doctor talked about preferences for cancer treatment and clarified things most important to them given their illness. Analyses were done with Kruskal-Wallis and Wilcoxon tests. **Results:** For 22 randomized oncologists in the study, 137 post-imaging encounters were audiotaped. The median face-face time oncologists spent during a GoC encounter with an advanced cancer patient was 15 minutes. Encounter times when GoC discussions were expected varied between the four sites, ranging from 9.5 minutes to 18 minutes, p = 0.05. The encounters where no GoC discussions occurred were longer, taking 16.5 minutes vs 13 minutes, p = 0.05. Visits that took place after progression of disease took longer, 18 minutes vs 13 minutes, p = 0.006. **Conclusions:** Visit times vary by hospital type and average 15 minutes. With disease progression, visit time is longer. Despite physician perceptions, GoC discussions do not lengthen visits. Clinical trial information: NCT02374255.

Community-based palliative care utilization in elderly pancreatic cancer patients. *First Author: Zhanni Lu, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Community-based Palliative Care (CBPC) has shown to stabilize symptoms, alleviate psychological and spiritual burdens, satisfy care preferences, and improve quality of life among care recipients. We evaluated CBPC utilization and predictors in pancreatic cancer patients ≥66 years. **Methods:** Palliative Care (PC) encounters among pancreatic cancer patients were identified by ICD-9-CM codes using SEER-Medicare data from 2007 to 2013, and patients were followed until 2014. PC encounters outside hospital settings were classified as CBPC. We tested time trends of CBPC utilization and time to PC referral after cancer diagnosis. Multivariable random intercept logistic models were used to determine the predictors of CBPC utilization at the patient and Health Service Area (HSA) levels. **Results:** 16,106 patients were included, of whom 27.8% used palliative care; of those, 1,530 (9.5%) used CBPC, and 2,956 (18.3%) used Hospital-based Palliative Care (HBPC). CBPC utilization increased from 8.2% in 2007 to 9.4% in 2013 (p = .014). Median (IQR) PC referral time after cancer diagnosis decreased from 5 (2, 11) mo. in 2007 to 2 (1, 5) mo. in 2013 (p = .001). Being female (OR 1.27 [1.12, 1.45]; p < .001), a diagnosis of advanced cancer stage (III/IV: OR 1.29 [1.002, 1.67]; p = .049), cancer treatment participation (OR 2.24 [1.92, 2.60]; p < .001), or residing in an urban area (OR 1.57 [1.03, 2.39]; p = .035) were positively associated with CBPC utilization. Those living in the poorest communities (OR 0.62[0.47, 0.81]; p = .001) and southern SEER Registries (Georgia, Kentucky and Louisiana) (OR 0.15 [0.09, 0.24]; p < .001) were less likely to use CBPC. HSAs with high density of HBPC programs (an indicator of regional health care resources) were positively associated with CBPC usage (OR 1.50 [1.03, 2.20]; p = .035). **Conclusions:** CBPC usage increased and referral time decreased over 6 years. Patient-level factors, geographic area characteristics, and regional health care resources were associated with likelihood of receiving CBPC.

10109 Poster Session (Board #97), Mon, 1:15 PM-4:45 PM

Patterns of palliative care utilization in stage IV non-small cell lung cancer in the National Cancer Database. *First Author: Urshila Durani, Mayo Clinic, Rochester, MN*

Background: Early integration of Palliative Care (PC) improves survival in stage IV non-small cell lung cancer (NSCLC). Here we explore patterns in PC utilization in this group. **Methods:** We queried years 2004-2014 of the National Cancer Database for adults with stage IV NSCLC. Patients receiving pain management +/- other palliative procedures were PC utilizers. In addition to descriptive statistics, multivariable logistic regression models with interaction analyses identified predictors of PC utilization. **Results:** Of 341,993 patients, 3.2% received PC at initial treatment. PC utilization increased significantly from 2004-2006 to 2013-2014 (2.3% vs 4.2%, p < 0.01). Whites had higher PC utilization (3.3%) than blacks (2.6%) and Hispanics (2.3%, p < 0.01 for both). Significant predictors of PC on multivariable regression are listed in the Table. Interaction analyses found that Hispanics and Asians had a slower increase (p < 0.01) in PC utilization over time compared to Whites or Blacks. An additional 13.8% and 5.3% received palliative radiation or chemotherapy, respectively. 0.9% received palliative surgery, and 1.4% received some combination of the 3 modalities. **Conclusions:** PC utilization in stage IV NSCLC is markedly low and plagued by racial and socio-economic disparities despite guidelines advocating early PC integration.

Multivariable regression of PC utilization in Stage IV NSCLC.

Comparisons of palliative care utilization in metastatic cancer patients between multi-payer non-universal health care and single-payer universal health care systems. *First Author: Raymond Nienchen Kuo, National Taiwan University, Taipei City, Taiwan*

Background: Previous studies reported that private insurance was associated with receiving recommended care and better outcomes. However, it is unclear whether insurance type is associated with the utilization of palliative care among metastatic cancer patients who survived for less than 6 months following diagnosis. This study compares the utilization of palliative care among patients in the U.S. and patients in Taiwan. **Methods:** Analysis was conducted using data for the period 2010 – 2013 obtained from the U.S. National Cancer Database and Taiwan Cancer Registry. This study include patients newly diagnosed with metastatic (M1) breast, colorectal, lung, and prostate cancers and who died within six months after diagnosis. Logistic regression models were used to compare the odds of receiving palliative care under different health insurance schemes. **Results:** This study included 70,084 U.S. patients (49,374 lung, 13,591 colorectal, 4,837 breast, 2,285 prostate) and 8,882 Taiwanese patients (6,131 lung, 2,188 colorectal, 255 breast, 308 prostate). Among these cases, 18,458 patients in the U.S. (26.3%) and 5,338 patients in Taiwan (60.1%) received palliative care before dying. In the U.S., breast, colorectal, and lung cancer patients covered by private health insurance were more likely to utilize palliative care (17.6% - 31.1%), than were patients covered by public health insurance (16.0% - 28.7%). Multivariate logistic regression analysis revealed that after controlling for demographic factors, disease severity and treatment type, there were no differences in the administration of palliative care among patients covered by private health insurance and those covered by public health insurance. **Conclusions:** This study revealed that there were no differences in the administration of palliative care among patients covered by private health insurance and those covered by public health insurance. Nonetheless, Taiwanese patients were more likely to undergo palliative care than were patients in the U.S. This implies that the lower cost and more comprehensive benefit scheme may improve access to palliative care.

10111 Poster Session (Board #99), Mon, 1:15 PM-4:45 PM

Patient-reported outcomes in light of supportive medications in treatment-naïve lung cancer patients. *First Author: Johnny Hoang, Department of Pharmacy Practice and Translational Research, University of Houston College of Pharmacy, Houston, TX*

Background: Symptom burden of cancer patients is high and can be assessed using patient-reported outcomes (PROs). However, the impact of supportive medications on PROs has not been systematically assessed. We describe the supportive medications used by treatment-naïve lung cancer patients at hospital admission and assess the association between their use and PROs. **Methods:** Patients with a diagnosis of non-small cell or small cell lung cancer who had not received any form of cancer therapy at the initial visit and completed the MD Anderson Symptom Inventory (MDASI) survey within 45 days of diagnosis were included. Baseline patient and tumor characteristics and a complete medication list (categorized based on USP v7.0) were abstracted using the EPIC system. Symptoms were compared using Mann-Whitney U test in patients taking a supportive care medication. **Results:** Lung cancer patients (N = 459) with median age of 66 years (range: 23-90) were included in this study. About half (46%) of patients took any analgesics with 27% of patients taking opioid-containing regimen. One-third (31%) of patients with moderate to severe pain (5 or above on a 0 -10 scale) were not on any analgesics. Compared to patients not taking any analgesics, those on the opioid-containing regimen had significantly worse median pain scores (6 vs. 0), but not those on non-opioid analgesics (1 vs. 0). This was despite higher proportion of patients with moderate to severe pain taking opioid-containing regimen compared to those with mild pain (52% vs. 16%) . Patients on opioid-containing pain regimen also reported worse drowsiness, fatigue, disturbed sleep, shortness of breath, lack of appetite, general activity, mood, work, relations with others, walking, and enjoyment of life. Patients taking antidepressants did not significantly differ in any individual MDASI symptoms associated with depression compared to those not on the therapy. **Conclusions:** Treatment-naïve lung cancer patients presenting at MD Anderson had poorly managed pain and associated functional symptoms and interference. Since patients' functional status may result in suboptimal cancer therapy, our results suggest a need for better pain and symptom management in these patients.

10112 Poster Session (Board #100), Mon, 1:15 PM-4:45 PM

The impact of pain in recurrent ovarian cancer patients: An individual participant data meta-analysis of the North-Eastern German Society of Gynecological Oncology (NOGGO) of 1226 patients. *First Author: Hannah Woopen, Department of Gynecology, European Competence Center for Ovarian Cancer, Charité, University Medicine of Berlin, Campus Virchow Klinikum, Berlin, Germany*

Background: Pain has a major impact on quality of life in ovarian cancer (OC) patients. The influence of pain on survival is unclear in OC. Aim of this study was to analyze the impact of pain on quality of life and survival in recurrent OC patients. **Methods:** Raw data including the QLQ-C30 questionnaire from three phase II/III trials ("Topotecan phase III", "Hector" and "TRIAS") conducted by the North-Eastern German Society of Gynecological Oncology (NOGGO) were synthesized and analyzed using logistic and cox regression analyses. **Results:** Out of 1226 patients there were data on pain available for 952 patients. More than one third of patients (36.6%) experienced moderate to severe pain, defined as pain $\geq$ 50 in the QLQ-C30 symptom scale, which was independent from the administered chemotherapy. 31% were taking non-opioid pain medication and 16% opioids. Median age at randomization was 61 years (range 25-84). Most patients (84.7%) were diagnosed in advanced stages. Pain was independent from age, FIGO stage, grading, amount of recurrences and chemotherapy free interval. ECOG was significantly worse in patients with pain ($p < 0.001$). These patients experienced more frequently fatigue, nausea/vomiting, sleeping disorders, abdominal symptoms such as loss of appetite, diarrhea and constipation (all $p < 0.001$). Quality of life was significantly diminished ($p < 0.001$). Pain was also an independent marker for overall survival (OS). Median OS was 18.2 months in patients with pain compared to 22.0 months in patients without pain ($p = 0.013$, HR 1.25, 95% confidence interval 1.05-1.48). OS was shorter in patients with pain and without pain medication compared to those on sufficient pain medication, whereas OS was mostly decreased in patients having pain despite pain medication (18.5, 19.6 and 15.0 months respectively; $p = 0.026$). There was no difference regarding progression free survival and prior treatment discontinuation. **Conclusions:** Effective pain management is crucial for both quality of life and overall survival in patients with recurrent ovarian cancer. Patients shall therefore receive best supportive care as early as possible.

10113 Poster Session (Board #101), Mon, 1:15 PM-4:45 PM

Prospsective phase II pilot study to evaluate the use of intravenous iron in the treatment of anemia in cancer patients. *First Author: Youjin Kim, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of (South)*

Background: Iron deficiency anemia (IDA) are common complications in cancer patients. Evidence on intravenous (IV) iron for treatment of chemotherapy-induced anemia (CIA) is emerging. Herein, we evaluated the efficacy of IV iron for improvement of anemia in cancer patients. **Methods:** This prospective single arm phase II study aims at evaluation of efficacy of IV iron without additional ESA for correction of CIA. Patients received Ferinject® (ferric carboxymaltose) 1000mg injection on the first day of chemotherapy . Thereafter, hemoglobin (Hb) response defined by increase of Hb $\geq$ 1.0g/dL was assessed at visit 1, visit 2 and visit 3. To identify biochemical parameter predictive for Hb response, TSAT, sTFR, hepcidin, EPO, IL-6, CRP were also assessed at each visit. **Results:** Between Oct 2010 and Jul 2017, a total of 104 patients were enrolled, and 92 patients were available for for injection. Hemoglobin response was observed in 36, 53 and 61 patients at visit 1 (39.1%), visit 2 (57.6%) and visit 3 (66.3%), respectively. When excluding 19 patients (20.6%) with absolute IDA defined by ferritin $<$ 30ng/mL or TSAT $<$ 20%, Hb response rate was 83.5% (61/73). Of 73 patients without absolute IDA, there were i) 56 patients whose serum ferritin were between 30- 500 ng/ml , ii) 6 patients whose serum ferritin were between 500-800 ng/ml and TSAT $<$ 50 % , and iii) 10 patients whose ferritin levels were $>$ 800ng/mL or TSAT $\geq$ 50% . In patients groups of i), ii) and iii), Hb response was observed in 60.7% (34/56), 50% (6/6), and 50%(5/10), respectively. Regarding anemia related biochemical parameters, responders had significantly lower levels of hepcidin (13.5 vs. 35.2 ng/mL, $p = 0.007$), CRP (0.7 vs. 2.5mg/mL, $p = 0.044$) and ferritin (249.2 vs. 575.3 ng/mL, $p = 0.048$). When comparing Hb response by baseline hepcidin level, there were significantly more responders in the low hepcidin (58/61, 95.1%) compared to the high hepcidin group (3/61, 4.9%) at the cut-off value of 34.1 ng/mL ($p = 0.002$). **Conclusions:** IV iron supplementation alone showed promising result in improving anemia in cancer patients. Hepcidin may predict response to IV iron in cancer and chemotherapy induced anemia, and is superior to TSAT or ferritin for this purpose. Clinical trial information: NCT02599012.

10114 Poster Session (Board #102), Mon, 1:15 PM-4:45 PM

Does cytotoxic chemotherapy (CT) have a role in palliative treatment of hepatocellular carcinoma (HCC)? *First Author: Guilherme Nader Marta, Instituto do Câncer do Estado de São Paulo - ICESP, Sao Paulo, Brazil*

Background: Palliative treatment of patients (pts) with HCC after progression to sorafenib represents a clinical challenge due to the usual concomitance with hepatic failure. Although new drugs have recently demonstrated survival benefit in phase III trials after sorafenib therapy, these agents are not widely available and their use is limited by the stringent inclusion criteria of the clinical trials. CT is broadly used as a palliative treatment in this clinical setting, although there is no proof of its efficacy. We analyzed a cohort of HCC pts treated with CT with the aim of evaluating the efficacy and safety of this approach. **Methods:** A cohort of pts with advanced HCC treated with CT after progression to sorafenib was retrospectively evaluated. Survival (PCS) was calculated from the first day of CT to death or last data record. PCS was estimated using Kaplan-Meier and curves were compared by log-rank test. **Results:** We analyzed 240 HCC pts treated with sorafenib from Oct-2007 to Jan-2017. At sorafenib discontinuation, best supportive care was the only treatment for 79.2%, while 18.3% received cytotoxic CT and 2.5% were enrolled in clinical trials. For pts treated with CT, median age 60 years (19-74), 75.6% male, 42.2% had HCV, 71.1% Child-Pugh (CP) A, 95.6% had extrahepatic spread, and 55.6% received doxorubicin-based CT. The median PCS was 8.0 months (3.9-12.1) and 53.3% had progressive disease as best response. Survival benefit from CT could not be predicted by CP A ($p = 0.66$), ECOG PS 0-1 ($p = 0.09$), CT regimens used ($p = 0.97$) or α-fetoprotein ($p = 0.29$). Grade 3 or 4 toxicities occurred in 37.7% of pts and the most common grade 3 or 4 adverse events (AE) were nausea/vomiting (20%), mielotoxicity (18%) and fatigue (11%). CT was most commonly discontinued due to unacceptable AE (44.4%) and disease progression (37.8%). **Conclusions:** Palliative treatment of HCC pts with CT after sorafenib failure is associated with high rates of toxicity and low efficacy. These data suggest that CT seems to have very limited activity in a group of pts with a very poor prognosis without a clear survival benefit and should only be recommended in very selected cases.

10115 Poster Session (Board #103), Mon, 1:15 PM-4:45 PM

Incorporating geriatric patient reported outcomes into novel screening tool of distress and supportive care concerns. *First Author: Christine B. Weldon, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: The Institute of Medicine (IOM) 2013 Report recommends that supportive oncology care start at cancer diagnosis; the Commission on Cancer (CoC) Standard 3.2 requires distress screening and indicated action. The Supportive Oncology Collaborative, collaborative of 100+ clinicians funded by The Coleman Foundation, developed a patient-centric screening tool (CSOC-ST) adapted from ASCO Distress, NCCN Distress Problem List, IOM report and CoC standards, and other validated sub-tools (Weldon, ASCO-Q 2017). The Collaborative then revised the CSOC-ST tool to align with geriatric guidelines. **Methods:** Literature and guidelines review of geriatric screening, added items to CSOC-ST, and piloted at 4 sites. Descriptive statistics and Fisher's exact test used. **Results:** 473 patients screened with added geriatric relevant items to CSOC-ST: self-care concerns (PROMIS Instrumental Support), living alone (ASCO Distress 2014), and memory / cognition (PROMIS item bank). Treatment/care concern items were revised to identify interest in health care power of attorney and advance directives. Geriatric related items endorsed by patients, see Table. PHQ4, Anxiety and Depression, average score 2.4 (mild $>$ 3). Higher scores on the PHQ-4 were significantly associated with each of the following: self-care concerns, memory/cognition concerns and specific treatment/care concerns ($p <$ .0001). **Conclusions:** Pilot results and comparison to geriatric guidelines identified important items to support geriatric patient reported outcomes screening. After pilot, added 3 items for falls/frailty. Eight sites implementing this CSOC-ST.

Screening Item	Frequency n = 473
I want help letting my family, friends and team know my medical wishes if unable to do so myself [health care power of attorney]	38%
I want help discussing, with my family and friends, my treatment options and what is important to me [advance directives]	36%
I have difficulty concentrating, difficulty remembering things, and/or difficulty finding the words I want to say	35%
Are you concerned about having someone available to help: if you cannot get out of bed, you feel sick and cannot do daily chores, and/or you cannot run errands?	31%
I live alone	26%

10116 Poster Session (Board #104), Mon, 1:15 PM-4:45 PM

Barriers to palliative care (PC) utilization in hematopoietic stem cell transplantation (HCT). *First Author: Areej El-Jawahri, Massachusetts General Hospital, Boston, MA*

Background: Despite the benefits of PC for patients undergoing HCT, transplant recipients rarely utilize PC. We assessed transplant physicians' attitudes about PC and perceived barriers to PC utilization. **Methods:** We conducted a cross-sectional survey of transplant physicians recruited from the American Society of Blood and Marrow Transplantation. We examined physicians' attitudes about PC and their perceived barriers to PC utilization. As noted in prior literature, we used a composite score of physicians' attitudes about PC (mean = 16.9, SD = 3.37) and a linear mixed model to explore predictors of attitudes about PC. **Results:** 277/1005 (28%) completed the survey. The majority (76%) stated that they trust PC clinicians to care for their patients, but 40% felt that PC clinicians do not have enough understanding to counsel their HCT patients. Nearly half (46%) perceived the service name 'palliative care' as a barrier for them to refer patients; 51% thought it was synonymous with hospice and end-of-life (EOL) care; and 67% endorsed that it decreased hope in patients and families. Only 8% perceived 'supportive care' as a barrier to refer patients, 7% thought it was synonymous with hospice and EOL care, and 11% endorsed that it decreases hope in patients and families. Physicians endorsed the following barriers to PC utilization 1) patients' and families' discomfort with discussing EOL care issues (80% and 83% respectively); 2) lack of knowledge about PC by transplant physicians (60%); and 3) cultural factors influencing EOL care (84%). Female sex (β = 0.85, P = 0.024), having less than 10 years of clinical practice (β = 1.39, $P < 0.01$), and perceived quality of PC (β = 0.60, $P < 0.001$) were associated with a more positive attitude towards PC. Physicians' perception of unmet PC needs in HCT was not associated with their attitude towards PC. Higher sense of ownership over patients' PC issues (β = -0.36, $P < 0.001$) was associated with a more negative attitude towards PC. **Conclusions:** The majority of transplant physicians trust PC, but have substantial concerns about PC clinicians' knowledge about HCT and patients' perception of the term 'palliative care'. Interventions are needed to promote collaboration and enhance integration of PC in HCT.

10117 Poster Session (Board #105), Mon, 1:15 PM-4:45 PM

Quality of life(QoL) outcomes including neuropathy associated scale (FACT-T) from a phase II, multicenter, randomized trial of eribulin plus gemcitabine(EG) versus paclitaxel plus gemcitabine(PG) as first-line chemotherapy for human epidermal growth factor receptor 2 (HER2)- negative metastatic breast cancer (MBC): Korean Cancer Study Group trial (KCSG BR13-11). *First Author: Ji-Yeon Kim, Samsung Medical Center, Seoul, Republic of Korea*

Background: A phase II, multicenter, randomized clinical trial of EG and PG as first-line chemotherapy for patients with HER2-negative MBC showed that EG was less neurotoxic, but conferred a survival outcome similar to that of PG. In this study, we analyzed FACT-T questionnaires from patients participating in this clinical trial to determine their health-related Quality of life (HR QoL). **Methods:** Patients were randomly assigned to either EG or PG chemotherapy arm in a 1:1 ratio. QoL was assessed using the Korean version of the FACT-T questionnaire. After baseline assessment, HRQoL was assessed every 2 cycles for 12 cycles and every 3 cycles after 13 cycles of chemotherapy. The linear mixed model was used to evaluate the difference in HRQoL between the two treatments. **Results:** Of 118 patients, 117 patients except 1 patient in PG arm responded to the FACT-T questionnaires at baseline. Baseline FACT-T subscale QoL scores and overall QoL scores were not different between the EG and PG arms. During treatment, overall QoL scores and other FACT-T subscale scores did not differ between EG and PG arm. In terms of taxane-associated HRQoL, PG arm much increased taxane subscale scores after 2 cycles of chemotherapy compared to EG arm until the 13^{th} cycle of treatment (all ps < 0.05, except 11^{th} cycle [$p = 0.164$]). Of taxane subscale scores, neuropathy specific subset scores were presented as similar pattern to taxane subscale scores. After 13 cycles of treatment, both groups had similarly intense symptoms. Therefore, although taxane subscale score and neuropathy specific subset score were higher in the PG arm compared to the EG arm, there was no statistical significance ($p = 0.086$ and $p = 0.062$, respectively). **Conclusions:** EG delayed and decreased chemotherapy induced adverse events including neuropathy compared to PG. Therefore, eribulin would be a reasonable substitute for paclitaxel as first line treatment in MBC, especially concerning neurotoxicity. Clinical trial information: NCT02263495.

10118 Poster Session (Board #106), Mon, 1:15 PM-4:45 PM

Efficacy of omega-3 (ω3) supplementation versus omega-6 (ω6) supplementation for reducing pain among breast cancer survivors: A URCC NCORP RCT. *First Author: Luke Joseph Peppone, University of Rochester Medical Center, Rochester, NY*

Background: Pain is a highly prevalent side effect of breast cancer therapy. High pain levels can reduce treatment adherence and increase discontinuation rates for hormonal therapies (HT) while reducing quality of life. We conducted a multi-site, blinded phase II RCT examining the efficacy of ω3 fatty acid (fish oil) supplementation versus ω6 fatty acid (soybean oil) supplementation for improving pain through the URCC NCORP. **Methods:** Breast cancer survivors between 4-36 months post-adjuvant therapy were randomized into 3 arms: 1) High-dose ω3 (ω3; 6 g/day), 2) Low-dose ω3/ω6 (ω3/ω6; ω3: 3 g/day and ω6: 3 g/day) and 3) High-dose ω6 (ω6; 6 g/day) for 6 weeks. Pain was assessed via the Brief Pain Inventory (BPI) at pre- and post-intervention. Serial blood was collected for serum fatty acid and inflammatory biomarker analysis. ANCOVAs, controlling for baseline pain and type of HT (AI, tamoxifen, or none), were used to calculate mean change from baseline to post-intervention for this secondary data analysis. **Results:** 108 female breast cancer survivors were accrued (93% white, mean age = 60). Biochemical blood analyses confirmed high compliance in all arms with minimal contamination. Mean baseline Worst Pain levels did not differ between groups (ω3 = 4.9, ω3/ω6 = 5.6, ω6 = 4.7; p = 0.43). The mean Worst Pain score decreased by 0.8 points for ω3, by 0.8 points for ω3/ω6, and by 1.7 points for ω6 (ω3 vs ω6 p-value = 0.18). The mean change in Current Pain score was more pronounced (Change score: ω6 = −1.8 vs ω3/ω6 = −0.8 vs ω3 = −0.5; ω3 vs ω6 p = 0.05) and indicated a dose-response. Similar changes were found for Average Pain and Least Pain but the differences were not significant. The ω6 group had a significant reduction in the inflammatory biomarker IL-6 compared to the ω3 group (IL-6 change: ω3 = +0.17 vs ω6 = −0.30; $p < 0.01$). **Conclusions:** ω6 supplementation reduced pain levels compared to ω3 supplementation in breast cancer survivors. ω6 also significantly reduced IL-6 levels compared to ω3, indicating a potential mechanism of action. Further research is needed on the effects of ω6 fatty acids in cancer patient. Funding: NCI R03CA175599 & UG1CA189961. Nordic Naturals Inc. supplied all study agents. Clinical trial information: NCT02352779.

10119 Poster Session (Board #107), Mon, 1:15 PM-4:45 PM

Longitudinal patient-reported symptom severity and symptom interference with activity-related and mood-related functioning and survival in patients with advanced cancer on early-phase clinical trials of immunotherapeutic or targeted agents. *First Author: Goldy George, Department of Symptom Research, Department of Investigational Cancer Therapeutics (Phase I Program), The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: We examined longitudinal changes in symptom severity and symptom interference with activity-related (WAW: work, general activity, walking) and mood-related (REM: relations with others, enjoyment of life, mood) functioning and their association with overall survival in patients with advanced cancer in early-phase clinical trials of immunotherapeutic and targeted agents. We also examined effects of therapeutic class. **Methods:** Patients completed the MD Anderson Symptom Inventory (MDASI) at baseline (within 1 day before start of an early-phase clinical trial), and twice-weekly assessments thereafter for 60 days. Linear mixed models and Cox proportional hazards modeling with time-dependent covariates were used. **Results:** 579 MDASI questionnaires were completed by 40 patients (mean age 57y, 50% male) on trials of targeted agents (50%) or immune mono/combination therapy (50%). At least 1 severe symptom ($\geq$7 on 0-10 scale) was reported by 55% of patients and the most frequent severe symptoms were pain (28% of patients), fatigue (25%), disturbed sleep (25%), distress (18%), dry mouth (18%), drowsiness (15%), and lack of appetite (15%). Skin rash ($P < 0.00$) and symptom interference with WAW ($P < 0.001$) and REM ($P = 0.024$) worsened from baseline to Day 60. From baseline to last completed MDASI, worsening by $\geq$2 points (0-10 scale) was seen in 28% of patients for WAW and 15% of patients for REM; improvement by $\geq$ 2 points was seen in 8% of patients for WAW and 5% of patients for REM. Targeted therapy was associated with worse fatigue ($P = 0.039$), drowsiness ($P < 0.001$), disturbed sleep ($P = 0.014$) and lack of appetite ($P < 0.001$); immune therapy was associated with worse REM ($P = 0.042$). Worsening of composite symptoms, WAW, or REM was associated with lower overall survival ($P < 0.001$ for each). **Conclusions:** Symptom burden trajectories varied by class of therapeutic agent. Longitudinal symptomatic assessments during early-phase clinical trials can provide a fuller view of patients' symptomatic experience and facilitate needed supportive care.

10120 Poster Session (Board #108), Mon, 1:15 PM-4:45 PM

Determinants of quality of life and survival in ambulatory oncology patients receiving chemotherapy. *First Author: Derek Gerard Power, Mercy University Hospital, Cork, Ireland*

Background: Identifying prognostic variables that may improve outcome in patients (pts) with cancer is a cornerstone of research. Recently, there has been interest in the prognostic value of nutritional status in pts with cancer. **Methods:** A prospective cohort study of ambulatory adult oncology pts undergoing chemotherapy between 2012-16 was conducted. A survey was devised, incorporating lifestyle, clinical, nutritional, biochemical [CRP, albumin] and quality of life (QoL) data. Nutritional status was evaluated using the cancer cachexia (CC) consensus definition and body composition was assessed using computed tomography. Skeletal muscle index (SMI) and mean muscle attenuation (MA) were obtained. Random forest algorithms were used to identify predictors of QoL and survival. Partial dependence plots were used to assess the direction and association of these predictors with outcome. **Results:** 1015 pts with solid tumors participated, 56% male, median age of 64 years [IQR 55-71]. Colorectal cancer was the most prevalent (27%). The majority (54%) of pts had stage IV disease. Overweight and obesity (BMI > 25 kg/m^2) was highly prevalent (57%), despite high rates of cachexia (42%), sarcopenia (39%) and low MA (45%). Percentage weight loss was the biggest predictor of global QoL. Weight stable pts had the highest global QoL scores after adjustment for other variables. Significant prognostic variables for survival were cancer site and stage, followed by systemic inflammation, anorexia, weight loss and mean MA, collectively considered hallmarks of CC. Highest predicted 1 and 3 year survival rates were observed in pts with a low CRP, high albumin ($>$ 38 g/L), without anorexia, who remained weight stable with a high mean MA ($>$ 36 HU). **Conclusions:** Malnutrition and abnormal body composition features are common in pts receiving chemotherapy but are often masked by adiposity. WL adversely impacts QoL. Nutritional parameters were more reliable prognostic indicators than many clinical variables, such as performance status, age and smoking status. Identifying significant prognostic variables provides conceptual guidance for the development of evidence based prediction models and tools. Further investigation is warranted.

10121 Poster Session (Board #109), Mon, 1:15 PM-4:45 PM

Intensive 4-weeks' mindfulness therapy in the treatment of chronic pain in patients with cancer: Pilot study. *First Author: Anna Kieszkowska-Grudny, Minds of Hope, Warsaw, Poland*

Background: Cancer pain can occur at any stage of disease and occurs on average in 51% of patients (pts) with cancer. Badly managed pain in cancer patients causes suffering and a significant reduction in the quality of life. Chronic pain (ChP) pts expect quick improvement in pain reduction. This pilot study was designed to check whether shortened and modified version of mindfulness training and therapy (MFNT) can help in ChP decrease in cancer patients' group. **Methods:** 83 (63%F) oncological pts with ChP (21-90y,M = 52,4y; SD = 18,7y) took part in this longitudinal study. Patients were invited to 4-weeks MFNT (1session/w), which was 2times shortened than standard Mindfulness Based Stress Reduction Therapy. Each session (90 min) included 30min of psychoeducation and 60min of practice. In addition, pts participated in 4h MFN day (only practice) and practiced MFN 30min every day. Participants based on questionnaires rated the pain intensity 4x (each session), psychological functioning and quality of life (QoL) 2x (before and after 4w). **Results:** There was a significant change in the intensity of pain symptoms recorded in the morning ($F(3, 81) = 7,86; p < 0,001, \eta^2 = 0,23$), evening ($F(3, 81) = 10,72; p < 0,001; \eta 2 = 0,28$)and average during the day ($F(2,82) = 24,02; p < 0,001; \eta 2 = 0,37$). Additionally, pts observed depression ($t(83) = 9,95$; $p < 0,001$)and anxiety ($t(83) = 9,88$; $p < 0,001$) reduction, as well as improvement in QoL ($t(83) = 9,24$; $p < 0,001$). Pts assessed a whole participation in MFNT at 7,9 (scale0-10) and at 9 as a recommendations for other ChP pts. **Conclusions:** Intensive 4w MFNT seems to be an interesting supportive treatment option in ChP reduction, but also an effective alternative for 8w MBSR. It could be a way for better pain management, depression and anxiety symptoms decreasing and QoL increasing among cancer pts. In addition, MFNT meets the needs of patients in terms of length of therapy.

10122 Poster Session (Board #110), Mon, 1:15 PM-4:45 PM

The association of serum ghrelin, GIP, insulin, and leptin levels with sleep quality and cancer-related fatigue in cancer survivors. *First Author: Po-Ju Lin, University of Rochester Medical Center, Rochester, NY*

Background: Sleep disruption leads to metabolic alterations such as increased appetite and reduced insulin sensitivity. Sleep disruption often co-occurs and is likely associated with cancer-related fatigue (CRF) in cancer survivors. Whether metabolic alterations are also associated with CRF is unknown. This preliminary data analysis assessed the association of serum metabolic markers, ghrelin, gastric inhibitory polypeptide (GIP), insulin, and leptin, with sleep quality and CRF in cancer survivors. **Methods:** Serum samples collected from 36 cancer survivors in an ongoing multi-center RCT examining the efficacy of yoga, health education, and cognitive behavioral therapy in reducing insomnia were analyzed at baseline and post 4-week intervention. They were selected based on changes in CRF, evaluated by Multidimensional Fatigue Symptom Inventory (MFSI), with 12 survivors in each of improved, no-change, and worse fatigue groups. Sleep quality was measured by Pittsburgh Sleep Quality Index (PSQI). Serum ghrelin, GIP, insulin, and leptin were assessed by a Luminex Multiplex Immunoassay. Spearman's rank correlation was used to examine the association of metabolic markers with sleep and CRF. **Results:** Changes in PSQI were significantly correlated with changes in MFSI ($r = 0.44$, $p < 0.01$), indicating that higher sleep quality is associated with less CRF. Baseline ($r = 0.35$, $p = 0.04$) and changes in serum ghrelin ($r = -0.32$, $p = 0.06$) were correlated with changes in MFSI, suggesting that increased serum ghrelin level is associated with improvements in CRF. Baseline serum GIP ($r = 0.36$, $p = 0.03$) and leptin ($r = 0.34$, $p = 0.04$) were significantly correlated with MFSI at post-intervention, suggesting that lower baseline serum GIP and leptin levels are associated with improvements in CRF. A trend toward significant correlation was found between baseline serum insulin and changes in MFSI ($r = 0.30$, $p = 0.08$) and between changes in serum leptin and changes in PSQI ($r = -0.30$, $p = 0.08$). **Conclusions:** These exploratory findings suggest potential associations of metabolic markers with CRF in cancer survivors. More studies are needed to further establish the association of energy metabolism and CRF. Clinical trial information: NCT02613364.

10123 Poster Session (Board #111), Mon, 1:15 PM-4:45 PM

Incidence of dermatological toxicities and fatigue in patients with cancer treated with regorafenib: A systematic review and meta- analysis of randomized controlled trials. *First Author: Miguel Quirch, TTUHSC, Lubbock, TX*

Background: Fatigue and skin toxicities notably contributed to the quality of life of cancer patients undergoing chemotherapy. Regorafenib, an oral small molecule multi kinase inhibitor, targets signaling pathways implicated in tumor angiogenesis, oncogenesis and the tumor microenvironment and are utilized in many solid tumors. We performed a systematic review and meta-analysis of randomized controlled trials (RCT) to determine the risk of fatigue and dermatological toxicities among patients with cancer treated with regorafenib. **Methods:** We conducted a comprehensive literature search using MEDLINE, EMBASE databases and meeting abstracts from inception through August 2017. Phase 3 RCTs that mention hand foot syndrome (HFS), rash, fatigue and anorexia as adverse effects were incorporated in the analysis. Mantel-Haenszel method was used to calculate the estimated pooled risk ratio (RR) with 95% confidence interval (CI). Random effects model was applied. **Results:** A total of 1723 patients with hepatocellular, colorectal cancer and gastrointestinal stromal tumors from four phase 3 RCTs were eligible for analysis. Studies compared regorafenib versus placebo. All grade-HFS incidence was 603 (34.9%) in regorafenib arm vs 44 (2.55%) in control arm with a RR of 6.683 (95% CI: 4.392–10.169, $P < 0.0001$). High-grade HFS was reported in 178 (10.33%) in regorafenib group vs 2 (0.12%) in control group with a RR of 29.246 (95% CI: 9.381–91.176, $P < 0.0001$). The relative risks of all-grade rash was 6.435 (95% CI: 3.713–11.154, $P < 0.0001$); high-grade rash: 9.166 (95% CI: 1.753–47.927, $P = 0.009$); all- grade fatigue: 1.624 (95% CI: 1.376–1.917, $P < 0.0001$); high-grade fatigue: 2.209 (95% CI: 1.329 – 3.672, $P = 0.002$); all-grade anorexia: 2.425 (95% CI: 1.678–3.503, $P < 0.0001$); and high-grade anorexia: 1.704 (95% CI: 0.507–5.720, $P = 0.389$). **Conclusions:** Patients on regorafenib experienced a significant increase in all-grades of HFS with a relative risk of 29 for grade 3 and 4 HFS. They also contributed to significant toxicity of all-grade and high-grade rash and fatigue as well as all-grade anorexia.

10124 Poster Session (Board #112), Mon, 1:15 PM-4:45 PM

Opioid use in rural breast cancer patients. *First Author: Emilio Paul Araujo-Mino, Kymera Independent Physicians, Roswell, NM*

Background: The Epidemic opioid overuse spans different communities and cancer patients frequently develop pain from their disease, cancer therapy or sequela for which opioids are commonly used. Breast Cancer is a common malignancy seen across different practices. **Methods:** This is a retrospective study evaluating BC patients Stages I-III from January 2013 until January 2018 in three rural community cancer practices in Southeast New Mexico who had been prescribed opioids during their cancer diagnosis and treatment. Exclusions were development of Stage IV, other concurrent malignancies, remote history of cancer for which use opioid data was missing. Chi-square and logistic regression were performed to identify correlation and predictors of long term opioid use respectively. **Results:** A total of 664 patients were identified; among these 150 (23%) were prescribed an opioid at some point. 54 were excluded according to prespecified criteria. The rate of opioid use was 72% (69/96) at 3 months, 62 % at 6 months (60/96) and 52% (50/96) at 12 months. 72% of user at 3 months (50/69) were also using opioids at 12 months from initial prescription x2 40.8 p=<0.001. Also 83% (50/60) of opioid use at 6 months were opioid user at 12 months x2 62.6 p=<0.001. Patient with smoking history, type of initial opioid (tramadol), opioid prescribed by surgeon, history of mental health and residence in smaller rural communities were more likely to continue using long term opioid, however it was not statistically significant. **Conclusions:** Curable breast cancer patients with increased short-term use of opioids at 3 months are significantly associated with continued long-term use at one year. Several factors in the rural community may need to be further evaluated in larger studies.

TPS10125 Poster Session (Board #113a), Mon, 1:15 PM-4:45 PM

iMETx (Individualized Metabolic Rx): Pilot study of an environmental intervention to increase energy expenditure among breast cancer survivors. *First Author: Tarah Jean Ballinger, Indiana University, Indianapolis, IN*

Background: Physical activity (PA) is associated with improved quality of life and outcomes in breast cancer survivors. However, many are inactive at diagnosis and activity levels worsen following treatment. PA interventions in breast cancer survivors have suffered from low acceptability and sustainability. The motives, capability, and environment affecting each individual vary, and an effective PA intervention will need to account for these differences. Designed to address this need, this study pilots an individualized, dynamic intervention (iMETx) to increase energy expenditure in breast cancer survivors. **Methods:** Patients with history of stage 0-III breast cancer who have completed primary treatment are recruited from Indiana University Simon Cancer Center. Those with comorbidities precluding use of a stationary bicycle are excluded. Energetic capacity (power generation) is assessed at baseline using a stationary bicycle protocol designed to be accurate over a range of physical capabilities and feasible in a clinic setting. Patients wear a GPS/accelerometer activity monitor for 3 weeks to collect baseline energy expenditure. During the subsequent 12 week intervention, patients receive tailored "prescriptions" every 1-3 days from the iMETx web application. Prescriptions are based on individual power ability and environment, and are dynamic, adjusted to achieve pre-determined energy endpoints. Following the intervention, power generation is re-assessed. Patients are monitored for 12 additional weeks to estimate sustainability. Each assessment point also includes DEXA to determine body composition, serum for markers of inflammation and metabolism, and questionnaires assessing quality of life and psychosocial factors. Throughout the study, patients interact with the web application to provide continuous feedback and actively engage in the research process. Feasibility will be assessed by compliance with study procedures, and preliminary effect of the intervention will be determined by changes in energetic capacity, energy expenditure, body composition, and quality of life. Sixteen patients have accrued out of a planned 60. Clinical trial information: NCT03158519.

TPS10126 Poster Session (Board #113b), Mon, 1:15 PM-4:45 PM

Circuit aerobic and resistance exercise to target metabolic dysregulation in breast and prostate cancer survivors: The CARE trial study design. *First Author: Christina Marie Dieli-Conwright, University of Southern California, Los Angeles, CA*

Background: Breast and prostate cancer survivors are at an increased risk of developing comorbidities such as metabolic syndrome (MSY), diabetes, and cardiovascular disease exacerbated by cancer treatments. MSY is a cluster of risk factors including visceral adiposity, insulin resistance, hyperglycemia, hyperinsulinemia, low serum high-density lipoprotein cholesterol, and hypertension. Exercise is an effective strategy to target MSY and therefore, we designed a novel exercise intervention referred to as circuit aerobic and resistance exercise (CARE). Our primary objective is to determine whether a 16-week CARE intervention improves components of MSY among breast and prostate cancer survivors with the primary endpoint of MSY cumulative score. **Methods:** We are currently recruiting sedentary, overweight/obese (BMI > 25 kg/m^2) women and men diagnosed with Stage I-III breast cancer or prostate cancer, respectively, from the USC Norris Comprehensive Cancer Center and Los Angeles County Hospital. Participants are randomized to either the CARE or Attention Control group. The CARE group participates in supervised exercise sessions 3 times per week for 16 weeks. CARE is a systematically progressed program of aerobic and resistance exercise performed in a circuit that begins at a low intensity and gradually increases to high intensity over the duration. The Attention Control group performs a home-based stretching program 3 days per week. At baseline (month 0), post-intervention (month 4), and follow-up (month 8), all participants are tested for MSY components. Statistical analyses for each outcome will involve mixed effects linear regression models. The sample size (25/arm within each cohort) reflects the need to obtain unbiased estimates of differences with reasonable precision. We will recruit an additional 90 patients (at present time n = 10) over the next 3 years. It is expected that this intervention will improve components of MSY in breast and prostate cancer survivors when compared to the Attention Control group, thus defining intervention and biomarker variables for more definitive trials. Clinical trial information: NCT03284346.

TPS10127 Poster Session (Board #114a), Mon, 1:15 PM-4:45 PM

Early nutrition support therapy to improve the nutrition status of head and neck cancer patients accepted concurrent chemoradiotherapy (NSTIP): Interim analysis from a prospective randomized controlled clinical study. *First Author: Peng Zhang, Sichuan Cancer Hospital, Chengdu, Sichuan, China*

Background: We given nutrition support treatment according to the changes by nutrition status in head and neck cancer patients at the process of definitive concurrent chemoradiotherapy(CCRT). Analyze the relationship between nutrition support therapy and CCRT side effects, quality of life score, treatment effect, prognosis and other indicators. **Methods:** 100 patients with head and neck cancer undergoing definitive chemoradiotherapy were enrolled. They were randomly divided into a nutritional intervention group (n= 50) and a conventional diet group (n= 50). The nutritional intervention group treated with prophylactic enteral nutrition powder formula (645.43 kcal/day; 2701.3 kJ/day) feeding before the initiation of CCRT. All patients were subjected to a standardised follow-up programme which included prospective evaluation of psychological status and HRQoL, prior to, during and after CCRT. The psychological status of those two groups were evaluated by Patient Health Questionnaire 9(PHQ-9), Generalised Anxiety Disorder Assessment 7(GAD-7) and Distress Thermometer. The primary endpoint was the nutritional indicators including body weight, white blood cells, lymphocyte, albumin etc. The secondary endpoints were the psychological status.This study is ongoing; data for this interim analysis were collected at December 30, 2017. This trial is registered with www.chictr.org.cn, number. Clinical trial information: ChiCTR-IIR-17011243.

TPS10128 Poster Session (Board #114b), Mon, 1:15 PM-4:45 PM

Pilot and definitive randomised double-blind placebo-controlled trials evaluating an oral cannabinoid-rich THC/CBD cannabis extract for secondary prevention of chemotherapy-induced nausea and vomiting (CINV). *First Author: Antony Mersiades, NHMRC Clinical Trials Centre, The University of Sydney, Sydney, Australia*

Background: Up to half of patients receiving chemotherapy of moderate or high emetic risk experience CINV despite optimal anti-emetic prophylaxis. Limited evidence suggests cannabinoid medicine in the form of tetrahydrocannabinol (THC) may reduce CINV, and addition of cannabidiol (CBD) may improve efficacy and tolerance. The aim of this multi-centre, randomised, placebo-controlled, phase II/III trial is to determine efficacy and cost-effectiveness of the addition of an oral cannabinoid-rich THC/CBD cannabis extract for control of CINV. **Methods:** Target population is adult patients experiencing CINV during moderate and highly emetogenic chemotherapy regimens despite appropriate anti-emetic therapy, who are scheduled to receive at least 2 more consecutive cycles (A, B and, where applicable, C). Treatment consists of oral THC 2.5mg/CBD 2.5mg (Tilray TN-TC11M) capsules or placebo TDS days -1 to 5, in addition to guideline-consistent anti-emetics, including rescue medications. Patients will start with 1 tablet PO TDS and can dose-titrate to a maximum of 4 tables PO TDS based on nausea control and side-effects. In the pilot trial (N = 80), subjects are randomised for cycle A, cross-over for cycle B, and nominate preferred treatment for cycle C (if applicable). The planned definitive trial (N = 250) will randomise subjects to investigational product or placebo for cycles A, B and C in a parallel design. The primary end-point is the proportion of patients gaining a complete response (no emesis and no use of rescue medications) (0 – 120h), with additional end-points of (i) complete response, (ii) no emesis, (iii) no significant nausea and (iv) no use of rescue medication during the a) acute, b) delayed, and c) overall phases of cycle A, B and C, (iv) adverse events, (v) quality of life, and (vi) cost-effectiveness. As of 12/02/2018, 41 of 80 patients have been recruited to the pilot study, with expected recruitment completion in 2nd quarter 2018. Funding: NSW Department of Health. Acknowledgements: Trial participants, investigators and research staff. Drug supply by Tilray. ACTRN: 12616001036404 Clinical trial information: 12616001036404.

TPS10129 Poster Session (Board #115a), Mon, 1:15 PM-4:45 PM

Effect of nutritional support with highly purified, whey proteins for malnutrition and sarcopenia in patients affected with stage II-III colorectal or breast cancer: A blind, placebo controlled, randomized clinical trial. *First Author: Federica Mazzuca, S. Andrea Hospital, Sapienza University of Rome, Rome, Italy*

Background: Malnutrition and sarcopenia may arise in both colorectal and breast cancer since the first visit. Previous studies demonstrate that malnourished cancer patients have a decreased quality of life and experience more chemotherapy-toxicity. Protein supplementations could prevent loss of lean body mass that goes along with malnutrition and sarcopenia. Therefore, the role of whey proteins takes a great deal of interest. We propose a randomized study, placebo-controlled, aimed at evaluating the activity and safe of a highly purified, whey protein nutritional support (PROLYOTIN) in cancer patients undergoing adjuvant chemotherapy (EudraCT n. 2018-000122-64). **Methods:** Patients with histological diagnosis of stage II/III according to AJCC system, breast or colorectal cancer, referred for adjuvant chemotherapy, with no metabolic disease, will be eligible. Obtained written informed consent, all patients will be blind-randomized with 1:1 ratio in two arms: A (PROLYOTIN) vs. B (placebo). Patients will be assessed before starting chemotherapy (T0), after 3 (T1) and 6 months (T2), with respect to a physico-nutritional examination, skeletal muscle mass calculation by CT scan and Body Impedance Assessment. Mini Nutritional Assessment, Malnutrition Universal Screening Tools and Quality of life by EORTC QLQ C-30 will be also done. At the same time frames (T0, T1, T2) detailed medical records, tumor characteristics, dietary practices and laboratory values (blood count, serum proteins, cholesterol, triglycerides, amylases, lipases, ESR, CRP, glucose, tumor markers, cortisol, insulin, vitamin D, LDH and CK) will be collected by a specialist team of medical oncologists and dieticians. The patient-adherence to protocol will be also monthly evaluated. Primary objective is to evaluate the nutritional status at baseline, T1 and T2 and the difference between the PROLYOTIN and placebo arms. Secondary, correlations between nutrtional status and clinicopathological parameters, and the quality of life will be analyzed. A total of 220 patients will be enrolled (95% CI, β 10%). Clinical trial information: 2018-000122-64.

TPS10131 Poster Session (Board #116a), Mon, 1:15 PM-4:45 PM

A randomized phase II study of the nutritional and exercise treatment for the elderly patients with advanced non-small cell lung or pancreatic cancer: The NEXTAC-TWO study. *First Author: Satoru Miura, Niigata Cancer Center Hospital, Niigata, Japan*

Background: Most advanced cancer patients experience fatigue, anorexia, and declining physical function due to cancer cachexia and /or aging, for which effective treatment has not been established. We performed a phase I study, called NEXTAC-ONE, and demonstrated the feasibility of multi-modal interventions, namely, nutritional support and physical exercise in elderly cancer patients. We conducted the next-step multi-center, randomized phase II study to evaluate the efficacy of previously investigated multi-modal interventions in elderly cancer patients. **Methods:** Patients with chemonaïve advanced non-small cell lung cancer or pancreatic cancer, age $>=$ 70 years, PS $<=$ 2, with adequate organ function and without disability by the modified Katz index, will be eligible. Totally, 130 participants will be recruited from 15 Japanese institutions and will be randomized into either the intervention group or a control group. Interventions and assessment will be performed 4 times every 4$\pm$2 weeks from the date of randomization. Interventions will consist of nutritional counseling, nutritional supplements (rich in branched-chain amino acids), and a home-based exercise program. The exercise program will include low-intensity daily muscle training and life-style education to promote physical activity. The primary endpoint is disability-free survival. It is defined as the period from the date of randomization to the date of developing disability or death due to any cause. This trial also plans to evaluate improvement in nutritional status, physical condition, quality of life, activities of daily living, overall survival, and safety as secondary endpoints. Enrollment began in August 2017. Eighteen of the planned 130 participants have been enrolled at the time of this submission. Study results will demonstrate efficacy of multi-modal interventions for elderly cancer patients and application for maintenance of physical and nutritional condition of patients with cancer cachexia. This work is supported by a grant-in-aid from the Japan Agency for Medical Research and Development. Clinical trial information: UMIN000028801.

TPS10132 Poster Session (Board #116b), Mon, 1:15 PM-4:45 PM

A randomized phase II clinical trial of a fasting-mimic diet prior to chemotherapy to evaluate the impact on toxicity and efficacy. *First Author: Tanya B. Dorff, City of Hope, Duarte, CA*

Background: Chemotherapy toxicity impacts dose intensity as well as temporarily deteriorating quality of life; some toxicity can be permanent, such as neuropathy. We previously demonstrated that fasting induces Differential Stress Resistance and hypothesized that fasting may protect normal host cells from chemotherapy toxicity, while potentially sensitizing cancer cells to chemotherapy. A low calorie, low protein fasting-mimicking diet (FMD) may be more acceptable than pure fasting. We are studying whether FMD will reduce chemotherapy toxicity and/or enhance efficacy. Changes in glucose and insulin-like growth factor 1 (IGF1) may mediate or be biomarkers for the protective effects of fasting and will be studied in the trial population. **Methods:** Randomized phase II in 2 parallel cohorts (Prostate, n = 60, Breast n = 60). Treatment: Arm A = restricted diet consumed 3 days prior to and 24 hours after chemotherapy for 4 cycles. Arm B = regular diet. Eligibility: breast cancer with AC or TC in neoadjuvant setting, prostate cancer treated with Docetaxel, up-front or for mCRPC. BMI > 18.5. Exclusion: Diabetes Mellitus. Endpoints: Primary: Grade 2+ non-hematologic symptomatic toxicities experienced during 4 courses; additionally, radiographic (RECIST) response and PSA changes. Secondary: toxicity (all grade 2-4 events, dose reductions/delays) and efficacy (pathologic response for breast cancer, PSA/RECIST response for prostate cancer). Biomarker: plasma insulin, glucose, IGF1 and IGF binding protein (IGFBP) at baseline, and each cycle. Statistics: Proportion of patients with grade 2-4 symptomatic toxicities will be compared between treatment arms using stratified Mantel-Haenszel test; p-value ≤ 0.20 indicates the diet intervention is promising. With 60 patients in each cohort there is 88% power; initial analyses will evaluate breast/prostate cancer separately, yielding standard error no more than +/- 0.18 for estimates of the difference in the proportions of patients who experience a specific toxicity (or the composite). Quality of life will be assessed with SWOG questionnaire on day 1 of each chemotherapy cycle. Progress: 70 of 120 planned subjects have been accrued. Clinical trial information: NCT01802346.

10500 Oral Abstract Session, Sat, 3:00 PM-6:00 PM

COG AALL0434: A randomized trial testing nelarabine in newly diagnosed t-cell malignancy. *First Author: Kimberly P. Dunsmore, Carilion Children's, Roanoke, VA*

Background: Nelarabine (Nel) is a T-cell specific agent, FDA approved for patients who have failed at least two chemotherapy regimens. COG AALL0434 evaluated its safety and efficacy when incorporated into COG augmented BFM (ABFM) chemotherapy in newly diagnosed T-ALL and T-LL patients. **Methods:** AALL0434 enrolled 1,895 patients (2007-2014) and included a 2 x 2 pseudo-factorial randomization using the ABFM regimen. Patients were randomized to receive escalating dose methotrexate without leucovorin rescue + pegaspargase (CMTX) or High Dose MTX (HDMTX) + leucovorin rescue. Intermediate and high-risk patients with T-ALL and T-LL were randomized to receive or not receive six 5-day courses of (Nel) 650 mg/m^2/day. The intermediate and high risk T-ALL patients received prophylactic (1200 cGy) or therapeutic (1800 cGy for CNS3) cranial irradiation. T-ALL patients with induction failure were non-randomly assigned to HDMTX+Nel. **Results:** For all randomized T-ALL patients, the 4-year disease-free survival (DFS) and overall survival (OS) rates were 84.3 +/- 1.1% and 90.2 +/- 0.9%. The 4-year DFS rate for T-ALL patients randomized to Nel (N = 323) vs no Nel (N = 336) was 88.9 +/- 2.2% vs 83.3 +/- 2.5%, (p = 0.0332). Among T-ALL patients randomized to CMTX the 4-year DFS for Nel (N = 147) vs no Nel (N = 151) was 92.2 +/- 2.8% vs 89.8 +/- 3.0%, p = 0.3825. For those randomized to HDMTX, 4-year DFS was 86.2 +/- 3.2% with Nel (N = 176) vs 78.0 +/- 3.7% without Nel (N = 185), p = 0.024. Differences between DFS in a 4-arm comparison were highly significant (P = 0.002), with no significant interactions between MTX and nelarabine randomizations (p = 0.41). T-ALL induction failure patients (N = 43) assigned to HDMTX/Nel had a 4-year DFS of 54.8 +/- 8.9%. Nelarabine did not show an advantage for high risk T-LL patients, with 4-year DFS 85.0 +/- 5.6% vs 89.0 +/- 4.7% for Nel (N = 60) vs no Nel (N = 58), p = 0.2788. Overall toxicity and neurotoxicity were acceptable and not significantly different between all four arms. **Conclusions:** COG AALL0434 is the largest trial ever conducted for newly diagnosed T-ALL and T-LL, and showed outstanding overall outcomes. Nelarabine improves DFS for children and young adults with T-ALL and should become a new standard of care for this population. Clinical trial information: NCT00408005.

10501 Oral Abstract Session, Sat, 3:00 PM-6:00 PM

Effect of dexrazoxane on left ventricular function and treatment outcomes in patients with acute myeloid leukemia: A Children's Oncology Group report. *First Author: Kelly D. Getz, The Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Overall survival (OS) for pediatric acute myeloid leukemia (AML) has improved to > 65% due in part to the use of anthracycline (ATC)-containing chemotherapy regimens. ATC is also associated with increased cardiotoxicity risk. Cardioprotective agents such as dexrazoxane (DEX) may reduce cardiac injury during treatment. While data on the benefit of DEX are promising, studies in pediatric AML patients are limited. Given the very high ATC exposure in pediatric AML therapy, evaluating the utility of DEX in this population is critical. **Methods:** On Children's Oncology Group trial AAML1031, DEX was administered at the discretion of treating physicians. DEX exposure was documented at each treatment course, and ejection fraction (EF) and shortening fraction (SF) values were recorded after each course and in follow up. Absolute change in EF from baseline (ΔEF) was computed for each course. Early LVSD was defined as any EF < 50% or SF < 24% from the start of frontline therapy through the follow-up at one-year off-protocol. ΔEF at each course, occurrence of LVSD, and 3-year OS and disease free survival (DFS) were compared for DEX exposed and unexposed. **Results:** 1014 patients were included; 96 were DEX-exposed at each ATC course received and 918 were never exposed. Distributions of sex, age, race, initial white blood cell count, risk group, and treatment arm were similar for DEX exposed and unexposed. DEX exposed patients had smaller declines in EF than unexposed patients across courses (range of course-specific median ΔEF: 0 to -4.0 versus 0 to -6.4; all $p < 0.05$) and an overall lower risk for early LVSD (6.3% vs 19.2%, RR = 0.33, 95% CI: 0.15-0.72, p = 0.005). The effect of DEX on LVSD risk was particularly pronounced for female patients (RR = 0.16, 95% CI 0.05 – 0.65). DEX exposed patients had non-significantly higher 3-year OS (71.9% vs 63.0%, p = 0.093) and EFS (54.4% vs 44.2%, p = 0.070) compared to those unexposed. **Conclusions:** DEX is associated with smaller reductions in EF throughout pediatric AML therapy and a lower risk for early LVSD. Small numbers may have limited our ability to detect differences in OS and EFS. Longer follow-up is required to elucidate the sustained benefit of DEX.

10502 Oral Abstract Session, Sat, 3:00 PM-6:00 PM

Improved survival among children and adolescent and young adults with acute lymphoblastic leukemia (ALL) treated at specialized cancer centers in California. *First Author: Elysia Marie Alvarez, University of California, Davis School of Medicine, Sacramento, CA*

Background: We previously demonstrated that adolescent and young adult (AYA) patients who received induction treatment at specialized cancer centers (SCC; versus community hospitals) had lower early mortality within 60 days of diagnosis. However, the effect of location of treatment on long term survival has not yet been evaluated at the population-level. **Methods:** Using the California Cancer Registry linked to a statewide hospitalization database, we identified children (0-18 years) and AYAs (19-39 years) with first primary ALL who received inpatient treatment, 1991-2014 (n = 7,724). Patients were classified as receiving all or part/none of their treatment at a SCC (Children's Oncology Group or National Cancer Institute-designated cancer center) within 3 years of diagnosis. Propensity scores were created for treatment at an SCC in each age-group. Inverse probability of treatment-weighted, multivariable Cox regression models estimated the magnitude of associations between location of treatment, sociodemographic and clinical factors with leukemia-specific survival. Results are presented as hazard ratios (HRs) and 95% confidence intervals (CI). **Results:** Overall, 21.3% of children and 42.6% of AYAs died over the study period (median follow-up time: 11.6 years). Seventy-eight percent (n = 4511) of children and 19% of AYAs (n = 356) received all their treatment at SCCs. In multivariable models, receiving all treatment at a SCC (vs part/no care) was associated with better leukemia-specific survival (HR 0.86, CI 0.75-0.99) in children and AYAs (HR 0.83, CI 0.72-0.97). In both age groups, worse survival was associated with older age, Hispanic and African American race/ethnicity (vs non-Hispanic white), public insurance (vs private) and comorbidities. **Conclusions:** Our results demonstrate that treatment at a SCC through end of therapy is associated with better leukemia-specific survival in children and AYAs. In contrast to AYAs, the majority of children receive care at a SCC, but both age groups benefit from care at a SCC. This highlights the need for these patients to be referred to and treated at SCCs.

10503 Oral Abstract Session, Sat, 3:00 PM-6:00 PM

SPRINT: Phase II study of the MEK 1/2 inhibitor selumetinib (AZD6244, ARRY-142886) in children with neurofibromatosis type 1 (NF1) and inoperable plexiform neurofibromas (PN). *First Author: Andrea M. Gross, National Institutes of Health, Bethesda, MD*

Background: PN in NF1 can cause substantial morbidity, and there are no approved medical therapies. In a phase I trial of selumetinib, 17/24 (71%) patients (pts) had a partial response (PR)(Dombi, et al. *N Engl J Med 2016*; 375:2550-2560). This open-label phase II study (NCT01362803) determines the PR rate of PN treated with selumetinib and changes in PN related morbidities. **Methods:** Patients 2-18 years old with NF1, inoperable PN and ≥ 1 PN related morbidity received selumetinib at the recommended phase II dose (25 mg/m^2 PO BID) with continuous dosing (1 cycle = 28 days). Response was evaluated with volumetric MRI analysis (PR = target PN volume decrease ≥20%) and PN related morbidities (pain, disfigurement, functional morbidities) assessed with standardized evaluations after every 4 cycles. **Results:** Fifty children (30 male, median age 10.2 years, range 3.5, 17.4) enrolled. Disfigurement (n=44), motor dysfunction (n=33) and pain (n=28) were the most frequent PN related morbidities. As of November 5, 2017: median cycle number 19.5 (range 0, 29) with 38 pts remaining on treatment; median change in PN volume from baseline -27.7% (range -50.6%, 2.2%); best response PR (36 pts, 72%), stable disease (12 pts, 24%); 2 subjects (4%) had no re-staging. Of the 36 total PR, 32 were confirmed on ≥ two consecutive restaging scans and 22 continue to have a PR ≥ 1 year after it was first achieved. Between baseline and end of year 1 evaluations, parent and child-reported pain intensity and pain interference scores significantly improved ($p < 0.01$), as did strength (0-5 scale) and range of motion (degrees) of affected muscle groups/joints ($p < 0.01$). The most frequent toxicities were nausea/vomiting, diarrhea, asymptomatic creatine kinase increase, acneiform rash and paronychia. Selumetinib dose was reduced in 12 pts, of which 5 were removed from treatment. **Conclusions:** The response rate from this study (72%) confirms our previously observed response rate (71%). Most responses were sustained ≥6 months. Improvements in PN related pain and motor impairment demonstrate that selumetinib can provide clinical benefit. Data validation and further analyses are ongoing. Clinical trial information: NCT01362803.

10504 Oral Abstract Session, Sat, 3:00 PM-6:00 PM

Trametinib in pediatric patients with neurofibromatosis type 1 (NF-1)–associated plexiform neurofibroma: A phase I/IIa study. *First Author: Geoffrey Brian McCowage, The Children's Hospital at Westmead, Westmead, Australia*

Background: NF-1 loss-of-function alterations are associated with development of plexiform neurofibromas (PNs). NF-1–associated PNs can arise early in life in different locations, with variable and significant morbidity. Many patients (pts) progress following surgery, and currently there are no approved systemic therapies. The MEK inhibitor trametinib is being evaluated in pediatric pts across a spectrum of tumor types in a dose-escalation cohort of a phase I/IIa study (NCT02124772) to determine a recommended dose; disease-expansion cohorts include pts with NF-1 PN. Here we present an interim analysis of safety and clinical benefit of trametinib in pediatric pts with NF-1–associated PN. **Methods:** Pts aged 1 mo to < 18 y with medically significant, unresectable NF-1–associated PN were treated with trametinib 0.025 to 0.040 mg/kg/d. The primary objective was safety, and secondary objectives included tumor response assessed by independent review (IR) using published MRI volumetric criteria. **Results:** Twenty-six pts received trametinib (0.025 mg/kg/d, n = 21; 0.032 mg/kg/d, n = 1; 0.040 mg/kg/d, n = 4). Presented here are results from the disease-expansion cohort (n = 10). Median duration of exposure was 408 d (range, 360-429 d), and 8 pts (80%) had treatment ongoing at the data cutoff (September 2017). Median age was 5.5 y (range, 1-16 y), and prior therapies included surgery (n = 5), biologics (n = 1), and targeted therapy (n = 1). Treatment-related AEs (TRAEs) were reported in 9 of 10 pts (90%), and 1 pt discontinued due to a TRAE. The most frequent TRAEs were paronychia (50%) and rash (40%). No deaths occurred on treatment. Analysis of the full NF-1 PN cohort (n = 26) is ongoing; across this cohort, 12 of 26 pts (46%) had a PR (≥ 20% volume reduction) by IR, and 10 of the 12 responses (83%) were ongoing. **Conclusions:** Trametinib demonstrated a manageable safety profile in pediatric pts with NF-1–associated PN. Using volumetric criteria for response determination, the objective responses observed with trametinib support continued investigation in this pt population. Clinical trial information: NCT02124772.

10505 Oral Abstract Session, Sat, 3:00 PM-6:00 PM

Dabrafenib in pediatric patients with *BRAF* V600–positive high-grade glioma (HGG). *First Author: Darren R Hargrave, Great Ormond Street Hospital for Children, London, United Kingdom*

Background: The *BRAF* V600 mutation constitutively activates the MAPK/ERK pathway and is an oncogenic driver in many tumor types, including pediatric brain cancers. There are limited effective therapies for patients (pts) with HGG, ≈ 5% of whom have *BRAF* V600 alterations. The kinase inhibitor dabrafenib (which targets *BRAF* V600) demonstrated tolerability in pediatric pts across tumor types in a dose-escalation (ESC) cohort of a phase I/IIa study (Kieran et al, ASCO 2015; NCT01677741). Here we report preliminary analyses in this study of safety and clinical benefit with dabrafenib in pts with HGG across the ESC and disease-expansion (EXP) cohorts. **Methods:** Pts aged 1 to < 18 y with *BRAF* V600–positive HGG who had refractory or progressive disease after receiving ≥ 1 standard therapy were treated with dabrafenib (2 equal daily doses) either in the ESC cohort or with the recommended dose of 5.25 mg/kg/d (pts < 12 y) or 4.5 mg/kg/d (pts ≥ 12 y) in the EXP cohort. Measurable disease was not required. Primary objectives were safety and tolerability, and secondary objectives included tumor response and pharmacokinetics. Tumor response was reported by independent review (IR) and investigator assessment (INV) using RANO criteria. Exploratory analyses included independent histopathological review and tumor biology analysis (eg, mutation, methylation status). **Results:** Pts (n = 31) were treated with dabrafenib across the ESC (n = 8) and EXP (n = 23) cohorts. Median age was 14 y (range, 3 - < 18 y). Across both cohorts (n = 31), the most frequent AEs (any causality) were fatigue (48%), vomiting (42%), and headache (39%). Grade 3/4 AEs occurred in 12/31 pts (39%). No on-treatment deaths occurred. Median duration of exposure was 22 wk (range, 4-225 wk), and 10/31 pts (32%) had treatment ongoing. ORR by IR was 45% (14/31, with 3 CRs), and ORR by INV was 32% (10/31, with 4 CRs). By IR, median duration of response was 7.7 mo (95% CI, 3.0 mo-not estimable) and 13/19 pts with measurable lesions (68%) achieved a maximum tumor reduction of ≥ 50%. Tumor mutational and methylation analyses are ongoing. **Conclusions:** Dabrafenib was well tolerated in pediatric pts with *BRAF* V600–positive HGG, and a number of durable objective responses demonstrate the potential for clinical benefit. Clinical trial information: NCT01677741.

10506 Oral Abstract Session, Sat, 3:00 PM-6:00 PM

Efficacy and safety results from a phase I/IIa study of dabrafenib in pediatric patients with *BRAF* V600–mutant relapsed refractory low-grade glioma. *First Author: Mark W. Kieran, Harvard Medical School, Boston Children's Hospital, Dana-Farber Cancer Institute, Boston, MA*

Background: The primary treatment for many pediatric patients (pts) with low-grade glioma (LGG) remains surgical resection with curative intent. However, pts whose tumors cannot be completely resected or recur may require additional treatment, eg, radiotherapy or chemotherapy. Pediatric pts with *BRAF* V600–mutant LGG may benefit from treatment with the BRAF inhibitor dabrafenib. We report 2-y follow-up data from a 2-part phase I/IIa study investigating dabrafenib in pediatric *BRAF* V600–mutant LGG (NCT01677741). **Methods:** Part 1 determined the recommended phase 2 dose (RP2D); the Part 2 disease expansion evaluated efficacy and safety of dabrafenib in 4 pediatric tumor–specific cohorts, including LGG. Efficacy for LGG was determined by investigator and independent (IND) review per Response Assessment in Neuro-Oncology [RANO] criteria. Adverse events (AEs) were assessed per NCI-CTCAE version 4.0 criteria. **Results:** Thirty-two pediatric pts with relapsed, refractory, or progressive *BRAF* V600–mutant LGG were enrolled (Dec 2013 to Jul 2015). Fifteen pts were treated in Part 1 (n = 7 at RP2D) and 17 in Part 2. RP2D is 4.5 mg/kg/d for pts ≥ 12 y of age and 5.25 mg/kg/d for pts < 12 y of age, each divided into 2 equal doses per day. Common histologies included pilocytic astrocytoma (n = 13; 41%), ganglioglioma (n = 7; 22%), and pleomorphic xanthoastrocytoma (n = 3; 9%). At interim analysis (Sep 2017), median duration of exposure was 25 mo (range, 0.1-42.6 mo), with 15 ongoing. Most frequent reason for discontinuation was elective, following ≥ 1 yr of treatment. Across all dose levels, the confirmed overall response rate (ORR, complete response [CR] + partial response [PR]) per IND review was 44% (95% CI, 26.4%-62.3%), including 1 CR and 13 PR. Eleven pts had stable disease, and 2 had progressive disease as best response. Median PFS by IND review was 35 mo (95% CI, 12.9 mo-NE). Common AEs of all grades, regardless of causality, included pyrexia (72%), vomiting (53%), and headache (47%). **Conclusions:** Dabrafenib demonstrated clinical activity with tolerability in pediatric pts with relapsed, refractory, or progressive *BRAF* V600E mutation–positive LGG and supports its further clinical evaluation. Clinical trial information: NCT01677741.

10507 Oral Abstract Session, Sat, 3:00 PM-6:00 PM

The randomised induction for high-risk neuroblastoma comparing COJEC and N5-MSKCC regimens: Early results from the HR-NBL1.5/SIOPEN trial. *First Author: Alberto Garaventa, Istituto Giannina Gaslini, Genova, Italy*

Background: From 2013-2017 the HRNBL1.5/SIOPEN trial tested the hypothesis that the N5-MSKCC induction regimen *(Kushner, JCO 2004)* increases metastatic complete response (mCR) or event-free survival (EFS) compared to Rapid COJEC *(Ladenstein, JCO 2010).* **Methods:** Eligible patients had stage 4 or 4s with MYCN amplification (MNA) aged < 21 years, or without MNA aged 12-18 months with segmental chromosome alterations, and > 18 months with any genomic profile. Patients were stratified for national groups and metastatic sites. Further treatments included addition of 2 TVD *(Amoroso, Cancer Res Treat 2018)* if < mCR, primary tumour resection, BuMel megatherapy, primary site irradiation, ch14.18/CHO antibody ± IL2 plus 13-cis-RA. Primary endpoints were to increase mCR rate to 45% with N5 MSKC (33% for Rapid COJEC) and by 12.5% the 2-year EFS to 52.5%. **Results:** 630 patients were randomised (313 for Rapid COJEC, 317 for N5). 56% were female. 99% had stage 4. Median age: 3.2 years (0.2-20.4) with 16 infants and 56 aged 12-18 mos. Median follow-up: 1.7 years. No primary endpoint differences were observed: 2-year EFS was 53% ±4 for Rapid COJEC *vs* 51%±4 for N5-MSKCC. mCR rate after induction was 33% for Rapid COJEC *vs* 37% for N5-MSKCC. No difference was detected also in secondary endpoints: overall survival was 72%±3 for Rapid COJEC *vs* 69%±3 for N5-MSKCC. 2-year relapse-unrelated mortality was 8%±2 with Rapid COJEC *vs* 6%±2 with N5-MSKCC. Cumulative incidence of relapse/progression was 39%±3 for Rapid COJEC *vs* 43%±4 for N5-MSKCC. A comparison of CTC Grade 3-4 toxicities showed significant differences favouring Rapid COJEC over N5-MSKCC: non-haematological 47% *vs* 68% (*P*= .000), compromise of general conditions 12% *vs* 19% *(P*= .055); neutropenia 94% *vs* 98% (*P*= .020); low platelet count 91% *vs* 96% (*P*= .031); infections 24% *vs* 35% (*P*= .005); stomatitis 3% *vs* 26% (*P*= .000); nausea/vomiting 7% *vs* 16% (*P*= .001); diarrhoea 3% vs 7% (*P*= .033); hypertension 10% vs 6% (*P*= .050); central neurotoxicity 0% *vs* 1% (*P*= .049). **Conclusions:** As Rapid COJEC was less toxic and no differences in primary and secondary outcomes were observed it was maintained as standard induction for future SIOPEN studies. Clinical trial information: NCT01704716.

10508 Oral Abstract Session, Sat, 3:00 PM-6:00 PM

Phase II trial of irinotecan/temozolomide/dinutuximab/granulocyte macrophage colony stimulating factor (I/T/DIN/GMCSF) in children with relapsed/refractory neuroblastoma (NBL): A report from the Children's Oncology Group (COG). *First Author: Rajen Mody, University of Michigan, Ann Arbor, MI*

Background: COG ANBL1221 was a randomized Phase II selection design trial for patients (pts) with relapsed/refractory NBL. Randomization was stopped early when I/T/DIN/GMCSF was shown be the optimal combination for further study. In the small cohort assigned to I/T/DIN/GMCSF, the objective response rate was 53%. An expanded cohort was evaluated to more accurately assess response rate and better define the toxicity profile of this combination. **Methods:** Pts were eligible at first relapse/progression or first designation of refractory disease. Cycles were administered every 21 days. Objective responses were confirmed centrally. Toxicities were graded according to CTCAE v4.0. **Results:** 53 eligible pts were assigned to I/T/DIN/GMCSF; 17 during the randomized portion, 36 during study expansion. Median age was 5.1 years (range 1.3-15.9), 39 pts (74%) had measurable disease. Fourteen (26%) had *MYCN* amplified tumors, 20 (38%) had previously undergone high-dose chemotherapy with stem cell rescue, and 14 (26%) had received prior anti-GD2 antibody. 22 (42%) had relapsed disease and 31 (58%) had refractory/progressive disease (PD). Subjects received 378 total cycles (median 6). Of 53 pts assigned to I/T/DIN/GMCSF, 21 experienced objective responses [40%; 95% CI (26, 53)]; 10 PR, 11 CR. Seven had PD, 23 had stable disease. Two did not receive protocol therapy and did not undergo disease evaluations, but were included in the intention-to-treat analysis. Among responders, 4 (19%) had *MYCN* amplified tumors and 9 (43%) had previously received an anti-GD2 antibody. Of the 51 evaluable for toxicity, 13 (25%) had Grade 3 pain, 8 (16%) had Grade 3 diarrhea, and 4 (8%) had Grade 3 vomiting. Neutropenia (^{3}Grade 3) was observed in 14 (27%), Grade 3 thrombocytopenia in 5 (10%), and Grade 3 fever/infection in 11 (22%). **Conclusions:** I/T/DIN/GM-CSF showed significant anti-tumor activity in pts with relapsed/refractory NBL. This combination was well-tolerated in a cohort of $>$ 50 pts. Studies of biomarkers that may identify pts most likely to respond to this chemo-immunotherapeutic regimen are in progress. Clinical trial information: NCT01767194.

10509 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Subsequent malignant neoplasms (SMNs) among non-irradiated survivors of childhood cancer treated with chemotherapy in the Childhood Cancer Survivor Study. *First Author: Lucie Marie Turcotte, University of Minnesota, Minneapolis, MN*

Background: In recent treatment eras radiotherapy (RT) use decreased while chemotherapy (CT) increased. RT is an established risk factor for SMNs. Limited data exist on how CT increases risk for SMNs $>$ 5 years after childhood cancer. **Methods:** SMNs were evaluated in 5-year survivors diagnosed $<$ 21 years of age between 1970-99, treated with CT and not RT (N = 7447, 138,008 person-years follow-up). 30-year cumulative incidence and 95% confidence intervals (CI) and standardized incidence ratios (SIRs) for SMNs were estimated. SIRs were estimated for chemotherapy exposures [alkylator: 0, 1-3999, 4000-7999, $\geq$8000 mg/m^2; platinum: 0, 1-400, 401-750, $>$ 750 mg/m^2; anthracycline: 0, 1-100, 101-300, $>$ 300 mg/m^2; epipodophyllotoxin: 0, 1-1000, 1001-4000, $>$ 4000 mg/m2]. **Results:** There were 154 SMNs among 139 survivors. Cumulative incidence for SMNs at 30 years was 4.5% (95% CI 3.4-5.6) and risk for SMN was 3-fold greater than the general population. Survivors of leukemia, lymphoma, and sarcomas had increased risk for SMNs (Table), whereas, survivors of Wilms tumor, neuroblastoma and CNS cancer did not. Exposure to moderate- to high-dose alkylator ($\geq$4000 mg/m^2) or platinum ($>$ 400 mg/m^2) or high-dose anthracycline ($>$ 300 mg/m^2) or epiodophyllotoxin ($>$ 4000 mg/m^2) therapy had SIRs of $\geq$4.0. A combination of alkylators and platinum, one of the two being high-dose and the other being moderate or high-dose, had a SIR of 13.0 (95% CI 6.5-23.2). **Conclusions:** Non-RT exposed survivors are at increased risk for SMN and should be counseled regarding the potential for genetic predisposition and the need for increased surveillance for early detection of subsequent cancers.

SIRs (95% CI) for SMNs by childhood cancer diagnosis.

		SMN				
Primary Cancer	All SMNs (n = 154)	Leukemia/ Lymphoma (n = 21)	Breast (n = 34)	Soft tissue sarcoma (n = 14)	Thyroid (n = 20)	Melanoma (n = 15)
All diagnoses	3.1 (2.6-3.6)	2.9 (2.4-3.4)	6.3 (4.4-8.9)	4.1 (2.2-6.8)	3.5 (2.2-5.5)	3.4 (2.1-5.3)
Leukemia/lymphoma (n = 4309)	2.7 (2.2-3.4)	2.1 (1.2-3.4)	6.3 (3.7-10.1)	1.5 (0.3-4.3)	2.6 (1.2-5.0)	4.1 (2.3-6.9)

10510 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Risk-adapted therapy for pediatric Hodgkin lymphoma (HL) results in lower risk of late effects: a report from the Childhood Cancer Survivor Study (CCSS). *First Author: Kevin C. Oeffinger, Duke University, Durham, NC*

Background: The goal of multi-modal, risk-adapted therapy for HL is to increase cure rates while decreasing risk for late effects; this is particularly important for children due to their vulnerability to cytotoxic therapy and life expectancy. **Methods:** Severe, disabling, life-threatening and fatal chronic conditions (CTCAE v4.03 grades 3-5) were determined for 2,996 5-yr HL survivors from CCSS diagnosed age $<$ 21 from 1970-1999. Cox models evaluated hazard ratios (HR) and 95% confidence intervals (CI), comparing risks of grade 3-5 chronic conditions by age 40 among treatment regimens with historical total lymphoid irradiation (TLI) as the referent group. **Results:** HL survivors were a mean age of 35.6 years (range, 12-58). The cumulative incidence of any grade 3-5 condition by age 40 was 43.6% (95% CI 41.1-46.1). Risk-adapted therapy using hybrid chemotherapy with or without radiotherapy (RT) was associated with a substantial reduction in risk for serious late effects (Table). While omitting radiation was associated with a 3-fold reduction in risk of late effects, HL survivors with a history of recurrence and/or a hematopoietic transplant (HCT) had an overall risk similar to those treated with TLI. **Conclusions:** Risk-adapted therapy has resulted in a reduction in serious long-term outcomes. While omitting radiotherapy is associated with a further reduction in risk, this consideration must be balanced with the risk of recurrence and the serious morbidity associated with salvage therapy.

HR (95% CI) for selected treatment groups, adjusted for sex, age at HL, and other treatment regimens, for a grade 3-5 condition, subsequent malignant neoplasm (SMN), cardiopulmonary disease (CPD), or endocrinopathy (Endo).

10511 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Mortality following breast cancer in survivors of childhood cancer: A report from the Childhood Cancer Survivor Study. *First Author: Chaya S. Moskowitz, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Female childhood cancer survivors have a high risk of subsequent breast cancer (BC). Little is known about mortality following BC in this population. **Methods:** Risk of all-cause and BC-specific mortality were estimated in 274 5-year survivors of childhood cancer diagnosed with invasive (71% ER+) or in situ BC. Median age at first BC diagnosis was 38 years (range 20-58); median follow-up after BC was 8 years (range 0-26), 195 (71%) were treated with chest radiation (RT) for their primary cancer. Hazard ratios (HRs) were estimated from cause-specific proportional hazards frailty models comparing mortality with a population-based control group with BC selected in a 1:5 ratio from SEER matched on sex, race, stage, age and calendar year of BC diagnosis (69% ER+). Cumulative incidence was estimated accounting for competing risks. **Results:** 92 childhood cancer survivors died, 49 from BC. Risk of death from any cause after a BC diagnosis was higher among childhood cancer survivors compared to controls (HR = 2.2, 95% CI 1.7-3.0) and remained elevated after adjusting for BC treatment with RT (HR = 2.2, 95% CI 1.7-3.1), chemotherapy (HR = 2.3, 95% CI 1.8-3.2) or both (HR = 2.4, 95% CI 1.7-3.2). Risk of death after diagnosis with early stage BC was elevated compared to controls (Stage 0, 1 & 2, n = 200, HR = 2.6, 95% CI 1.9-3.7) but BC-specific mortality was not significantly higher among survivors (HR = 1.4, 95% CI 0.9-2.0). Ten-year cumulative incidence of all-cause mortality was 33% (95% CI 27-40%) among survivors and 16% among controls (95% CI 14-18%); for BC-specific mortality it was 20% (95% CI 15-25%) and 13% (95% CI 11-16%) and for deaths from other causes was 13% (95% CI 9-19%) and 3% (95% CI 2-4%), respectively. Other causes of deaths among childhood cancer survivors with BC included other subsequent neoplasms (44%) and cardiovascular disease (26%). **Conclusions:** Mortality after BC is high in childhood cancer survivors compared to women with BC in the general population, even in the setting of early stage disease. Future research should determine if this increased mortality reflects co-morbidity, limited therapeutic options and/or missed opportunities for risk-reducing interventions at the time of BC diagnosis.

10512 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Association of exercise with late mortality in adult survivors of childhood cancer: A report from the Childhood Cancer Survivor study. *First Author: Jessica Scott, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Adult survivors of childhood cancer are at excess risk for late mortality compared to the general population. Whether exercise attenuates this risk is not known. **Methods:** We examined the association between self-reported vigorous exercise [metabolic equivalent-hrs/week (MET-h/wk)] and cause-specific late mortality among 15,450 adult survivors participating in the Childhood Cancer Survivor Study using multivariable piecewise exponential regression analysis to estimate rate ratios (RR). Longitudinal change in vigorous exercise was evaluated among a subset of 5689 survivors. **Results:** During a median follow-up of 10 years (interquartile range: 15 years), 1063 deaths (811 health-related, 120 recurrence/progression of primary cancer, 132 external/unknown causes) were documented. At 15 years the cumulative incidence of all-cause mortality was 11.7% (95% CI, 10.57-12.80) for 0 MET-h/wk, 8.6% (95% CI, 7.42-9.72) for 3 to 6 MET-h/wk, 7.4% (95% CI, 6.23-8.57) for 9-12 MET-h/wk, and 8.0% (95% CI, 6.50-9.45) for 15-21 MET-h/wk ($P < 0.001$). There was a significant inverse association across quartiles of exercise and all-cause mortality after adjusting for chronic health conditions and treatment exposures (P_{trend}= 0.023). Among a subset of 5689 survivors, increased exercise (+7.9 ± 4.4 MET-h/wk) over an 8-year period was associated with a 40% reduction in all-cause mortality rate compared with maintenance of low exercise (RR = 0.60; 95% CI, 0.44 to 0.82, p = 0.01). **Conclusions:** Vigorous exercise in early adulthood and increased exercise over eight years is associated with lower risk of late mortality in adult survivors of childhood cancer.

10513 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Impact of exercise on psychological burden in adult survivors of childhood cancer: A report from the Childhood Cancer Survivor Study (CCSS). *First Author: Emily S. Tonorezos, Adult Long Term Follow-Up Program, Department of Medicine, Memorial Sloan-Kettering Cancer Center, New York, NY*

Background: Adult survivors of childhood cancer are at risk for adverse psychological outcomes. Whether exercise can attenuate this risk is unknown. **Methods:** Using a longitudinal design, 6199 CCSS participants (median [range] age 34 years [22-54] and median [range] age at diagnosis 10 years [0-21]) completed a baseline questionnaire assessing vigorous exercise, medical and psychological conditions. Psychological outcomes were evaluated in a subsequent questionnaire a median of 7.8 years later (range 0.1-10). Primary outcome was overall psychological burden, defined as: symptom level above the 90th percentile of population norms on the Brief Symptom Inventory-18 for depression, anxiety, or somatization ; cancer-related pain; cognitive impairment; or poor quality of life. Log-binomial regression estimated associations between exercise [total metabolic equivalent-hrs·wk^{-1} (MET-hrs·wk^{-1})] and these outcomes adjusting for cancer diagnosis/treatment, demographics, and baseline medical/psychological illness. **Results:** The prevalence of overall psychological burden at follow-up was 71.3%. The prevalence of depression was 11.4%, anxiety 7.4%, and somatization 13.9%. Among those not engaged in vigorous exercise, the prevalence of overall psychological burden was 75.9%, compared to 68.6% in those who exercised ≥3 MET-hrs·wk^{-1} ($p < 0.001$). Compared to 0 MET-hrs·wk^{-1} of vigorous exercise, the adjusted prevalence ratio (PR) for overall psychological burden was 0.98 (95% CI, 0.95-1.01) for 3-6 MET-hrs·wk^{-1}, 0.93 (95% CI, 0.90-0.96) for 9-12 MET-hrs·wk^{-1}, and 0.94 (95% CI, 0.90-0.98) for 15-21 MET-hrs·wk^{-1}. Compared to not reporting vigorous exercise, 9 to 12 MET-hrs·wk^{-1} was associated with an adjusted PR of 0.76 (95% CI, 0.62-0.93; p = 0.004) for depression and 0.79 (95% CI, 0.66-0.94; p = 0.003) for somatization. Vigorous exercise was associated with higher cognitive function in domains of task completion, organization, and working memory (p's < 0.05) but was not associated with cancer pain or quality of life. **Conclusions:** Vigorous exercise is associated with lower psychological burden and less cognitive impairment in long-term survivors of childhood cancer.

10514 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Patient-level predictors of lack of healthcare provider recommendation for human papillomavirus (HPV) vaccination as reported by childhood cancer survivors and their families. *First Author: Jocelyn M York, University of Alabama at Birmingham, Birmingham, AL*

Background: Childhood cancer survivors are at increased risk for HPV-related morbidities, yet HPV vaccine initiation rates in survivors are low. Lack of healthcare provider recommendation for HPV vaccination is strongly associated with vaccine non-initiation (OR = 10.8, 95%CI, 6.5-18.0; *J Clin Oncol*, 2017; 35:3582-90). We aimed to examine patient-level predictors of lack of provider recommendation for HPV vaccination as reported by childhood cancer survivors and their families (hereafter referred to as NO RECOMMENDATION). **Methods:** Cancer survivors age 9-26y and 1-5y post-treatment completed a cross-sectional survey (parent-completed for survivors age 9-17y). NO RECOMMENDATION was evaluated as the outcome of interest in a multivariate logistic regression model that included relevant patient-level sociodemographic, clinical, and vaccine-related variables. **Results:** Participants included 955 survivors; 54% were male, 66% were non-Hispanic white, 59% had leukemia/lymphoma. Survivor age at survey (Mean±SD) was 16.3±4.7y; time off therapy was 32.8±14.7 months; 72% of participants reported NO RECOMMENDATION. Patient-level predictors associated with increased odds of NO RECOMMENDATION included perceived lack of insurance coverage for vaccine (OR = 3.7, $p < .0001$), male sex (OR = 3.2, $p < .0001$), black race (OR = 2.4, p = .003), and endorsement of barriers to vaccination (e.g., time, cost; OR = 1.8, p = .003). Predictors associated with decreased odds of NO RECOMMENDATION included older age (13-17y: OR = 0.3, $p < .0001$; 18-26y: OR = 0.3, $p < .0001$; referent group: 9-12y), non-Christian religion (OR = 0.4, p = .02), parent-child communication regarding HPV vaccine (OR = 0.6, p = .0001), and endorsement of social influences (e.g., opinions of friends/family) as important in HPV vaccine decision-making (OR = 0.8, p = .03). **Conclusions:** Nearly 3 in 4 childhood cancer survivors reported not receiving a healthcare provider recommendation for HPV vaccination. Interventions targeted to increase vaccine uptake should focus on factors influencing the provision of provider recommendation for HPV vaccination to all young cancer survivors.

10515 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Targeted resequencing of pediatric rhabdomyosarcoma: report from the Children's Oncology Group, the Children's Cancer and Leukaemia Group, The Institute of Cancer Research UK, and the National Cancer Institute. *First Author: John Frederick Shern, Pediatric Oncology Branch, National Cancer Institute, Bethesda, MD*

Background: Rhabdomyosarcoma (RMS) is the most common soft tissue sarcoma of childhood. Despite aggressive therapy, the 5-year survival rate for patients with metastatic or recurrent disease remains poor. Genomic studies by our group and others have identified 39 genes as known or potential somatic driver mutations in RMS. We therefore performed a large-scale validation study through an international consortium to more accurately determine the incidence of driver mutations and their association with clinical outcome. **Methods:** Formalin fixed paraffin embedded material was collected from patients enrolled on Children's Oncology Group trials and UK patients enrolled on MMT trials. Pathology was reviewed centrally and extracted DNA subjected to targeted capture sequencing. Mutations, indels, deletions, gene amplifications and genome-wide copy number variation was called using analysis pipelines developed at the NCI. **Results:** DNA from six hundred and thirty-one patients was suitable for analyses. A median of 2 variant calls were found per tumor. Mutation of a RAS isoform was found in 29% of all fusion negative cases, mutation of a RAS pathway member was seen in greater than 50% of cases, and 24% had no putative driver mutation identified. *BCOR* (15%), *NF1* (11%) and *TP53* (12%) mutations were found at a higher incidence than previously reported. Interestingly, mutations in *HRAS* were notable in the infant population whereas those in *NRAS* were enriched in adolescents. Among infants < 1 year, 71% of cases harbored a mutation in *HRAS* or *KRAS*. In contrast, mutation of *MYOD1* was associated with an older age and parameningeal primary site. Finally, 29% of the evaluated tumors harbored multiple driver mutations consistent with subclonal variation and tumor heterogeneity in fusion negative RMS. Detailed analyses of the association of mutations with anatomical location, histology and outcome are currently underway. **Conclusions:** This is the largest genomic characterization of clinically annotated patients with RMS tumors to date and adds to the understanding of the biology of this disease.

10516 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

A prospective study of pediatric renal cell carcinoma: A report from the Children's Oncology Group study AREN0321. *First Author: James I. Geller, Cincinnati Children's Hospital Medical Center, Cincinnati, OH*

Background: Although renal cell carcinoma (RCC) is the second most common pediatric kidney cancer, no previous prospective clinical trials have been conducted. AREN0321 tested the hypothesis that RCC with localized completely resected disease, including those with lymph node involvement, has a favorable prognosis without adjuvant medical therapy. **Methods:** From 2006 to 2012, patients up to age 30 years with centrally reviewed pathology confirmation of RCC were prospectively enrolled. Patients with completely resected disease were followed without adjuvant therapy, independent of TNM stage. **Results:** 62 eligible patients enrolled (35 male: 27 female; median age 13.2 yr (range 0.17 - 22.1)). Histology was TFE-associated RCC (TRCC; 33, 53.2%), RCC NOS (21, 33.9%), papillary RCC (5, 8.1%) and Renal Medullary Carcinoma (RMC; 3, 4.8%). 58 (93.5%) patients had all disease completely resected at diagnosis with stages 1 (27, 43.5%), 2 (7, 11.3%), and 3 (24, 38.7%) disease. Three patients with stage 4 (M1) and one with stage 3 had an incomplete resection. Surgery included radical nephrectomy (50) and partial nephrectomy (12). Lymph node (LN) status was N0 (21 (33.9%)), N1 (19 (30.6%)), and Nx (22 (35.5%)). Histology for patients with N1 disease was: TRCC (13, 68.4%), RCC NOS (4, 21.1%) and RMC (2, 10.5%). Four-year EFS and OS for the completely resected group were: 87.2% (95% CI 77.0 – 97.4) and 94.6% (87.6-100), respectively; and by stage were: 1 (92.4% (80.7-100) and 96.2% (87.7-100)), 2 (100% and 100%), and 3 (77.6% (57.6 – 97.6) and 91.3% (77.1-100)) (EFS p-value 0.294, OS p-value 0.722). Four-year EFS and OS by histology for the overall group were: TRCC: 87.7% (74.2-100) and 93.6% (83.3-100), papillary RCC: 100% and 100%, RCC NOS: 87.7% (70.3-100) and 100%, and RMC: 33.3% (0-86.7) and 33.3% (0-86.7). For the 15 patients with completely resected N1M0 disease (of which 13 had TRCC), the four-year EFS and OS were 86.7% (64.7-100) and 93.3% (76.6-100), respectively. **Conclusions:** Favorable outcomes can be achieved without adjuvant therapy in children and adolescents with completely resected RCC, including those with locally advanced disease and lymph node involvement. Clinical trial information: NCT00335556.

10517 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Hope and benefit-finding among adolescents and young adults with cancer: Results from the PRISM randomized controlled trial. *First Author: Abby R. Rosenberg, Seattle Children's Cancer and Blood Disorders Center, Seattle, WA*

Background: Adolescents and Young Adults (AYAs) with cancer are at risk for poor psychosocial outcomes, perhaps because they have not acquired the skills to navigate illness. We previously reported that a novel, brief, age-appropriate, skills-based intervention ["Promoting Resilience in Stress Management" (PRISM)] was associated with improved quality of life and psychological distress. In this secondary analysis, we aimed to determine if PRISM also improved targeted skills of hopeful thinking, benefit-finding, and goal-setting. **Methods:** PRISM consists of 4, 30-60 minute, in-person, 1:1 sessions plus a facilitated family-meeting targeting stress-management, goal-setting, cognitive reframing, and meaning-making. English-speaking AYAs (ages 13-24 years) with cancer were randomized to receive either PRISM or psychosocial usual care (UC). Participants completed surveys upon enrollment and 6 months later. Mixed effects regression models estimated associations between PRISM and hopeful patterns of thought (Snyder Hope Scale), benefit-finding (benefit-finding scale for children), and goal-setting (queried with open-ended items about short- and long-term goals, then evaluated by 3 blinded coders with a 10-point, *a priori* defined tool to identify specific, measurable, and actionable goals) at 6 months. **Results:** Of N = 92 enrolled AYAs (48 PRISM and 44 UC), 73% were 13-17 years-old, 43% were female, and 62% had a diagnosis of leukemia or lymphoma. Attrition was similar in each arm and primarily due to medical complication or death; n = 36 (72%) PRISM and n = 38 (76%) UC participants completed 6 month surveys. After adjusting for baseline scores, PRISM was associated with improved hope and benefit-finding with moderate-to-large effect sizes: Hope: +3.6 points, 95% CI 0.7,6.4, Cohen's *d* effect size = 0.6, p = 0.01; Benefit-finding: +3.1 points, 95% CI 0.0,6.2, *d* =0.6, p = 0.05. We did not detect changes in goal-setting (Goals: -0.5 points, 95% CI -1.2,0.3, *d* = -0.3, p = 0.23). **Conclusions:** A novel intervention targeting skills for AYAs with cancer was associated with significant improvements in hope and benefit-finding, 2 key skills which may mitigate later psychosocial risk. Clinical trial information: NCT023408.

Matched targeted therapy for pediatric patients with relapsed, refractory or high-risk leukemias: A report from the LEAP consortium. *First Author: Yana Pikman, DFCI, Boston, MA*

Background: Despite the remarkable pace in characterizing the genomics of acute leukemias, integration of sequencing into clinical practice is lagging. With increased availability of targeted therapies, optimism exists in matching a patient's genetic lesion to a targeted drug with goals of improving survival and decreasing toxicity. **Methods:** We established the first pediatric leukemia genomics consortium, Leukemia Precision-based Therapy (LEAP) Consortium, which includes 13 major US pediatric cancer institutions. Using a combination of a next-generation sequencing panel and gene fusion testing, we are conducting a feasibility clinical trial aimed to identify, in real-time, actionable alterations with a matched targeted therapy for patients with high-risk leukemias. **Results:** To date, we have enrolled 84 pediatric patients. Based on targeted sequencing results, 68% of the patients had a recommendation for targeted therapy, tiered based on the level of evidence for the mutation within the patient's specific leukemia type. Of the 44 patients with clinical follow-up data, 5 (11%) have had changes in therapy based upon our genomic results. Targetable lesions identified include mutations resulting in RAS signaling pathway activation and mutations/translocations involving *ABL1*. These genomic data refined diagnosis and supported additional germline assessment in a subset of patients. We are establishing mouse patient-derived xenograft models in which to conduct correlative preclinical targeted therapy studies. We are further deploying *in vitro* drug and siRNA sensitivity assays to study response of leukemia cells to targeted therapies and to assess correlation with underlying genetic events. **Conclusions:** This first multi-institutional prospective pediatric leukemia genomics trial brings state-of-the-art clinical genetic testing to pediatric patients with leukemia, impacting diagnosis, treatment and selection of patients for germline testing. Moreover, our collaboration brings together cutting edge correlative biology studies to impact pediatric leukemia discovery and to inform future genomics-guided therapeutic trials and drug discovery efforts. Clinical trial information: NCT02670525.

10519 Poster Discussion Session; Displayed in Poster Session (Board #192), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

Aqueous humor genomics predicts eye salvage in retinoblastoma. *First Author: Liya Xu, University of Southern California, Los Angeles, CA, US*

Background: Retinoblastoma was one of the first cancers to demonstrate a genetic basis to the development of cancer. However, unlike many cancers, Rb cannot be directly biopsied due to the high risk of extraocular cancer spread. Therefore, unless the eye is enucleated, tumor tissue is not evaluated for genetic and genomic changes and these alterations are not used to inform diagnosis or prognosis for this disease. However, in a recent publication in JAMA Ophthalmology,(Berry JL, Xu L et al. JAMA Ophthalmol, 2017) we demonstrated that tumor-derived cell-free DNA can be extracted from the aqueous humor (AH) of Rb eyes, which is safe to extract even with active intraocular disease. The purpose this current study was to identify somatic chromosomal copy number alterations (sCNA) in tumor-derived cell-free DNA in the AH of Rb eyes and to correlate with clinical outcomes particularly tumor relapse requiring enucleation. **Methods:** AH was extracted via paracentesis from Rb eyes during intravitreal injection of chemotherapy or enucleation. Shallow whole genome sequencing was performed to assess for cell-free tumor DNA fractions and highly-recurrent sCNAs in Rb which include gain of 1q, 2p, 6p and loss of 13q and 16q. Globe salvage was recorded. **Results:** 26 patients were included; 3 patients had both eyes included for 29 eyes. From these, 63 samples of AH were analyzed; 5 post-enucleations and 58 during intravitreal chemotherapy injection. Ultimately 13 eyes required enucleation and 16 eyes were salvaged. Follow-up ranged from 8-43 months (median 17 months). 6p gain was the most common sCNA found in 10/13 enucleated eyes (77%) compared to 4/16 (25%) of salvaged eyes (p = 0.009). The mean amplitude of 6p gain was 1.47 in the enucleated group versus 1.07 in the salvaged group (p = 0.001). The presence of a detectable sCNA in enucleated eyes was 92% while in salvaged eyes was 38% (p = 0.022). The probability of globe salvage was improved in eyes without detectable sCNAs (p = 0.0028). **Conclusions:** This is the first study to correlate globe salvage with highly-recurrent sCNAs in the AH from Rb eyes. This study suggests that not only can the AH serve as a surrogate to tumor biopsy but could contribute to prognostication of tumor response to therapy.

Parallel genomic and immune profiling of relapsed and metastatic osteosarcoma to reveal bases of low immunogenicity. *First Author: J Andrew Livingston, Department of Sarcoma Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Despite the high levels of point mutations, rearrangements, and other genomic instability events such as kataegis and chromothripsis, immune checkpoint inhibitors have shown limited clinical activity in osteosarcoma (OS). We completed in-depth parallel genomic and immune profiling in a cohort of 48 patients with high-grade osteosarcoma (relapsed or metastatic in 42) to determine potential mechanisms of primary resistance to immunotherapy and identify strategies to enhance immunogenicity. **Methods:** We utilized whole-genome sequencing (average coverage 75X), RNA sequencing, and immune profiling by T-cell receptor (TCR) sequencing and immunohistochemistry to analyze mutation load, cytotoxic and suppressive cell activity, relevance of checkpoint-related genes, and characterize immune infiltration in a clinically annotated set of primary resection, local relapse, and metastatic OS tumor specimens and matched normal tissue. **Results:** We observed high levels of gene rearrangements in approximately 60% of OS patient samples, however transcriptome sequencing showed a lack of fusion transcript expression from these rearrangements. Further, $<$ 10% of point mutations were expressed, generating few neoantigens. Immune-related pathways, including immunosuppressive *PD-L1* were upregulated in samples from older patients as compared to younger patients. Higher numbers of deleted genes were associated with higher immune infiltrate. Overall TCR clonality was low and did not correlate with mutation burden. T cell clonality did not differ by PTEN or HLA status. **Conclusions:** In the majority of OS, there is a lack of neoantigen expression and presentation. However, a subset of patients exhibit increased PD-L1 expression associated with lower levels of T-cell clonailty, for which immune checkpoint blockade may be beneficial and warrants further investigation.

The influence of surgical excision on survival in high-risk neuroblastoma revisited after introduction of ch14.18/CHO immunotherapy in the HR-NBL1/SIOPEN trial. *First Author: Keith Holmes, St George's Hospital, London, United Kingdom*

Background: The effect of complete macroscopic excision (CME) of the primary tumour on event free survival (EFS) in high-risk neuroblastoma remains controversial. We therefore investigated the influence of CME in patients enrolled on the HR-NBL1/SIOPEN Trial and compared the effect in the pre immunotherapy era. **Methods:** Eligibility criteria were: inclusion in HR-NBL1/SIOPEN Trial between 2002-2015, stage 4 disease; completion of Rapid COJEC induction $\pm$ 2 courses of TVD; no progression/relapse/death; no prior attempt at resection and complete operation data. Intended therapy following operation comprised: HDT/SCT (BuMel or CEM, after 2011 BuMel), 21Gy radiotherapy to the primary site, 13-cis RA and after 2009 ch14.18/CHO antibody $\pm$ IL2 in addition. 1504 patients fulfilled these criteria; 737 were treated prior to ch14.18/CHO availability (2002-2009) and 767 in the immunotherapy era. Median observation time was 4.9 years (0.1-14 years). **Results:** CME was achieved in 77%, incomplete macroscopic excision (IME) in 21% and 2% were inoperable (0E). Surgical mortality was 0.46% (7/1504). Five year event-free survival (5y-EFS $\pm$ standard error) was 39%$\pm$2% with CME and 30%$\pm$3% with IME or 0E ($p = 0.002$). The cumulative incidence of local relapse (CILR) was 0.17$\pm$0.01 (CME); 0.31$\pm$0.03 (IME) and 0.42 $\pm$0.10 (0E) ($p < 0.001$). 88% of patients received radiotherapy (78% CME; 21% IME and 1% 0E). 5y-EFS for patients with CME who received radiotherapy was 44$\pm$2%, but 31$\pm$6% without (reasons included very young age and very large primary tumours) ($p = 0.013$) and 35$\pm$3% with less than CME compared to 20$\pm$1% without radiotherapy (NS). CILR was 0.14$\pm$0.01 in patients with CME who received radiotherapy compared to 0.28$\pm$0.06 in patients who did not ($p = 0.005$). 5y-EFS was significantly higher (42$\pm$2%) for patients enrolled after 2009 compared to before (32$\pm$2%) ($p = 0.000$). 5-y EFS for patients after 2009 who achieved CME was 45$\pm$2% vs. 36$\pm$2% after IME and 26$\pm$13% after 0E respectively ($p = 0.034$); compared to 33$\pm$2% vs. 26$\pm$4% (IME) and 17$\pm$11% (0E) ($p = 0.059$) prior to 2009. **Conclusions:** In the immunotherapy era, CME in Stage 4 patients who received local radiotherapy resulted in improved 5-EFS. Clinical trial information: NCT01704716.

10522 Poster Discussion Session; Displayed in Poster Session (Board #195), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

A phase I NANT study of lenalidomide with ch14.18 and isotretinoin (RA) in patients with refractory/recurrent neuroblastoma (RR-NB). *First Author: Araz Marachelian, Children's Hosp Los Angeles, Los Angeles, CA*

Background: Ch14.18 (dinutuximab) increases event free and overall survival in patients with high-risk NB when given in a regimen with GM-CSF/IL-2. However, this therapy has significant toxicities, and 40% of patients relapse. LEN has immunomodulatory effects in pediatric solid-tumor patients and is well tolerated. The combination of LEN with ch14.18, was supported by preclinical data that demonstrate the activity in NB. We conducted a phase I trial to determine the tolerability of LEN with ch14.1 and RA in patients with RR-NB. **Methods:** LEN dose escalation followed a 3+3 design (25, 50, 75 and 100mg /m2/day). The administration schedule is: LEN days 1-21, ch14.18 (17.5mg/m2/day) days 8-11, and RA (160mg/m2/day) days 15-28 (Dose level 2-5). **Results:** 27 patients enrolled with a median age of 8 years (range: 3-20), of whom 23 were evaluable for dose escalation. The median number of courses was 4 (range 1–12). No MTD was identified. There were 7 patients with dose limiting toxicities (course): grade 3 diarrhea(C1), grade 3 diarrhea/delayed neutrophils(C1), delayed neutrophils(C2), grade 4 ALT(C8), anaphylaxis(C5), delayed platelets(C5), delayed neutrophils(C4), delayed neutrophils/grade 4 sinus bradycardia(C6). Overall regimen was tolerable with no grade 3 capillary leak, 7% grade 3 hypotension and 4% grade 3 fever. there was 1 complete response, 3 partial responses, 3 minor responses, 8 stable diseases and 6 progressive diseases in 21 patients evaluable for response. Immunomodulation was seen with statistically significant increases in frequency of circulating effector NK cells, an increase in the frequency of CD4+ (T-helper) effector memory T lymphocytes and increased antibody dependent cytotoxicity (ADCC) in patients. Plasma protein concentrations demonstrated statistically significant therapy-associated increases in granzyme B, IL-15, IFNg, CXCL9, CXCL10, CXCL11, sIL-2R, and GM-CSF as well as IL-6, IL-8, IL-10, MCP-1, and M-CSF. **Conclusions:** LEN 100 mg/m2 QD for 21 days per cycle is tolerable with ch14.18 and RA, and is associated with antitumor response and immunomodulatory effects. Further studies are warranted in studying this combination. Clinical trial information: NCT01711554.

10523 Poster Discussion Session; Displayed in Poster Session (Board #196), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

ROR1-specific CAR for neuroblastoma using *sleeping beauty*-modified t cells. *First Author: Fiorela Natali Hernandez Tejada, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Adoptive transfer of chimeric antigen receptor (CAR)-modified T cells is predicted to provide a treatment option for advanced/refractory neuroblastoma. One potential target, receptor tyrosine kinase-like orphan receptor-1 (ROR1), is a cell surface protein that is aberrantly expressed on solid organ tumors including neuroblastoma. **Methods:** A ROR1-specific CAR was developed by linking a ROR1-specific scfv to a mutated IgG4-Fc stalk and co-stimulatory endodomains CD3-zeta and CD28 (ROR1R*CD28 CAR). Human T cells were genetically modified to express the ROR1-CAR by electro-transfer of DNA plasmids from *Sleeping Beauty* system and (i) directly injected the next day under technology designated as point-of-care (P-O-C) or (ii) numerically expanded for 14 days on $ROR1^+$ activating and propagating cells (AaPC). Redirected specificity for ROR1 was assessed *in vitro* by chromium release assay and cytokine release. To demonstrate therapeutic potential, the ROR1R*CD28 CAR manufactured under the two conditions, were infused into NSG mice bearing disseminated CHLA 255 $ROR1^+$ neuroblastoma cells expressing firefly luciferase. **Results:** The day after electroporation, T cells had 20-30% CAR expression from episomal and integrated transgene and by day 14, 90% of $CD3^+$ T cells expressed CAR. CAR^+ T cells were able to lyse neuroblastoma lines and produce IFN-gamma in a ROR1-specific manner. *In vivo*, POC and 2-stim manufactured CAR^+ T cells both exhibited similar antitumor activity. This antitumor effect was confirmed by histological evaluation of metastatic liver lesions and correlated with the presence of circulating human $CD3^+$ T cells. **Conclusions:** Genetically modified T cells with CAR infused after being manufactured under P-O-C or propagated on AaPC can specifically target and lyse neuroblastoma cells significantly reducing the tumor burden in mice. These data reveal that shortening the manufacturing time from 14 days to 1 day result in anti-tumor effects with CARs that signal via chimeric CD28. Shortening the manufacturing from 14 days to 1 day is predicted to broaden the application of CAR^+ T cells as this avoids the need for *ex vivo* tissue culture and thus reduced the costs and expense of manufacture.

Survival and delayed effects of risk-stratified hepatoblastoma patients treated in the JPLT-2 trial. *First Author: Eiso Hiyama, Hiroshima University, Hiroshima-Shi, Japan*

Background: The Japanese Study Group for Pediatric Liver Tumor (JPLT) -2 trial (2000-2012) has been conducting to evaluate the efficacy of the CITA regimen, consisting of cisplatin/pirarubicin, in patients with hepatoblastoma (HB) stratified by risk according to the PRETEXT staging system. **Methods:** In JPLT-2, PRETEXT I/II tumors were initially resected or underwent two courses of low-dose CITA before resection and an additional four courses of CITA after resection. Of the PRETEXT III/IV or metastatic tumors, those that responded to two courses of CITA underwent four more courses of CITA, and the non-responsive tumors received four courses of a second-line regimen consisting of ifosfamide, pirarubicin, etoposide, and carboplatin. Highly metastatic or refractory tumors were treated with high-dose chemotherapy and stem cell transplantation. **Results:** Among the 360 patients who were eligible in the JPLT-2 trial, 5-year event-free/overall survival rates of patients with PRETEXT I/II/III HB were 94/82%, while those of patients with PRETEXT IV and metastatic HB were 65.4/74.6% and 44.3/60.9%, respectively (Table). Except for 40 patients who underwent primary resection, complete resection of the primary tumor after CITA was achieved in 86%, 66%, and 56% of patients with PRETEXT II/III, PRETEXT IV, and metastatic tumors, respectively. The outcomes of the patients who received high-dose chemotherapy did not improve. Of those patients who survived, 68 experienced late-phase complications with otoxicity, 12 cardiotoxicity, 5 maldevelopment, and 12 second malignancies. **Conclusions:** Compared with other multicenter cooperative protocols, treatment with the CITA regimen achieved similar rates of survival and resectability. However, the rates of otoxicity and a second malignancy were higher and that of cardiotoxicity lower compared with other studies. Reduction of the chemotherapy dose should be considered in low-risk patients, while more promising strategies such as novel targeted drugs should be developed for intermediate- and high-risk patients with HB. Clinical trial information: UMIN000001116.

KEYNOTE-051: An update on the phase 2 results of pembrolizumab (pembro) in pediatric patients (pts) with advanced melanoma or a PD-L1–positive advanced, relapsed or refractory solid tumor or lymphoma. *First Author: Birgit Geoerger, Gustave Roussy, Villejuif, France*

Background: In the phase 1 portion of KEYNOTE-051 (NCT02332668), the 2-mg/kg-Q3W dose of pembro was identified as the pediatric recommended phase 2 dose. We provide an update on the safety and efficacy of this dose by tumor type in the ongoing phase 2 trial. **Methods:** Pts aged 6 mo to $<$ 18 y with advanced melanoma or a PD-L1–positive, advanced relapsed/refractory solid tumor or lymphoma and measurable disease per RECIST v1.1 received pembro 2 mg/kg Q3W until confirmed disease progression per irRECIST by investigator review, intolerable toxicity, or pt/investigator decision to discontinue. Key efficacy end points were ORR and PFS per RECIST v1.1 by investigator and OS (data cutoff Oct 10, 2017). **Results:** 689 of 748 prescreened pts had PD-L1–evaluable tumors. Of these, 229 (33.2%) were PD-L1–positive; 125 pts (median age, 13 y [range, 1-17]) were enrolled and treated (10 Hodgkin lymphoma [HL]; 115 other tumors). Median follow-up was 5.7 mo (range, 0.2-29). Primary diagnoses were other non–central nervous system (CNS) solid tumors (46%), sarcoma (19%), CNS tumors (26%), and lymphoma (9%). Seven (6%) pts experienced grade 3-5 treatment-related AEs; of these, 2 (1.6%) discontinued (1 due to increased aspartate aminotransferase; 1 with renal medullary carcinoma died of treatment-related pulmonary edema). No major untoward effects on the developing immune system were observed. One pt (10.0%) with HL achieved CR and 5 (50%) achieved PR. Six (5.2%) pts with other tumors achieved prolonged PR (2 adrenocortical carcinoma and 1 each epithelioid sarcoma, mesothelioma, malignant ganglioglioma, and lymphoepithelial carcinoma). ORR was 60.0% (95% CI, 26.2-87.8) in pts with HL and 5.2% (95% CI, 1.9-11.0) in pts with all other tumor types. Median PFS was 12.2 mo in HL and 1.9 mo in any other tumor type; 12-mo PFS was 56.3% and 8.3%, respectively. Four (40.0%) pts with HL and 19 (16.5%) with any other tumor type survived $\geq$12 months. **Conclusions:** Pembro was well tolerated and showed response in HL and in a few rare tumor types, which warrants further study. Enrollment in KEYNOTE-051 is ongoing. Clinical trial information: NCT02332668.

10526 Poster Discussion Session; Displayed in Poster Session (Board #199), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

The association between atopy and Hodgkin's lymphoma in teenagers and young adults: A UK nationwide case control study. *First Author: Meena Rafiq, University College London (UCL), London, United Kingdom*

Background: Hodgkin's Lymphoma (HL) is the commonest cancer in teenagers and young adults (TYAs). Incidence in this age group has been increasing since the early 1990s in the UK, Australia, Canada and several US states. The cause in the majority of cases remains unknown. Previous studies have shown conditions involving impaired immune regulation, including HIV, immunosuppressive treatment and some autoimmune conditions, are associated with increased HL risk. However, few studies have investigated the link between atopy, the commonest form of childhood immune dysregulation, and HL and the results have been conflicting and inconclusive. This study uses large scale, UK data to investigate the association between atopic disease and immunosuppression with development of HL in TYAs. **Methods:** We conducted a case control study using primary care data from the UK Clinical Practice Research Database linked to hospitalization data. 1,238 cases with HL diagnosed between the ages of 0-49 years were individually matched using concurrent sampling to six controls each by age, sex and follow up time (7,428 controls). Multivariable logistic regression was used to investigate the association between atopic diseases (asthma, eczema, hay fever) and immunosuppression with HL incidence. **Results:** A prior diagnosis of asthma was associated with 26% increased odds of developing HL (Adjusted Odds Ratio (AOR):1.26, 95%CI 1.08-1.49 p = 0.005). There was weak or no evidence for an association between eczema or hay fever and HL (AOR:1.15, 95%CI 0.98-1.34 p = 0.09; AOR:0.88, 95%CI 0.73-1.05 p = 0.15, respectively) or that HL risk was increased in individuals with more than one atopic diagnosis (p = 0.07). Consistent with previous studies, immunosuppressed individuals had 14 times the odds of developing HL (AOR:13.79, 95% CI 5.67-33.50 p $<$ 0.001). **Conclusions:** This study has identified asthma as a risk factor for developing HL in early life. These findings add to the growing evidence that immune dysregulation is involved in development of HL in TYAs. Understanding the immune components and pathways underlying this relationship could help uncover markers for HL detection, recurrence and to develop new therapeutic interventions.

Intravenous fosaprepitant for the prevention of chemotherapy induced vomiting in children: A double blind placebo controlled, phase III randomized trial. *First Author: Archit Joshi, Cancer Institute (WIA), Chennai, India*

Background: Fosaprepitant, is a Neurokinin-1 (NK-1) receptor antagonist, approved in adults for the prevention of vomiting associated with administration of moderately or highly emetogenic chemotherapeutic agents. The efficacy and safety of fosaprepitant in children is not known. Therefore, we conducted a phase III randomized trial to assess the safety and efficacy of fosaprepitant in children. **Methods:** The study was a phase III, single centre, double blind, randomized placebo controlled trial. Children aged 1-12 years with documented malignancy, who were scheduled to receive moderately or highly emetogenic chemotherapy, were randomly assigned to arm A (Fosaprepitant) or arm B (Placebo). Arm A received intravenous ondansetron (0.15 mg/kg) plus dexamethasone (0.075 mg/kg) followed by fosaprepitant (3 mg/kg) short infusion. Arm B received intravenous ondansetron (0.15 mg/kg) plus dexamethasone (0.15 mg/kg) followed by normal saline as placebo. Oral ondansetron and dexamethasone were continued for 48 hours after completion of chemotherapy. Primary end-point of the study was the proportion of patients who achieved a complete response (defined as no vomiting, no retching) during the 25–120 hours (delayed phase) after administration of fosaprepitant. Secondary end-points were proportion of patients who achieved complete response during the acute (0–24 hours) and overall phases after administration of fosaprepitant. **Results:** 135 patients were analyzed (68 in fosaprepitant arm and 67 in placebo arm). Complete response rates were significantly higher in fosaprepitant arm compared to placebo arm during acute phase (84% vs. 57%, p $<$ 0.001), delayed phase (79% vs. 51 %, p $<$ 0.001) and overall phases (69% vs. 42%, p = 0.0014). Three (4%) patients in fosaprepitant arm and fourteen (21%) patients in the placebo arm required rescue anti-emetics (p = 0.004). No fosaprepitant related grade 3-4 adverse events were observed. **Conclusions:** Addition of fosaprepitant to ondansetron with dexamethasone is safe and effective for the prevention of chemotherapy induced vomiting in children being treated with moderately or highly emetogenic chemotherapy. Clinical trial information: CTRI/2017/02/007925.

The challenge of pediatric oncology: New business models to accelerate innovation. *First Author: Sonya Das, MIT Laboratory for Financial Engineering, Cambridge, MA*

Background: Few patient populations are as helpless and in need of advocacy as pediatric cancer patients. Pharmaceutical companies have historically faced significant financial disincentives to pursue pediatric oncology therapeutics, including low incidence, high costs of conducting pediatric trials, and a lack of funding for early-stage research. One way to accelerate innovation in this field is the formation of a collaborative business model involving private, public, and philanthropic stakeholders. We explore this idea by simulating the financial returns of a hypothetical collection of pediatric cancer drug projects under several different business structures. **Methods:** Using published studies of pediatric oncology research and the cost of drug development, and existing clinical trials of pediatric oncology therapeutics at clinicaltrials.gov, we identified 77 potential drug development projects to be included in a hypothetical portfolio. The returns of this portfolio were simulated so as to compute the financial returns and risk. Simulated business strategies include combining projects at different clinical phases of development, obtaining partial funding from philanthropic grants, and obtaining government guarantees to reduce risk. **Results:** The purely private-sector portfolio exhibited expected returns ranging from -34.2% to 0.0%, depending on the model parameters assumed. This suggests significant financial disincentives for pursuing pediatric oncology therapeutics and implies that financial support from the public and philanthropic sectors is essential. Phase diversification increases the likelihood of a successful drug, and yielded expected returns of -17.8% to 36.4%. Standard philanthropic grants had a marginal impact on expected returns. Government guarantees were more effective by reducing downside exposure, with returns ranging from -9.5% to 12.8%. **Conclusions:** A combination of financial and business strategies has the potential to maximize expected return while eliminating some downside risk—in certain cases enabling expected returns upwards of 36.4%—which can overcome current financial disincentives and accelerate the development of pediatric oncology therapeutics.

The social value of tisagenlecleucel, a CAR-T cell therapy, for the treatment of relapsed or refractory pediatric acute lymphoblastic leukemia in the United States: What are consequences of treatment delays? *First Author: Julia Thornton Snider, Precision Health Economics, Oakland, CA*

Background: Despite the recent approval of tisagenlecleucel, a CAR-T cell therapy, to treat pediatric and young adult patients with relapsed or refractory acute lymphoblastic leukemia (pALL) in the United States, patients have faced barriers to treatment. This study quantifies the social value of tisagenlecleucel and the value lost from treatment delays. **Methods:** The social value of tisagenlecleucel reflects its economic value to patients and the manufacturer, relative to the standard of care (clofarabine). To quantify the social value, we obtained estimates of life expectancy, quality-adjusted life years (QALYs), and healthcare costs from a cost-effectiveness model for tisagenlecleucel and valued each QALY gained at $150,000. Health and monetary values were discounted at 3.0%, and costs were inflated to 2016 US dollars. The social value of tisagenlecleucel was calculated using a price of $475,000. To quantify lost value from monthly treatment delays, we assumed patients would start clofarabine treatment while awaiting access to tisagenlecleucel. Expected survival for patients on clofarabine was obtained from a clinical trial, and social value and QALYs gained with tisagenlecleucel were calculated conditional on surviving to receive it. **Results:** Our study population included 20 incident cohorts of 500 patients with pALL. Patients treated with tisagenlecleucel gained 37,018 QALYs. The total social value was $4.6 billion. However, when treatment was delayed 1- 3 months, $452 million to $2.1 billion of social value and 3,634 to 17,100 QALYs were lost. Over half the social value, value to patients, and QALYs from tisagenlecleucel were lost when treatment was delayed 4 months. **Conclusions:** Innovative therapies such as tisagenlecleucel have the potential to provide substantial social value from improvements in life expectancy, QALYs and productivity. However, the magnitude of benefit depends upon the ability of patients to access these treatments promptly. Efficient payment mechanisms and sufficient technological capabilities will be required to minimize treatment delays for patients.

10530 Poster Session (Board #203), Sat, 8:00 AM-11:30 AM

Association of regulatory- and helper-T- cells with inferior survival of neuroblastoma patients treated with long-term infusion of ch14.18/CHO combined with interleukin-2. *First Author: Holger N. Lode, University Medicine Greifswald, Greifswald, Germany*

Background: Long-term infusion (LTI) of the anti-GD_2 antibody (Ab) ch14.18/CHO in combination with interleukin-2 (IL-2) prolongs survival in patients (pts) with high-risk neuroblastoma compared to historical controls. We investigated a correlation between lymphocyte subsets, functional immune-parameters and survival in treated patients. **Methods:** 53 pts received 5 cycles (35 days (d)) of $6x10^6$ IU/m^2 subcutaneous IL-2 (d1-5; 8-12), LTI of 100 mg/m^2 ch14.18/CHO (d8-18) and 160 mg/m^2/d oral 13-cis RA (d22-35) in a closed single center program (APN311-303). The counts of cytotoxic NK cells ($CD16^{++}/CD56^{dim}$), helper T cells ($CD3^+/CD4^+$), cytotoxic T cells ($CD3^+/CD8^+$), regulatory T cells (Treg; $CD4^+/CD25^+/CD127^-$) and granulocytes ($CD64^+$) were determined by flow cytometry (cycle 1; d1, 8 and 15). Ab-dependent cellular cytotoxicity (ADCC) was determined and correlation between cell counts and progression-free survival (PFS) was analyzed. **Results:** IL-2 treatment resulted in a strong increase of cytotoxic NK cells, cytotoxic- and helper T cells and Treg on d8 compared to baseline (d1) (2.4-, 3.9-, 2.6- and 15.0-fold increase, respectively). Subsequent combined treatment with IL-2 and ch14.18/CHO did not further increase lymphocyte counts on d15. In contrast, elevation of granulocytes occurred during the combined treatment. We did not observe any correlation between cell counts and ADCC on d15 as well as between cytotoxic NK and cytotoxic T cells and PFS. Similar observations were made for granulocytes. In contrast, pts with low Treg ($\leq$ 138 cells/μl) on d15 (n = 11) showed a better PFS compared to high Treg pts (n = 31) (P = 0.072). The 5-year PFS was 44% (95% CI [0.13, 0.74]) and 19% (95% CI [0.05, 0.33]) for low and high Treg counts, respectively. On d15, pts with low helper T cells (n = 11, $\leq$ 365 cells/μl) also showed an improved PFS compared to those who had high helper T cells (n = 31; P = 0.013). The 5-year PFS was 53% (95% CI [0.23, 0.83]) and 16% (95% CI [0.03, 0.29]) for low and high helper T cell count, respectively. **Conclusions:** IL-2-dependent elevation of helper T- and Treg-cells may negatively affect efficacy of ch14.18/CHO combined with IL-2.

10531 Poster Session (Board #204), Sat, 8:00 AM-11:30 AM

Evaluation of pegaspargase (PEG-ASP) adverse events among adolescents and young adults (AYAs) and younger patients with lymphoid malignancies (LM) at the Children's Hospital of Eastern Ontario (CHEO). *First Author: Nicole Mathies, University of Ottawa, Ottawa, ON, Canada*

Background: PEG-ASP is a common component of the chemotherapy regime for LM, but with significant side effects. The aim of this study was to determine the prevalence of major adverse events: allergic reactions, pancreatitis and thrombosis/hemorrhage among pediatric patients treated with PEG-ASP, and whether there is an association between age and a specific adverse event. **Methods:** Patients aged 0-18 years diagnosed with LM from January 1, 2007 to June 30, 2017 at CHEO, a tertiary care pediatric hospital, were eligible for this retrospective cohort study. A stratified, discrete-time, multivariable Cox regression model was fitted to elucidate the relationship between age at diagnosis and risk to adverse event. Model covariates included sex, body mass index and route of PEG-ASP administration (intravenous versus intramuscular). **Results:** Among 186 eligible patients, the median duration of follow-up was 2.0 years (IQR: 1.0-3.0). There were 34 allergic reactions, 8 cases of pancreatitis, and 32 cases of thrombosis/hemorrhage were observed. Estimates of 4-year cumulative incidence were 18.9% [95%CI:13.9, 25.4], 4.5% [95%CI:2.3, 8.7], and 19.4% [95%CI: 13.8, 26.9] for the three adverse events, respectively. Cox regression revealed a significant association between age at diagnosis and risk of allergic reaction (adjusted Hazards ratio (HR) = 2.18 [95%CI:1.45, 3.28], $p < .001$ for a 5-year increase in age) and risk of pancreatitis (adjusted HR = 1.93 [95%CI:1.02, 3.63], p = 0.04 for a 5-year increase in age), but not the risk of thrombosis/hemorrhage (adjusted HR = 1.25 [95%CI: 0.84, 1.85], p = 0.28, for a 5-year increase in age). The Cox model concordance index was 0.58. **Conclusions:** Evidence of an association between age at diagnosis and 2 of 3 adverse events (allergic reaction and pancreatitis) was revealed among pediatrics patients treated with PEG-ASP. In light of the study results, cautious observation is further warranted when administering PEG-ASP particularly to AYAs with lymphoid malignancies.

10532 Poster Session (Board #205), Sat, 8:00 AM-11:30 AM

Predictors of differential response to induction chemotherapy in high-risk neuroblastoma: A report from the Children's Oncology Group (COG). *First Author: Navin R. Pinto, Seattle Children's Hospital, Seattle, WA*

Background: Induction chemotherapy plays an important role in the management of patients with high-risk neuroblastoma. Predictors of response to Induction therapy itself are largely lacking. We sought to describe clinical and biological features associated with differential response to Induction. **Methods:** Patients from the following COG high-risk trials with at least one disease evaluation during Induction were included: A3973; ANBL02P1; ANBL0532; and ANBL12P1. Response at end-Induction was evaluated by the 1993 International Neuroblastoma Response Criteria. The primary endpoint was partial response (PR) or better. A series of univariate analyses (Fisher's exact or chi-squared tests) were performed to compare response as a function of clinical or biologic predictor variables. For each predictor variable, the Holm-Bonferroni method was used to correct for multiple testing, using an overall α=0.05. A multivariate logistic regression model using significant predictors from univariate analyses was constructed to model PR or better. **Results:** The analytic cohort included 1,242 patients (79.8% with PR or better; 20.8% with CR; 9.1% with PD). Baseline factors significantly associated with a PR or better included age <18 months (87.4% with PR or better vs. 78.7% if older; p=0.0103), age <5 years (82.0% vs. 70.6% if older; p<0.0001), INSS <Stage 4 (89.0% vs. 78.4% if Stage 4; p=0.0016), *MYCN* amplification (85.5% vs. 77.1% if non-amplified; p=0.0006), 1p loss of heterozygosity (LOH; 85.6% vs. 76.0% if no LOH; p=0.0085), no 11q LOH (84.8% vs. 70.9% if 11q LOH; p=0.0004), and high mitosis-karyorrhexis index (MKI); 84.5% vs. 77.5% if low-intermediate MKI; p=0.0098). On multivariate analysis (n=407), the absence of 11q LOH was the only factor that remained significantly associated with PR or better (odds ratio: 1.962 compared to 11q LOH; 95% confidence interval 1.104-3.487; p=0.0216). **Conclusions:** Clinical and biological factors are associated with differential response to Induction chemotherapy. These findings may further improve our ability to predict treatment response.

10533 Poster Session (Board #206), Sat, 8:00 AM-11:30 AM

The addition of cycles of irinotecan/temozolomide (i/T) to cycles of vincristine, doxorubicin, cyclophosphamide (VDC) and cycles of ifosfamide, etoposide (IE) for the treatment of Ewing sarcoma (ES). *First Author: Paul A. Meyers, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Treatment for ES in North America has evolved to include cycles of VDC and IE. A regimen including these 5 agents with interval dose compression has achieved 5 year EFS of 73% for localized ES. At Memorial Sloan Kettering (MSK) we have instead used the strategy of increasing doses of alkylating agents to achieve dose intensification and reported similar results. The combination of i/T given as irinotecan 20 mg/m2/day for 10 days with temozolomide 100 mg/m2/day for 5 days has achieved objective responses for patients who recur after initial therapy with the 5 drug combination. Our prospective protocol incorporates cycles of i/T with cycles of VDC and IE for the treatment of newly diagnosed patients with ES. **Methods:** We have enrolled patients with and without clinically detectable metastatic disease at initial presentation. For patients with localized ES we administer high dose alkylator therapy with 4 cycles of VDC and 3 cycles of IE, followed by 6 cycles of i/T. For patients who present with metastases we intercalate 10 cycles of i/T with the same 7 cycles of high dose alkylating agent therapy. **Results:** We have enrolled 22 patients with localized and 16 patients with metastatic ES. With a median followup of 14 (3-51) months, patients with localized ES have achieved a 3 year EFS of 95% and overall survival (OS) of 95%. With a median followup of 20 (8-51) months, patients with metastatic ES have achieved a 3 year EFS of 55% and OS of 70%. **Conclusions:** The addition of multiple cycles of i/T to conventional 5 drug therapy for ES is feasible and may be associated with an improved probability for both EFS and OS. Clinical trial information: NCT01864109.

10534 Poster Session (Board #207), Sat, 8:00 AM-11:30 AM

Rhabdomyosarcoma in the first year of life: outcome data from five trials and one registry of the Cooperative Weichteilsarkom Studiengruppe (CWS). *First Author: Monika Sparber-Sauer, Klinikum Stuttgart - Olgahospital, Stuttgart Cancer Center, Zentrum für Kinder-, Jugend- und Frauenmedizin, Pediatrics 5 (Oncology, Hematology, Immunology), Stuttgart, Germany*

Background: Infantile soft tissue sarcoma (STS) has been associated with worse survival than STS in older children. Age, histology, molecular phenotype and treatment adjustment according to age may affect the outcome of patients with rhabdomyosarcoma (RMS) diagnosed during the first year of life. **Methods:** The records of 5 trials and one registry, conducted by the Cooperative Studiengruppe (CWS) between 1981–2016, were reviewed to identify children diagnosed with RMS during the first year of life. Patient characteristics, treatment data and outcome were evaluated. **Results:** A total of 155 infants ≤ 12 months with histological diagnosis of RMS were identified, including 115 cases of embryonal RMS (RME), 38 cases of alveolar RMS (21/25 PAX7/3:FOXO1-positive (PF+)), 1 case of botryoid RMS and 1 case of spindle-cell RMS. 144 infants presented with localized disease (LD); 11 with metastatic disease (MD). 150 children received age- and weight-adapted chemotherapy (1/3 dose reduction in infants ≤6 months): VAIA/VACA/CEVAIE (n = 100), IVA/VA/VAC/other (n = 50). Resections were achieved R_0 (n = 64), R_1 (n = 37), R_2 (n = 37) and biopsies (n = 17). Adjuvant radiotherapy (RT) was administered to 37 children. After a median follow-up of 7.55 years [0.24- 30], the 5-year overall survival (OS) and event-free survival (EFS) rates were 66% and 49% for the whole group. Significant prognostic factors were LD (OS 69% vs 12% in MD, p = 0.000), tumor size and resection status. For patients with LD, tumor size and best resection (R_0/R_1/R_2) were no prognostic factors and RT did not improve survival. 2nd malignancy occurred in 6 infants. OS and EFS rates of newborns (≤1 month, n = 15) were significantly worse (31% and 17%, respectively) compared to those > 1 month and ≤ 12 months (n = 140, OS 69% and EFS 52%, p = 0.001 and 0.001). Children with RMA (41% and 24%) and/or PF+-RMS achieved significantly worse regarding OS and EFS (36% and 19%) than those diagnosed with RME (72% and 56%; p = 0.018 and 0.003). **Conclusions:** Survival of infants with RMS is comparable to older children. Metastatic disease, RMA histology/ PF+ status and age below 1 month are factors relevant for inferior outcome. RT did not improve survival in LD.

10535 Poster Session (Board #208), Sat, 8:00 AM-11:30 AM

Phase 1/2 intra-patient dose escalation study of vorinostat in children with relapsed solid tumor, lymphoma, or leukemia. *First Author: Cornelis Martinus van Tilburg, KiTZ Clinical Trial Unit, Hopp Children's Cancer Center at the NCT Heidelberg (KiTZ), German Cancer Research Center (DKFZ) and Heidelberg University Hospital, Heidelberg, Germany*

Background: In preclinical pediatric cancer models, the HDAC inhibitor vorinostat showed significant activity only at higher concentrations compared with those achieved with currently recommended dosing regimens. The aim of this trial was to intra-individually dose escalate to an individual maximum tolerated dose (MTD) in order to increase the likelihood of response whilst keeping toxicity acceptable. **Methods:** Children 3 – 18 years old with relapsed or therapy-refractory solid tumor, lymphoma or leukemia were eligible. In phase 1 an intra-patient dose (de)escalation was performed until the MTD was reached. After identification of MTD, patients did continue treatment in phase 2 at their individual MTD until progression. **Results:** Fifty-two patients were enrolled and 50 received treatment. 27/50 patients completed the intra-patient (de)escalation phase 1 part and entered phase 2. A safe starting dose of 130mg/m^2/day with weekly increments of 50mg/m^2 was determined (maximum: 580mg/m^2/day). 46/50 (92%) patients experienced treatment related AEs, in 44 patients (88%) ≥ CTCAE grade 3. Of the patients who reached phase 2, 24/27 patients (89%) experienced treatment related AEs, in 17 patients (63%) ≥ grade 3. Most of the grade 3-4 AEs were reversible hematologic toxicity (mostly thrombocytopenia), fatigue, nutrition and gastrointestinal disorders and weight loss. The median MTD was 280mg/m^2/day (range 130 - 580mg/m^2/day). Overall response rate (CR + PR + SD) in the phase 2 was 6/27 (22%). 5 patients stayed on treatment for > 12 months receiving doses of 280 – 580mg/m^2/day. 3 patients with histological high grade glioma and one with metastasized SETTLE tumor showed PR, one with a medulloblastoma showed prolonged SD. 1 patient was on drug for > 4 years. **Conclusions:** A safe starting dose of 130mg/m^2/day for individual dose escalation with weekly increments of 50mg/m^2 was identified. This resulted in higher drug exposure associated with responses and long-term disease stabilization confirming that activity can only be expected at doses higher than currently recommended. The toxicity profile was compatible with published adult and pediatric safety data. PK, PD and biomarker analysis are ongoing. Clinical trial information: NCT01422499.

10536 Poster Session (Board #209), Sat, 8:00 AM-11:30 AM

Phase 1 study of entrectinib (RXDX-101), a TRK, ROS1, and ALK inhibitor, in children, adolescents, and young adults with recurrent or refractory solid tumors. *First Author: Ami Vijay Desai, University of Chicago Medical Center, Comer Children's Hospital, Chicago, IL*

Background: Entrectinib (RXDX-101) inhibits TRKA/B/C, ROS1, and ALK tyrosine kinases with $IC_{50} < 2$ nM. *In vivo*, entrectinib is active in several fusion-driven solid tumor and TRKB-expressing neuroblastoma (NB) models. Central nervous system (CNS) penetration enables targeting of CNS metastases and primary tumors. Entrectinib has clinical activity in adults with malignancies harboring *NTRK1/2/3*, *ROS1*, or *ALK* gene fusions [Drilon 2017]. **Methods:** Patients (age 2-21 years) with recurrent or refractory extracranial solid tumors were eligible for this multicenter Phase 1 study. 4 doses levels (250, 400, 550, 750 mg/m^2) were evaluated using a 3+3 design to determine the recommended phase 2 dose (RP2D). Entrectinib capsules were administered orally, once daily, on continuous 4-week cycles. Adverse events were graded using CTCAE v4.03; response assessed by RECISTv1.1 and detailed pharmacokinetic sampling was completed. **Results:** 16 patients enrolled; 15 were evaluable (9 male, 6 female) with median (range) age 10 (4-20) years. Diagnoses included NB (n = 10), inflammatory myofibroblastic tumor (IMT; n = 2), salivary gland adenocarcinoma (n = 1), synovial sarcoma (n = 1), and infantile fibrosarcoma (IFS, n = 1). Somatic target gene fusions were identified in IMTs (*DCTN1-ALK, TFG-ROS1*) and IFS (*ETV6-NTRK3).* Dose-limiting toxicities included grade (G) 2 creatinine increase > 7 days in 1/6 patients receiving 550 mg/m^2 and 1 patient each with G2 dysgeusia/fatigue > 7 days and G3 pulmonary edema out of 3 patients receiving 750 mg/m^2, thus confirming the pediatric RP2D as 550 mg/m^2. Overall toxicity profile and drug exposure were comparable to the adult RP2D. 4 patients (2 IMT, 1 IFS, 1 NB) continue protocol therapy. All 3 fusion-positive patients have experienced an objective response. **Conclusions:** The RP2D of entrectinib in children, adolescents, and young adults with solid tumors is 550 mg/m^2 daily. Preliminary antitumor activity has been seen in gene fusion-positive patients. Entrectinib continues to be investigated in expansion cohorts of patients with primary CNS tumors, extracranial solid tumors harboring *NTRK*, *ROS1*, or *ALK* fusions, and patients with NB. Clinical trial information: NCT02650401.

10537 Poster Session (Board #210), Sat, 8:00 AM-11:30 AM

Phase 1 trial of trametinib alone and in combination with dabrafenib in children and adolescents with relapsed solid tumors or neurofibromatosis type 1 (NF1) progressive plexiform neurofibromas (PN). *First Author: Birgit Geoerger, Gustave Roussy, Villejuif, France*

Background: Mitogen-activated protein kinase (MAPK) pathway aberrations are common in cancer and NF1 PN. Dabrafenib, a BRAF inhibitor, is active in children with *BRAF* V600–mutant tumors; however, activation of MAPK signaling in *BRAF* WT cells increases skin toxicity. Trametinib, a MEK inhibitor, targets MAPK activation in tumors harboring *BRAF* fusions and *NF1* gene loss. This trial sought to establish the trametinib dose alone and in combination with dabrafenib in patients (pts) with relapsed solid tumors or progressive PN. **Methods:** Part A: safety and pharmacokinetics (PK) of trametinib (0.0125, 0.025, 0.04 mg/kg daily) were evaluated. Dose-limiting toxicity (DLT) during the first 4 wk and trough concentrations were used to determine the recommended dose (RD). Three age groups (< 2 y, 2-12 y, > 12 y) were evaluated based on initial PK; trametinib 0.032 mg/kg was assessed in pts < 6 y. Part C: pts with *BRAF* V600–mutant tumors received the trametinib RD in combination with 50% or 100% of the established age-specific dabrafenib RD. **Results:** Part A: 40 pts (median age, 8 y [range, 0-18 y]) were enrolled. Median treatment (Tx) duration was 81 wk (range, 3-124 wk); 21 (53%) continue on Tx. DLTs (mucositis [n = 3 overall]) occurred in 5/15 pts receiving 0.04 mg/kg and 3/19 receiving 0.025 mg/kg. Frequent Tx-related adverse events (TRAEs) were paronychia (58%), diarrhea (48%), and rash (45%). Tx-related serious AEs (TRSAEs) occurring in > 1 pt included hyponatremia and pyrexia (2 each). The trametinib RD is 0.025 mg/kg daily for pts ≥ 6 y and 0.032 mg/kg for pts < 6 y. Part C: 12 pts (median age, 12 y [range, 2-18 y]) were enrolled. No DLTs were observed at 50% or 100% of the dabrafenib age-specific RD in combination with trametinib 0.025 mg/kg in pts ≥ 6 y. Median Tx duration was 41 wk (range, 11-67 wk); 8 pts continue on Tx. Frequent TRAEs were rash (67%) and pyrexia (50%). Decreased ejection fraction (n = 2) was the only TRSAE in > 1 pt. Assessment of pts < 6 y is ongoing. **Conclusions:** Age-specific dose, safety, and tolerability of trametinib alone and combined with dabrafenib were defined for children and adolescents; $> 50\%$ of pts continue on Tx. Clinical trial information: NCT02124772.

10538 Poster Session (Board #211), Sat, 8:00 AM-11:30 AM

G_{D2} as a circulating tumor biomarker (CTB) for neuroblastoma (NBL). *First Author: Frank M. Balis, Children's Hospital of Philadelphia, Philadelphia, PA*

Background: CTBs that reflect tumor burden or viability can improve the accuracy and sensitivity of assessing tumor response in phase 2 trials and substantially shorten the timeline of phase 3 trials if they are predictive of relapse or survival. G_{D2} is a ganglioside present in the plasma membrane of NBL tumor cells, is measurable in the serum of patients with high-risk NBL, and could serve as a CTB. **Methods:** We developed and validated a sensitive and specific high-pressure liquid chromatography/tandem mass spectroscopy assay for G_{D2} in serum and plasma and quantified its circulating lipoforms that differ in the chain length of the fatty acid moiety (C_{18} and C_{20}) in the ceramide portion of the molecule. We measured G_{D2} lipoforms in serum or plasma from 40 normal children (controls) and pretreatment samples from 128 (86 high-risk) children with NBL and 8 to 12 children each with 10 other childhood cancers. **Results:** The C_{18} lipoform was the predominant circulating form of G_{D2} in controls and in patients with NBL. The median concentration of the C_{18} lipoform in children with high-risk NBL at diagnosis was 156 nM (range, 4-1060 nM), which was > 25-fold higher than the median concentration (5.6 nM) in controls. G_{D2} was not measurable (< 2.4 nM) in 16 of 40 controls, and the highest concentration in controls was 15 nM. G_{D2} was not elevated in children with 10 other childhood cancers except for medulloblastoma (median, 34 nM; range, 6-111 nM). *MYCN* amplification ($p < 0.0001$), high-risk disease ($p < 0.0001$), and INSS stage 4 ($p < 0.0001$) were associated with higher G_{D2} concentration. Median G_{D2} concentration in non-high-risk NBL was 9.9 nM. **Conclusions:** These preliminary data indicate that G_{D2} may be a sensitive and specific CTB for high-risk NBL. G_{D2} will be studied prospectively and longitudinally in new COG frontline, high-risk NBL treatment trials to determine if pretreatment G_{D2} concentration or change in G_{D2} concentration post-treatment are predictive of response or survival and if G_{D2} concentration is predictive of response to G_{D2}-targeted immunotherapy. Although our focus is on developing G_{D2} as a surrogate clinical trial endpoint, the associations noted above with other prognostic markers also suggest it may also be useful as a diagnostic or prognostic CTB.

10539 Poster Session (Board #212), Sat, 8:00 AM-11:30 AM

Immunotherapy with anti-GD2 antibody ch14.18/CHO±IL2 within the HR-NBL1/SIOPEN trial to improve outcome of high-risk neuroblastoma patients compared to historical controls. *First Author: Ruth Lydia Ladenstein, St. Anna Children's Hospital and Department of Paediatrics, Medical University, Vienna, Austria*

Background: Randomization of immunotherapy versus standard was not possible in the HR-NBL1/SIOPEN trial. In order to explore an impact of immunotherapy on outcome, we used trial patients prior to availability of ch14.18/CHO as control. **Methods:** Trial patients received rapid COJEC, two courses of TVD if needed, surgery, HDT/SCT (BuMel or CEM) and radiotherapy. MRD treatment (MRDT) consisted of isoretinoin alone from 2002 - 2009 (control population, CP) and from 2009 - 2013 with ch14.18/CHO (5 cycles ch14.18/CHO, ± IL2) (immunotherapy population, IP). Patients (844) were ≤9 months between diagnosis and HDT/SCT, PR or better prior to HDT/SCT and had no progression after HDT/SCT until start MRDT (median time 109 days) (CP 466, IP 378). Sex, age groups, stage 4 MycN amplified (MNA) and response prior HDT/SCT were balanced between cohorts. Imbalanced (IP vs CP) were metastatic compartments (MC > 1) [80% vs 71%; $p = 0.0034$)], TVD given [12% vs. 32%; $p < 0.001$], MNA localised disease [8% vs. 13% $p = 0.0019$], type of HDT = CEM [8% vs. 45%; $p < 0.001$)], time point of surgery $<$ day120 after diagnosis [60% vs. 73%; $p < 0.0001$] and radiotherapy given [94% vs. 88%; = 0.0034]. Median follow up was 5.8y (0.05-13.8y). **Results:** The 5y-EFS was 57%±3% for the IP and 42%± 2% for the CP ($p < 0.001$). Univariate analysis of risk factors identified no 5y-EFS difference for sex, stage 4 ± MNA and was borderline for radiation given (5y-EFS if yes: 50%±2%, no: 38%±6%, $p = 0.073$). Risk factors with 5y-EFS differences were age, stage, MC > 1, delayed surgery, response pre HDT/SCT and type of HDT. However, MVA analysis identified patients at a higher risk without immunotherapy ($p = 0.0002$, HR 1.573), with CEM ($p = 0.0029$; HR 1.431), response $<$ CR prior MRD ($p = 0.0043$, HR 1.494) and $>$ 1MC at diagnosis (< 0.001 HR 2.665). After adjustment for age, stage, MC, TVD and pre-MRD response, a benefit for immunotherapy was confirmed in BuMel- ($p = 0.0066$; HR 1,439) with 5yEFS of , 56±3% vs 48±3% (IP vs CP) and in CEM-treated patients ($p = 0.0107$; HR 2.334) with 5yEFS of 67±9% vs 35±3% (IP vs. CP). **Conclusions:** Introduction of ch14.18/CHO immunotherapy achieved a major improvement in outcomes for patients on the HR-NBL1 trial. Clinical trial information: NCT01704716.

10540 Poster Session (Board #213), Sat, 8:00 AM-11:30 AM

Cediranib phase II study in children with metastatic alveolar soft part sarcoma (ASPS). *First Author: John Glod, National Cancer Institute at the National Institutes of Health, Bethesda, MD*

Background: ASPS, a rare, highly vascular sarcoma with a clinically indolent course, frequently presents with metastases at diagnosis. Standard sarcoma chemotherapy is ineffective. Vascular endothelial growth factor (VEGF) is a promising therapeutic target. In a phase II trial of the VEGF receptor inhibitor cediranib for adults with ASPS, the partial response (PR) rate (RECIST v1.0) was 35% (15/43;95% CI:21-51%); (Kummar S,et al. ***J Clin Oncol*** 2013; **31**(18): 2296-302). We evaluated the objective-response rate [PR + complete response] of cediranib in the pediatric population (NCT00942877). **Methods:** Patients (pts) ≤16 years old (yo) with metastatic, unresectable ASPS received cediranib at the pediatric maximum tolerated dose of 12 mg/m^2 (≅70% of the fixed adult phase II dose of 30 mg) orally daily [1 cycle (cy) = 28 days]. Response was assessed every 2 cy (RECIST v1.0). A Simon two-stage optimal design (target response rate 35%, rule out 5%, alpha = 0.1, beta = 0.1) was used. With ≥ 1 response in 6 pts, enrollment would expand to 12 pts; with responses in ≥2/12pts, cediranib would be considered active. **Results:** 7 pts (4 female), median age 13 yo, (range 9-15), all with pulmonary metastases, enrolled on stage 1. Best response was stable disease (SD) (median cy number = 18). 2 pts were removed from study for disease progression (cy 4 and 5), and one pt for surgical resection of primary tumor (cy 16) per pt and local oncologist choice. 5 of 7 pts had SD for ≥14 months. 4 pts with SD remain on study after 18-44+ cy. Each of these pts had 1 (n = 3) or 2 (n = 1) cediranib dose reductions for grade 2 hypertension (n = 1, cy 2), fatigue (n = 2, cy 2), and proteinuria (n = 1, cy 38), and grade 3 ALT elevation (n = 1, cy 1). No growth plate toxicity was detected on MRI. **Conclusions:** Cediranib did not reach the target response rate in this small pediatric cohort; thus, no additional pts were enrolled. This is in contrast to the adult 35% PR rate. Pediatric dosing was 30% lower compared to adult dosing, which may have contributed to response differences. Prolonged SD was observed in 5 pts, but given the indolent nature of ASPS, SD cannot be clearly attributed to cediranib. Cediranib has an acceptable safety profile, with no growth plate toxicity, with several pts experiencing prolonged SD. Clinical trial information: NCT00942877.

10541 Poster Session (Board #214), Sat, 8:00 AM-11:30 AM

Phase 1 study of olaratumab as monotherapy and in combination with doxorubicin, vincristine/irinotecan, or high-dose ifosfamide in pediatric patients with relapsed or refractory solid tumors: Part A results. *First Author: Steven G. DuBois, Dana-Farber Cancer Institute/Boston Children's Cancer and Blood Disorders Center, Boston, MA*

Background: Olaratumab (O), a PDGFRα antagonist, is a targeted human IgG1 monoclonal antibody that specifically binds PDGFRα, blocking PDGF-AA, -BB, and -CC binding and receptor activation, and has improved survival outcomes in adults with advanced sarcoma. **Methods:** This ongoing Phase 1, multicenter, dose-escalation study (NCT02677116) enrolled patients (pts) aged < 18 years, with a diagnosis of relapsed or refractory solid tumors, to 2 dose levels (Parts A and B) of O combined with fixed doses of standard chemotherapy with doxorubicin (D), vincristine/irinotecan (VI), or high-dose ifosfamide (I). Pts in Part A received 1 cycle (21 days) of O monotherapy at 15mg/kg IV on Days 1 and 8 followed by O + (D, VI, or I) for subsequent 21-day cycles. Each combination arm was complete when 6 pts received 2 full cycles. The primary objective of Part A was to determine the safety and tolerability of O 15mg/kg + (D, VI, or I) based on any dose-limiting toxicity (DLT) and O serum exposure matching between adult and pediatric pts. **Results:** Pts enrolled by O + chemotherapy regimen (n) were D (11), VI (10), and I (9). One pt (3.3%) experienced a DLT during the DLT period (Cycles 1 and 2), which consisted of grade (G) 4 elevated ALT while on O monotherapy. No ≥G3 infusion- or cardiac-related treatment emergent adverse events (AEs) occurred. Treatment-related AEs (TRAEs) ≥G3 reported in ≥2 pts are presented (Table). Serum concentrations of O in pediatric pts were within expected ranges based on adult exposure. **Conclusions:** Based on Part A results,O 15mg/kg as monotherapy or in combination with D, VI, or I is tolerable in pediatric pts with relapsed or refractory solid tumors. Part B of this trial is currently enrolling. Clinical trial information: NCT02677116.

10542 Poster Session (Board #215), Sat, 8:00 AM-11:30 AM

Phase I multicenter trial of CUDC-907 in children and young adults with relapsed/refractory solid tumors, CNS tumors, and lymphomas. *First Author: David Stephen Shulman, Dana-Farber Cancer Institute/Boston Children's Hospital, Boston, MA*

Background: CUDC-907 is a first-in-class small molecule inhibitor of histone deacetylases and phosphatidylinositol-3-kinases. Data from pediatric preclinical models, and adult clinical studies suggest that CUDC-907 can downregulate Myc/Mycn, providing a potential therapeutic strategy for Myc/Mycn-driven pediatric tumors. **Methods:** Using a 3+3 dose escalation design, CUDC-907 was administered at 3 dose levels to patients 1-21 years of age with relapsed/refractory solid tumors, brain tumors and lymphomas (NCT02909777). Primary objectives were to determine the pediatric recommended phase II dose (RP2D), describe toxicities, and describe PK parameters. Other endpoints included antitumor activity and pharmacodynamic effects. Patients received CUDC-907 orally on a 5 days on / 2 days off ("5/2") schedule in 28-day cycles, with a pediatric mini-tab formulation for children who could not swallow pills. **Results:** As of 11/16/2017, 15 patients enrolled, with a median age of 15 (4.6-20.9) years. Diagnoses included: osteosarcoma (n = 4); alveolar rhabdomyosarcoma (n = 3); DIPG (n = 2); ependymoma (n = 2); Ewing sarcoma (n = 2); CNS germ cell tumor (n = 1); and alveolar soft part sarcoma (n = 1). Patients received a median of 2 (1-7+) cycles. No DLTs were observed in 3 evaluable patients each at dose levels 1 and 2. A single first cycle DLT (grade 3 metabolic acidosis) was observed in 1 of 6 evaluable patients at dose level 3 (45 mg/m2; 128% of the adult RP2D). The most common treatment-related AEs were: thrombocytopenia (87%), nausea (80%), lymphopenia (80%), diarrhea (73%), leukopenia (73%), anemia (67%), tachycardia (67%), vomiting (67%), fatigue (67%), and anorexia (67%). The mean T_{max} was 2.5 hrs and $T_{1/2}$ was 1.4 hrs. No objective responses were seen. One patient with Ewing sarcoma and one patient with ependymoma had stable disease for 6 and 7+ cycles, respectively. Pharmacodynamic studies are pending. **Conclusions:** CUDC-907 was well tolerated with a pediatric RP2D of 45 mg/m2 administered orally on a 5/2 schedule. An expansion stage will evaluate this dose in groups of interest: mature B-cell lymphoma; *MYCN* amplified neuroblastoma; and solid tumors with *MYC/MYCN* amplification/high-copy gain. Clinical trial information: NCT02909777.

10543 Poster Session (Board #216), Sat, 8:00 AM-11:30 AM

First-in-child trial of celyvir (autologous mesenchymal stem cells carrying the oncolytic virus ICOVIR-5) in patients with relapsed and refractory pediatric solid tumors. *First Author: Manuel Ramirez, Hospital Universitario Niño Jesús, Madrid, Spain*

Background: Outcome for relapsed/refractory pediatric solid tumors is dismal so there is an urgent need for new therapies. Immunotherapy with oncolytic viruses show great promise in adult cancers but have scarcely been explored in children. The results of a first-in-man, first-in-child trial (NCT01844661) using Celyvir, autologous mesenchymal stem cells (MSC) carrying an oncolytic adenovirus are presented. **Methods:** Patients (1-18 yrs) with advanced relapsed/refractory solid tumors, adequate organ function and performance status were included. Autologous MSCs were collected from a bone marrow aspirate (BMA). Celyvir was manufactured within 6 weeks from BMA and then given IV weekly for 6 weeks at doses from 2x10^6 cells/Kg and 2x10^4 viral particles (vp) per cell. Dose was based in a previous compassionate use program (Melen et al. 2016;371:161). Primary objective was to determine safety and toxicity. Secondary objective was preliminary antitumor activity. Biomarker studies included oncolytic viral replication and immune response. **Results:** Fifteen patients had BMA performed, 6 progressed before treatment could be started, 9 received Celyvir and completed the planned 6 weeks treatment and were evaluable. The total number of cells administered ranged from 89 to 468 million, 1,78 – 8,36x10^{12} vp. Celyvir was well tolerated showing no grade 3/4 toxicities. Most frequent adverse event was pyrexia (37,5% patients). Adenoviral replication detected by PCR was found in all but two patients and humoral antiadenoviral response was detected in all but one patient. Circulating T lymphocytes numbers raised with Celyvir administration, mostly CD8 effector cells. No radiological responses were seen. Two patients with neuroblastoma showed disease stabilization per RECIST, one of them continued on treatment for up to 6 additional weeks. **Conclusions:** Celyvir, the combination of MSCs and oncolytic adenovirus is safe and warrants further evaluation in the pediatric phase 2 setting. The use of MSCs may be a strategy to increase the amount of oncolytic virus administered to patients, minimizing toxicities and avoiding direct tumor injections. Clinical trial information: NCT01844661.

10544 Poster Session (Board #217), Sat, 8:00 AM-11:30 AM

Various checkpoint proteins, and tumor infiltrating lymphocytes in common pediatric solid tumors: Possibilities for novel immunotherapy. *First Author: Kazuhiro Mochizuki, Fukushima Medical University, Fukushima, Japan*

Background: Despite the significant improvements of long-term survival rates for pediatric cancers, prognosis of refractory/relapsed solid tumors are extremely poor, and novel strategies are desired. Recently, tumor immunotherapies such as anti-PD-1/PD-L1 antibodies have been recognized as an effective option for many intractable cancers. However, there are still a substantial number of patients who do not show objective responses to the PD-1/ PL-L1 blockades. On the other hand, like PD-1/PD-L1, other immune checkpoint pathways such as TIM3/GAL9, LAG3/MHC-II, and BTLA/HVEM have been reported to regulate immune responses in tumor microenvironment. Although these pathways could be alternative targets for novel immune therapies, almost no information is available whether pediatric solid tumors express these molecules. Herein, we characterized the expression of various checkpoint proteins, and tumor infiltrating lymphocytes (TILs) in tumor specimens from untreated children with common pediatric solid tumors. **Methods:** Sections cut from formalin-fixed, paraffin-embedded tissue blocks were processed and evaluated for GAL9, MHC-II, and HVEM on tumor cells, and TIM3, LAG3, and BTLA on TILs by immunohistochemistry. **Results:** Specimens from 65 patients, including 16 neuroblastomas, 11 rhabdomyosarcomas, 12 osteosarcomas, 10 hepatoblastomas, 10 Wilms tumors, and 6 Ewing sarcomas were evaluated. Although in neuroblastoma and Ewing sarcoma, checkpoint proteins on the tumor were rarely detected, 64% of the patients with rhabdomyosarcoma and 83% with osteosarcoma expressed moderate to high levels of HVEM. TILs were detected in all tumor types among which CD8 positive T cells were the most dominant population following CD4 positive T cells. Interestingly, in rhabdomyosarcoma, and osteosarcoma, more than 70% of the TILs expressed moderate to high levels of BTLA. **Conclusions:** A subset of pediatric solid tumors demonstrated tumor associated checkpoint expressions, and TILs also expressed corresponding ligands of the checkpoints, which suggested immunogenic environments may be created, and the checkpoint blockades could induce favorable immune responses.

10545 Poster Session (Board #218), Sat, 8:00 AM-11:30 AM

Visceral primary non-rhabdomyosarcoma soft tissue sarcoma (NRSTS) in patients < 30 years of age: Findings of Children's Oncology Group (COG) study ARST0332. *First Author: Meena Kadapakkam, Stanford University School of Medicine, Stanford, CA*

Background: Little is known about the clinical features, optimal management, and prognosis of young patients with primary visceral NRSTS. **Methods:** We analyzed clinical features, treatment, and outcomes of patients with visceral tumors (defined as intrathoracic, intraperitoneal, retroperitoneal, pelvic and perineal) enrolled in COG ARST0332, which evaluated a risk-based treatment strategy for NRSTS patients aged < 30 years (surgery +/- radiotherapy +/- chemotherapy based on tumor size, grade, extent of surgery, and extent of metastases). Variables analyzed included gender, age, race, ethnicity, tumor grade/size/invasiveness, extent of metastases, extent of surgery, and event-free and overall survival. **Results:** Visceral tumors occurred in 114/551 enrolled patients (21%), were most likely to occur in patients > 10 years (67%) and be > 5 cm (92%), high-grade (89% by POG, 73% by FNCLCC), non-metastatic (78%), and grossly resected prior to study entry (58%). Compared to patients with non-visceral tumors, those with visceral tumors were more likely to have high-risk features: high POG and FNCLCC grade, > 5 cm diameter, deep location, and invasiveness (all $p < 0.001$), metastases ($p = 0.03$), and microscopic residual tumor after gross total resection ($p = 0.01$). Due to these features, they were more often assigned to intermediate-/high-risk therapy (87% vs. 50%). Event-free and overall survival by risk group were 85.1% and 82.5% (low), 67.9% and 82.8% (intermediate), and 44.0% and 44.0% (high), and did not differ significantly from outcomes for the rest of the population. **Conclusions:** Patients with primary visceral tumors were more likely than those with tumors at other anatomic sites to have high risk features such as > 5 cm tumor diameter, high grade, deep location, invasiveness, metastases, and microscopic disease after gross resection. However, with risk-adapted therapy, their event free and overall survival were similar to those of patients with non-visceral tumors. Clinical trial information: NCT00346164.

10546 Poster Session (Board #219), Sat, 8:00 AM-11:30 AM

Risk group accurately predicts outcome in primary extremity non-rhabdomyosarcoma soft tissue sarcomas (NRSTS) in patients <30 years of age: Findings from Children's Oncology Group study ARST0332. *First Author: Sara Regina Kreimer, Stanford University School of Medicine, Stanford, CA*

Background: Data are limited on primary extremity NRSTS in pediatric patients. **Methods:** This ARST0332 subset analysis evaluated the clinical features and outcomes of extremity (including shoulder/hip girdle) NRSTS in < 30 year old patients risk-stratified to receive surgery +/- radiotherapy +/- chemotherapy based on clinicopathologic characteristics including tumor size, grade, extent of surgery, and presence of metastases. Other variables analyzed included age, gender, race, tumor invasiveness, and depth. **Results:** Primary extremity tumors comprised 297/551 cases (100 upper and 197 lower extremity) treated with surgery only (n = 137), adjuvant radiotherapy (n = 9), adjuvant chemoradiotherapy (n = 38), or neoadjuvant chemoradiotherapy followed by surgery if feasible (n = 113). Extremity site correlated with older age ($p = 0.0059$), diameter < 5 cm ($p = 0.0421$), lower grade ($p < 0.0001$), superficial location ($p = 0.0314$), and non-invasiveness ($p < 0.0001$). However, among patients with extremity tumors, older patients more commonly had > 5 cm ($p < 0.0001$), deep ($p = 0.0010$), invasive ($p = 0.0037$) tumors, and distant metastases ($p = 0.0003$). Estimated 5-year cumulative incidence of local and distant recurrence was 5% and 20%, respectively. Five-year overall survival (OS) for low-, intermediate- and high-risk patients was 96.7%, 78%, and 25.4%, respectively, and was not statistically significantly different than for non-extremity tumors. Older age, size > 5 cm, invasiveness, and higher risk group predicted inferior event-free survival; only higher risk group predicted inferior OS. **Conclusions:** Although extremity NRSTS are more likely to have low-risk features (size < 5 cm, lower grade, superficial location, non-invasiveness) compared to non-extremity tumors, their outcomes are similar with risk-adapted therapy. Older patients had more high-risk features. Risk group was the most important predictor of overall survival. Clinical trial information: NCT00346164.

10547 Poster Session (Board #220), Sat, 8:00 AM-11:30 AM

Nasopharengeal carcinoma in children: Demographic, clinical, therapeutic characteristics and long term outcome of 97 patients. *First Author: Rejin Kebudi, Istanbul University, Cerrahpasa Faculty of Medicine and Oncology Institute, Pediatric Hematology-Oncology, Istanbul, Turkey*

Background: The aim of this study is to evaluate the demographic, clinical and therapeutic characteristics and long-term outcome in childhood nasopharyngeal carcinoma (NPC) in a single center. **Methods:** Data of 97 patients < 18 years with NPC, treated in the Istanbul University Oncology Institute from November 1989 to January 2018 were evaluated retrospectively. All patients received three courses of neoadjuvant chemotherapy (1989-1991; cisplatinum, 5-fluorouracil; 1992-2008: Bleomycin, epirubicin and cisplatinum- BEP; since 2008-EP) followed by radiotherapy given both to the primary tumor and to the metastatic cervical lymph nodes. **Results:** Sixty-nine boys and 28 girls (M:F = 2.5) with a median age of 14 yrs (6-18), presented mostly with a lump in the neck, headache, and ear and nose problems. Median follow-up was 83 months (3 months-26.6 years). Ninety percent of the biopsies of NPC were WHO type III tumors. Most patients had advanced stage tumors, 5 had distant metastatis. Chemotherapy was followed with radiotherapy 60-66 Gy to the primary tumor and involved lymph nodes, and 50-54Gy to the uninvolved cervical nodal region. The 10-year overall survival (OS) rate was 79%. There was no significant difference in OS in patients who received BEP or EP. Seventeen patients died, 2 due to accident/suicide, 3 with second primary cancer, 12 with recurrent/progressive disease. Seven second malignancies developed in six patients, six in the irradiated field at a median of 12 years (5- 25 years). Late effects included hypothyroidism, neck fibrosis, xerostomia, bony hypoplasia, skin problems and hearing loss. **Conclusions:** Children with advanced NPC treated with neoadjuvant chemotherapy and radiotherapy have a high locoregional control rate and much higher long-term survival (OS 79 %) than that reported in our center before 1990's when most recieved only radiotherapy (46%) or radiotherapy and adjuvant chemotherapy (58 %) (IJ Radiation Oncology Biol Phys 1996). Neoadjuvant therapy with EP chemotherapy seems to be as effective as BEP. Survivors should be followed for long-term morbidities, including second malignancies.

10548 Poster Session (Board #221), Sat, 8:00 AM-11:30 AM

Outcomes for young children with molecularly defined ependymoma treated on the multi-institutional SJYC07 clinical trial. *First Author: Santhosh Upadhyaya, St. Jude Children's Research Hospital, Memphis, TN*

Background: Retrospective reports of poor outcomes of ependymoma (EPN) subgroups, posterior fossa A (PF-EPN-A) and supratentorial *C11orf95–RELA* (ST-EPN-RELA), need confirmation in prospective trials. **Methods:** Fifty-four children (median age 1.6 y, range 0.4–3.1) with newly diagnosed EPN (WHO grade II/ III) were treated (2008–2016) with maximal safe surgical resection + chemotherapy (high-dose methotrexate, vincristine, cisplatin and cyclophosphamide), consolidation using focal conformal radiation therapy (RT) to 54Gy (M0) or additional cyclophosphamide/topotecan with no RT (M+) and 6 months of oral maintenance chemotherapy. DNA methylation was performed using Infinium MethylationEPIC BeadChip and profiled on the DKFZ MN2.0 classifier. Fluorescent in-situ hybridization was used to determine tumor 1q status. **Results:** No participant had imaging evidence of metastatic disease at diagnosis (M0 = 40, M1 = 1, CSF not obtained = 13). At a median follow-up of 3.6 y (range, 1.0-9.3), 49 patients (91%) were alive with a 4-y PFS = 77.0%±7.5% and OS = 91.3%±5.2%. There was no significant difference in outcomes by subgroup [4-y PFS: PF-EPN-A (n = 42), 74.3%±8.2%; ST-EPN-RELA (n = 8), 80%±20.7%; ST-EPN-YAP (n = 4), 100%, p = 0.42]. Five patients with PF-EPN-A had 1q gain but no difference in outcome (p = 0.59 for OS and p = 0.15 for PFS). For 6 patients with subtotal resection (STR) prior to RT, outcome was inferior to those of the 48 with gross-total or near-total resection (4-y PFS = 27.8%±16.7% vs 81.7%±7.3%, p = 0.047). Fourteen patients experienced progression at a median time of 28 mos (range, 1.7m–7.3 y). Recurrence was distant (n = 7), local (n = 6), or combined (n = 1), 3/14 recurred at 6 (n = 2) and 7 years post diagnosis. **Conclusions:** In a uniformly treated, prospective EPN cohort, we found no significant difference in PFS or OS by molecular subgroup; however, the number of ST-EPN-RELA was small. In our data, 1q was not associated with outcome in PF-EPN-A, though only 5 subjects had 1q gain. Patients with STR prior to RT had inferior outcomes. Close surveillance and follow-up beyond 5 years is warranted due to risk of metastasis and late progression. Clinical trial information: NCT00602667.

10549 Poster Session (Board #222), Sat, 8:00 AM-11:30 AM

Final results of the phase II, single arm trial of irinotecan and cisplatin in children with high-risk glial tumors. *First Author: Ofelia Cruz, Hospital Sant Joan de Déu, Esplugues Llobregat-Barcelona, Spain*

Background: We conducted an open label, single arm phase II clinical trial with irinotecan and cisplatin (I/C) for pediatric patients with glial tumors (EudraCT:2009-010742-59). **Methods:** Patients diagnosed with high-risk (HR) gliomas at diagnosis (HGG, Ependymomas, DIPG, or HR-LGG) received sixteen weekly outpatient iv cycles of Cisplatin (30mg/m2) and Irinotecan (65mg/m2). Malignant gliomas received radiation upon progression. Objective response was evaluated by MRI volumetric analysis. Clinical and neurological changes were assessed. **Results:** From November 2009 until December 2012 39 patients aged 7m to 17y (mean 84 months) diagnosed with DIPG (n = 7); HGG (n = 5); Ependymoma (n = 6); atypical neurocytoma (n = 1); LGG (n = 22); pilocytic (n = 7) or pilomyxoid Astrocytoma (n = 1); Astrocytoma NOS (n = 5); Ganglioglioma (n = 2); and NF1 related LGG (n = 3) were included. Most frequent events were nausea/vomiting (5/39 grade $>$ 2); 17 patients (43.6%) with grade-1 diarrhea. Three of 31 (9.7%) evaluable patients developed hypoacusia, all grade 1. Five (45.5%) patients with HGG, 1 relapsed HGG (100%), 7 DIPG (100%) and 3 LGG (15%) progressed during treatment. Objective response rate (ORR) at the end of therapy (week 21) is 54.4% for HGG; 0% for DIPG; and 85% for HR-LGG. After a median follow-up of 67.5 months OS/EFS for relapsed HGG and DIPG is 0%/0%; for high-grade glial tumors 62%/23%; and 95%/43% for HR-LGG. Radiation was avoided in 19 of 20 HR-LGG patients. **Conclusions:** The I/C regimen was well tolerated and showed anti-tumor activity and clinical benefit for children with HR-LGG. Clinical trial information: NCT01574092.

10550 Poster Session (Board #223), Sat, 8:00 AM-11:30 AM

Risk prediction based on post induction bone marrow response and genomic profile: A new way to stratify stage M neuroblastoma patients? *First Author: Stefan Fiedler, St. Anna Kinderspital, Veinna, Austria*

Background: So far, and apart from minor adaptations, high-risk neuroblastoma patients have been treated uniformly by not taking biological features of the tumor into consideration. To mend this oversight and address the lack of biological data, we evaluated the prognostic relevance of a combined analysis of genomic aberrations of tumor cells and minimal residual disease (MRD) of stage M neuroblastoma patients. **Methods:** Diagnostic/post-induction bone marrow (BM) samples from 115 (83 fulfilled all criteria) stage M patients enrolled in the HR-NBL1/SIOPEN high-risk neuroblastoma trial were automatically searched for GD_2/CD56/DAPI positive disseminated tumor cells (DTCs), which provided excellent sensitivity and specificity. Information on somatic copy-number aberrations (SCNAs), *MYCN* amplification, aberrations in *ATRX*, *TERT*, and *PTPRD* genes from 139 patients was generated by high-density single-nucleotide polymorphism (SNP) arrays. **Results:** The 3-year event-free survival (EFS) of 184 patients was 39±4% with a 3-year cumulative incidence of relapse (CIR) of 56±6% (median observation time: 55.5 months). BM-MRD negative patients had a 3-year EFS of 67±9% (CIR:39±7%), whereas non-clearing patients had only 27±7% EFS (CIR:71±7%) (p = 0.001). Genomic analysis found a higher relapse incidence in patients whose tumors showed a gain/loss on chromosome 1q and/or aberrations in the *TERT* and/or *PTPRD* genes. Patients lacking these genomic markers and with BM clearing had the most favorable outcome (3-year EFS 92±7%) whilst those with two or more of the above mentioned genomic markers and positive BM-MRD fell into the ultra-high risk group (3-year EFS of 0%; p = $<$ 0.001). **Conclusions:** Combination of BM-MRD monitoring and genomic analysis enables early risk assessment and merits further evaluation.

10551 Poster Session (Board #224), Sat, 8:00 AM-11:30 AM

Pediatric preclinical testing consortium evaluation of the EZH2 inhibitor tazemetostat in orthotopic PDX models of pediatric brain tumors. *First Author: Xiao-Nan Li, Laboratory of Molecular Neuro-Oncology, Program of Preclinical Neuro-Oncology Research, Texas Children's Cancer Center, Baylor College of Medicine, Houston, TX*

Background: Tazemetostat (EPZ-6438) is an EZH2 inhibitor that has entered clinical trials both in pediatric and adult patients. Over-expression of EZH2, the catalytic subunit of Polycomb Repressive Complex 2 that catalyzes H3K27me3, has been detected in a series of pediatric malignant brain tumors. **Methods:** Expression of EZH2 mRNA was examined in 23 patient derived orthotopic xenograft (PDOX) mouse models (10 GBMs, 11 medulloblastomas and 1 ATRT) with comparison to normal tissue levels. H3K27me3 was evaluated with immunohistochemical staining and Western blotting. Tazemetostat (250 mg/kg and 400 mg/kg) was tested in 4 PDOX models (1 GBM, 2 medulloblastomas and 1 ATRT) both as a single agent and in combination with cisplatin (5mg/kg days 8 and 11) and/or radiation (2 Gy/day x 5 days). Kaplan-Meier estimate of median time-to-event, ratio in median time-to-event between the treated and control groups (EFS T/C), and EFS p values were calculated and compared between the treatment groups. **Results:** Over-expression of EZH2 mRNA was detected in all GBM models (34.6±12.7) and medulloblastoma models (6.2±1.7 in group 3, 6.0±2.4 in group 4) accompanied by increased H3K27me3. INI1 mutation was confirmed in the ATRT model. In 3/4 models, tazemetostat at 250 mg/kg caused significant extension of median survival times ($P<$ 0.05), with EFS T/C ranging from 1.32 to 1.39. Increasing drug dose from 250mg/kg to 400mg/kg resulted in significant EFS prolongation only for the ATRT model (EFS T/C 1.39 vs 2.01). When compared with cisplatin and radiation used alone, tazemetostat was not significantly more active. When combined with cisplatin and/or radiation, tazemetostat did not significantly prolong survival compared to the standard therapy used alone. A group 3 medulloblastoma was not responsive to any treatment tested. **Conclusions:** Tazemetostat prolonged survival times in 3/4 PDOX models tested, with the greatest treatment effect observed in the INI1 mutant ATRT model at the higher 400 mg/kg dose. These data are consistent with the BBB in these PDOX models not preventing anti-tumor activity of tazemetostat. The addition of tazemetostat to standard therapies did not lead to improved survival.

10552 Poster Session (Board #225), Sat, 8:00 AM-11:30 AM

Preclinical effect of selinexor (KPT-330), a selective inhibitor of nuclear export, in pediatric rhabdoid tumors. *First Author: Lianna Jean Marks, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Malignant rhabdoid tumors (MRTs) are rare, aggressive pediatric solid tumors characterized by a 22q11 chromosome rearrangement that inactivates the SMARCB1 gene. Outcomes remain poor despite multimodality treatment. MRTs are among the most genomically stable cancers and lack therapeutically targetable genetic mutations. We used the Virtual Inference of Protein-activity by Enriched Regulon analysis (VIPER) algorithm to computationally infer protein activity from MRT whole transcriptomic data available in the TARGET database to identify candidate non-genetically encoded vulnerabilities. This approach identified markedly aberrant activation of the nuclear export protein Exportin-1 (XPO1) in MRTs compared to other tumor types. We hypothesized that MRTs may be dependent on high XPO1 activity and this dependence can be co-opted as a novel non-oncogene directed therapeutic approach using the XPO1 inhibitor selinexor. **Methods:** A panel of 6 MRT and 3 atypical teratoid/rhabdoid tumor (ATRT) cell lines were used for *in vitro* studies. Two patient-derived xenograft (PDX) mouse models of MRT were treated with selinexor to determine anti-tumor effects. **Results:** All MRT cell lines demonstrated marked baseline activation of XPO1. The median IC_{50} following 72 hour selinexor treatment was 200 nM (IQR 175-435 nM) for MRT, 460 nM (IQR 400 nM-1.4 μM) for ATRT and 1.1 μM (IQR 580 nM-1.4 μM) for 5 non-MRT cell lines. There was a correlation between inferred XPO1 activity and IC_{50} with cell lines with the highest inferred activity being the most sensitive to selinexor. Treatment with selinexor *in vitro* led to cell cycle arrest and induction of apoptosis in MRT cell lines. Post-perturbation RNAseq of selinexor treated cell lines with VIPER dynamic protein activity inference demonstrated decreased activity of XPO1, SWI/SNF complex proteins, kinetochore regulators and cell cycle regulators. *In vivo* treatment of two MRT PDXs with oral selinexor for 15 days significantly inhibited tumor growth in both models ($p < 0.0001$ and $p = 0.0002$). **Conclusions:** Selinexor demonstrates efficacy in preclinical models of MRT. These results supports further investigation of selinexor in a phase II study in children with MRT.

10553 Poster Session (Board #226), Sat, 8:00 AM-11:30 AM

Identification and validation of a 24-gene expression signature for subtype classification of medulloblastoma. *First Author: Qinghua Xu, Institute of Machine Learning and Systems Biology, College of Electronics and Information Engineering, Tongji University, Shanghai, China*

Background: Medulloblastoma is the most common malignant brain tumor in children accounting for about 10% of all pediatric cancer deaths. According to the 2016 WHO Classification, four molecular subtypes of medulloblastoma including WNT, SHH, Group 3 and Group 4 were characterized by high-throughput gene expression profiling. These molecular subtypes display distinct clinical, demographic and genetic features that are associated with prognostic and therapeutic differences. Because it is currently impractical to perform microarray analysis in clinical settings, distinguishing the four molecular subgroups of medulloblastoma in the daily treatment of patients, as well in the setting of clinical trials, remains an important challenge. **Methods:** Three medulloblastoma microarray datasets were curated to perform integrative analysis. To identify a reliable biomarker, a training - validating approach were adopted in this study. The gene expression profiles of 103 samples were selected as a training set for signature identification. Additional 358 samples were used for signature validation.The Gene Ontology and KEGG pathway analysis were performed to reveal the biological features of candidate genes. **Results:** A 24-gene expression signature derived from the training set was strongly associated with the molecular subtypes of medulloblastoma. The 24-gene expression signature was validated in 8 WNT, 61 SHH, 62 Group 3 and 227 Group 4 samples. With the 24-gene expression signature, 8 samples were classified as WNT, 63 as SHH, 73 as Group 3 and 214 as Group 4. The gene expression-based assignments reached a 95.5% overall agreement with the reference diagnoses (342 of 358; 95% CI: 0.928 to 0.974). Sensitivity ranged from 94% to 100%, while specificity ranged from 96% to 100%. The functional enrichment analysis showed that 24 genes were significantly associated with signal transduction and WNT signaling pathway. **Conclusions:** A 24-gene expression signature that could accurately discriminate molecular subtypes of medulloblastoma was identified in this study. Our results may prompt further development of this gene expression signature into a molecular assay amenable to routine clinical practice.

10554 Poster Session (Board #227), Sat, 8:00 AM-11:30 AM

Plasma cell-free DNA for noninvasive molecular profiling in high-risk stage 4 neuroblastoma. *First Author: Prachi Kothari, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Cell-free DNA (cfDNA) allows real-time molecular analysis of solid tumors. Neuroblastoma, the most common extracranial pediatric solid tumor, is known to have a higher mutational burden at relapse. In this study, we evaluate the value of cfDNA profiling in a cohort of 21 high-risk stage 4 neuroblastoma (NB) patients. **Methods:** Plasma cfDNA samples were collected near diagnosis or at time of relapse from 21 patients. FISH analysis confirmed 5/21 patients were MYCN amplified. Tumor mutational profiles are known from targeted NGS analysis in 19/21 patients. Plasma cfDNA was analyzed by MSK-IMPACT (468 genes panel) to profile somatic mutations, and shallow whole genome sequencing (sWGS) to look for MYCN amplification. We also evaluated the utility of sWGS to assess tumor-derived mutant allele fractions (MAF) in cfDNA using genomewide z-scores (GWZ). Matched control samples were used to filter germline variants. **Results:** We detected somatic mutations in tumor tissue and cfDNA of 17/19 and 12/21 patients, respectively. These included recurrent drivers such as ALK and ATRX. In 5 patients with MYCN-amplified NB, sWGS sequencing confirmed the same finding in 4. The patients with a GWZ above 2.5 at the time of blood draw were associated with a decreased overall survival. In 1 patient, longitudinal samples were collected after 1 cycle of chemotherapy and pre-/post-surgery, the GWZ decreased as the patient responded to therapy. Two patients with GWZ > 5 (MAF~10%) were selected for WES to perform more comprehensive analysis. WES revealed FGFR1, ARID1A and FOXP1 mutations which have been reported in relapsed high-risk NB patients. Mutational signature analysis using WES data from cfDNA also revealed signature 18 that has previously been reported predominantly in neuroblastoma. **Conclusions:** This study shows the utility of cfDNA analysis through multiple platforms to noninvasively profile the genetic heterogeneity of neuroblastoma, reveal somatic copy number alterations and monitor response to therapy. These findings call for cfDNA analysis to be incorporated in clinical trial to further evaluate its utility for clinical management of NB patients.

10555 Poster Session (Board #228), Sat, 8:00 AM-11:30 AM

Prospective study of ophthalmic artery chemosurgery (OAC) as alternative to enucleation in retinoblastoma. *First Author: Isabelle Aerts, Institut Curie, Paris, France*

Background: Over the past twenty-five years, the introduction of systemic chemotherapy combined to local treatments has enabled to dramatically increase globe retention for retinoblastoma (RB) patients (pts) without using external beam radiation (EBR). OAC has more recently emerged as a primary conservative treatment of RB. **Methods:** We conducted a prospective phase II non randomized study to determine (i) the efficacy of Melphalan OAC in terms of globe salvage rates, without EBR 18 months after inclusion, (ii) patient survival and (iii) adverse events. Pts with unilateral RB group B, C or D without diffuse vitreous seeding or very asymetric bilateral RB including one group D eye were eligible. Pts were nationally referred to Institut Curie and treated by OAC at the Interventional Neuroradiology Department of the Fondation Rothschild. **Results:** Between February 2012 and December 2016, 39 pts with unilateral RB classified by the International Classification of Retinoblastoma as Group B (10.3%), Group C (33.3%), Group D (56.4%), were included. Two pts did not receive OAC, one due to initial catheterization failure, the second to prolonged general anesthesia contra-indication (severe RSV bronchiolitis). Median age at OAC was 19.3 months (3.2-61.6). Median number of OAC cycles was 4 (range 1-6). For 31 pts, OAC was associated to ophthalmological local treatment, starting after the second cycle, by diode laser (31) or cryotherapy (10). All pts are alive, with a median follow-up of 27.1 months from inclusion (2.9 -60.2). Twelve pts did not receive the planed complete treatment: 2 because of secondary catheterization failure, 1 for progressive disease, 3 for medical decision, 4 for intra-arterial procedure related serious complications, 1 for ptosis, 1 for retinal hemorrhage. Twelve serious adverse events were declared including 4 vascular retinal occlusions. 8 pts presented leucopenia. No extraocular RB, second cancer or life-threatening complication occurred. As follow-up of the last pts is actually under 18 months, enucleation rate cannot be yet assessed. **Conclusions:** For advanced RB focal OAC is feasible and generally well tolerated but may expose to some systemic and retinal vascular toxicity. Clinical trial information: NCT02866136.

10556 Poster Session (Board #229), Sat, 8:00 AM-11:30 AM

ADVL1513: Results of a phase 1 trial of entinostat, an oral histone deacetylase inhibitor, in pediatric patients with recurrent or refractory solid tumors. *First Author: Suman Malempati, Oregon Health and Science University, Portland, OR*

Background: Histone modification plays a key role in oncogenesis and progression of malignancy. Histone deacetylase (HDAC) inhibition has shown promise as anti-cancer therapy. Entinostat is an oral small molecule inhibitor of class I and IV HDACs that has not previously been evaluated in pediatric patients. We report the results of a phase 1 study of entinostat in children and adolescents with solid tumors. **Methods:** Children and adolescents (age £ 21 years) with relapsed or refractory solid tumors, including CNS tumors were eligible. Body-surface area ³ 1.17 m^2 was required. Entinostat (1 or 5 mg tablets) was administered orally, once weekly, in 4-week cycles. A rolling 6 design was used to evaluate two dose levels of 3 or 4 mg/m^2. A pharmacokinetic (PK) cohort was enrolled at the recommended dose. **Results:** Twenty eligible patients (10 male, 10 female), median (range) age 14.4 (8 -20) years were enrolled. Diagnoses included patients with CNS tumors (n = 11), sarcomas (n = 6) or other solid tumors (n = 3). Twelve patients were evaluable for DLT. Eight patients were not evaluable due to progression of disease prior to receiving the required percent of protocol prescribed therapy. No DLTs were observed at 3 mg/m^2 (n = 3) or among 9 patients (6 in dose escalation and 3 in the PK cohort) at the 4 mg/m^2 dose level. Grade 3 toxicities included neutropenia (n = 4), lymphopenia (n = 1), and leukopenia (n = 1). Most common non-hematologic toxicities (all grade £ 2) were elevated AST, fatigue, and hypophosphatemia (n = 4 each) and elevated ALT, hypoalbuminemia, and vomiting (n = 3 each). Pharmacokinetics of entinostat were evaluated and will be reported. **Conclusions:** Entinostat was well-tolerated with no DLTs observed. The recommended phase 2 dose in pediatric patients with solid tumors is 4 mg/m^2. Evaluation of entinostat in combination with other agents is planned. Clinical trial information: NCT02780804.

10557 Poster Session (Board #230), Sat, 8:00 AM-11:30 AM

In vitro and xenograft anti-tumor activity, target modulation and drug synergy studies of PV-10 against refractory pediatric solid tumors. *First Author: Lucy Swift, Alberta Children's Hospital, Calgary, AB, Canada*

Background: Children with refractory malignancies who fail conventional treatment protocols endure significant morbidity and mortality. Therefore, studies to identify tolerable and effective therapeutic agents are urgently needed. PV-10 (4,5,6,7-tetrachloro-2',4',5',7'-tetraiodofluorescein) is a novel therapeutic that in adult tumors induces direct cytotoxicity and stimulates tumor specific immune activation via immunogenic cell death, and is the subject of ongoing clinical study in combination with checkpoint inhibition (NCT02557321). Our studies aim to identify the potential of PV-10 in future clinical trials for refractory pediatric malignancies. **Methods:** A panel of cell lines derived from relapsed pediatric neuroblastoma, Ewing sarcoma, rhabdomyosarcoma and osteosarcoma (n = 20) were treated with increasing concentrations of PV-10 and cell viability was measured by alamar blue assay. Target modulation and induction of cell death pathways were investigated by western blots. The activity of PV-10 in combination with either radiation or a panel of chemotherapeutic agents was measured by cell survival assays and time-lapse microscopy. Mouse xenografts of pediatric solid tumors were injected with PV-10 and tumor growth dynamics were quantified by bioluminescence imaging. **Results:** PV-10 induced cell death in all pediatric solid tumor cell lines (IC50: 20-100 mM) with a measurable therapeutic-window. Western blot analyses showed dose dependent activation of caspases 3, 7 and 9 and PARP cleavage, indicating induction of apoptosis. Drug combination studies showed synergy with DNA damaging agents (including radiation) and agents that target mitosis and cytokinesis such as vincristine and inhibitors of Plk1 and Aurora A kinase. Xenograft studies showed significant reduction of tumor burden in treated mice by comparison to control animals, with corresponding increase in overall survival. **Conclusions:** Our studies provide pediatric solid tumor directed preclinical data for the activity, mechanisms of action, drug synergy and *in vivo* activity of PV-10, to support the formulation of an early phase clinical trial in this population.

10558 Poster Session (Board #231), Sat, 8:00 AM-11:30 AM

NANT 2012-01: Phase 1 study of DFMO and celecoxib with cyclophosphamide and topotecan for relapsed or refractory high-risk neuroblastoma. *First Author: Araz Marachelian, Children's Hosp Los Angeles, Los Angeles, CA*

Background: *MYC* drives polyamine expansion to support its oncogenic functions. Ornithine decarboxylase (Odc) is a direct *MYC* target that is rate-limiting for polyamine synthesis, and is itself amplified in a poor-outcome subset of NB. Difluoromethylornithine (DFMO) is an Odc inhibitor with preclinical activity via protein translation and immunomodulatory effects. We studied dose-escalated DFMO added to celecoxib (polyamine export inducer), Cyclo/Topo. **Methods:** Patients 2-30 years with RR HR NB were eligible. DFMO was studied at four dose levels (DL1-3,000; DL2/2A-4,500; DL3A-6,750; and DL4A-9,000mg/m^2/day po daily) with celecoxib (500mg/m^2/daily), Cyclo (250mg/m^2/day) and Topo (0.75mg/m^2/day) IV for 5 days, with G-CSF. DFMO pharmacokinetics and biomarkers of *ODC* regulation (promoter SNP) and polyamine depletion were performed. **Results:** Twenty-four patients enrolled; median age 6.8 years. Patients received 124 total cycles (range, 1-17). DL1 and 2 used 21d cycles (DFMO given 14/21d). Due to delayed platelet recovery, DL 2A-4A used 28d cycles (DFMO given 21/28d). Toxicities were predominantly hematologic/fever-related. There were three cycle-1 DLTs (hematologic; anorexia; transaminitis) and two DLTs in later cycles (cycle-2 hematuria; cycle-11 hypotension). Eight patients stopped therapy by choice; two due to DLT; 9 due to PD; 3 completed therapy (CR = 1, PR = 2; all at dose-levels ≥4500 mg/m^2/day DFMO); and 2 remain on therapy. Median time-to-progression was 19.8 months. Dose-level 4A exceeded tolerability (2/6 with DLT). Dose-level 3A (6,750mg/m^2/day) is the RP2D. Steady-state C_{min} for DFMO increased by dose-level with median C_{min} of 125mM at DL3A, equivalent to DFMO concentrations achieved in preclinical murine studies in water, and above the exposure needed to inhibit protein translation. **Conclusions:** DFMO and celecoxib added to Cyclo/Topo is tolerable in heavily pretreated NB patients, with a RP2D of 6,750mg/m^2/day. Achievable DFMO concentrations at this dose have demonstrable bioactivity using in vitro and in vivo preclinical models. Further testing with DFMO in combination with chemotherapy in this population is warranted. Clinical trial information: NCT02030964.

10559 Poster Session (Board #232), Sat, 8:00 AM-11:30 AM

Gene expression analysis for improved subtyping of high-risk neuroblastoma. *First Author: Jacob Pfeil, UCSC Genomics Institute, Santa Cruz, CA*

Background: One of the hallmarks of neuroblastoma is molecular heterogeneity, which leads to spontaneous remission in some patients and aggressive, resistant disease in others. Patients with low or intermediate risk have a high 5-year survival rate (90-95%), but high-risk neuroblastoma patients have a survival rate of 40% despite receiving high intensity therapies. **Methods:** Genome-wide transcriptome profiling can be used to stratify high-risk neuroblastoma patients and identify opportunities for molecularly targeted therapies. We developed a gene expression analysis for identifying molecular subtypes in large cancer gene expression cohorts (n > 100). Our method does not rely on a reference normal sample and thus can be applied to pediatric cancers where adequate normal samples are lacking. We applied the method to the TARGET NBL gene expression dataset (N = 162). **Results:** Our analysis identified 6,736 differentially expressed genes. We recapitulated amplification status of the transcription factor MYCN as originally determined in DNA-based assays by TARGET investigators (F1 score = 91%). We also identified two NTRK1 expression subtypes. The first was characterized by over-expression of MYCN, which downregulates expression of NTRK1. Tumors of the second subtype have lower activity for transcription factors that activate NTRK1 expression. Samples with the second subtype also have worse event-free survival than samples with higher NTRK1 expression (Log-rank test: p = 0.013). Thus, the low NTRK1/non-MYCN amplified subtype may benefit from an alternative treatment strategy. Finally, we used our gene expression approach to characterize the immune infiltrate of neuroblastoma patients and identified a subset of samples (~20%) with elevated expression of cytotoxic and regulatory T cell markers, including expression of inhibitory receptors and ligands. **Conclusions:** Our gene expression subtyping approach can tbe used to stratify high-risk neuroblastoma patients and identify opportunities for immunotherapy. Validation of this approach in preclinical models may lead to novel therapeutic strategies for high-risk neuroblastoma.

10560 Poster Session (Board #233), Sat, 8:00 AM-11:30 AM

Impact of survivorship care plans (SCPs) on adherence to surveillance for second malignant neoplasms (SMNs) and cardiac dysfunction in the Childhood Cancer Survivor Study (CCSS). *First Author: Adam Paul Yan, The Hospital for Sick Children, Toronto, ON, Canada*

Background: Since specific treatments increase the risk of SMN and cardiac dysfunction in childhood cancer survivors, the Children's Oncology Group (COG) has published guidelines for SMN and cardiac surveillance. In 2006, the Institute of Medicine recommended that survivors receive a SCP documenting their required surveillance in order to maximize their adherence. The impact of this recommendation on adherence is not known. **Methods:** A survey completed between 2014-2016 by 10,791 survivors in the CCSS ascertained adherence to COG guidelines among those for whom surveillance for breast cancer (N = 657; mammogram/MRI), colorectal cancer (N = 951; colonoscopy), skin cancer (N = 5468; skin exam) and cardiac dysfunction (N = 4310; echocardiogram) was recommended. We estimated adherence rates and identified factors associated with adherence using multivariable logistic regression. **Results:** Median age at diagnosis was 7 years (range 0-21) and time from primary cancer diagnosis was 36 years (16-66). Adherence to recommended breast, colorectal, skin and cardiac surveillance was 45.7% (95 % CI 41.9-49.5%), 38.2% (CI 35.1-41.3%), 22.6% (CI 21.6-23.7%) and 42.3% (CI 41.0-43.6), respectively. 26.9% of survivors and 19.8% of primary care providers (PCPs) had a copy of the SCP. Providing the PCP with a SCP was associated with increased skin cancer surveillance (OR 1.4, CI 1.1-1.7) only. Survivors' having a SCP was associated with increased cardiac surveillance (OR 1.8, CI 1.5-2.2) only. Visiting a specialized survivor clinic in the last year (vs. never) was associated with increased breast (OR 2.0, 95% CI 1.1-3.8), skin (OR 1.3, CI 1.1-1.7) and cardiac (OR 8.9, CI 6.4-12.7) surveillance. **Conclusions:** Less than half of survivors at high risk for SMN or cardiac dysfunction adhere to surveillance guidelines. Few survivors and PCPs have SCPs, and possession of SCPs has limited impact on surveillance. Adherence was most strongly associated with attending a specialized survivor clinic. New initiatives to improve adherence must be developed and tested.

10561 Poster Session (Board #234), Sat, 8:00 AM-11:30 AM

Cardiac outcomes in childhood cancer survivors (CCS): A population-based study. *First Author: Ashna Khanna, University of Toronto, Toronto, ON, CA*

Background: CCS are at an elevated risk for cardiac morbidity due to cancer treatments such as anthracycline chemotherapy and thoracic radiation. Morbidities include congestive heart failure (CHF), arrhythmias, valve abnormalities, pericarditis, and coronary artery disease (CAD). However, cohort-based studies have focused primarily on CHF risk. We conducted a population-based study to determine the incidence of all types of cardiac disease in CCS. **Methods:** Using a provincial pediatric cancer registry, we identified all children $<$ 18 years of age at cancer diagnosis who were treated at a pediatric cancer center in Ontario, Canada between 1987- 2010, and who survived $\geq$5 years from diagnosis. Each CCS was matched to population controls in a 1:5 ratio by age, sex and geographic region. The index date was 5 years after cancer diagnosis. Administrative health datasets were linked to determine the incidence of CHF, arrhythmias, valve disorders, pericardial disease, CAD (including myocardial infarction), and cardiac-related death using established algorithms. Cumulative incidence of cardiac events was calculated in both cohorts, accounting for competing risks of non-cardiac death and adult cancer events. **Results:** We studied 7,354 CCS (median diagnosis age 6 years, IQR 2-12) and 36,647 matched controls. During median follow-up of 11 years (IQR 5-17) from index, 2.5% of survivors vs. 0.8% of controls experienced $\geq$1 cardiac event. At 15 years from index, the cumulative incidence of any cardiac disease was 3.7% (95% CI 3.2-4.3%) in survivors and 1.2% (95% CI 1.1-1.4%) in controls (HR 3.3, CI 2.8-3.9, $p < 0.0001$). Among survivors, the 15-year cumulative incidence of morbidities was: CHF (2.0%, CI 1.6-2.4%), arrhythmias (1.5%, CI 1.2-1.9%), valve disorders (0.5%, CI 0.3-0.7%), pericardial disease (0.5%, CI 0.3-0.7%), and CAD (0.2%, 95% CI 0.1-0.4%). The 10-year incidence of cardiac-related death was 0.1% (CI 0-0.2%) vs $<$ 0.01% (CI 0-0.03%) in controls. **Conclusions:** CCS are at elevated risk for multiple types of cardiovascular disease. Their absolute risk at 15-year follow-up is low, but is expected to increase as they age. Follow-up care of CCS should assess and manage general cardiovascular risk rather than limiting to CHF.

10562 Poster Session (Board #235), Sat, 8:00 AM-11:30 AM

The effect of medical social rehabilitation on quality of life in children with brain tumors: Interim results of observational prospective study. *First Author: Grigory Ja. Tseitlin, Dmitry Rogachev National Medical Research Center of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation*

Background: Medical social rehabilitation is promising to support cancer children with the re-entry into 'normal' life. We aimed to study quality of life (QoL) changes in children with brain tumors (BT) after rehabilitation and identify independent predictors of QoL changes. **Methods:** Children of 6–17 y.o. underwent 4-week medical social rehabilitation after the end of cancer treatment (EOT). Children filled out child form of PedsQL and parents – parent form of PedsQL before and after rehabilitation. Statistical analysis included Generalised Estimation Equations (GEE), univariate logistic regression and multiple linear regression. **Results:** In total 82 survivors and their parents (44.4±11.1 y.o., 85% mothers) were enrolled. Mean age of children – 11.8±3.1 y.o.; 57% boys; 19 (23%) pts have overweight/obesity and other 19 (23%) pts have underweight/depletion according to the Body Mass Index (BMI); median duration time after EOT – 26 mos (1–123). According to child-reports QoL increased mainly in terms of emotional and psychosocial functioning ($p < 0.05$); according to parent-reports social, school and psychosocial functioning of children improved ($p < 0.05$). In general, child QoL improvement was revealed with adjustment for age, gender, time after EOT and baseline QoL (GEE, $p < 0.05$). Meaningful QoL improvement (QoL total score change $\geq$4.4) was observed in 58% of survivors. In the final logistic regression model ($\chi 2 = 6.9$, $p < 0.05$), overweight/obesity was independently associated with negative QoL changes after rehabilitation (OR = 6.71, p = 0.008). In multiple regression analysis, overweight/obesity (β -5.52, p = 0.05) and long period ($\geq$5 yrs) after EOT (β -9.56, $p < 0.01$) were associated with negative QoL changes after rehabilitation (R^2= 0.32, $p < 0.05$). **Conclusions:** Medical social rehabilitation is accompanied with QoL improvement in surviving children with BT. Rehabilitation program is not effective in terms of QoL in survivors with overweight/obesity and in those having long period after EOT. It might be taken into account for optimizing rehabilitation in survivors with childhood BT.

10563 Poster Session (Board #236), Sat, 8:00 AM-11:30 AM

Neurofibromatosis type 1 and risk of late outcomes after a primary tumor: A report from the Childhood Cancer Survivor Study. *First Author: Peter de Blank, University of Cincinnati, Cincinnati Children's Hospital Medical Center, Cincinnati, OH*

Background: It is not known whether survivors of childhood cancer with neurofibromatosis type 1 (NF1) are at increased risk for poor long-term health outcomes. **Methods:** 1,936 $>$ 5yr survivors of childhood cancer diagnosed between 1970-1999 (176 with NF1 and 1,760 non-NF1 survivors matched on diagnosis and diagnosis era) and 5,051 siblings were compared on self-reported chronic medical conditions (CTCAE v 4.0) and cognitive impairment (defined as $> 90^{th}$ percentile of siblings on the CCSS Neurocognitive Questionnaire) using logistic and Poisson regression to adjust for age at survey, age at diagnosis, sex, race, CNS radiation and other treatment exposures. **Results:** Among survivors with NF1, CNS astrocytoma was the most common primary tumor (n = 142, 78%). Compared to non-NF1 survivors, NF1 survivors were more likely to report a serious health condition (grade 3-4; RR[95% CI] 2.2[1.9-2.6]) and multiple chronic conditions (grade 2-4, 1.9[1.6-2.2]). Specific health risks (grade 1-5) are shown below. Curiously, diabetes and abnormal thyroid were less common in NF1 survivors compared to non-NF1 survivors and siblings. Survivors with NF1 were more likely to report impaired organization (OR 1.9 [1.0-3.4]), task completion (1.7 [1.1-2.8]) and learning/memory (1.6 [1.3-1.8]). NF1 survivors were less likely to attend college (0.4 [0.2-0.7]) and be employed (0.6 [0.4-0.9]). **Conclusions:** NF1 impacts risk of health/cognitive outcomes in adult survivors of childhood cancer. Further research should investigate the underlying mechanisms of these risks.

	RR [95%CI]	
Condition	vs nonNF1 survivor	vs Sibling
Diabetes	0.14 [0.07-0.27]	0.22 [0.12-0.43]
Abnormal Thyroid	0.25 [0.19-0.33]	0.54 [0.41-0.73]
Speech Deficit	0.38 [0.18-0.81]	0.64 [0.30-1.35]
Hearing Loss	0.57 [0.48-0.68]	1.24 [1.05-1.4]

10564 Poster Session (Board #237), Sat, 8:00 AM-11:30 AM

Radiation dose and volume to the pancreas and subsequent risk of diabetes mellitus: A report from the Childhood Cancer Survivor study. *First Author: Danielle Novetsky Friedman, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Childhood cancer survivors exposed to abdominal radiotherapy (abdRT) are at increased risk for diabetes mellitus (DM). We examined the association between DM risk and pancreatic radiation dose and dose-volume metrics. **Methods:** Participants included 4,527 5-year survivors (median age 35 years, range 10–58; median follow-up 21 years, range 2–34) diagnosed 1970–1999 and treated with abdRT, excluding total body irradiation. We estimated maximum radiation dose to the abdomen, whole pancreas, pancreatic head, body and tail, and volume of the pancreas absorbing ≥10, 20, and 30 Gy (V10, V20, V30). Prevalence of DM, defined by DM medication use, was compared to 4,853 siblings and 15,944 survivors without a history of abdRT using a GEE model with a Poisson distribution adjusted for attained age. **Results:** Survivors exposed to abdRT were 2.9 times more likely than siblings (95% confidence interval [CI] 2.0–4.3) and 1.6 times more likely than survivors not exposed to abdRT (95% CI 1.3–2.1) to have DM. Among those treated with abdRT, the prevalence of DM was 2.9% for survivors aged 31–40 years and 4.7% for those over 40. In multivariable analysis of survivors treated with abdRT, attained age (RR = 1.09, 95% CI 1.06–1.11, $p < 0.001$); body mass index (< 18.5: RR = 1.1, 95% CI 0.4–2.7; 18.5–24.9: reference; 25–29.9: RR = 2.7, 95% CI 1.6–4.6; ≥30, RR = 7.7, 95% CI 4.8–12.4, $p < 0.001$); and pancreatic tail dose (0.1–9.9 Gy: reference; 10–19.9 Gy: RR = 6.3, 95% CI 2.1–18.8; 20–29.9 Gy: RR = 4.7, 95% CI 1.4–16.3; ≥ 30 Gy: RR = 11.4, 95% CI 3.6–36.3, $p < 0.001$) were associated with increased DM risk. An interaction was noted between age at diagnosis and pancreatic tail dose ($p < 0.001$), with the largest differences between tail doses found among those diagnosed at age < 10. Radiation to other regions of the pancreas, by dose or volume, as well as exposure to cranial irradiation, alkylating agents, and corticosteroids, were not associated with DM risk. **Conclusions:** Among survivors treated with abdRT, DM risk is associated with higher pancreatic tail dose, but not with other dosimetric or volumetric factors. Research is needed to identify interventions to decrease cardiometabolic risk in survivors treated with abdRT.

10565 Poster Session (Board #238), Sat, 8:00 AM-11:30 AM

Exercise intolerance among survivors of childhood cancer exposed to cardiotoxic therapy: Identification of survivors at increased risk through myocardial strain and ejection fraction. *First Author: Kirsten K. Ness, St. Jude Children's Research Hospital, Memphis, TN*

Background: Exercise intolerance is an established risk factor for heart failure and death in the general population. Exercise capacity and factors associated with intolerance have not been extensively studied in adult survivors of childhood cancer exposed to cardiotoxic therapy. **Methods:** Survivors exposed to cardiotoxic therapies, without clinical heart failure (N = 577, 52% male, mean age 35.8±8.2 years), and community controls (N = 286, 48% male, mean age 34.4±10.0 years) completed maximal cardiopulmonary exercise testing to determine exercise capacity ($pkVO_2$; intolerance defined as < 20^{th} % tile of age- and sex-specific predicted values) and echocardiography for EF and global longitudinal strain (GLS). EF < 50% and GLS ≥2 SD above age and sex normative values were evaluated for associations with exercise intolerance among survivors in models adjusted for race, pulmonary function, neuropathy, strength, physical activity and smoking. **Results:** Exercise intolerance (93.7%) and abnormal EF (7.6%) and GLS (27.6%) were common among survivors, differing significantly from controls: lower mean $pkVO_2$ (25.8±8.0 vs. 32.9±9.4, $p = 0.001$) and EF (57.6±5.5 vs. 60.3±5.5, $p < 0.001$) and higher GLS (-19.6±2.6 vs. -20.4±3.2, $p < 0.001$). **Conclusions:** Survivors exposed to cardiotoxic agents have dose dependent impairment in exercise capacity. Abnormal GLS, but not EF, is associated with exercise intolerance among survivors, and should be considered in screening guidelines for survivors.

	$pkVO_2$	EF	GLS
Control	32.9±9.4	60.3±5.5	-20.4±3.2
1-199 mg/m^2 anthracyclines	28.7±6.4*	58.4±5.4*	-20.2±2.8
200-349 mg/m2 anthracyclines	27.6±6.5*	58.4±5.4*	-20.2±2.8
350+ mg/m^2 anthracyclines	25.4±6.1*	57.2±4.9*	-19.5±2.6*
Chest RT, any anthracyclines	27.5±4.8*	57.0±3.9*	-19.5±2.0*
Chest RT, no anthracyclines	25.4±7.1*	58.2±6.0*	-19.1±3.0*

*$p < 0.05$ for comparison with control In adjusted models, EF < 50% was not (OR 2.2, 95% CI 0.4-11.1), but GLS ≥2 SD was (OR 3.0, 95% CI 1.1-8.2) associated with exercise intolerance among survivors. In models limited to survivors with EF > 50% GLS identified survivors with exercise intolerance (OR 3.7, 95% CI 1.1-13.0).

10566 Poster Session (Board #239), Sat, 8:00 AM-11:30 AM

Long-term renal function after treatment for Wilms tumor: A report from the St. Jude Lifetime Cohort (SJLIFE) study. *First Author: Daniel M. Green, St. Jude Children's Research Hospital, Memphis, TN*

Background: The impact of specific treatment modalities on long-term renal function among adult survivors of Wilms tumor (WT) has not been well-documented. **Methods:** We clinically evaluated 40 WT survivors and 35 non-cancer controls (NCC) with creatinine and cystatin C, estimated the glomerular filtration rate (eGFR) using the Chronic Kidney Disease – Epidemiology (CKD-EPI) equations with and without cystatin C, and, among survivors only, measured ^{99m}Tc diethylenetriamine pentaacetic acid (DTPA) plasma clearance. WT survivors consisted of 20 treated with unilateral nephrectomy (UN), non-nephrotoxic chemotherapy (NNC) and whole abdomen radiation therapy (WART) (mean – 20.2 Gy; standard deviation (SD) – 9.12 Gy), and 20 treated with UN, no radiation therapy, and NNC. Pairwise comparisons between WT survivors treated with and without WART, and of each group to NCC were performed using two-sample t-test. **Results:** WT survivors were female (n = 26), non-Hispanic white (n = 33). Results are shown in the Table. **Conclusions:** Among WT survivors who have undergone UN, long-term renal function is normal in those without WART, and only mildly impaired in some with WART. These data can guide development of future surgical recommendations for patients with WT.

	WART Mean (SD)	No WART Mean (SD)	Controls Mean (SD)	WART vs. No WART p-value	No WART vs Controls p-value	WART vs Controls p-value

10567 Poster Session (Board #240), Sat, 8:00 AM-11:30 AM

Racial/ethnic differences in neurocognitive, emotional and quality of life outcomes in adult survivors of childhood cancer: A report from the Childhood Cancer Survivor Study (CCSS). *First Author: Stephanie Dixon, St Jude Children's Research Hospital, Memphis, TN*

Background: Survivors are at risk of impaired neurocognitive/emotional functioning and health related quality of life (HRQOL). The impact of CNS-directed therapy by race/ethnicity has not been reported. **Methods:** Analyses included 12,257 ≥5-yr survivors of childhood cancer: median age at follow-up 31.2 yrs (range 16.1-54.1), 490 non-Hispanic Black (NHB), 725 Hispanic (H) survivors and 2994 siblings. Self-reported neurocognitive (working memory, task efficiency, emotional regulation, organization), emotional (depression, anxiety, somatization) and HRQOL (components assess physical, emotional and mental health, social functioning, pain and vitality) outcomes were evaluated using the CCSS Neurocognitive Questionnaire, BSI-18 and SF-36. Impact of cranial radiotherapy (CRT) was investigated using general linear models adjusted for clinical/demographic factors to estimate differences in mean scores between survivors and siblings within racial/ethnic stratum. The magnitude of differences for NHBs and Hs were compared to those of non-Hispanic Whites (NHW). **Results:** Among non-CRT exposed survivors, no significant differences were observed between NHB, H and NHW for all neurocognitive, emotional, and HRQOL outcomes. Among CRT exposed survivors, while there were no significant differences for neurocognitive outcomes by race/ethnicity, mean scores for depression differed between H survivors vs siblings (49.9. vs 46.5, $p < 0.001$), which was greater than NHW survivors vs siblings (49.2 vs. 47.7, $p < 0.001$; p comparing differences in means between H and NHW = 0.047). Survivor-sibling differences in mean HRQOL scores for social functioning for NHB (-7.70, $p = 0.02$) and H (-6.27, $p = 0.01$) survivors exposed to CRT were greater than for NHW (-1.48). **Conclusions:** After CRT exposure, there were no differential effects on neurocognitive outcomes based on race/ethnicity. However, minority survivors who received CRT had increased risk for depression and reduced social function. The role of environmental and socio-economic factors in helping survivors recover from CRT exposure should now be investigated.

10568 Poster Session (Board #241), Sat, 8:00 AM-11:30 AM

Chronic pain and disability in long-term survivors of childhood cancer: A report from the Childhood Cancer Survivor Study (CCSS). *First Author: Cynthia Karlson, University of Mississippi Medical Center, Jackson, MS*

Background: Chronic pain has not been well characterized in survivors of pediatric cancer. The current study is the first to examine prevalence and predictors of chronic pain and pain-related disability in this population. **Methods:** Participants included 10,012 adult survivors (48.7% female; median age 31 years; *M* time since diagnosis 15.3 years) from the CCSS. Participants completed the Short-Form 36 and Brief Symptom Inventory-18 on two occasions between 2002 and 2011. Chronic pain was defined as self-report of moderate to severe pain at both time points. Pain-related disability was defined as pain that interferes with normal work at either time point. Covariates included sex, age, time since diagnosis, treatment, and grade 3-4 chronic health conditions. Multinomial logistic regression estimated relative risk (RR) and 95% confidence intervals (CI) for predictors. Structural equation models examined associations between pain, depression, anxiety, and vitality. **Results:** 29% of survivors reported moderate to severe pain at either time point, 32% reported moderate to severe pain-related disability, and 10% reported chronic pain. Compared to survivors of leukemia, survivors of sarcoma (RR 1.33, CI 1.32-1.34) and solid tumors (RR 1.04, CI 1.03-1.06) reported more chronic pain. Survivors with a history of amputation (RR 1.54, CI 1.52-1.56) and, in separate models, those with chronic health conditions (RR 1.57, CI 1.56-1.59) were more likely to report chronic pain. Survivors with symptoms of depression (RR 1.11; CI 1.09-1.12) and anxiety (RR 1.25; CI 1.24-1.27) were also more likely to report chronic pain. Similar patterns were observed for pain-related disability. Controlling for demographics, treatment, and chronic health conditions, vitality mediated the effects of depression and anxiety on chronic pain (RMSEA 0.011) and pain-related disability (RMSEA 0.000). **Conclusions:** Adult survivors of childhood cancer experience chronic pain and pain-related disability that is associated with amputation, chronic health conditions, depression, anxiety, and poor vitality. Increased screening and comprehensive treatment of pain is warranted, particularly for these risk factors.

10569 Poster Session (Board #242), Sat, 8:00 AM-11:30 AM

Is physical activity and cardiorespiratory fitness reduced among childhood cancer survivors? *First Author: David Mizrahi, UNSW Australia, Sydney, Australia*

Background: Survivors of childhood cancer experience an increasing incidence of late sequelae with age, with the effect on health likely compounded by limited physical activity and low cardiorespiratory fitness (CRF). This study aimed to determine survivors' physical activity levels and to objectively measure CRF, compared with controls. **Methods:** *Stage 1:* We collected physical activity data from parents of survivors aged 7-18 years, ≥5 years after diagnosis, from 11 Australian and New Zealand hospitals and from age-matched controls (International Physical Activity Questionnaire). We compared moderate-vigorous physical activity with American Cancer Society guidelines (≥300 min/week). *Stage 2:* We assessed CRF in survivors aged 8-18 years, ≥1 year after treatment completion, by cardiopulmonary exercise test (Bruce Protocol), 6-minute walk test (6MWT), and self-reported fitness (International Fitness Scale). **Results:** *Stage 1:* 192 parents of survivors (age = 12.9±2.3 years) and 111 parents of control children (age = 12.3±2.7 years) participated. Parents reported survivors participated in more physical activity than controls (248.4±217.6 vs 184.8±213.6 min/week, p = 0.036), with 31% of survivors meeting physical activity guidelines, compared with 22.7% of controls (p = 0.011). *Stage 2:* 31 survivors (age = 13.0±3.5 years) and 10 controls (age = 10.6±1.1 years) completed CRF assessments. Survivors appear to have similar CRF compared with controls in terms of VO2max (41.1 vs 46.8ml/kg/min, p = 0.09; 40^{th} vs 60^{th} percentile, p = 0.11) and 6MWT distance percentile (69^{th} vs 78^{th} percentile, p = 0.30). Among survivors, a weak linear relationship existed between self-perceived CRF and VO2max percentile (r^2= 0.20, p = 0.017). **Conclusions:** Only one-third of childhood cancer survivors met physical activity guidelines, whilst survivors and controls reported similar fitness. Considering the late-effects risks during aging in survivors, regularly assessing physical activity and CRF provides clinicians with vital information to monitor survivors. Although survivors accurately perceived their CRF, the weak relationship reinforces the need for accurate assessment to provide insight into cardiovascular risk.

10570 Poster Session (Board #243), Sat, 8:00 AM-11:30 AM

Neurologic morbidities, psychological distress, and functional independence in adult survivors of childhood cancer treated with CNS-directed therapies: A report from the Childhood Cancer Survivor Study. *First Author: Stefanie C. Vuotto, St. Jude Children's Research Hospital, Memphis, TN*

Background: Survivors of childhood cancer who received CNS-directed therapies are at risk for neurologic sequelae, which may adversely impact psychological functioning and independence in adulthood. **Methods:** Participants included 7,942 survivors of childhood cancer treated from 1970-99 with cranial radiation, intrathecal methotrexate or cytarabine (59% leukemia; 27% CNS tumor; 11% non-Hodgkin; 3% other; mean[SD] age = 25.5[5.8] yrs, time since diagnosis = 17.7[4.6] yrs). Self-reported neurologic conditions included stroke, seizure, sensory deficits, focal neurologic dysfunction, and severe headaches. Emotional distress symptoms (BSI-18) included anxiety, depression, and suicide ideation (SI). Functional independence was assessed using latent class analysis with six indicators (independent living, assistance with routine needs, assistance with personal care needs, ability to attend work/school, driver's license, marital status). Multivariable regression models, adjusted for age, sex, race, pain, and health status, estimated relative risks (RR) and odds ratios (OR) for associations of neurologic morbidity with emotional distress and functional independence. **Results:** Prevalence of neurologic conditions was: 3% stroke; 11% seizure; 25% sensory deficits; 29% focal neurologic dysfunction; 31% severe headaches. In multivariable models, risk of emotional distress was associated with focal neurologic dysfunction (anxiety: RR 1.6; 95% CI 1.3-2.1; depression: RR 1.4; CI 1.2-1.7), sensory deficits (anxiety: RR 1.3; CI 1.0-1.6; depression: RR 1.3; CI 1.1-1.5; SI: RR 1.3; CI 1.0-1.6), and severe headaches (anxiety: RR 1.5; CI 1.2-1.9; depression: RR 1.6; CI 1.4-2.0; SI: RR 1.5; CI 1.2-1.8). Stroke (OR 0.3, CI 0.2-0.5), seizure (OR 0.2, CI 0.2-0.3), and focal neurologic deficits (OR 0.26, CI 0.2-0.3) were associated with decreased likelihood of functional independence. **Conclusions:** Childhood cancer survivors who develop neurologic morbidities are at-risk of emotional distress symptoms, including suicide ideation, and failure to attain independence in adulthood.

10571 Poster Session (Board #244), Sat, 8:00 AM-11:30 AM

Longitudinal assessment of patient-reported cumulative symptom burden as an indicator of chronic health conditions in adult survivors of childhood cancer: A joint report of the St. Jude Lifetime Cohort (SJLIFE) and the Childhood Cancer Survivor Study (CCSS). *First Author: I-Chan Huang, St. Jude Children's Research Hospital, Memphis, TN*

Background: Adult survivors of childhood cancer experience a high cumulative burden of therapy-related chronic health conditions (CHCs). However, longitudinal evaluation of patient-reported symptoms has not been examined as an indicator of CHCs in this population. **Methods:** 735 long-term adult survivors of childhood cancer completed three symptom surveys through participation in both SJLIFE and CCSS across 25 years (1992-2016). Surveys included 10 symptom domains: sensory, cardiac, pulmonary, musculoskeletal, memory, pain, fatigue, nausea, anxiety and depression. Domains were classified as present vs. absent at each time point and summated with possible scores ranging from 0 to 30. Cardiac, pulmonary and endocrine CHCs were clinically determined after the last survey and graded using modified CTCAE criteria. Poisson regression identified associations of cumulative symptom burden (dichotomized as high [top quartile of the symptom burden scores] vs. low [bottom three quartiles]) with each organ system-specific CHC (grades 2-4 vs. 0-1) and severe/life-threatening CHCs (any grades 3-4 vs. 0-2), adjusting for age, sex, race and education. **Results:** Across the three symptom surveys, survivors' mean ages were 27, 36 and 40 years; mean years from diagnosis was 31 years at the final clinical assessment. Survivors were mostly female (51%), Caucasian (90%) and treated for leukemia (46%). Survivors with high cumulative symptom burden had a 30% increased risk of hypertension/dyslipidemia (RR 1.3, 95% CI 1.1 1.6) and endocrine dysfunction (RR 1.3, 95% CI 1.0 1.7), and a 40% increased risk of respiratory disorders (RR 1.4, 95% CI 1.2 1.8) compared to survivors with low symptom burden. High cumulative symptom burden was associated with a 50% increased risk of having severe/life-threatening CHCs (RR 1.5, 95% CI 1.2 1.9) compared to those with low symptom burden. **Conclusions:** Routine symptom screening may help identify adult survivors of childhood cancer who are at concurrent and/or future risk of hypertension/dyslipidemia, endocrine and respiratory disorders.

10572 Poster Session (Board #245), Sat, 8:00 AM-11:30 AM

The impact of CMV reactivation on HSCT outcomes in children with malignancies: A 13 years single center experience. *First Author: Francesco Baccelli, University of Pisa, Pisa, Italy*

Background: After the introduction of pre-emptive therapy, the incidence of CMV disease dramatically decreased in HSCT recipients, while indirect effects of CMV infection (CMVI) are still under investigation. **Methods:** We retrospectively analyzed children (< 18 years) who underwent first allogeneic HSCT for malignancies at our institution between 01/2003 and 12/2016. CMVI was defined as the presence of pp65 or DNA in any body fluid. Patients were classified according to their CMVI status. 5-years probabilities of OS, DFS, GVHD-free relapse-free survival (GRFS) and infections were estimated using Kaplan-Meier method and log-rank test. Cumulative incidence and Gray's test were used to assess differences in relapse, NRM, aGVHD grades 2-4, extensive cGVHD (e-cGVHD), neutrophils and platelets engraftment. Cox regression was performed to identify possible correlations. Major endpoints are reported in Table 1 with standard errors (SE). **Results:** 92 HSCT were included (CMVI+ N = 40). Groups were homogeneous for age, sex, diagnosis, donors, HSC source and graft composition with the exception of lower median cellularity in UCBU. No significant differences were reported for OS, DFS, infections, GRFS, relapse, NRM, and both neutrophils and platelets engraftment ($p > 0.05$). The mean day of CMVI diagnosis was 39.6 (28.2-51.0). Although statistically non-significant aGVHD grade 2-4 was higher in CMVI+, suggesting a possible association. Noticeable, aGVHD has often preceded CMVI (N = 7 vs N = 1). In contrast, e-cGVHD was less frequent in CMVI+ patients. Remarkably, infections were slightly higher in the early period in CMVI+. **Conclusions:** Despite variations in HSCT procedures and the limited sample size, pre-emptive therapy determined a dramatical decrease in CMV indirect effects. Moreover, aGVHD is a possible risk factor for CMVI but not vice versa. However, further evidences are needed to enlighten the role of CMV in the modern era of pediatric HSCT.

Endpoints (SE)	CMVI+	CMVI-	p
OS	70.0 (.07)	64.5 (.07)	ns
DFS	59.9 (.08)	64.1 (.07)	
Relapse	25.1 (.07)	24.2 (.06)	
NRM	5.0 (.04)	4.1 (.03)	
aGVHD	20.0 (.06)	9.6 (.04)	
e-cGVHD	6.3 (.04)	13.1 (.07)	
GRFS	35.0 (.08)	46.4 (.07)	
Infections	58.3 (.09)	47.8 (.08)	

10573 Poster Session (Board #246), Sat, 8:00 AM-11:30 AM

Comprehensive molecular characterization of pediatric treatment-induced glioblastoma: Germline DNA repair defects as a potential etiology. *First Author: John Thomas Lucas, St. Jude Children's Research Hospital, Memphis, TN*

Background: Pediatric treatment-induced high grade glioma (TIGs) are an incurable late complication of cranial radiation therapy or combined radiation/chemotherapy. We now evaluate copy-number, sequence and epigenetic alterations in an expanded TIG cohort. **Methods:** Whole Genome (WGS) or Whole Exome Sequencing (WES), and Illumina Infinium 450/850K methylation profiling was performed on TIG (N = 34) and non-TIG (N = 29) pediatric high grade gliomas (pHGG) from a multi-institutional cohort and the Childhood Cancer Survivors Study Group. WGS/WES was performed on matched germline DNA from 15 TIGs and 23 non-TIG pHGG. **Results:** Survival between TIG and non-TIG pHGG was comparable (p = 0.43). On methylation profiling, 19/27 TIGs clustered into a subclass of IDH-wild type midline GBM. Recurrent copy number alterations included 1p loss (13/34), 1q gain (13/34), Ch.13 loss (13/34), PDGFRA gain/amplification (17/34), and CDKN2A loss (14/34). WGS identified a mean germline mutation load of 1.50 mut/Mb. There was no difference in the number of coding and noncoding mutations in TIG and non-TIG groups. Noncoding and coding region mutational spectrums seemed to be biased toward A–>G and C–>T respectively. TIG cases had frequent pathogenic germline alterations in DNA repair genes including BARD1, BRCA1, BRCA2, ATR, and PMS1. **Conclusions:** TIGs are enriched for specific defined epigenetic subgroups, and are characterized by recurrent chromosomal aberrations and frequent germline defects in DNA repair pathways.

10574 Poster Session (Board #247), Sat, 8:00 AM-11:30 AM

Retrospective study of age-adjusted growth patterns for height, weight and body mass index in pediatric acute leukemia and lymphoma. *First Author: Charles Phillips, Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Pediatric patients with acute lymphoblastic leukemia (ALL) have a significantly higher body mass index (BMI) than their peers with an expected increase in age-adjusted mean Z-score of 0.81 after completion of cancer treatment. Growth patterns are less well understood for other types of pediatric hematologic malignancies including acute myeloid leukemia (AML), Hodgkin's Lymphoma (HL) and Non-Hodgkin's Lymphoma (NHL). Understanding the differences in growth patterns between different pediatric malignancies is critical to discern who is most vulnerable to unhealthy weight changes and stunted growth. We describe a single institutional retrospective study of height, weight, and BMI patterns for patients with hematologic malignancies. **Methods:** Study population included patients at the Children's Hospital of Philadelphia from 2011-2017. Anthropomorphic measurements were abstracted from the electronic health record and contained in an electronic health record derived research network, PEDSnet. All acute leukemia and lymphoma patients who received at least one dose of chemotherapy were included. Anthropomorphic measurements were standardized with day 0 corresponding to the day of first chemotherapy administration and followed for 1 year. **Results:** A total of 650 patients met inclusion criteria with the following diagnosis frequency: ALL 377, AML 83, HL 93, NHL 97. As expected, mean BMI Z-score for ALL patients increased during therapy and increased by 0.5 at 1 year. At 1 year, mean BMI Z-score decreased for AML patients by 0.4, increased for NHL by 0.5, and was unchanged for HL. All four cancer groups had a mean weight Z-score change of < 0.3. HL was the only cancer not to have a mean weight Z-score fall during the first 6 months of treatment. Regarding height, ALL and AML patients had a decrease in mean height Z-score of about 0.4 while HL and NHL had no change. **Conclusions:** Acute lymphoblastic leukemia, acute myeloid leukemia, Hodgkin's Lymphoma, and Non-Hodgkin's Lymphoma have unique growth patterns in the first year after cancer diagnosis. Hodgkin's lymphoma had the smallest changes in mean height, weigh and BMI Z-scores while acute myeloid leukemia had the largest changes.

TPS10575 Poster Session (Board #248a), Sat, 8:00 AM-11:30 AM

Open-label, dose-escalation, phase 1 study of venetoclax in combination with navitoclax and chemotherapy in patients with relapsed acute lymphoblastic leukemia. *First Author: Thomas Alexander, Department of Pediatrics, University of North Carolina School of Medicine, Chapel Hill, NC*

Background: Acute lymphoblastic leukemia (ALL) relapse in children and adults is associated with poor prognosis. Venetoclax (VEN) is a potent, highly selective BCL-2 inhibitor, and navitoclax (NAV) inhibits various BCL family proteins, including BCL-2, BCL-W, and BCL-X_L. VEN and NAV have shown activity in a variety of ALL cell lines and xenografts, and their combination resulted in synergistic antitumor effect in most ALL xenografts (Khaw et al. Blood 2016;128:1382-95). This trial evaluates VEN in combination with NAV and chemotherapy in patients with relapsed ALL. **Methods:** This is an open-label, multicenter phase 1 dose-escalation trial (NCT03181126) in patients 4–45 years old with relapsed or refractory ALL. Patients receive daily oral VEN, weight-adjusted to match the adult-equivalent exposure of 400 mg. Daily oral NAV administration starts on day 3. Based on the patients' weight, up to 3 dose levels (25, 50, and 100 mg) will be explored. Chemotherapy consists of peg-asparaginase (1,250 IU/m^2 intravenous [IV] on days 9 and 22), vincristine (1.5 mg/m^2 IV on days 9, 15, 22, and 29), and dexamethasone (20 mg/m^2/day orally on days 9–13 and 22–26). At the investigator's discretion, chemotherapy may be delayed, not administered, or repeated for a second cycle. Dose escalation is guided by a Bayesian optimal interval design. For each weight group (< 45 kg and ≥45 kg), the initial cohort at each dose level enrolls ≥3 dose-limiting toxicity (DLT)-evaluable patients, and additional cohorts ≥2. DLTs are assessed during the first 42 days. In the absence of progressive disease, patients may receive VEN + NAV for up to 9 months; thereafter, therapy may be continued for those with ongoing benefit. Primary endpoints are safety and DLTs of VEN + NAV and chemotherapy, and safety and pharmacokinetics of VEN + NAV. Secondary objectives include assessments of antitumor activity and number of patients who proceed to stem cell transplantation. BH3 profiling and comprehensive genomic analysis will be performed to explore biomarkers of disease response. Approximately 42 patients are planned to be enrolled. As of Jan 5, 2018, 3 patients were enrolled at dose level one. Clinical trial information: NCT03181126.

TPS10576 Poster Session (Board #248b), Sat, 8:00 AM-11:30 AM

Phase 1 multicenter trial to assess the maximum tolerated dose, safety, pharmacokinetics, and pharmacodynamics of pazopanib in combination with irinotecan and temozolomide (PAZIT) for children and young adults with advanced sarcoma. *First Author: Kieuhoa Tran Vo, University of California San Francisco, San Francisco, CA*

Background: Sarcomas express pro-angiogenic factors that may represent therapeutic targets. Pazopanib, an oral multi-kinase inhibitor of VEGFR-(1-3), c-kit, and PDGFR, is FDA-approved for the treatment of advanced soft tissue sarcomas. In a phase 1 study of single-agent pazopanib in children with recurrent or refractory solid tumors, this agent was well tolerated and the clinical activity was encouraging in this heavily pre-treated population. Preclinical studies have demonstrated a potential additive or synergistic interaction between anti-angiogenic agents and cytotoxic chemotherapy. The combination of irinotecan and temozolomide is well tolerated and provides a modest degree of antitumor activity in heavily pre-treated sarcoma patients, thus making it a useful platform onto which new compounds may be tested. **Methods:** This is a phase 1, open-label, multicenter trial of pazopanib in combination with irinotecan and temozolomide (PAZIT) in children and young adults ages 6-30 years with relapsed or refractory sarcomas (NCT03139331). The primary objectives are to determine the recommended phase 2 dose, describe toxicities, and describe pharmacokinetic parameters in this population. Secondary and exploratory objectives include evaluation of disease response and exploration of pharmacodynamic effects of PAZIT. Pazopanib is administered orally on days 1-21 of 21-day cycles according to assigned dose level. All patients receive fixed doses of irinotecan IV (50 mg/m^2/day) or PO (90 mg/m^2/day) and temozolomide 100 mg/m^2/day PO on days 1-5. Oral cephalosporin diarrhea prophylaxis is required. Dose escalation follows a standard 3+3 design evaluating up to three pazopanib dose levels. Following dose escalation, up to 10 additional patients will be enrolled to the dose expansion cohort to obtain additional toxicity and efficacy data. Correlative studies include changes in plasma angiogenic factors and circulating tumor DNA. Enrollment began in May 2017 and is ongoing. Clinical trial information: NCT03139331.

11000 Clinical Science Symposium, Sun, 11:30 AM-1:00 PM

Addressing the burden of cancer in East Africa through cascaded training and education by local doctors. *First Author: Jennifer Eastin, Royal College of Physicians of London (RCP), London, United Kingdom*

Background: Development of cancer services in low and middle income countries (LMIC) is a challenge. The Medical Education, Training and Fellowship (METAF) program aims to improve early detection, research and treatment of cancer in East Africa (EA). Through clinical training courses, participating physicians will be better equipped to diagnose, triage and manage cancer within local hospitals. **Methods:** The EADB, which is responsible for the development of infrastructure in EA, through the British Council, appointed the RCP as the technical partner in this 4-year project. During Year 1, a needs assessment was carried out in Kampala with oncologists from Kenya, Tanzania, Uganda and Rwanda. Course conveners were recruited, curricula developed and two intensive "training of trainers" (TOT) courses delivered with RCP volunteers teaching alongside local faculty. In Year 2, 5 training courses were delivered, including the first round of 'cascaded' courses, facilitated by trainers who participated in the previous TOT workshops, supported by a member of local faculty and an RCP volunteer. Quantitative feedback to evaluate learning was gathered using multiple choice tests at the beginning and end of training. Qualitative feedback was gathered from written evaluations at the end of each course. Course content is continually amended based on country specific needs and participant and faculty feedback. **Results:** Since the launch of the program in 2016, 7 clinical training activities have been delivered; 3 oncology ToT workshops and 4 oncology cascaded training courses. During Years 1 and 2 the total number of doctors trained across East Africa as part of the METAF programme was 137. Participant feedback suggests that over 935 clinical staff will benefit from the knowledge gained on the clinical courses through mentoring by course participants at home facilities. **Conclusions:** The TOT solution to the need for a rapid cascade of knowledge has been well received and demonstrated to be effective within this multinational program. The methodology may be applicable to similar needs in LMIC settings. Lessons learned to date will be implemented during Years 3 & 4.

11001 Clinical Science Symposium, Sun, 11:30 AM-1:00 PM

Bridging the gap in global advanced radiation oncology training: Impact of a web-based open-access interactive three-dimensional contouring atlas on radiation oncology practice in Russia. *First Author: Natalia Dengina, Ulyanovsk Regional Cancer Center, Ulyanovsk, Russian Federation*

Background: Radiation oncologists (ROs) in Russia face a number of unique professional difficulties including lack of standardized training and continuing medical education. To combat this, under the auspices of the Russian Society of Clinical Oncology (RUSSCO), our group has developed a series of ongoing in-person interactive contouring workshops that are held during the major Russian oncology conferences in Moscow, Russia. Since November 2016 during each workshop, we utilized a web-based open-access interactive three-dimensional contouring atlas as part of our didactics. We sought to determine the impact of this resource on radiation oncology practice in Russia. **Methods:** We distributed an IRB-approved web-based survey to 172 practicing ROs in Russia. We inquired about practice demographics, RUSSCO contouring workshop attendance, and the clinical use of open-access English language interactive contouring atlas (eContour). The survey remained open for two months until November 2017. **Results:** Eighty ROs completed the survey with a 46.5% response rate. Mean number of years in practice was 13.7. Sixty respondents (75%) attended at least one RUSSCO contouring workshop. Of those who were aware of eContour, 76% were introduced during a RUSSCO contouring workshop, and 81% continue to use it in their daily practice. The greatest obstacles to using the program were language barrier (51%) and internet access (38%). Nearly 90% reported their contouring practices changed since they started using the program, particularly for delineation of clinical target volumes (57%) and/or organs at risk (46%). More than 97% found the clinical pearls/links to cooperative group protocols in the software helpful in their daily practice. The majority used the contouring program several times per month (43%) or several times per week (41%). **Conclusions:** Face-to-face contouring instruction in combination with open-access web-based interactive contouring resource had a meaningful impact on perceived quality of radiation oncology contours among Russian practitioners and has the potential to have applications worldwide.

11002 Clinical Science Symposium, Sun, 11:30 AM-1:00 PM

The teaching of multi-disciplinary cancer care: A flipped classroom approach. *First Author: Helen Sarah Winter, University of Oxford, Huntingdon, CAMBS, United Kingdom*

Background: Multi-disciplinary team (MDT) cancer care was introduced to improve cancer outcomes in UK. Teaching of MDTs involves observation from the "back of the room". A flipped classroom approach was used as a tool for experiential learning of participation in a meeting. Team dynamics, shared decision-making and representing patient views are important in MDTs. **Methods:** Four true-to -life cancer cases requiring a multi-modality approach were developed. A flipped classroom was developed following feedback from students. Participants were given cases; individual roles with speciality-specific information; links to cancer resources and guidelines for case discussions. Following preparation facilitators set the scene and supported the groups to run the case discussion. Observers gave feedback on the decision-making, team dynamics and how the patient's views were voiced. Participants gave feedback on their participation within the team, reflections on their role, and their learning of cancer care. **Results:** Eighty 4th year medical students each participated in two cases, with on average of 10 participants per case. Students compared their learning with their observational experiences of attending MDTs. Students rated this experience highly as a learning experience. Attendance was high, although not all students had prepared their roles. Feedback on the sessions was positive with the majority of students preferring this as a method for learning about MDTs. Results included reflections on how it felt be to be a member of the team with a different opinion, how group dynamics affected decision-making and suggestions for improvements for the flipped classroom approach. **Conclusions:** A flipped classroom approach to teaching cancer management was rated highly by students. This approach offers a flexible, learning tool that stimulates knowledge application and conceptual understanding. Other professional skills were developed by chairing, presenting evidence from prior preparation and considering the patient's wishes and values. The evaluation of a new innovative way to teach cancer care was well-supported by the students who overwhelmingly have advised to implement the pilot fully into the undergraduate clinical course

11003 Clinical Science Symposium, Sun, 11:30 AM-1:00 PM

Professional development improves geriatric focused oncology activities in settings across the nation. *First Author: Denice Economou, City of Hope, Duarte, CA*

Background: Although older adults represent the majority of patients with cancer, oncology nurses receive little training in the care of older patients. In an effort to bridge this knowledge gap, an NCI-funded R25 grant supported the development and implementation of an educational curriculum in geriatrics for oncology nurses. **Methods:** Competitively chosen 3-person nursing teams (manager, educator, and clinical provider) from cancer settings across the nation participated in a 2 $^1/_2$ day course in geriatrics for oncology nurses. Teams developed 3 goals aimed to improve geriatric oncology care in their settings. Goals were coded into detailed subcategories by PI and Co-Is. Code categories included: research-focused, clinical care, education, geriatric assessment, symptom focused, caregiver-related, infrastructure/team building, and other. Progress in implementing the goals was tracked at 6, 12, and 18 months post course. Goal completion rate over time was analyzed using generalized estimating equation for repeated measure. **Results:** 99 nurses (34 teams) participated in the 1st conference. A single goal may have had 2-3 codes applied and therefore 3 goals per 34 teams yielded a total of 181 codes. The most common goals focused on improving geriatric oncology clinical care (23%; N = 41 codes), professional education (23%; N = 41), geriatric assessment (9%; N = 16), infrastructure/team building (8%; N = 14) and resource development (7%; N = 13). Overall goal achievement at 6, 12, and 18 months was categorized as never started (29%, 7%, 4%), stopped (2%, 10%, 15%), stalled (9%, 20%, 13%), in process (48%, 38%, 30%) and completed (13%, 25%, 37%). Fourteen (8%) of the 41 clinical care goals and 8 (4%) of the education goals had stopped or stalled. Four teams had goals that were not started by 18 months. Goal completion rate increased significantly from 6 to 18 months ($P < .0001$). By 18 months, 67% of the goals were either in process or completed. **Conclusions:** An education curriculum in geriatrics for oncology nurses was implemented. Over the subsequent 18 months, nurses enacted goals to improve geriatric oncology care in their institutions. Continued follow-up and support is needed post course to foster goal completion.

11004 Poster Session (Board #1), Mon, 8:00 AM-11:30 AM

Quantitative assessment of learning behaviors for oncology providers. *First Author: Marie Wood, University of Vermont, Burlington, VT*

Background: Understanding how different types of providers choose topics and activities for learning is key to meeting their needs. We sought to identify these needs in a diverse group of oncology providers. **Methods:** An online focus group study was conducted between November 2015 and August 2016. Participants were ASCO members and chosen by convenience and stratified random sampling. Participants included international, domestic, academic, and private practice providers as well as physicians and advanced practitioners (AP). Providers were asked monthly to journal their learning needs and explain how they identified that need. They were then asked what learning activity they chose to meet that need and what informed their choice. **Results:** 201 journal entries from 32 providers were reviewed; 47% from academic settings, 9% APs, and 41% international. Individuals provided an average 6 entries (range 1 to 17). Learning needs were associated with practice setting and professional role, with a significant association between practice setting and a making a choice based on a self-identified knowledge gap ($p = .005$). Colleague recommendation impacted learning needs for APs ($p < .001$), and patient cases drove $> 50\%$ of identified learning needs across groups. Preference for learning activity type, formal versus informal, was associated with practice setting ($p = .02$). The choice of learning activity was associated with practice setting, professional role, and geographic location, with international providers more likely to consider cost ($p = .001$) and provider reputation ($p = .03$) when selecting activities. Colleague recommendation was important for APs ($p = .011$). Over 75% of learner responses identify convenience and quality of content as factors in choosing an activity. **Conclusions:** To our knowledge, this study represents the first quantitative assessment of learning behaviors for oncology providers and shows that identification of learning needs and activity selection differ among them. Our cohort was small and may limit the generalizability of our findings. Future research should focus on educational needs of different members of the oncology care team and rank priorities for learning.

11006 Poster Session (Board #3), Mon, 8:00 AM-11:30 AM

Development and implementation of an instrument for assessing the proficiency of oncology fellows in the delivery of bad news. *First Author: Mark Allan Hoffman, Long Island Jewish Medical Center, New Hyde Park, NY*

Background: Breaking bad news is the quintessential difficult communication task for oncologists. Baile et. al., (The Oncologist, 2000) published SPIKES, a six step protocol for delivering bad news. "S" stands for optimizing the environment and physical approach to the patient, "P" assessing the patient's perception, "I" obtaining invitation to give the news, "K" giving knowledge, "E" addressing emotion and "S" summary and strategy. **Methods:** At Northwell Cancer Center, we have recently developed a 2-month Communication Course for multidisciplinary first year oncology fellows, addressing core communication skills, spirituality/coping, assessing for depression, discussing sexuality, delivering bad news, communication with adolescents/young adults, communication with families and transition to palliative care. We have formulated a version of SPIKES, named "MR. SPIKES" for teaching bad news delivery. "MR." represents pre-encounter Mental preparedness and Rehearsal (agenda setting, anticipating patient's concerns). The "S" now encompasses six functions: Summary, Strategy, Survey of all concerns, Sustaining realistic hopes/goals, Support/reinforcement of coping systems and Statement of continuing partnership. A 21-item assessment tool was synthesized assessing the expanded SPIKES component of MR.SPIKES (2 items for setting, 6 items for emotion/empathy,1 item for perception, 1 for invitation,2 for preparation,4 for delivery of news, 1 for strategy, 1 for concerns,1 for hope/goals, 1 for coping assessment, 1 for partnership). The tool was then used by 4 experienced raters to assess videotaped encounters between trainees and standardized patients. **Results:** Preliminary assessment of inter-rater reliability using Gwet's $'AC_1$ resulted in coefficients ranging from moderate to substantial (0.47 to .075) agreement. Inter-item reliability was also good (Cronbach's alpha of 0.84). **Conclusions:** A 21 item instrument based a modified version of SPIKES has been developed to assess proficiency of trainees in breaking bad news, and has shown very promising reliability.

11007 Poster Session (Board #4), Mon, 8:00 AM-11:30 AM

Creation of a high-fidelity simulation tool to teach competency in radiation oncology treatment plan evaluation. *First Author: Jenna Adleman, Radiation Medicine Program Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Although treatment plan evaluation (TPE) is a core competency for radiation oncology residents, gaps in teaching exist. The purpose was to create an interactive TPE case bank for residents to improve competency. **Methods:** A needs assessment informed case bank development. Residents assessed their confidence in TPE using a 10-point Likert scale (1 = least, 10 = most confident). A list of clinically unacceptable plans were compiled and categorized by clinical site, reason for rejection and relevance. An interactive web-based DICOM-RT tool was used to query and interact with the case bank database. A companion software tool, acting as an interactive simulation platform, was created allowing user interaction. **Results:** Twenty-three participants (70%) responded to the needs assessment: 6 junior, 7 senior and 10 former residents. Opportunities for improving TPE were identified; the mean confidence scores were: target coverage assessment (6.3+ 2.7), doses to normal tissue (6.2+2.5), conformity (5.5 +2.6), plan acceptability (5.4+2.5) and ability to suggest improvements (4.8+2.3). Extracted themes for case bank development included incorporating diverse clinical sites, target coverage/normal tissue assessment, conformity and provision of feedback. Of the 677 clinically unacceptable plans, a final list of 50 were selected for inclusion. They were categorized, anonymized and imported. Additional (un)acceptable plans were generated to augment the case bank where required. The companion simulation software platform describes each clinical scenario and allows residents to enter their assessment and suggested corrective action (if applicable). The platform then provides immediate feedback, including error description and correction strategy. **Conclusions:** An innovative TPE case bank has been created to address a learning gap in radiation oncology training. The high fidelity simulation format allows case interactivity and feedback with the goal of improving TPE competency. This platform can be leveraged for teaching/assessment in competency based medical education. Future work will evaluate resident satisfaction with and effectiveness of the case bank as a learning tool.

11008 Poster Session (Board #5), Mon, 8:00 AM-11:30 AM

Implementation of a model for training and career development in the emerging academic field of global oncology. *First Author: Rebecca Deboer, University of California, San Francisco, San Francisco, CA*

Background: As interest in global oncology increases, the need to support early career investigators is a priority, as advocated by the ASCO Global Oncology Leadership Task Force. The Global Cancer Program (GCP) at UCSF strives to implement a novel multifaceted strategy to support trainees from UCSF and our partner institutions in low and middle-income countries in pursuing careers focused on global cancer research and capacity-building. **Methods:** In 2017, the GCP launched a Global Cancer Fellowship (GCF) for post-doctoral trainees, Future Global Cancer Leaders (FGCL) monthly seminar, and quarterly Global Cancer Lecture Series. GCF protects research time, provides mentorship, and lends credibility to an unprecedented career track in this emerging field. FGCL is a multi-disciplinary group of students, residents, fellows, and others who convene to share experiences, present works-in-progress (WIPs), and interact with faculty mentors and visiting experts. After one year GCP evaluated the feasibility and adoption of this strategy and measured early indicators of effectiveness with an anonymous survey administered to FGCL members. **Results:** Post-doctoral trainees in public health (DB; Nepal), medical oncology (RJD; U.S.), and surgery (MM; Kenya) were selected as inaugural GCF recipients in 2017-18. Monthly FGCL seminars were regularly attended; 21 trainees responded to the survey. Despite variable training levels and disciplines, 19 (90%) reported that the meetings were "just right" for their level. All meeting formats were rated as very or extremely valuable to career development (4-5 on a 5-point Likert Scale) by a majority of respondents. The most preferred formats were "town halls" with visiting experts (89% Likert 4 or 5), faculty lectures (85%), presenting a WIP (74%), and reviewing a WIP presented by a peer (70%). **Conclusions:** A multifaceted strategy to support trainees in pursuing global oncology careers is feasible, adopted with high fidelity, and effective by early measures. In 2018, the GCP aims to expand support for trainees at partner institutions; for example, providing funding and mentorship for pilot research projects submitted by trainees at our partner institution in Tanzania.

11009 Poster Session (Board #6), Mon, 8:00 AM-11:30 AM

Global oncology fellowship electives: The impact on cancer care and international collaborations. *First Author: John Butonzi, Ministry of Health, Butaro, Rwanda*

Background: To meet the rising demand for cancer care in low-middle-income countries (LMIC's), an accredited Global Health track in Hematology-Oncology Fellowship programs (HOFP) is needed. To determine feasibility, the Geisel School of Medicine at Dartmouth (GSMD) HOFP piloted a bi-annual, one-month elective in Rwanda supervised by GSMD faculty. Objectives included exchange of knowledge in a resource-stratified setting and engagement in scholarly collaborations. **Methods:** Program objectives were implemented by GSMD HOFP in partnership with the Rwandan Ministry of Health, the NGO Partners In Health, and the Butaro Hospital Cancer Center of Excellence (BCCOE) in Butaro, Rwanda. Mentorship opportunities, formal lectures, organizational changes, research projects and funding sources were tracked. Fellows were evaluated using ACGME clinical competencies. **Results:** The 2-year pilot program was 100% enrolled by fellows from 3 US HO programs and one rising first year HO fellow (N = 4). Seven educational, research and quality improvement projects and three organizational changes were implemented. Three grant proposals for research collaborations are in process. Fifty percent of participating fellows plan to pursue careers in Global Health. The HO fellows gained perspective on cancer care and capacity-building in a LMIC, and confidence in teaching. BCCOE staff gained knowledge and mentorship, ideas for quality improvement, and increased expertise with treatment protocols. Rwandan colleagues valued the solidarity generated by a long-term partnership. Faculty were funded by a combination of CME, Fellowship and Vacation time. **Conclusions:** A global oncology fellowship elective is feasible and has a qualitative impact on care delivery and collaboration in LMICs influencing fellows' career choices and professional growth of colleagues at partner sites. Long-term partnerships complement the task-sharing approach to cancer care. Financial sustainability requires formal institutional support for faculty participation. A Global Health track in HO that includes international applicants from LMICs will encourage multi-disciplinary collaboration and expand our capacity for quality global cancer care.

11010 Poster Session (Board #7), Mon, 8:00 AM-11:30 AM

Ten years of ASCO/ESMO global curriculum for training in medical oncology implementation at Instituto Oncologico Nacional in Panama City, Panama. *First Author: Omar Orlando Castillo Fernandez, Instituto Oncologico Nacional, Panama City, Panama*

Background: Cancer is a leading cause of death in Panama. In 2007 the Instituto Oncologico Nacional endorsed the ASCO/ESMO global curriculum core (GCC) for training in Medical Oncology with a view to address the lack of cancer specialists in the country. The aim of this study is to evaluate the benefit of GCC to our institution. **Methods:** We assess the benefit in three ways: Human resources benefit (the number of medical oncologist before and after the GCC implementation, numbers of fellows, number of fellows visiting from others countries/ programs), Academic benefit (papers published and posters presentations in International Oncology meetings) and Inter-institutional benefit (number of academic center outside Panama receiving our fellows for observership and clinical rotations). **Results:** The proportion of medical oncologist in the institution has increased in 300% (from 4 to 14). Over this decade 15 fellows have been admitted (12 from Panama, 3 from Dominican Republic. 10 graduated and 5 currently in training). We have hosted clinical rotation visits from others medical oncology regional programs: 3 from Dominican Republic, 1 from Peru, 1 from El Salvador, 1 pathologist from Colombia, 1 surgical oncology form Nicaragua and 1 interventional radiologist from Costa Rica. Eight papers have been published in collaboration with mentors from others institutions and 18 posters were presented in International Oncology Meetings (1 ASCO Annual Meeting , 4 ESMO Congress, 4 ENETS Conference, 2 SABCS, 2 IASLC WCLC, 2 ESMO-WCGC, 4 LALCA-IASLC). Our fellows have undergone clinical rotations in academic centers in United States (Memorial Sloan Kettering Cancer Center, Cleveland Clinic, Massachusetts General Hospital Cancer Center) and Europe (Vall d´Hebron University Hospital, Instituto Valenciano de Oncologia and Instituto Oncologico Rosell). **Conclusions:** To integrate ASCO/ESMO GCC to local training programs offers assistance and academic benefits to institutions in developing countries. Closer relations with mentors and academic centers in developed countries is key to inspire and motivate fellows and trainers.

11011 Poster Session (Board #8), Mon, 8:00 AM-11:30 AM

Use of medical simulation for cancer education in Nigeria. *First Author: Kelechi Ngozi Eguzo, University of Saskatchewan, Saskatoon, SK, Canada*

Background: Among the many limitations of cancer control in Nigeria are lower awareness/competence and poorer training of healthcare professionals (HCP). These manifest as deficiencies in advocacy, screening /diagnostic practices, and patient management. Medical simulation (MS) using models is an effective approach for sustainably improving the competence of HCP, especially regarding clinical breast examination (CBE), pelvic examination (PE) and digital rectal examination (DRE). Study evaluates the effect of MS during a Nigerian training course focusing on CBE, PE and DRE. It answers the question: what are the perspectives of HCP on use of MS for cancer education? **Methods:** Participants included a convenience sample of Nigerian physicians and nurses who attended the ASCO-sponsored Multidisciplinary Cancer Management Course. Intervention was MS using high-fidelity models. The models demonstrated normal anatomic and common pathologic features of the breast, cervical and prostate. Participants cycled through MS stations (i.e. CBE, PE and DRE). Pre-and post-training surveys with comments evaluating self-reported comfort levels were basis for comparison. Data analysis included descriptive statistics, Wilcoxon signed rank test, chi-square and thematic analysis. **Results:** Of the 92 course participants (physicians-36, nurses-16), 51 completed the course evaluation forms (response rate = 55.4%; 51/92), and average number of years in practice was 8 (±5.2) years. Pre-training survey showed non-significant differences in practices patterns; 71% (22/35) of physicians rarely performed PE (p = 0.92), and 93% (14/16) of nurses rarely performed DRE (p = 0.07). According to some participants, "the use of simulation is quite commendable as it gives room for improvement before using a human; "it is the best method of learning I have ever enjoyed." **Conclusions:** MS-based training significantly improved the comfort levels of participants regarding CBE and PE, as well as their likelihood to perform CBE, PE and DRE. Participants recommend widespread use of MS for continuing medical education and undergraduate training.

Comfort levels	Median	IQR	P-value
CBE (Pre)	4	4-4	< 0.01
CBE (post)	5	4-5	
PE (Pre)	4	2-5	< 0.01
PE (Post)	5	4-5	
DRE (Pre)	3	1-5	0.01
DRE (Post)	3	1-4	

11012 Poster Session (Board #9), Mon, 8:00 AM-11:30 AM

Assessing trainee's need and readiness for e-cancer education and training in Africa. *First Author: Omoruyi Credit Irabor, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA*

Background: As a prerequisite to launching a virtual education and training platform, the African Organization for Research and Training in Cancer (AORTIC) assessed the educational needs and e-Learning readiness of Sub-Sahara African oncology staff before designing ICT support systems. **Methods:** Using existing assessment models, we developed a self-assessment tool for a cross-sectional survey. Competence areas assessed include basic knowledge, early detection and diagnosis, clinical skill, cancer registry, and cancer management respectively. Components of e-Learning readiness assessed include access to technology, technological skills/ competence, capacity for self-directed learning, confidence prerequisite skills, and motivation. We calculated an average score for each component as (Sum of positive response/Sum of responses). **Results:** There were 128 respondents. 33%, 44%, 48%, 58% and 60% felt they needed further training in the areas of basic knowledge, early detection and diagnosis, clinical skill, cancer registry, and cancer management respectively. Reported internet access for e-Learning is 100%, significantly higher than the 31.2% internet penetration of Sub-Sahara Africa. However, only 15.7% have a bandwidth of quality to support real-time visual learning. Weighted averages for technological access, skill, competence, capacity for self-directed learning, motivation, and prerequisite skills was 69%, 86%, 51% 42% and 80% respectively. **Conclusions:** There are deficiencies in the training of oncology health professionals in all five competency areas, and e-Learning can supplement ongoing traditional training to meet the gap. The low access to the internet in Africa may not be disruptive to asynchronous oncology training but may limit real-time video-based synchronous learning which involves more intense interaction between trainees and trainers. However, African bandwidth growth trend indicates this limitation is fast diminishing. African oncology health professionals are technologically competent for e-Learning and score high in the prerequisite skills. There is, however, a low ability for self-directed learning, and many may need a support system for the advanced virtual education.

11013 Poster Session (Board #10), Mon, 8:00 AM-11:30 AM

Impact of closed Facebook group participation on women hematology/oncology physicians. *First Author: Julia Lee Close, University of Florida, Gainesville, FL*

Background: Making meaningful connections is an important aspect of career satisfaction. The Hematology Oncology Women Physician Group (HOWPG) is a private Facebook (FB) group of 936 women who practice within the hematology and oncology (H/O) field. We hypothesized that HOWPG adds value to the education, emotional wellness, and practice of oncology for its membership. A survey was conducted within HOWPG to define the impact this group has on members. **Methods:** A voluntary, anonymous 12-question online survey was distributed to members of HOWPG by sharing the survey link in the FB group 4 times between 11/16/2017-1/03/2018. Participants were surveyed regarding demographic data, general FB use vs. exclusive use of HOWPG, and opinions regarding HOWPG value and impact. Survey was approved by University of Florida institutional review board. **Results:** Of the 936 members of the site, between , and 169 completed the survey. 9% were fellows, 65% in practice $<$ 10 years, 26% $>=$ 10 years. 62% were less than 40 years of age and 35% between the ages of 40-49. 85% practice adult H/O, and the remainder divided between pediatric H/O, radiation oncology, surgical specialty and palliative care. 90% use FB at least daily, with 82% accessing the HOWPG group at least daily, 16% using less than daily but at least twice per week. The most common uses for the site included education (65%-89%), advice on complex cases (65%), emotional support (65%), and networking (55%). On a scale of 1-10, learning from clinical cases (9.0) and emotional support (8.4) were rated the most beneficial aspects. The aspects of the group rated most important were: membership limited to women, physicians, in the H/O field, secret group. **Conclusions:** The HOWPG FB group has provided an opportunity for education, clinical and emotional support. Social media can be an effective venue to educate physicians, augment patient care via advice, foster networking, reduce burnout, and improve career satisfaction amongst women physicians in the field of hematology and oncology.

11014 Poster Session (Board #11), Mon, 8:00 AM-11:30 AM

Oncology education for family medicine (FM) residents and family physicians (FPs): A needs assessment survey. *First Author: Steven Yip, BC Cancer Agency Vancouver Cancer Centre, Vancouver, BC, Canada*

Background: Cancer care demands in FM continue to grow. This study aimed to determine the current state of oncology education in FM and examine opinions regarding optimal FM oncology education. **Methods:** A survey was designed to evaluate ideal and current oncology teaching, topics and objectives in FM post graduate medical education (PGME) and continuing medical education (CME). The survey was pilot-tested and sent to FM residents and FM program directors (PDs) across Canada and FP Cancer Care Committee members of the College of Family Physicians of Canada. **Results:** From May 1 - August 31, 2017, 131 FM residents and 15 FM PDs affiliated with 16 of 17 Canadian medical schools and 42 FPs completed the surveys. The PGME survey results are in Table 1. Residents reported that the best way to learn oncology is through clinical experiences alone. PDs stated that case-based and didactic teaching are also important. Residents and PDs agreed that the most important topics are cancer prevention, cancer screening, breaking bad news, and palliative care. These topics were taught to 89-100% of residents. Yet, the other important topics of appropriate cancer patient referrals, managing cancer complications and post-treatment surveillance were only taught to 52%, 40% and 36% of residents, respectively. According to 40% of FPs, the amount of oncology CME completed was inadequate; 21% reported that CME inadequately updates their knowledge in cancer patient management. **Conclusions:** Current FM PGME oncology education is sub-optimal across Canada, although the degree differs between the opinions of the residents and PDs. Sub-optimal oncology teaching is also likely for FM CME. FM oncology education can be improved using suggestions generated from this survey.

PGME results.

	Residents	PDs
There is an oncology clinical rotation	118/130 (91%)	15/15 (100%)
There are oncology learning objectives	17/130 (13%)	5/15 (33%)
Cancer topics are taught in clinic	73/127 (57%)	15/15 (100%)
Oncology education provided is adequate	10/130 (8%)	3/15 (20%)
Training adequately prepared me to care for cancer patients	11/130 (8%)	2/15 (13%)
Standardized oncology learning goals, objectives and competencies would be useful	93/128 (73%)	8/15 (53%)

11015 Poster Session (Board #12), Mon, 8:00 AM-11:30 AM

Utilization of a web-based supportive oncology training curriculum for healthcare professionals (HCPs). *First Author: Shelly S. Lo, Loyola University Medical Center, Maywood, IL*

Background: A challenge in supportive oncology, is training the HCP workforce. A collaborative funded by The Coleman Foundation of 30+ clinicians (faculty) from 25 institutions (academic, community & safety net) developed a unique and easily accessible supportive oncology training curriculum (Trosman JR JNCCN 2017). **Methods:** Using data provided by The National Comprehensive Cancer Network (NCCN) Continuing Education team, we evaluated completion rates of survivorship and supportive oncology education courses using simple frequencies. **Results:** Over 4748 on-line courses were completed (pretest, course, post-test, evaluation) of 7184 accessed. Of 4748 courses, nurses completed 45%, physicians 17%, advance practice clinicians 16%, and others 22% (social workers, chaplains, MAs). Course completion improved from 65% to 69% after articles describing collaborative work were published in Cure and Oncology Nursing News, p = 0.0014. **Conclusions:** A variety of HCPs successfully completed supportive oncology education via the NCCN's education portal. These on-line courses are an efficient way to train HCPs in supportive oncology. Curriculum advertising improves course completion.

Education Course	Accessed	Completed	Completion Rate
Distress: Impact on Care, Screening for and Addressing	621	456	73%
Survivorship Factors: Lifestyle/Behavior, Psychosocial Challenges, Late & Long-term Effects	569	404	71%
Primary Palliative Care vs. Specialized Palliative Care and Reasons to Refer to Hospice and Palliative Care	465	324	70%
Cancer Survivorship Defined, Patient Needs, and CoC Requirements for care plans	584	405	69%
Supportive Care and Documenting Patient's Supportive Needs	507	350	69%
How to Discuss Practical and Family Concerns	384	263	68%
Comprehensive Care for Cancer Survivors	485	326	67%
Cancer Survivor Screening and Genetic Testing	523	341	65%
Pain Assessment: The Basics	542	352	65%
Nausea/Vomiting, Constipation, Dyspnea & Shortness of Breath	690	441	64%
Goals of Care and Advance Care Planning over Time	408	248	61%
Pain Management: Beyond the Basics	619	373	60%
POLST Paradigm: Physician Orders for Life Sustaining Treatment Paradigm	284	169	60%
How to Communicate Prognosis	503	296	59%
Totals	**7184**	**4748**	**66%**

11016 Poster Session (Board #13), Mon, 8:00 AM-11:30 AM

Gender differences in faculty rank amongst radiation oncologists in United States: A cross-sectional study. *First Author: Irbaz Bin Riaz, Mayo Clinic, Rochester, MN*

Background: Female faculty in academic medicine is underrepresented in leadership positions and reportedly has fewer publications, lower h-indices and grant funding. However, there is a lack of evidence examining whether this gender disparity persists after adjusting for scholarly productivity and clinical experience among academic radiation oncologist. **Methods:** We used the Fellowship and Residency Electronic Interactive Database (FREIDA) to identify faculty members of radiation oncology residency training programs in the US . Faculty rank (assistant, associate and full professor) was obtained by review of program website. Data on physician gender, clinical experience in years, number of publications, *h*-index, clinical trial investigator, advance degree and ranking of medical school was collected using program websites, Doximity and Scopus databases. Primary outcome of the study was a binary outcome odd of professorship versus assistant plus associate professorship. We used a multivariable logistic regression model to estimate the gender difference in full professorship after adjusting for these factors. **Results:** A total of 906 radiation oncologists were included in the final analysis. 70.2% (n = 636) were men and 29.8% (n = 270) women. Women had less clinical experience (median of 10 years vs 14 years, $p < 0.0004$), fewer publications (median of 17 vs 32 publications, $p < 0.0001$), less *h*-index (median of 7 vs 12, $p < 0.0001$), less likely to be clinical trials investigator (41% vs 48%, p = 0.05), less likely holding advance degree (22% vs 28%, p = 0.067) but were more likely to be graduate of top 20 medical schools in research (27% vs 25%, p = 0.66). Women were under represented at higher faculty rank with 43 out of 270 (15.9%) were full professors compared to 194 out of 636 (30.5%) men with the absolute difference of 14.6% ($p < 0.001$). Moreover, women were found less likely to be full professors compared to men (odds ratio, 0.55; 95% confidence interval, 0.32-0.94; p = 0.029) in adjusted logistic regression analysis. **Conclusions:** Among radiation oncology faculty gender disparity exists at higher faculty ranks even after accounting for academically relevant factors influencing the academic progress.

11017 Poster Session (Board #14), Mon, 8:00 AM-11:30 AM

Opportunities for provider education in the use and interpretation of liquid biopsy. *First Author: Christine Elaine Lee, Guardant Health, Inc., Redwood City, CA*

Background: Increasingly affordable comprehensive genomic profiling (CGP) has exponentially expanded the amount of data available to oncologists, and liquid biopsy has made CGP more accessible. Given comprehensive liquid biopsy has only been commercially available since 2014, and the average age of a practicing oncologist is 52, liquid biopsy education was not a component in the majority of providers' formal training. Data from both community and academic settings suggests physicians' confidence around interpretation of genomic tests may play a critical role in clinical decision making. Physician knowledge is also a strong predictor of physicians' anticipated use of testing. Although liquid biopsy has gained in popularity and acceptability, little is known about providers' confidence in interpreting these results. **Methods:** Between 1/2016 and 1/2018, we prospectively documented provider calls with test-related questions. We then attempted to characterize major themes in provider inquiries related to genomic testing and liquid biopsy. **Results:** 811 consecutive provider contacts were recorded. Of those, 434 included completed survey data. Approx. 75% of these contacts originated from community-based practices and almost 70% of contacts were from providers who had ordered 5 or less tests. Of genomic questions, 49% were specific to liquid biopsy and most providers had ≥ 2 questions. Common questions about cfDNA results included: Is there enough mutation present to warrant treatment? (13%), What is the ideal timing of testing? (11%), Could this mutation be hereditary? (11%), What does mutant allele fraction mean? (8%). Interestingly, over 25% of all providers surveyed had questions regarding basic genomic principles not specific to liquid analysis. The remainder of questions varied, but many were related to NGS technology. **Conclusions:** Providers in both community and academic centers sought genomics support when interpreting a comprehensive liquid biopsy result. Questions regarding general genomics and liquid biopsy were asked at similar rates in this analysis. Though liquid analysis is an emerging field, our data suggests there is still a need for basic genomic education across provider types.

11018 Poster Session (Board #15), Mon, 8:00 AM-11:30 AM

Prospective study of the perceptions of oncology residents about learning from tumor boards. *First Author: Ramachandran Venkitaraman, Ipswich Hospital, Ipswich, United Kingdom*

Background: Tumor boards are a unique and integral component of oncology practice. Participation in the tumor board is an important aspect of education of oncology residents. This qualitative study based on phenomenological methodology, was conducted to assess the perception of residents and supervisors about how learning happens in tumor boards. **Methods:** Semi-structured interviews of ten oncology residents and five supervisors were conducted. The participants were requested to describe their experience of participating in and their perceptions of learning from tumor boards. The transcripts of the interviews were analysed by thematic analysis, to identify unifying themes which could explain how learning happens in tumor boards **Results:** All the residents and the supervisors perceived the tumor board meetings to be a good learning opportunity. The major underlying themes about learning from tumor boards that emerged from the interviews were: Educational gain (Positive experience vs Constraints), Involvement of the residents (Passive vs Active), Progression of residents (Junior vs Senior), Multi-Disciplinary Team dynamics (Integrated/Motivating vs Hierarchical/Intimidating), Background Reading and Learning (Pre-tumor board preparation vs Post- tumor board learning) and Feedback and Reflection (Formal vs Informal). **Conclusions:** Learning in tumor boards occur by active involvement of the residents. According to the residents, pre- tumor board preparation and post- tumor board reading are important for educational gain. The residents felt that their active involvement and learning from the tumor board meetings improved as they progress through their programme. Multi-disciplinary team dynamics was perceived to be an important determinant of resident learning in tumor boards

11019 Poster Session (Board #16), Mon, 8:00 AM-11:30 AM

The MD CaREs initiative: Tailoring oncology education to ethnically and culturally diverse students. *First Author: Zuanel Diaz, Miami Cancer Institute, Baptist Health South Florida, Miami, FL*

Background: Although more than 23,000 oncologists are practicing in the United States, a markedly small number of these are Hispanic/Latino. Related perhaps are statistics reflecting the poor representation of minorities in clinical trials, even for tumors from which minority outcomes are disproportionately poor compared to non-minority patients. **Methods:** To address these issues, we establish a partnership between a hybrid academic-community cancer center and a college of medicine, both with a history of addressing the needs of Hispanics/Latinos, a minority and typically underserved population. This partnership aims to increase participation of minority undergraduate, medical and graduate students in cancer research through a novel educational approach. Its curriculum concentrates on emerging fields in oncology, features research experiences, participation in execution of clinical trials and incorporates an outreach program to underserved populations. **Results:** Departing from well-established programs, we injected innovative education elements. We created a competency-based mixed modality course that includes an on-line interactive sessions for medical students to expand their skills in cancer screening and prevention at the individual, community, and health systems levels, with an emphasis on breast and cervical cancer, disparities and underserved populations. We also created an advanced Multidisciplinary Oncology Clinical Elective for 4th year medical students that introduces biospecimen banking science, tumor molecular profiling, medical physics, clinical research, and clinical cancer genetics. Finally, we enriched two long-standing programs which target undergraduate minority students, aimed at increasing the number of underrepresented candidates accepted to medical school, by providing opportunities to learn cutting-edge methodologies. **Conclusions:** A strong partnership that focuses on cancer research, education and training should contribute to a more diverse clinical and research workforce, an initiative that is ideally implemented in South Florida.

TPS11020 Poster Session (Board #17a), Mon, 8:00 AM-11:30 AM

A feasibility study to examine the role of a mindfulness-based wellness curriculum for early clinical trainees. *First Author: Monica Sheila Chatwal, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

Background: Physician wellness has become a topic of great interest within the medical field as rates of burnout, depression, and career dissatisfaction have increased. This topic is of particular interest in oncology, with 45%-80% of practicing oncologists worldwide reporting symptoms of burnout (Hlubocky et al. ASCO 2017). Despite the growing interest, there are few programs to address these issues in early clinical trainees, specifically hematology oncology fellows. Mindfulness is a strategy that can be used to recognize and cope with stress and burnout and foster resiliency. Several studies evaluate its use in chronic illness, but also physician burnout. The goal is not to focus on relaxation, but rather on self-awareness, thus extending into a form of "reflective practice" (Epstein, JAMA 1999). This may translate into more effective clinical experiences and stress management skills. **Methods:** This is a single-center, non-randomized pilot project to assess the feasibility and impact of a mindfulness-based wellness curriculum. All hematology oncology fellows at our institution are eligible for enrollment. A total of six monthly 30 minute sessions will be conducted within the framework of the existing didactic conferences. Each session is led by a social worker trained in mindfulness techniques. Participants will complete questionnaires pre- and post-intervention. Primary aim is feasibility determined through recruitment, participation, completion and compliance rates. This will also provide data for sample size estimation for a full-scale RCT. Secondary aim is acceptability, assessed using post-intervention questions addressing usefulness of the program. Exploratory aim is to collect and examine data on self-reported stress and self-awareness – Mindful Attention Awareness Scale (MAAS) (Carlson, 2005) and Perceived Stress Scale (PSS) (Cohen, 1983). Enrollment began in December 2017 and 27 of 28 eligible participants have enrolled and completed pre-session questionnaires. One session has been conducted to date. To our knowledge, this is the first study assessing this type of intervention in this population.

TPS11021 Poster Session (Board #17b), Mon, 8:00 AM-11:30 AM

Establishment of a medical student elective on the oncology consult service using the seven principles of teaching. *First Author: Hari Anant Deshpande, Yale Cancer Center, New Haven, CT*

Background: A busy academic oncology consult service has challenges for effective student teaching. The aim of this research is to establish an academic oncology elective through signature pedagogies - learning in the practice setting. **Methods:** The Seven Principles of teaching and learning will be used to develop an effective teaching model for the Inpatient Oncology Consult service. 1 Prior knowledge is the key to learning 2 Prior knowledge must be activated 3 Learners must be actively involved in constructing personal meaning (ie: understanding) – the links are more improtant than the elements 4 Making more and stronger links requires time 5 Context provides important cues for storing and retrieving information 6 - A Intrinsic motivation is associated with deep approaches to learning; B Extrinsic motivation and anxiety are associated with surface approaches to learning 7 - Teaching should be geared toward making the teacher increasingly unnecessary; that means the development of learner autonomy as well as intellect To address these principles: 1 - A short 10 question quiz to ascertain prior knowledge of general oncology 2 - Activate prior knowledge by asking about experiences or planting concepts at the beginning of the discussion. This should reflect the students' interests: e.g.. focusing on the disease, the social aspects, financial aspects, symptom management or end of life care. 3 - Encourage teachers to be guides, coaches or co-inquirers more than a source of knowledge during rounds to encourage deep and holistic rather than surface discussions. 4 - Allow students time to elaborate their knowledge base – make links between subjects as well as between theory and practice to focus on intrinsic motivation. Limit the size of the teaching service. 5 - Teach in the context from which they eventually use their knowledge. Observe patient encounters and critique their presentations. 6 - A flipped curriculum where the student studies an aspect that then can be discussed in more detail; this becomes the basis for constructing a management plan. 7- A feedback session to stay within the students' zone of proximal development and maintain in the course. Development of a smartphone app for assessment.

11500 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Phase III, randomized, double blind, placebo-controlled trial of sorafenib in desmoid tumors (Alliance A091105). *First Author: Mrinal M. Gounder, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY*

Background: DT is a rare cancer of connective tissue affecting young patients (pts), arising in any location, with a wide natural histories. DT is locally infiltrative and may cause pain, loss of mobility, bowel obstruction and visceral organ compromise. Death is rare. There is no standard of care (SoC), but surgery, observation and systemic therapies are used. S is an oral drug inhibiting VEGFR2/PDGFRB/RAF, showing activity in DT in case series. **Methods:** We conducted an international prospective study to evaluate efficacy of S (400 mg qd) in unresectable progressive (PD) or symptomatic DT. Pts were randomized 2:1 (S:P) and crossover to S upon RECIST 1.1 PD. Stratification: pain-level and disease site. Primary endpoint was progression-free survival (PFS). 75 pts yielded 90% power (1-sided $\alpha = 0.025$, 1 interim analysis) to detect a hazard ratio (HR) of 0.4 (favoring S), assuming 6 month (mo) median (md) PFS for P and 15 mo for S, requiring 52 PFS events. Other endpoints: response rates (RR); toxicity (tox); overall survival; patient-reported outcome (PRO); tumor and imaging biomarkers. **Results:** 87 pts (37 P, 50 S) enrolled over 17 mo at 25 sites [69% female, md age 37 years (yr) (range 18-72), 62% chemo-naive, 9% prior RT]. Tumor location and pain level were balanced. 30% (11/37) P and 38% (19/50) S pts continue; 18% (9/50) ended S due to tox (0% P). 33% (16/49) S, 14% (5/36) P pts had grade 3-4 tox, primarily rash, hypertension, fatigue, pain. For the 1st 75 evaluable pts (med f/u 26 mo): PD 69% (22/32) P, 16% (7/43) S, 1 death (S); Durable partial RR 33% (14/43, 2–28 mo) on S and 21% (7/32, 4–17 mo) on P ($p = 0.3$); 1-yr PFS: 43%-P, 87%-S; Med PFS: 9.4 mo (95% CI 5.7-NE) for P, not reached for S [HR = 0.14 (95% CI 0.06-0.33), $p<0.0001$)]. Analyses of PRO, MRI T2 signal and tumor biopsy are ongoing. **Conclusions:** Phase III studies in rare cancers are feasible and rapidly conducted in an NCTN group setting. Here, S was well tolerated with significantly improved PFS. Spontaneous RR on P is consistent with observational trials in DT. The study exceeded its primary endpoint for PFS. DSMB recommended unblinding (P offered S). S may represent a new 1st-line or subsequent-line SoC in select pts with DT. Support: U10CA180821, U10CA180882, U24CA196171, R01FD005105. Clinical trial information: NCT02066181.

11501 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

DESMOPAZ pazopanib (PZ) versus IV methotrexate/vinblastine (MV) in adult patients with progressive desmoid tumors (DT) a randomized phase II study from the French Sarcoma Group. *First Author: Maud Toulmonde, Institut Bergonié, Department of Medical Oncology, Bordeaux, France*

Background: DT are a group of locally aggressive tumors of fibroblastic origin that can lead to significant morbidity. No randomized trial assessing systemic treatment activity in this rare disease has been reported previously. **Methods:** DESMOPAZ is a multicenter non-comparative randomized phase II trial based on a two-stage optimal Simon's design assessing safety and efficacy of PZ in DT adult patients (pts). All pts had to have documented progressive disease (PD) according to RECIST 1.1 based on two imaging within a 6-months interval. Pts were randomly assigned to receive PZ 800 mg/day orally continuously, or M (30 mg/m²) + V (5mg/m²) intravenously once a week for 6 months and then every 15 days for 6 months. Treatment was administered until PD (cross-over then permitted), unacceptable toxicity, and for a maximum of 1 year. The primary endpoint was 6-month non-PD rate according to RECIST 1.1. Based on the following hypotheses: P0 = 60%, P1 = 80%, $\alpha = 5\%$ and $\beta = 20\%$ and a 2:1 randomization, a total of 43 assessable pts were needed in PZ-arm and 22 pts in MV-Arm. PZ could be regarded as an active drug if at least 31/43 6-month non-PD. Archive FFPE samples of tumor tissue were mandatorily collected at baseline, and an on-treatment tumor biopsy at Cycle 2 was optional. **Results:** Accrual started in September 2012 in 12 centers of the French Sarcoma Group. As of December 2017, 72 pts (26 males, 46 females) were included: 48 in PZ-arm (46 assessable) and 24 in MV-arm (20 assessable). Median age was 40 years (18-79). The median number of previous lines of treatment was 1 (0-3). After central pathological and radiological review, 38 assessable pts (82.6%) in PZ-arm had tumor shrinkage, resulting in PR in 17 (37%) and SD in 21 (45.7%). In MV-arm, 11 assessable pts (55%) has tumor shrinkage resulting in PR in 5 (25%) and SD in 6 (30%). The 6-month non-PD rate was 86% (95%CI = 72.1-94.7) in PZ-arm (37/43) and 50% (95%CI = 27.2-72.8) in MV-arm (10/20). **Conclusions:** The primary endpoint of the DESMOPAZ study was reached. PZ has meaningful clinical activity in pts with progressive DT. Safety, quality of life and pharmacodynamics translational data will be presented at the meeting. Clinical trial information: NCT01876082.

11502 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Final results of ENLIVEN: A global, double-blind, randomized, placebo-controlled, phase 3 study of pexidartinib in advanced tenosynovial giant cell tumor (TGCT). *First Author: William D. Tap, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: TGCT is a rare neoplasm of the joint/tendon sheath associated with colony-stimulating factor 1 (CSF-1) overexpression. No approved systemic therapy is available. Pexidartinib (Pex), a selective inhibitor of CSF-1 receptor, KIT, and FLT3-ITD, showed promising Phase 1 activity in TGCT. Two severe liver toxicity cases (1 required liver transplant, 1 associated with death) have been observed with Pex across the non-TGCT development program. **Methods:** Patients (pts) ≥18 yr with symptomatic TGCT, for whom surgery would be associated with potentially worse function or severe morbidity, were randomized (1:1) to Pex or placebo (Pbo) 1000 mg/d x 2 wks then 800 mg/d PO x 22 wks (Part 1). Pts completing Part 1 could continue into an open-label Pex extension (Part 2). The primary endpoint was centrally reviewed overall response rate (ORR) by RECIST at Week 25 for which the study was powered to detect a 25% difference (35% vs 10%). **Results:** 120 pts were treated, 61/59 on Pex/Pbo. Due to 2 cases of nonfatal, serious hepatic toxicity, the DMC halted enrollment 6 pts short of target and stopped entry of pts on Pbo into Part 2. At the end of Part 1, ORR by RECIST in the ITT population was 39.3% vs 0% ($P< 0.0001$); after a median 6-mo follow-up (longest 17 mos), no responders have progressed. Secondary endpoints for Pex vs Pbo were ORR by tumor volume score (55.7% vs 0%, $P< 0.0001$), range of motion (+15.1% vs +6.2%, $P =0.0043$), PROMIS physical function (+4.06 vs -0.89, $P =0.0019$), worst stiffness (-2.45 vs -0.28, $P <0.0001$), and pain response (31.1% vs 15.3%, 1-sided $P= 0.032$). Hepatic toxicities were more frequent with Pex (AST ≥5X ULN 11.5%, ALT ≥5X ULN 19.7%, total bilirubin ≥2X ULN 4.9%). 8 pts discontinued Pex due to hepatic effects; 4 were serious nonfatal AEs with increased bilirubin, one lasting ~7 mos. Other AEs ≥15% and more common with Pex included hair color changes, vomiting, fatigue, dysgeusia, and periorbital edema. **Conclusions:** Pex resulted in significantly improved ORR and clinical benefit in terms of functional outcomes. Serious liver toxicity was observed in some pts. Pex may offer a relevant treatment option for select pts. Clinical trial information: NCT02371369.

11503 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Anlotinib for metastasis soft tissue sarcoma: A randomized, double-blind, placebo-controlled and multi-centered clinical trial. *First Author: Yihebali Chi, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: No standard therapy is available in China for soft tissue sarcoma (STS) patients progressed after first-line chemotherapy. Anlotinib has shown single-agent activity in a phase II study presented orally at 2016 ASCO. This study aimed at confirming anlotinib's efficacy and safety in advanced STS patients after failure of standard chemotherapy. **Methods:** Patients aged 18 years and older with angiogenesis inhibitor naive, histologically proven advanced STS, intolerance or failure to anthracycline-based chemotherapy, at least one measurable lesion according to RECIST 1.1, were eligible. Those patients were randomly assigned (2:1) to receive anlotinib (12 mg per day 2 weeks on and 1 week off) or placebo. The pathologic subtypes enrolled were: synovial sarcoma (SS), alveolar soft part sarcoma (ASPS), leiomyosarcoma (LMS) and others. Different pathologic subtypes were also randomly assigned (2:1) to each arm. The primary endpoint was progression-free survival (PFS). This trial was registered with ClinicalTrials.gov, number NCT02449343. **Results:** 233 patients were randomly assigned to either anlotinib (n = 158) or placebo (n = 75) and included in the final analysis. The median PFS was 6.27 months (95% CI : 4.30-8.40) for anlotinib compared with 1.47 months (95% CI : 1.43-1.57) for placebo (HR = 0.33, $p < 0.0001$); objective response rate was 10.13% versus 1.33% ($p = 0.0145$); disease control rate was 55.7% versus 22.67% ($p < 0.0001$). For SS (n = 57), the median PFS was 5.73 months versus 1.43 months (HR = 0.2, $p < 0.0001$). For ASPS (n = 56), the median PFS was 18.23 months versus 3 months (HR = 0.14, $p < 0.0001$). For LMS (n = 41), the median PFS was 5.83 months versus 1.43 months (HR = 0.19, $p < 0.0001$). The most common grade 3 or higher adverse events were hypertension (18.99% with anlotinib *vs* 0 with placebo, p = 0.00), gamma glutamyl transferase elevation (4.43% *vs* 1.33%, p = 0.44), triglyceride increase (4.43% *vs* 0, p = 0.10), low density lipoprotein elevation (3.16% *vs* 2.67%, p = 1.00), hyponatremia (3.16% *vs* 1.33%, p = 0.67) and neutrophil count reduction (3.16% *vs* 0, p = 0.18). **Conclusions:** Anlotinib is a new treatment option for patients with advanced STS after failure of standard chemotherapy. Clinical trial information: NCT02449343.

11504 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Results of randomized, placebo (PL)-controlled phase II study evaluating efficacy and safety of regorafenib (REG) in patients (pts) with metastatic osteosarcoma (metOS), on behalf of the French Sarcoma Group (FSG) and Unicancer. *First Author: Florence Duffaud, La Timone University Hospital, Marseille, France*

Background: Oral multikinase inhibitor REG has shown activity in GIST and non-adipocytic soft tissue sarcomas. We designed REGOBONE as a non-comparative phase II, double-blind, PL-controlled trial to study the efficacy and safety of REG for pts with metOS and other types of bone sarcomas. This trial consisted of 4 independent cohorts : metOS, Ewing sarcoma, chondrosarcoma, and chordoma. We report here the metOS cohort results. **Methods:** metOS pts were randomized (2:1) to receive either REG (160 mg/d, 21/28d) or PL with optional cross-over at the time of confirmed central review of progressive disease (PD). Key-eligibility criteria were age ≥10 years, histologically confirmed diagnosis of OS, confirmed measurable PD not amenable to curative-intent, 1-2 previous chemotherapy (CT) regimen(s) for metastatic disease, and ECOG 0-1. 24 pts were planned in the REG arm based on A'Hern's single-stage design for phase II trials (1-sided $\alpha = 0.05$, and 80% power) to detect a 27% benefit in the progression-free rate at 8 weeks (P0 = 40%). Major secondary endpoints were PFS (per modified RECIST1.1), OS and safety. **Results:** From June 2014 to April 2017, 43 metOS pts were included. Five pts were not eligible for efficacy analysis. Of 38 efficacy-evaluable pts (12 in PL arm and 26 in REG arm) ; 24 were men, median age was 33 (18-74) years, 28 (74%) had 1 previous CT regimen. 17 pts (65.4% ; one-sided CI95% = [47.4%-]) were non-progressive at 8 weeks in the REG arm vs. 0 in the PL arm. Median PFS was 13.7 (CI95% = 8.0-27.3) vs. 4 (CI95% = 3.0-5.7) weeks for REG and PL arms, respectively. PFS rate at 24 weeks was 35% (CI95% = 17-52) in the REG arm vs. 0 in the PL arm. 1-year OS was 53% (CI95% = 31-71) and 33% (CI95% = 10-59) for REG and PL arms, respectively. Ten pts crossed-over to REG after centrally-confirmed PD on PL. The most common ≥Gr3 REG-related AEs during the double blind period were hypertension (24%), hand-foot skin reaction (17%), asthenia (10%) and diarrhea (7%). **Conclusions:** REG demonstrates very promising activity, with acceptable toxicity, in metOS after failure of conventional chemotherapy, justifying confirmatory trials. Clinical trial information: NCT02389244.

11505 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

A randomized, double-blind, placebo-controlled, phase II study of regorafenib vs placebo in advanced/metastatic, treatment-refractory liposarcoma: results from the SARC024 study. *First Author: Richard F. Riedel, Duke University Medical Center, Durham, NC*

Background: Pazopanib, a multi-targeted tyrosine kinase inhibitor, has shown activity in various soft tissue sarcomas. Activity in liposarcoma, however, is limited. Regorafenib is a multi-kinase inhibitor with anti-angiogenic properties similar to pazopanib. We conducted a randomized, phase II study of regorafenib (R) vs. placebo (P) in refractory liposarcoma patients (pts). **Methods:** Pts with advanced/metastatic, treatment-refractory liposarcoma were randomized 1:1 to receive regorafenib 160 mg daily or placebo (3 weeks on/1 week off). Pts. with well-differentiated liposarcoma only were excluded. Crossover for placebo pts was allowed upon progression. The primary objective was progression-free survival (PFS) for R vs P. Stratification factors included prior lines of therapy (1 vs 2+) and WHO performance status (0-1 vs 2). The study was powered to detect a difference of ≥ 3 months in median PFS. Secondary objectives included AE assessments, overall response rate (ORR), time to tumor progression (TTP), PFS at 8 and 16 weeks, overall survival (OS), and disease–specific survival (DSS). **Results:** Forty-eight subjects were enrolled with 47 (27 M: 20 F) having follow-up information. Median follow-up was 3.8 months (0.2-15.3). More women were randomized to R than men (58% vs. 42%; $p < 0.03$), otherwise baseline characteristics were similar between cohorts. Thirty-three dedifferentiated, 12 myxoid/round cell and 2 pleomorphic liposarcomas were included in the analyses. Most common grade 3-4 AEs observed with R included: grade 3 abdominal pain (13%), hypertension (13%), rash (13%), anemia (8%), anorexia (8%), generalized weakness (8%), and elevated lipase (8%); (grade 4 – none). One grade 5 event occurred in R and 3 in P. Median PFS was 1.9 (0.9-3.7) months for R vs 2.1 (1.6-3.1) months for P; stratified HR 0.87 (0.47, 1.64), p-value = 0.68. No responses were seen in R. One PR was observed in P. Median OS was NR (4.2-NR) for R vs 8.1 (2.9-NR) months for P, stratified p-value = 0.13. **Conclusions:** Regorafenib did not achieve the primary outcome of improved PFS in treatment-refractory liposarcoma. No new safety signals were observed. Clinical trial information: NCT02048371.

11506 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Randomized comparison of pazopanib (PAZ) and doxorubicin (DOX) in the first line treatment of metastatic soft tissue sarcoma (STS) in elderly patients (pts): Results of a phase II study (EPAZ). *First Author: Viktor Grünwald, Clinic for Hematology, Hemostaseology, Oncology and Stem Cell Transplantation, Medical School Hannover, Hannover, Germany*

Background: The systemic treatment standard of advanced, inoperable STS in elderly pts is single agent DOX. We tested the hypothesis whether PAZ has comparable efficacy to DOX in elderly STS pts, while offering better tolerability. **Methods:** Key inclusion criteria: age ³60 years, no prior systemic treatment for STS, progressive disease, ECOG 0-2, adequate organ function. DOX 75 mg/m2 q3wks for a total of 6 cycles or PAZ 800 mg OD continuously were given after 1: 2 randomization. ECOG 2 and liposarcoma histology were used for stratification. The primary endpoint was progression free survival (PFS) in the per protocol (PP) population. A non-inferiority design was applied with an upper limit of the 95% confidence interval (CI) of less than 1.8. Key secondary endpoints were neutropenia and febrile neutropenia in hierarchical order. EORTC QLQ-C30 was utilized to measure quality of life. Cox regression analysis, ANCOVA and Kaplan-Meier curves were applied (NCT01861951). **Results:** Between 10/2012 and 03/2016, 39 pts were randomly assigned to DOX and 81 to PAZ. The median follow-up was 11.8 months (mo). The median age was 71 years (range: 60-88). In the PP population, DOX vs. PAZ achieved a PFS of 5.3 vs. 4.4 mo (HR 1.00; 95%CI 0.65-1.53; P = .993), respectively. The incidence of neutropenia CTC grade 4 and neutropenic fever in patients were 56% and 10% for DOX and 0% and 0% for PAZ, respectively. OS was 14.3 vs. 12.3 mo. (HR 1.083; 95%CI 0.68-1.72; P = .735) for the intention to treat population. Most frequent AEs for DOX were fatigue (64.9%), alopecia (56.8%) and nausea (48.6%), and for PAZ fatigue (58.0%), nausea (43.2%) and diarrhea (43.2%). Similar outcome was reported for global EORTC QLQ-C30 measures. **Conclusions:** This study showed that PAZ was non-inferior compared to DOX, rendering PAZ a putative therapeutic option in the first line treatment of STS of pts above 60 years of age. The distinct AE profile may be used to council pts and tailor therapy to individual needs. Clinical trial information: NCT01861951.

Outcome of primary and key secondary endpoints

	DOX	PAZ	HR	95%CI	P value
PFS	5.3 mo	4.4 mo	0.998	0.650-1.533	0.993
Neutropenia grade 4	56%	0%	-	-	< 0.0001
Febrile neutropenia	10%	0%	-	-	0.003

11507 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Randomized phase II trial of trofosfamide vs. adriamycin in elderly patients with previously untreated metastatic soft tissue sarcoma. *First Author: Joerg Thomas Hartmann, Franziskus Hospital Bielefeld, Catholic Hospital Consortium Estern Westphalia, Bielefeld, Germany*

Background: DOX is still the standard in metastatic STS. We assessed the efficacy and safety of oral TRO. **Methods:** This is a randomized phase 2 trial at 15 german and 1 french centers. We included pts with metastatic high-grade STS, older than 60 yrs of age, with an ECOG of 0-1. They were randomly (1:2) assigned to either (A) DOX (60 or 75 mg/sqm i.v., on day 1, q 22 d for 6 cycles) or arm B (oral TRO, 300 mg, d1-7, then 150mg daily continuously p.o.) as first-line tx. Randomisation was stratified by presence of liver mets, and PS (0 vs 1). Pts were treated until PD or unacceptable toxicity. Primary aim was a 6-months (mos) PFS rate of at least 20 % in Arm B; secondary: safety, ORR, survival. **Results:** Between 8/04 and 10/12 40 pts were randomly assigned to arm A and 80 to Arm B, median age 70 yrs (60-89). Median duration of f/u of surviving patients was 18.4 mos (range, 3.8-94.7). Median treatment duration was 2.8 mos (0-4.6) in A and 2.8 mos (0.4-41.4) in B. No difference in terms of ORR with 7.7% (1.6-20.9) in arm A and 6.7% (2.2-14.9%) in arm B (p = 0.99); disease control rate (including disease stabilization) (53.8% (95%-CI, 37.2-69.9%) vs. 41.3% (95%-CI, 30.1-53.3%), p = 0.23), PFS (4.3 mos; 95%-CI, 2.2-5.9 vs. 2.8 mos; 95%-CI, 1.6-3.5), p = 0.99) and OS (9.6 mos; 95%-CI, 6.4-11.6 vs. 12.1mos; 95%-CI, 9.5-16.0), p = 0.59) were seen, without difference in ITT- and per-protocol populations. Duration of response lasted 5.0 mos in arm A (range, 1.3-8.0) and 4.0 mos (0-46.6) in arm B; however, in pts achieving a CR or PR duration was longer in favor of cohort B (0 vs. 27.7 mos resp. 4.3 vs. 8.2 mos). Primary study endpoint (6-mos PFR) was 27.6% in Arm B (95%-CI, 18.0-39.1). Safety analyses in 115 pts showed at least one side effect in 97.4% vs. 96.1% pts (p = 0.99); of note, side effects G3-4 were lower in favor of Arm B (59% vs. 30.3%; p = 0.005). TRO caused more often dyspnoe, fatigue (but only minor degree); DOX leukocyto- and neutropenia as well as mucositis, G1-4. Discontinuation rate other than PD was 15.4% vs. 7.9%. **Conclusions:** In an elderly population of pts who received either standard Dox or oral TRO for metastatic STS, equal median PFS and OS have been achieved. TRO associated with a more favorable toxicity profile. Clinical trial information: 00204568.

11508 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Results of a prospective randomized phase III T-SAR trial comparing trabectedin (T) *vs* best supportive care (BSC) in patients with pretreated advanced soft tissue sarcoma (ASTS): A French Sarcoma Group (FSG) trial. *First Author: Axel Le Cesne, Gustave Roussy Cancer Campus, Villejuif, France*

Background: With the exception of a study in translocation-related STS (Kawai, 2015), T has never been compared to BSC in a study including patients (pts) with all sarcoma histotypes. The efficacy, safety and quality of life of T *vs* BSC as second or later treatment line were evaluated in pts with ASTS in a multicenter FSG trial. **Methods:** The study enrolled pts ≥18 years of age with histologically proven ASTS who progressed after at least 1 anthracycline-containing regimen (≤3 previous chemotherapy (CT) lines), stratified by L-STS (lipo-leiomyosarcoma) and non L-STS and with a WHO performance status score 0-1. Pts were randomized 1:1 to receive either T (1.5 mg/m^2 24h every 3 weeks) or BSC until disease progression (PD), unacceptable toxicity, or patient's request. Pts allocated to BSC could cross over to T at PD. The primary endpoint was progression-free survival (PFS). **Results:** Between January to November 2015, 103 pts (median 65 yrs (range 22-84), grade 3 ASTS in 57% of cases, median number of 1 prior CT lines) were enrolled by 16 FSG centers, 52 in the T arm and 51 the BSC arm. Pts with L-STS and non L-STS represented 60% and 40% of pts, respectively. Two pts refused to be allocated in the BSC arm and received other CT. The objective response rate (ORR) in the T arm was 11.8%, all observed in the L-STS group (ORR: 18.8% in L-STS). 23% of pts in the T arm received more than 9 cycles of T. The median PFS were 1.5 months (m) in the BSC arm and 3.1m in the T arm (HR: 0.39, $p < 0.0001$). In the L-STS cohort, the median PFS were 1.4m and 5.1m in the BSC and T arm (HR: 0.29, $p < 0.0001$), respectively, whereas in the non L-STS group they were 1.5m and1.8 m ($p = 0.16$). A cross-over was performed in 92% of pts included in the BSC arm. By After a median follow-up of 25.7 months, the differences on OS were not statistically significant between the two arms, 13.6 m vs 10.8 m in the T and BSC arms respectively ($p = 0.86$). **Conclusions:** This study met its first endpoint as a preplanned PFS analysis showed a significant improvement in median PFS with T over BSC in pts with pretreated ASTS of multiple histologies. L-STS pts benefit the most from T therapy in terms of prolonged tumor control. Clinical trial information: NCT02672527.

11509 Poster Discussion Session; Displayed in Poster Session (Board #254), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 3:00 PM-4:15 PM

A phase I pharmacokinetic (PK) and pharmacodynamic (PD) study of PLX9486 alone and in combination (combo) with the KIT inhibitors pexidartinib (pexi) or sunitinib (su) in patients (Pts) with advanced solid tumors and gastrointestinal stromal tumor (GIST). *First Author: Andrew J. Wagner, Dana-Farber Cancer Institute, Boston, MA*

Background: Most metastatic GISTs have primary (1^0) mut in KIT exons (ex) 9 or 11, which confer sensitivity to imatinib and other agents. Tumors develop clonal secondary (2^y) resistance mut, typically in ex 13, 14, 17, and 18. PLX9486 inhibits KIT 1^0 mut and ex 17 and 18 2^y mut. Pexi (PLX3397) and su inhibit 1^0 mut and ex 13 and 14 2^y mut. Combo of PLX9486 with pexi or su may have activity against a broader spectrum of mutations. **Methods:** 3 + 3 dose escalation study in pts with solid tumors and GIST who had progressed on imatinib and other TKI. Safety, efficacy per RECIST, and PK were assessed. Ct DNA was assessed as a biomarker. Part (P) 1: single agent PLX9486 dose escalation once (QD) and twice daily (BID). P2: combos of PLX9486 500 mg QD with pexi 600 mg QD fed and fasted or su 25 mg QD with food. **Results:** As of January 8, 2018, 36 pts (31 GIST; Part 1-20 pts, part 2-11 pts) were enrolled; median age was 63 years (range 49-82). GIST pts had a median of 4 prior therapies (range 1-7), and all progressed on imatinib. Most pts had tumors with ex 11 and 17 mut. QD dosing of PLX9486 had saturable absorption at steady state with a half-life of 71.4 hrs. No PK advantage to BID dosing and no food effect. One DLT of Grade (G) 3 anemia was reported at the 1000 mg dose level. Escalation stopped due to PK plateau; the RP2D was 1000 mg QD. In P2, no DLTs were observed at the doses studied. PK of PLX9486 was not affected by pexi. Pexi food effect was observed. Adverse events (AEs) in P1 in ≥ 20% pts (N = 24) were diarrhea, nausea, increased AST (29% each) and fatigue (21%). AEs in P2 in ≥ 20% pts (N = 12) were hair color changes (42%), anemia (25%), nausea (25%), and anorexia (25%). Majority were G1-2. No ≥ G3 LFT changes in P1 or P2. In P1, 2 partial responses (PR) were seen with PLX9486 1000 mg and PFS was > 24 weeks. In P2, 1 pt had a PR in the pexi/PLX9486 combo, and the median PFS has not been reached. **Conclusions:** PLX9486 alone and in combo with pexi was generally well tolerated with evidence of activity against resistant GIST. Combos with su and pexi, agents with complementary activity against KIT 2^y resistance mut in GIST, are accruing. Clinical trial information: NCT02401815.

11510 Poster Discussion Session; Displayed in Poster Session (Board #255), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 3:00 PM-4:15 PM

Phase Ib study of rapid alternation of sunitinib (SU) and regorafenib (RE) in patients (pts) with advanced gastrointestinal stromal tumor (GIST). *First Author: Cesar Serrano, Vall d'Hebron University Hospital Institute of Oncology (VHIO), Barcelona, Spain*

Background: Polyclonal emergence of KIT secondary mutations (muts) is the main mechanism of imatinib (IM) progression in GIST. Although approved KIT inhibitors SU and RE each suppress only a subset of these muts, they have shown complementary activity in GIST models and clinical trial correlates. Preclinical evidence suggests that rapid alternation of SU and RE broadens the spectrum of IM-resistant subclones targeted, compared to either agent as monotherapy. **Methods:** This phase Ib study of rapid alternation of SU and RE was performed in pts with IM-resistant advanced GIST. A standard 3+3 dosing schema was utilized to determine the recommended phase II dose (RP2D). Pts received continuous treatment with cycles of 3 days of SU followed by 4 days of RE. Plasma samples for pharmacokinetics and ctDNA studies (deep next generation sequencing and ddPCR) were collected at several timepoints. **Results:** Fourteen pts were enrolled, and 13 received treatment. Median age 64 (range 42-78), 43% female, median prior therapy 4 (range 3-7, all pts had ≥ 3 prior therapies). SU 37.5mg daily 3 days followed by RE 120mg daily 4 days was established as the RP2D. Two dose limiting toxicities (DLTs) occurred at DL2 (asymptomatic G3 hypophosphatemia). Non-DLT G3/4 toxicities were hypertension (1/13 pts) and hand-food syndrome (2/13 pts). 8/13 patients experienced dose modification, delay, or both. No unexpected toxicities were observed. Of the 13 pts with evaluable CT scans, stable disease (SD) was the best response observed in 4 pts by RECIST. Median progression free survival was 8.4 weeks (95% CI of 6.0-15.7). SU and RE did not reach the steady state, although pts with SD had higher median drug concentration than progressing pts. ctDNA studies show that GIST has low ctDNA shedding and remains KIT-driven even at late stages of disease, with a predominance for activation-loop secondary mutations. **Conclusions:** Rapid alternation of drugs with complementary activity is a well-tolerated treatment strategy. Drug exposure is critical to target effectively specific subpopulations. Although GIST sheds low ctDNA in this heavily pretreated population, identifying KIT muts in plasma is feasible. Clinical trial information: NCT02164240.

11511 Poster Discussion Session; Displayed in Poster Session (Board #256), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 3:00 PM-4:15 PM

Mutation profile of drug resistant gastrointestinal stromal tumor (GIST) patients (pts) enrolled in the phase 1 study of DCC-2618. *First Author: Suzanne George, Dana-Farber Cancer Institute/Harvard Medical School, Boston, MA*

Background: GIST is driven by primary and secondary driver mutations in KIT/PDGFRα and cell-free tumor (ct) DNA may provide the opportunity to assess disease status and response to therapy. The pan-KIT/PDGFRα switch control inhibitor DCC-2618 has demonstrated durable disease control in heavily pre-treated GIST pts in the ongoing Phase 1 study (NCT02571036). **Methods:** Pts with advanced GIST were treated in either the escalation stage or in expansion cohorts of the Phase 1 study with oral DCC-2618. Tissue and liquid biopsies were performed and tested via next generation sequencing (NGS) of tumor tissue and/or plasma ctDNA. **Results:** A total of 136 2nd to 7th line (median of 3 prior therapies) GIST pts (KIT or PDGFRα mutations by local testing) were enrolled as of January 18, 2018 and treated with doses of ≥100 mg per day. 132 patients had a ctDNA sample available for baseline assessment by NGS. To date, activating mutations in KIT or PDGFRα were identified in 71% of baseline ctDNA analyzed from 77 pts. In the 53 confirmed KIT mutant GIST pts, exon 13/14 mutations were detected in 16 patients (30%); while exon 17/18 mutations were detected in 33 patients (62%). Notably, multiple patients had mutations in both exons 13/14 and 17/18. 92 GIST patients had at least one additional ctDNA sample available at first restaging. The correlation between tumor tissue and ctDNA, and the change in KIT/PDGFRA mutant allele frequency for GIST pts following the first 2 cycles of treatment with DCC-2618 will be presented. 76% of 136 pts are still on treatment. In 99 GIST pts with ≥1 on-study tumor assessment, the overall response rate (ORR) was 16%. **Conclusions:** Identification of ctDNA by NGS in the majority of patients in this cohort was feasible. The mutation profile of GIST in both tumor and plasma suggests the need for a pan-KIT inhibitor across various lines of therapy. DCC-2618 is being tested in a pivotal, randomized phase 3 study, INVICTUS, (NCT03353753) in the 4th+ line population with plans to be tested in a second Phase 3 study in 2nd line GIST. ctDNA in this patient population deserves further study as a non-invasive marker of disease heterogeneity and response assessment. Clinical trial information: NCT02571036.

Phase 2 results of selinexor in advanced de-differentiated (DDLS) liposarcoma (SEAL) study: A phase 2/3, randomized, double blind, placebo controlled cross-over study. *First Author: Mrinal M. Gounder, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY*

Background: Locally advanced DDLS is incurable with an overall survival of 11 – 20 mo with palliative therapies. Ideal imaging criteria for efficacy is currently undefined. Selinexor (S) is an oral, selective inhibitor of nuclear export that specifically blocks exportin 1, leading to the nuclear accumulation and reactivation of tumor suppressor proteins. S demonstrated anti-tumor activity against DDLS in preclinical studies and a Ph 1b study in patients (pts) with soft tissue sarcomas. **Methods:** Eligible pts had DDLS and progressive disease (PD) with $\geq$ 1 prior systemic therapy. Pts were randomized 1:1 to receive blinded S (60 mg) or placebo (P) twice weekly; 42 day cycle until PD or intolerability. Pts with PD on P may cross over to S. The primary endpoint was progression-free survival (PFS) by WHO criteria. Pre-specified analyses using RECIST v1.1 (R v1.1) was included. **Results:** Ph 2 enrollment is complete. 56 evaluable pts (33 M, 23 F) were randomized to S or P. Median age: 61 yrs and median prior treatments: 2 (1-9). Treatments for 51 pts were unblinded (24 S, 27 P). The main reason for ending blinded treatment was PD confirmed by Independent Central Radiological Review by WHO Criteria. Common AEs Grade 1/2 (S:P) were: nausea (85% : 31%), anorexia (62% : 14%), and fatigue (58% : 45%). Grade 3/4 AEs were: hyponatremia (15% : 0%), anemia (15% : 7%), and thrombocytopenia (12% : 0%). 12 pts on S had dose reductions due to AEs. There was no difference in median PFS by WHO. By R v1.1, median PFS on S: 5.6 mo; P: 1.8 mo, hazard ratio of 0.64 (p 0.21, not powered in Ph 2). (Table 1). Some pts ended treatment early with small changes in tumor burden due to PD by WHO criteria. **Conclusions:** R v1.1 may be better criteria than WHO to evaluate drug efficacy in DDLS. Improvement of PFS (R v1.1) is promising and supports continuation of the Ph 3 portion of S in DDLS. Clinical trial information: NCT02606461.

Median PFS by R v1.1 and WHO criteria.

Treatment Arm	R v1.1 - PFS (mo)	Hazard Ratio (95% CI)	WHO - PFS (mo)	Hazard Ratio (95% CI)
Selinexor (N = 24)	5.6	0.64 (0.31, 1.32) p = 0.21	1.4	0.92 (0.52, 1.63)
Placebo (N = 27)	1.8		1.4	

11513 Poster Discussion Session; Displayed in Poster Session (Board #258), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 3:00 PM-4:15 PM

Whole exome sequencing (WES) of metastatic leiomyosarcoma (LMS) and liposarcoma (LPS) and correlation of genomic aberrations with clinical outcomes in the phase III randomized trial of trabectedin (T) vs. dacarbazine (D). *First Author: Gurpreet Kapoor, Scientific Operations, LabConnect LLC, Seattle, WA*

Background: This phase 3 study (NCT01343277) showed statistically significant improvement in disease control by T vs. D in patients (pts) with metastatic LMS and LPS (Demetri et al., JCO, 2016). WES was done to explore associations between genomic alterations and clinical outcomes in this prospective database. **Methods:** Of 518 pts enrolled on study, archival tumor samples were collected from 456 (88%) pts: 180 uterine LMS (uLMS), 149 non-uterine LMS (non-uLMS), 66 de-differentiated LPS (ddLPS), 46 myxoid LPS (mLPS) and 15 pleomorphic LPS (pLPS). Peripheral blood samples from a subset of 346 patients were also analyzed as matched normal to filter noise from nonpathogenic variants in WES. **Results:** Consistent with sarcoma TCGA data, these LMS and LPS samples had frequent homozygous gene deletions with relatively low mutational load. TP53 & RB1 alterations were frequent in LMS compared to LPS, and showed no association with clinical outcomes. Analyses of 103 DNA damage response (DDR) genes showed frequent ($>$ 20%) somatic alterations across subtypes, correlating with improved PFS only in uLMS tumors (HR: 0.63, p = 0.03). Genomic alterations in PI3K pathway genes were noted in 30% of mLPS and associated with worse PFS (HR: 3.0, p = 0.045). A trend towards better OS was noted in ddLPS tumors with MDM2 amplification (90%) compared to normal MDM2 copy number. Certain subtype-specific genomic aberrations in immune modulation pathways (uLMS and ddLPS) were associated with worse clinical outcomes, whereas alterations in immune suppressors (non-uLMS) and lipid metabolism (ddLPS) were associated with improved clinical outcomes. **Conclusions:** This detailed genomic analysis of a large cohort of metastatic LMS and LPS pts matched with prospective data on treatment outcomes suggests that aberrations in oncogenic pathways (DDR, PI3K, MDM2-p53) and immune modulation may contribute to response or resistance to treatment with T or D. Further analyses should inform our understanding of sarcomas and may aid clinical decision making for LMS and LPS.

A phase 1 study of MDM2 inhibitor DS-3032b in patients with well/de-differentiated liposarcoma (WD/DD LPS), solid tumors (ST) and lymphomas (L). *First Author: Todd Michael Bauer, Sarah Cannon Research Institute/Tennessee Oncology, Nashville, TN*

Background: Inactivation of p53 is the most frequent event in cancer driven by mutations in *TP53* or overexpression of MDM2, a negative regulator of p53. DS-3032b is an oral small molecule that disrupts the MDM2-p53 interaction, resulting in reactivation of wild type p53 and causing growth arrest/apoptosis. We characterized the safety, tolerability, maximum tolerated dose (MTD), pharmacokinetics (PK) and pharmacodynamics (PD) and preliminary efficacy of DS-3032b. **Methods:** Patients (pts) received DS-3032b orally in 28 days cycle as per Table. TP53 status was confirmed post-enrollment. **Results:** 94 pts were enrolled with ST (50, 53%), WD/DD LPS (40, 43%), L (4, 4%). Doses, schedules (Sch), MTDs and responses are tabulated below. Median age was 60.5 years, 50% male, 63% had $\geq$ 3 prior therapies. 73/84 (87%) pts tested had WT TP53. The most common ($>$ 10%) TEAEs were nausea 71%, vomiting 31%, diarrhea 40%, decreased appetite 37%, abdominal pain 16%, dry mouth 11%, thrombocytopenia 61%, neutropenia 28%, anemia 43%, fatigue 55%, dysgeusia 18%, headache 19%, cough 19% and peripheral edema 14%. There were 8 dose limiting toxicities (DLT): six Gr 2-4 thrombocytopenia +/- neutropenia; 3 events resolved, 3 unresolved. One Gr 3 nausea, vomiting and anorexia and another Gr 2 fatigue. Sch D (3/14 days) had the best safety profile. In 79 efficacy-evaluable pts, 47 (60 %) achieved stable disease (SD). Median duration of SD was 6.7 (1.6 to 36.4) months. Partial responses (PR) were seen in DDLPS, synovial sarcoma and lung ca (SC).PK parameters AUC0-24h and Cmax were dose proportional with median Tmax 3 hours. PD biomarker MIC-1 correlated with drug exposure. In paired biopsies, MDM2 inhibition resulted in increase of nuclear p53 levels (IHC) in 5/6 pts (83%). **Conclusions:** DS-3032b has acceptable safety profile with intermittent dosing. Objective responses and durable SD were seen in MDM2 amplified ST and DDLPS warranting further studies Clinical trial information: NCT01877382.

Schedule, days	Doses, mg	N = 94 pts	Histology	MTD, mg	Best Response
A – 21/28	15 – 240	40	ST/L	120	SD

IMMUNOSARC: A collaborative Spanish (GEIS) and Italian (ISG) Sarcoma Groups phase I/II trial of sunitinib plus nivolumab in selected bone and soft tissue sarcoma subtypes—Results of the phase I part. *First Author: Javier Martin Broto, Virgen del Rocio University Hospital, Institute of Biomedicine Research (IBIS)/CSIC/Universidad de Sevilla, Seville, Spain*

Background: Disruption of angiogenesis substantially enhances the efficacy of immune-based cancer therapies. The combination of an antiangiogenic drug (sunitinib or pazopanib) plus anti- PD1 (nivolumab) exhibited both higher activity and toxicity compared with antiangiogenic drug alone in renal cell carcinoma (RCC). We hypothesized that sunitinib (SU) and nivolumab (NI) could be synergistic in some sarcoma subtypes and the toxicity profile could be different from RCC. We present the results of phase I part of the combination of SU-NI in advanced sarcoma patients (pts). **Methods:** Pretreated progressing pts, ECOG 0-1 and diagnosed with UPS, synovial sarcoma (SS), clear cell sarcoma (CCS), angiosarcoma (AS), epithelioid hemangioendothelioma (EH), solitary fibrous tumor (SFT), epithelioid sarcoma (ES), osteosarcoma (OS), Ewing sarcoma (EWS) or dedifferentiated chondrosarcoma (DCh) were eligible. SU 37.5 mg/d as induction was given for the first 14 days. The dose-finding stage (from day 15 to 45) would be completed when 10 dose limiting toxicity (DLT)-evaluated pts had been treated with DLT rate $<$ 0.33. Two level- doses were designed: (0 initial) SU 37.5 mg/d or (-1) SU 25 mg/d along with NI 3 mg/kg/2w for both. SU-NI was maintained up to progression or intolerance. **Results:** From May to October 2017, 16 pts (M/F 10/6), median age 38y (25-78) were enrolled. Diagnosis was: CSS in 4 (25%), ASPS in 3 (19%); AS, OS, SS (2 each, 12.5%); UPS, extraskeletal OS and Ch (1 each, 6%). There were three DLT in the first 6 pts at dose level 0 (G3 fatigue in 2 and G4 septic shock) and 1 DLT in the following 10 pts at level -1 (febrile neutropenia). G3/4 toxicity: fatigue 25%, thrombocytopenia 19%, mucositis 13% and neutropenia 13%. There were 6 RECIST PR (42.8%), 4 SD (2 of them 25% of shrinkage) and 4 PD in 14 evaluable pts. PR occurred in 2 CCS and in one of AS, Ch, SS, ASPS while 2 cases (ASPS and UPS) shrank 25%. **Conclusions:** At the RDP2 (SU 25 mg/d and NI 3 mg/kg/2w), SU-NI is a feasible combination with manageable toxicity. SU-NI has induced objective responses in several sarcoma subtypes. The study is currently on a phase II part. Clinical trial information: NCT03277924.

A phase II study of talimogene laherparepvec (T-VEC) and pembrolizumab in patients with metastatic sarcoma. *First Author: Ciara Marie Kelly, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: T-VEC is an oncolytic immunotherapy derived from HSV type-1 that is modified to selectively replicate within tumors and produce GM-CSF. Pembrolizumab (P) demonstrated activity in selective sarcoma (SAR) subtypes. The combination of T-VEC and P has shown favorable safety and efficacy in melanoma. We performed an open-label, single-center, phase II study evaluating T-VEC and P in patients (pts) with advanced SAR who failed at least one standard systemic therapy where available. **Methods:** Pts received P (200mg/dose) and ≤4ml of T-VEC injected into palpable tumor site (s). Both drugs were administered on day 1 of a 21-day cycle. The primary endpoint was best objective response rate (RR) (complete response and partial response [PR]) at 24 weeks by RECIST 1.1, with 30% as promising and 5% as not promising. If ≥ 3 responses were observed in 20 pts the combination would be claimed to be positive. Secondary endpoints included adverse events (AEs), RR by irRECIST, progression free and overall survival. Correlative studies included PD-L1 expression by IHC (Qualtek), multiplex IHC, characterization of tumor infiltrating lymphocytes, mutational burden/neoantigen analysis, and T cell receptor clonality. **Results:** 20 pts were enrolled [median age 63.5 yrs (range, 24-90), 60% female]. Represented histological subtypes included: leiomyosarcoma (25%), cutaneous angiosarcoma (15%), SAR not otherwise specified (15%), undifferentiated pleomorphic SAR (10%) and "other" SAR subtype (35%). Pts were refractory to 0 (10%), 1 (20%), and ≥ 2 (70%) prior regimens. Grade (G) 3 treatment related AEs (TRAEs) occurred in 2 pts (10%); fever from TVEC & pneumonitis from P. No G4/5 TRAEs were seen. 1pt stopped P due to G3 TRAE. Among 19 evaluable pts 4 confirmed PRs (21%), 9 stable diseases (SD) (47%) and 6 progressions (32%) were observed by RECIST 1.1. Two of the SDs had decrease in tumor burden of 17% and 28.6% at their first (week8) interval scan. PRs were seen in 3 histologies. The time to PR ranged from 8 to 32 weeks (wks) and all PRs are ongoing (range 1 -36 wks). **Conclusions:** TVEC and P demonstrated acceptable safety and promising anti-tumor activity across a range of SAR histologies. 4 pts maintain a PR. Correlative analyses are ongoing. Clinical trial information: NCT03069378.

Compared descriptive analysis of immunologic landscape in soft tissue sarcoma and GIST. *First Author: Armelle Dufresne, Centre Léon-Bérard, Lyon, France*

Background: Development of immune therapy in sarcoma faces a high heterogeneity of the different histological subtypes, molecular subtypes and immune infiltrate. This is likely to account for the limited response rates in sarcomas of single agent PD1/PDL1 Ab in most series. The objective of this study was to provide a description of immunologic landscape of sarcoma to guide the next clinical trials of immune therapy in these diseases. **Methods:** All patients included in this study had soft tissue sarcoma (STS) and were managed in expert centers of the French Sarcoma Group. Tumor samples were obtained from surgical resection of the primary tumor. Clinical characteristics of patients, tumor and disease evolution were extracted from the Netsarc databases. Gene expression of 90 immune check point (ICP) and membrane markers (MM) of immune cells were performed using Agilent Whole Human Genome Microarrays and correlated to pathological diagnosis and survival. **Results:** This study included 87 STS with complex genetics (SCG), 60 gastrointestinal stromal tumors (GIST), 58 synovial sarcomas (SS) and 50 myxoïd liposarcomas. Overall, there was substantial level of expression of almost all of the ICP/MM across the 4 sarcoma sub types even if important expression heterogeneity was observed across sarcoma subtypes, and across patients within the same tumor type. A strong correlation existed between specific ICP/MM expression profile and the 4 different sarcoma subtypes allowing unsupervised hierarchical clustering to discriminate the histological sub types. Among the 90 genes studied, 40 had a prognostic impact on at least one subgroup. IDO1 seems interesting to target in SCG, NK cells had a strong role in GIST, and SS had an unexpected profile and a T cell-related poor prognosis. **Conclusions:** Sarcomas are heterogenous diseases in terms of histotypes, molecular subtypes, and now as shown here, in terms of MM and ICP expression. To elaborate strong rationale of immune therapy approaches in each sarcoma sub types, present data of ICP and MM expression and prognosis will have to be integrated with mutational load and aneuploidy that appears relevant predictive factors.

11518 Poster Discussion Session; Displayed in Poster Session (Board #263), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 3:00 PM-4:15 PM

Prognostic stratification using the nomogram sarculator and its impact on study results in a randomized controlled trial (RCT) for localized soft tissue sarcomas (STS): A secondary analysis of the EORTC-STBSG 62931. *First Author: Sandro Pasquali, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: To determine whether high-risk STS patients identified using individual patient data and the nomogram Sarculator, benefitted from adjuvant chemotherapy in a RCT which failed to detect any overall survival (OS) differences between chemotherapy and observation. **Methods:** Data from the EORTC 62931 RCT comparing adjuvant doxorubicin plus ifosfamide (Adj) and observation (Obs) for STS (Lancet Oncol 2012;13:1045-1054) were analysed. 10-yr predicted probability of OS (P-OS) was computed using a validated nomogram (Lancet Oncol 2016;17:671-80) for each participant with extremity and trunk wall STS (N = 290/351). Patients were divided in 3 categories of P-OS. OS and disease-free survival (DFS) were calculated at the study median follow-up (8-yr). **Results:** Nomogram P-OS were dispersed (median 72%, IQR 57-83%) and had prognostic value for OS and DFS (Log-Rank test: $P < 0.001$). Patients were grouped in 3 arbitrary P-OS categories: > 66% (high P-OS), > 51≤ 66 (intermediate P-OS), ≤ 51% (low P-OS). Most patients were in the high P-OS category (N = 170 [58.6%], 90 Obs/80 Adj), while 68 (23.5%, 34 Obs/34 Adj) and 52 (17.9%, 24 Obs/28 Adj) fell in the intermediate and low P-OS category, respectively. Adjuvant chemotherapy halved the risk of death in patients with low P-OS (HR = 0.46, 95%CI 0.23-0.94) with a 21.2% 8-yr absolute risk reduction (ARR) of death (8-yr OS: 42% and 21% for Adj and Obs, respectively). This effect was not detected in the intermediate (HR = 1.00, 95%CI 0.53-1.88) and high P-OS categories (HR = 1.08, 95%CI 0.61-1.90). There was a DFS benefit for chemotherapy in low P-OS (HR = 0.46, 95%CI 0.24-0.89) but not in the intermediate (HR = 0.74, 95%CI 0.41-1.34) and high P-OS (HR = 0.90, 95%CI 0.54-1.50) categories, leading to a 21% 8-yr ARR for adjuvant chemotherapy (8-yr DFS: 34% and 13% for Adj and Obs, respectively). **Conclusions:** In this RCT patients with a low predicted P-OS (i.e., high-risk patients) have a statistically significant higher OS and DFS when treated with the study doxorubicin-ifosfamide chemotherapy, although the analysis on all study patients was negative. Clinical trial information: NCT00002641.

Efficacy and safety of lurbinectedin (PM1183) in Ewing sarcoma: Final results from a phase 2 study. *First Author: Vivek Subbiah, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Patients (pts) with relapsed Ewing sarcoma (ES) have a poor outcome. New therapeutic agents are needed. L is a new anticancer drug that blocks transcription and induces DNA double-strand breaks, leading to apoptosis. Moreover, in sarcomas associated with translocations, such as ES, in which the translocation produces a fusion protein that acts as a deregulated transcription factor, L might interfere with the binding of this protein to specific DNA promoters and thus with the synthesis of downstream proteins. **Methods:** A multicenter phase 2 trial to assess efficacy and safety of L in several types of advanced solid tumors (basket trial), including ES, is ongoing. In the ES cohort, 15 adult pts who had received no more than two prior chemotherapy regimens for advanced disease were recruited. If one confirmed response was observed, recruitment was to be increased to at least 25 evaluable patients. The study treatment was lurbinectedin 3.2 mg/m^2 in a 1-hour infusion every 3 weeks. **Results:** 28 evaluable pts were enrolled. Median age was 33 years (range, 18-74) and 16 (57%) were males. 26 (93%) had an ECOG of 0/1. ES was extraosseous in 15 pts; 7 pts had ≥3 disease sites and 27 had received ≥2 lines of prior chemotherapy. 28 pts received a median of 4 cycles of L (range, 1-12) and a median total dose of 11.9 mg/m^2 (range, 3.2-38.4). Efficacy: 4 pts (14.3%) had a partial response and 12 (42.8%) had disease stabilization, 6 of them for ≥4 months. Median duration of the response was 2.9 months (range, 2.9-5.5) and median progression-free survival was 2.8 months (CI 95% 1.4-4.2). Safety: Most common adverse events were related to myelosuppression: 53.6% neutropenia grade (G) 3/4, 14.3% febrile neutropenia, and 18% thrombocytopenia G 3/4; 6 pts had dose delay due to neutropenia G 2-4 or thrombocytopenia G1, and 6 pts had dose reduced because of neutropenia G2-4. G-CSF was given to 12 pts. There were no withdrawals or deaths due to toxicity. **Conclusions:** L as a single agent has shown activity in pretreated pts with advanced ES, with acceptable safety profile and tolerability. Myelotoxicity was well controlled with dose adjustments and G-CSF. Further and larger studies of L alone or in combination regimens are warranted for pts with advanced ES. Clinical trial information: NCT02454972.

Apatinib for advanced osteosarcoma after failure of standard multimodal therapy: An open label phase 2 clinical trial. *First Author: Lu Xie, Peking University People's Hospital, Beijing, China*

Background: Anti-angiogenesis Tyrosine kinase inhibitors (TKIs) have been proved to show promising effects on prolonging progression-free survival (PFS) for advanced steosarcoma after failure of standard multimodal Therapy. Methylsulfonic apatinib is one of those TKIs which specifically inhibits VEGFR-2. We aimed to assess the activity of apatinib in patients with locally advanced or multiple metastatic high-grade osteosarcoma progressing after standard treatment. **Methods:** This non-randomised phase 2 trial was done in Peking University People's Hospital. We enrolled participants (≥16 years) with relapsed or unresectable osteosarcoma progressing after standard treatment (methotrexate, cisplatin, doxorubicin, and ifosfamide). Participants received 750 mg or 500mg apatinib according to body surface area (BSA) once daily until disease progression or unacceptable toxicity. The primary endpoint was objective response rate (CR+PR at least 3 months according to RECIST 1.1) and PFS at 4 months. All analyses were intention-to-treat. **Results:** 37 participant were enrolled between March 17th, 2016 and June 9th, 2017. Until final follow-up, the objective response rate (CR+PR at least 3 m) was 56.76% (21/37). And the 4-m PFS rate was 52% (95% CI 32%–68%). However 9/37 (24.32%) patients was progression free at 6 months. Median PFS and OS were 4.44 (95% CI 3.12–7.08) and 8.77 (95% CI 6.73–16.70) months, respectively. Toxic effects led to dose reductions, or interruptions in a total of 25/37 (67.57%) patients. The most common grade 3–4 adverse events were pneumothorax in 5 (13.51%) patients, wound dehiscence in 4 (10.81%), abdominal cramps in 3 (8.11%), hypokalemia in 2 (5.41%) and bilirubin increase, proteinuria, hypertriglyceridaemia, hand–foot skin reaction and anemia each in one (2.70%). No other serious adverse events were reported during the trial. There were no treatment-related deaths. **Conclusions:** Apatinib was a sensitive drug for advanced osteosarcoma with high response rate after failure of chemotherapy, with almost the same duration of response comparing to other TKIs. Clinical trial information: NCT02711007.

11521 Poster Session (Board #266), Sat, 8:00 AM-11:30 AM

Neoadjuvant denosumab for the treatment of resectable giant cell tumor of bone: First results of Russian multicenter study. *First Author: Alexander A. Fedenko, Federal State Budgetary Institution N.N. Blokhin Medical Research Center of Oncology of the Ministry of Health of the Russian Federation, Moscow, Moscow, Russia*

Background: Giant cell tumor of bone (GCT) is a relatively rare, benign but locally aggressive osteolytic skeletal neoplasm of young adults. This study is non-interventional observational GCT treatment study in the Russian Federation (RF). Designed to detect epidemiology data as well as the clinical efficiency of surgical and/or denosumab (Db) treatment of GCT in the RF. **Methods:** Between August 2016 and October 2017, 112 adult patients (pts) with GCT were enrolled. Ten Russian Cancer Center are included in this study. The primary endpoint was Time-To-Progression (TTP). Adult and skeletally mature adolescent pts with resectable and unresectable GCT (N = 54) received subcutaneous Db 120 mg every 4 weeks with a loading dose of 120 mg SC on study days 8 and 15. Options for surgical treatment (N = 25) include intralesional curettage (InC) (alone or followed by filling of the defect with bone cement), marginal excision (MEx), a wide local excision, or en bloc resection with or without reconstructive surgery. **Results:** 112 pts were enrolled, 71 were evaluable for efficacy evaluation. Median follow-up was 12.5 months. Enrolled subjects were 51.8% women, median age 35 years old. The most commonly affected sites are the epiphyses of the long bones (63%), 44% of all cases affect the distal femur or proximal tibia. Less commonly involved vertebra (3.5%), pelvis (8%), the skull (0.8%) and the small bones of the hands (2.6%). Of 112 pts enrolled, 54 received Db, and 16 with resectable GCT were evaluable for efficacy and underwent surgery - InC and MEx. 6 (37.5%) of 16 pts had disease progression; TTP was 6 months after surgery (11 injection of Db in average). 25 of 71 pts received only surgical treatment, in 4 (16%) of 25 pts InC and MEx were performed, 2 (50%) of 4 pts had disease progression, TTP was 7 months after the surgery. **Conclusions:** In this study, only 37.5% of pts with resectable GCT, who received neoadjuvant Db, had disease progression vs 50% of pts, received only surgical treatment. This study confirms that neoadjuvant Db is a possible treatment option for the resectable GCT to avoid mutilating surgery and decrease the risk of recurrences. Further investigation is awaited.

11522 Poster Session (Board #267), Sat, 8:00 AM-11:30 AM

Genome and transcriptome profiling of relapsed and metastatic osteosarcoma. *First Author: Chia Chin Wu, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Osteosarcoma (OS) is characterized by genomic complexity and significant genetic heterogeneity. However, it is unknown whether relapse and metastatic samples incur additional insults to genomic integrity. To examine this, we conducted in-depth genomic profiling in a cohort of 48 pediatric and adult patients with high-grade OS including 42 patients with relapsed/metastatic disease. **Methods:** Whole-genome sequencing, RNA sequencing, and functional proteomic profiling were conducted on primary resection, local relapse, and metastatic OS tumor specimens and matched normal tissue/blood samples. Features including somatic mutations, structural rearrangements, copy number alterations, telomere length, and clonality were characterized. Proteomics analysis is underway. **Results:** Genome doubling (GD) occurred in 58% (22/38) of samples and significantly more rearrangements were found in the samples with GD than those without GD (p =0.01). *TP53* (75% of samples) and *RB1* aberrations (60%) were found in samples both with and without GD, with the majority being losses of heterozygosity. This indicates that *TP53* and *RB1* aberrations are early events and GD further propagates genome instability in OS. Mutational signatures 5 and 8 were most prevalent; mutation signature 8 significantly correlated with mutation burden ($p <$ <0.001) and disease-free survival (p =0.02). There were no significant differences amongst genomic features analyzed when comparing primary tumors and lung metastases or tumors by OS histologic subtype. **Conclusions:** Despite inherent genomic complexity, the genomic landscape of OS at relapse and metastasis is comparable to post-treatment primary tumors. Profiling of primary tumors may be appropriate for guiding therapy at relapse. Introduction of novel therapies in the upfront setting could be considered for poor risk patients.

11523 Poster Session (Board #268), Sat, 8:00 AM-11:30 AM

Rare bone sarcoma: A retrospective analysis of 149 adult patients from the French Sarcoma Group. *First Author: Pascaline Boudou-Rouquette, Department of Medical Oncology, ARIANE, Cochin Hospital, Paris Descartes University, AP-HP, CARPEM, Paris, France*

Background: the benefit of neo-adjuvant/adjuvant chemotherapy (CT) in rare bone sarcoma is poorly documented. **Methods:** retrospective study from the French sarcoma network for bone tumors ResOs: 1) adult patients (pts) from 1976 to 2014, 2) Rare bone sarcoma: leiomyosarcoma, undifferentiated pleomorphic and radiation-associated bone sarcoma 3) with central pathological review. Clinical features, treatment modalities and outcome were recorded and analyzed. **Results:** we identified 149 pts from 14 centers. Of them, 109 (73%) presented with localized disease, the local treatment was associated or not with CT. In localized pts, median age was 53 (range 18-82) years (y), median tumor size was 7cm (range 3-18). Sites of disease were extremities (72%) or axial skeleton (28%). The most common histological subtypes were high-grade leiomyosarcoma (33%) and undifferentiated pleomorphic sarcoma (35%). Surgery was performed in 107 pts, conservative in 76.3%. R0 resection was achieved in 58 (82%) pts. Twenty-eight pts (26%) underwent upfront surgery or exclusive radiotherapy (RT)(> 50 Gy) without CT. Eighty-one pts (74%) received either neo-adjuvant CT (n = 13) or adjuvant CT (n = 23) or both (n = 45). The median duration of neo-adjuvant CT was 2.1 months (mo)(range: 0.1-5.7) and 2.4 mo for adjuvant CT (range: 0.7-6.4). Neo-adjuvant/adjuvant CT was mostly doxorubicin- (95%/85%) and cisplatin- (68%/63%) based, or methotrexate-based in 22%/21% of pts. Adjuvant RT was performed in 23 (22%) pts. An overall disease control rate (CR+PR+SD) of 86% was achieved after neo-adjuvant CT. Median follow-up was 5.6 y (95% CI 4.0-7.8). For patients with localized disease, the 3y and 5y-overall survival (OS) were 74.3% (95% CI: 64.1-82.0) and 62.4% (95% CI: 50.7-72.1). The 3y- and 5y-disease-free survival (DFS) were 52.5% (95% CI: 42.1-61.9) and 38.2% (27.7 and 48.5). In univariate analysis, age≤50y (p = 0.04) and neoadjuvant and adjuvant CT (p = 0.03) were associated with longer DFS, but no association was found with OS. **Conclusions:** in this retrospective study, patients with localized rare bone sarcoma treated according osteosarcoma standard of care, with pre- and post-operative chemotherapy, achieved better DFS.

11524 Poster Session (Board #269), Sat, 8:00 AM-11:30 AM

Drug repurposing as a source of innovative therapies in osteosarcoma. *First Author: Gauthier Bouche, The Anticancer Fund, Strombeek-Bever, Belgium*

Background: Chemotherapy and surgery achieve a 5-year event-free survival of 60-70% in localized osteosarcoma (OS), but little additional progress has been made in recent decades. Clinical research in OS is hampered by a limited pipeline of new agents. Drug repurposing, an alternative development pathway that seeks to reuse existing drugs as the source of new treatment options, represents an interesting opportunity to solve this issue. Repurposing benefits from existing data on safety, dosing and clinical experience. Our goal was to list existing non-cancer drugs active against OS to prioritize future research and trials. **Methods:** We used the Repurposing Drugs in Oncology (ReDO) list of 240 approved non-cancer drugs. We queried PubMed for each drug and screened all abstracts to assess relevance, type of evidence (in vitro, in vivo, human data) and mechanism(s) of action (MoA). **Results:** From the 240 drugs, 65 (27%) have evidence of activity against OS. Of these, 10 (15%) are supported by human data. We found certain MoA patterns and grouped drugs in 7 categories. Drugs affecting coagulation, adhesion and chemotaxis: aspirin, heparin, warfarin, plerixafor, disulfiram. Epigenetic drugs: histone deacetylase inhibitors, DNA methyltransferase inhibitors. Immunomodulators: *all-trans* retinoid acid (ATRA), thalidomide, sirolimus. Differentiating agents: calcitriol, ATRA. Drugs targeting osteosarcoma stem cells: plerixafor, metformin, disulfiram. Chemopotentiating drugs: caffeine, proton pump inhibitors, verapamil, piroxicam. Direct cytotoxicity drugs: simvastatin, glucocorticoids. **Conclusions:** 65 FDA-approved drugs have shown activity against OS. In terms of clinical setting, cytototoxic, epigenetic, differentiating and chemo-potentiating drugs could be tested in the neoadjuvant period to enhance the effect of chemotherapy. Immunomodulators and drugs affecting coagulation and chemotaxis could be tested during the perioperative period to prevent early recurrences. Based on our results, we are exploring the possibility of conducting international collaborative multi-arm trials to accelerate progress in OS.

11525 Poster Session (Board #270), Sat, 8:00 AM-11:30 AM

Can DNA methylation patterns be used as predictive biomarkers for chemotherapy response in osteosarcoma? *First Author: Sarbajit Mukherjee, University of Oklahoma Health Sciences Center, Oklahoma City, OK*

Background: Response to neoadjuvant chemotherapy correlates with a positive outcome in localized osteosarcoma patients. However, there are no reliable predictors of chemotherapy response. We investigated the role of DNA methylation patterns as a biomarker to chemotherapy response. **Methods:** We obtained 26 diagnostic biopsy specimens from the Children's Oncology Group tissue biobank: 13 with a good ($\geq$ 90% necrosis in the post-chemotherapy resected tumor specimen) and 13 with a poor chemotherapy response ($<$ 90% necrosis). Patient characteristics were similar between these groups. DNA was isolated from tissue and loaded onto Illumina arrays. Machine learning was used to discriminate responders from non-responders. Samples were randomly split into a development (70%) and a validation (30%) set. A GLMnet model optimized within the development set then tested on previously unseen data within the validation set. The random split, model development, and testing were then repeated for a total of 40 cycles. CpG sites used in at least 3 cycles were selected for further testing (n = 16). An optimized, supervised GLMnet predictive algorithm model was generated using the same procedure (40 cycles) based on these 16 CpG sites, and final performance metrics were recorded. **Results:** During initial algorithm development utilizing all methylation sites, the machine learning algorithms performed with an average 74.7% accuracy on previously-unseen data, corresponding to a receiver operator characteristic (ROC) area-under-the-curve (AUC) value of 0.76. The final optimized algorithms, based on 16 CpG highly discriminant CpG sites, improved to an average 91.87% accuracy to discriminate chemotherapy responders from non-responders, with a corresponding ROC-AUC of 0.97 (2x2 table: Fisher's p = 0.03). **Conclusions:** Based on distinct epigenomic patterns in osteosarcoma patients, we developed an algorithm which accurately differentiates chemotherapy responders from non-responders at the time of initial diagnostic biopsy. These findings have the potential to improve both prognostic accuracy and personalized therapy in osteosarcoma, pending confirmatory studies.

11526 Poster Session (Board #271), Sat, 8:00 AM-11:30 AM

Comprehensive genomic profiling of sarcomas in Chinese population. *First Author: Jie Lin, The Second Affiliated Hospital of Kunming Medical University, Kunming, China*

Background: Sarcomas consist of a broad family of mesenchymal malignancies with remarkable diversity. Currently, there are no targeted drugs approved for sarcomas except for pazopanib and imatinib. In this study, comprehensive genomic profiling of 221 sarcomas by targeted next generation sequencing (NGS) was performed, the clinical relevant genomic alterations (CRGAs) and potential therapeutic targets were explored. **Methods:** 211 sarcomas, including 30 leiomyosarcoma (LMS), 13 osteosarcoma (OS), 13 rhabdomyosarcoma (RMS), 9 synovial sarcoma (SS), 22 liposarcoma (LPS), and 124 other subtypes were sequenced by cancer gene panel (CGP) with all coding exons and splicing sites of 365 cancer-related genes plus selected introns from 25 frequently rearranged genes. Genomic alterations (GAs) including point mutations, short insertions and deletions, copy number variations, and rearrangements were called, and further confirmed manually using IGV. These CRGAs were annotated based on literature review and some of them are actionable. **Results:** There are 1215 GAs for all 211 sarcomas and average 5.5 mutations per sample. Among these subtypes, LPS has the highest number of mutations per sample (average 7.5), SS has the lowest number of mutations per sample (average 2.7). Interestingly, 49% GAs are structure variations (SVs). In addition, the top ranked altered genes were TP53 (36%), RB1 (13%), MDM2 (12%) and CDK4 (11%) in all sarcomas. The genomic alterations across all subtypes of sarcomas are enriched in cell cycle pathway. Furthermore, 88% of patients have at least one CRGA, 10 patients with CRGAs in FGFR1/2/3, VEGFA, KIT, FLT4 or KDR could benefit from pazopanib. 57 patients have at least one actionable mutation. Among them, 24 patients with CRGAs in CDK4, CDKN2A/B could benefit from palbociclib, 22 patients with CRGAs in MTOR , PIK3CA, NF1/2, PTEN, TSC1 or STK11 could benefit from everolimus, and 6 patients with CRGAs in BRCA2, ARD1A or ATM could benefit from olaparib. **Conclusions:** This study demonstrated that sarcomas are characterized predominantly by structure variations, most of sarcomas have at least one actionable mutation. In conclusion, comprehensive genomic profiling in a large cohort highlights the promise of targeted therapies.

11527 Poster Session (Board #272), Sat, 8:00 AM-11:30 AM

Single-agent expansion cohort of lenvatinib (LEN) and combination dose-finding cohort of LEN + etoposide (ETP) + ifosfamide (IFM) in patients (pts) aged 2 to $\leq$25 years with relapsed/refractory osteosarcoma (OS). *First Author: Nathalie Gaspar, Institut Gustave Roussy, Villejuif, France*

Background: LEN is a multikinase inhibitor of VEGFR1-3, FGFR1-4, PDGFRα, KIT, and RET. In human pediatric OS xenograft models, LEN enhanced the antitumor activity of IFM + ETP. In a phase (Ph) 2 study of sorafenib in pts with unresectable high-grade OS, progression-free survival at 4 months (PFS-4) was 46%. We report emerging data from a Ph 2 single-agent LEN expansion cohort and Ph 1b combination dose-finding cohort of LEN + ETP + IFM in pts with relapsed/refractory OS. **Methods:** Pts were age 2 to $\leq$25 years, had relapsed OS, and had $<$ 2 prior VEGF-targeted therapies. The recommended dose (RD; 14 mg/m^2) from Ph 1 was used in Ph 2. In Ph 1b, a 20% reduction of LEN (11 mg/m^2/day) was used as starting dose in combination with IFM 3000 mg/m^2 + ETP 100 mg/m^2 daily/3 days. Ph 2 and Ph 1b primary endpoints were PFS-4 per RECIST 1.1 and RD of the combination. Secondary objectives included best overall response (BOR), objective response rate, PFS, safety, and PK. Data cutoff was October 6, 2017. **Results:** In Ph 2, 16 pts received LEN 14 mg/m^2. Median (min, max) number of cycles received was 3.0 (1, 9). Most common any-grade TEAEs were diarrhea, hypothyroidism, and proteinuria (43.8% each). Most common Grade (G) 3 or 4 TEAEs were back pain and dyspnea (12.5% each). One pt discontinued due to TEAEs (myelodysplastic syndrome); 5 of 15 evaluable pts achieved PFS-4 and BOR was PR (n = 1) and SD (n = 7). In Ph 1b, 7 pts received LEN 11 (LEN 11 mg/m^2 + IFM + ETP) and 6 pts received LEN 14 (LEN 14 mg/m^2 + IFM + ETP). 1 pt had a DLT at LEN 11 (G3 thrombocytopenia) and 2 pts had DLTs at LEN 14 (G4 thrombocytopenia with G3 bleeding in 1 pt; G2 oral dysesthesia, G2 back pain, and G1 muscle spasms in 1 pt). G $\geq$3 TEAEs occurred in 85.7% and 66.7% of LEN 11 and LEN 14 pts, respectively. No pts discontinued due to TEAEs. BOR was PR (n = 1) and SD (n = 5). AUC at steady state of LEN and distributions of interindividual variability of oral clearance were comparable between LEN single agent and the combination. **Conclusions:** In Ph 2, LEN at 14 mg/m^2 achieved PFS-4 in 5 pts; BOR was PR in 1 pt and SD in 7 pts. In Ph 1b, LEN + chemotherapy had a manageable safety profile. The study is ongoing and updated data will be presented. Clinical trial information: NCT02432274.

11528 Poster Session (Board #273), Sat, 8:00 AM-11:30 AM

A comparison of outcomes, presentation, and treatment in pediatric (Ped) versus adult patients (Pts) with Ewing sarcoma. *First Author: Eric B Schwartz, Michigan Medicine, Ann Arbor, MI*

Background: Ewing Sarcoma (ES) afflicts 225 children and 180 adults in the US annually, but the vast majority of research is in ped pts. In multiple series, adults have poorer outcomes. The aim of this study is to evaluate clinical features that correlate with overall survival (OS)/progression-free survival (PFS). **Methods:** ES pts at University of Michigan from 2007-15 were identified using an institutional database. Charts were reviewed for demographic and clinical data. Ped pts were defined as age ≤18 at diagnosis. Two-sample t-tests or Chi-squared tests/Fisher's exact tests were used for comparisons. Survival outcomes were analyzed using Kaplan-Meier methods and Cox proportional hazards regression models. **Results:** Seventy-eight ES pts (26 peds, 52 adult) were included in analysis. Factors evaluated in multivariate analysis model included localized disease, age, surgery, radiation, tumor size, cumulative doxorubicin (DOX), osseous primary and no. of first-line chemo cycles. Localized disease correlated with improved PFS (HR = 0.20, p = < 0.0001) and marginally with OS (HR = 0.386, p = 0.0580). Five-yr OS was higher in ped pts vs adults (81% vs. 49%, p = 0.0218). Ped pts received more cycles of first-line chemo (14.0 vs 11.8, p = 0.003), which positively correlated with OS (HR = 0.78, p = 0.002) and PFS (HR = 0.82, p = 0.024). Other differences included higher cumulative DOX dose and increased incidence of extraosseous ES in adults, but these did not correlate with OS/PFS. **Conclusions:** In our series, younger age correlated with improved OS. Ped pts were more likely to have osseous ES and less DOX, but only increased number of first-line chemo cycles was associated with improved outcomes. Further evaluation of potential tissue biomarkers to differentiate the two groups and early progressors is planned.

Variable	Peds (n = 26)	Adult (n = 52)	p-value
Localized disease, n (%)	17 (65.4)	33 (63.5)	0.867
Mean no. of first-line chemo cycles	14	11.8	0.003
Cumulative DOX (mg/m2)	357.9	445.6	< 0.0001
Osseous primary, n (%)	21 (84)	22 (45.8)	0.002
Mean tumor size, cm (range)	8.2 (3.2 – 19.3)	9.6 (1.8 – 23.5)	0.384
Surgical Resection, n (%)	19 (73.1)	28 (53.8)	0.142
Progression during first line rx, n (%)	1 (4.2)	7 (15.2)	0.249

11530 Poster Session (Board #275), Sat, 8:00 AM-11:30 AM

To compare the efficacy of sunitinib and imatinib following cytoreductive resection in GIST patients with progression on imatinib: A multi-center controlled study. *First Author: Xinhua Zhang, Department of Gastrointestinal Surgery, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China*

Background: Imatinib is recommended to treat gastrointestinal stromal tumor (GIST) receiving surgery after localized tumor progression, but the progression free survival (PFS) is not satisfied. The objective of this study is to investigate the optimal therapy after cytoreductive surgery in GIST patients with unifocal or multifocal progression on imatinib. **Methods:** The data of GIST patients who received R0 resection or satisfied cytoreductive surgery after unifocal or multifocal progression followed by different TKIs were collected. The satisfied cytoreductive surgery was defined as the diameter of every residual tumor was less than 1cm, or the proportion of residual tumor was less than 25% after cytoreductive surgery. The primary endpoint is to evaluate the PFS of the patients receiving surgery followed by sunitinib comparing with that of followed by imatinib after tumor progression. PFS curves were constructed according to the Kaplan–Meier method and compared using a log-rank test. **Results:** From January 2006 to June 2017, 97 patients from 13 medical centers were enrolled in this study. Fifty-six patients continued imatinib therapy and 41 patients switched to sunitinib directly after R0 resection or satisfied cytoreductive surgery. The PFS of sunitinib group was longer than that of imatinib group (30.0 months vs 12.0 months, p = 0.009). In subgroup analysis, the PFS of sunitinib group and imatinib group were 25.5 months and 12.0 months in patients with multifocal progression (p = 0.008), 39.0 months and 13.0 months with unifocal progression (p = 0.156), respectively. Patients carrying a primary KIT exon 11 mutation had a PFS of 31 months in sunitinib compared with 11 months in imatinib (p = 0.036), respectively. And those of KIT exon 9 mutation or KIT/PDGFRA wild-type had a PFS of 25.5 months to 13 months (p = 0.06), respectively. The overall survival in sunitinib group and imatinib group were 37.0 months and 33.0 months, respectively (p = 0.794). **Conclusions:** R0 or satisfied cytoreductive surgery followed by sunitinib treatment in GIST patients with progression on imatinib could improve PFS compared with surgery followed by imatinib therapy.

11531 Poster Session (Board #276), Sat, 8:00 AM-11:30 AM

The prognostic value of blood neutrophil-to-lymphocyte ratio (NLR) factor in advanced gastrointestinal stromal tumors (GIST) treated with sunitinib after imatinib failure. *First Author: Piotr Rutkowski, Maria Sklodowska-Curie Institute - Oncology Center, Warsaw, Poland*

Background: Neutrophil-to-lymphocyte ratio (NLR) was shown to be prognostic in several solid malignancies. There are still limited data about predictive/prognostic value of NLR during targeted therapy of patients with advanced gastrointestinal stromal tumors (GIST). The aim of the study was to asses a clinical value of this ratio in patients with unresectable/metastatic GIST treated with sunitinib. **Methods:** Between 2001 and 2016, 146 of 230 patients with metastatic/unresectable GIST and fully available clinicpathologic data who progressed on the imatinib and received sunitinib as second line treatment were included to the analysis. In all patients the NLR was assessed at the baseline, after 3 months of treatment and upon disease progression (or last observation). The cut-off value for NLR was set at median of 2.4. Kaplan-Meier survival probability estimation with in log-rank test, and Cox's proportional hazards model were used for analysis. **Results:** Median Progression-Free Survival (PFS) on sunitinib treatment was 12 months, 2- and 5-year rate were 27% and 5% respectively; median Overall Survival (OS) – 23 months, 2- and 5-year rate 48% and 14% respectively. NLR > 2.4 at baseline was significantly associated with poorer OS: median OS was 30.0 months (95%CI 26.7-40.6) for NLR ratio ≤2.4 vs. 16.4 months (95%CI 14.1-22.8) for NLR > 2.4 (p = 0.002); median PFS was 18.2 (95%CI 10.8-24.2) vs. 9.6 (95%CI 6.9-15.1) respectively, which was close to statistical significance (p = 0.075). In multivariate OS model adjusted for mitotic index, localization of primary tumor (stomach vs. other) and driver oncogenic primary mutation in the tumor (KIT exon 11 mutation versus other) baseline NLR > 2.4 was proven to be statistically significant (HR 1.96 95%; CI 1.31-2.91; p < 0.001). Moreover, NLR value at last observation or disease progression was also prognostic factor for OS (HR 2.37, 95% CI: 1.42-3.96, p < 0.001). **Conclusions:** Our results demonstrate the usefulness of NLR as a prognostic and predictive marker in patients with advanced GIST treated with sunitinib.

11532 Poster Session (Board #277), Sat, 8:00 AM-11:30 AM

Role of resection following focal progression with standard doses of imatinib in patients with advanced gastrointestinal stromal tumor: Results of propensity score analyses. *First Author: Hyungwoo Cho, Department of Internal Medicine, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of (South)*

Background: Although the benefits of resection for focally progressive advanced gastrointestinal stromal tumors (GISTs) during imatinib (IM) treatment have been suggested, those benefits over IM alone have not been proven. We compared the clinical outcomes of resection plus IM dose escalation or maintenance (S group) with IM dose escalation alone (NS group) in patients (pts) with advanced GIST following focal progression (FP) with standard doses of IM. **Methods:** Between April 2003 and October 2016, 98 pts with histologically documented initially metastatic or distant recurrent GISTs experienced FP with standard doses of IM in Asan Medical Center, Seoul, Korea. Eight pts who received sunitinib without IM dose escalation after FP were excluded; 90 pts were thus included in this analysis. The primary endpoints were time to IM treatment failure (TTF) and overall survival (OS). TTF was defined as the duration from the date of FP to the date of disease progression on IM dose escalation or intolerance. **Results:** The median age was 61 years (range, 31–78) and 60 pts (66.7%) were male. The small bowel (n = 51, 56.7%) was the most common primary site followed by the stomach (n = 35, 38.9%). Compared to pts in the NS group (n = 52), pts in the S group (n = 38) had a higher proportion of primary tumor site involvement (26.3% vs. 7.7%, $p = 0.02$) and lower tumor burden (median largest tumor size: 34 mm vs. 52 mm, $p = 0.04$) at FP. With a median follow-up duration of 31.0 months, pts in the S group had significantly better TTF and OS than pts in the NS group (median TTF: 24.2 vs. 6.5 months, $p < 0.01$; median OS: 53.2 vs. 35.1 months, $p = 0.009$). Multivariate analysis revealed that along with low initial tumor burden, pts in the S group independently demonstrated better TTF (hazard ratio [HR] 0.29, $p < 0.01$) and OS (HR 0.47, $p = 0.04$). Even after applying inverse probability of treatment-weighting adjustments, pts in the S group demonstrated significantly better TTF (HR 0.36, $p < 0.01$) and OS (HR 0.58, $p = 0.049$). **Conclusions:** Our results strongly suggested that resection following FP with standard doses of IM in pts with advanced GIST may provide additional benefits over IM dose escalation alone.

11533 Poster Session (Board #278), Sat, 8:00 AM-11:30 AM

A retrospective natural history study of patients (pts) with PDGFRα D842V mutant advanced gastrointestinal stromal tumor (GIST) previously treated with a tyrosine kinase inhibitor (TKI). *First Author: Margaret von Mehren, Fox Chase Cancer Center, Philadelphia, PA*

Background: Activating mutations in *KIT* or *PDGFRA* kinases drive the vast majority of GIST in adult pts, making the disease highly amenable to targeted therapy. *KIT*-driven disease is more common (~80% of cases of advanced GIST), while *PDGFRA*-driven GIST is rare (~5-10% of cases of advanced GIST). TKIs have transformed therapy of advanced GIST; however, evidence suggests the benefit of currently approved TKIs has been predominantly in patients with *KIT*-driven GIST. We initiated this study to characterize response and survival of pts with PDGFRα D842 mutant GIST treated with currently approved TKIs. **Methods:** This was a multicenter, retrospective study of adult pts with locally advanced, metastatic, or recurrent PDGFRα D842 mutant GIST diagnosed between Jan 2000 and Jul 2016 who were treated with at least one TKI. Demographic and clinical data were collected through chart review and analyzed to determine overall survival (OS) and best overall response, duration of response, and progression-free survival (PFS) for each line of TKI therapy. **Results:** Twenty-two pts, all with PDGFRα D842V GIST, were identified at 3 US academic institutions: men, n = 15; median age, 57 y [range: 31-72]; median TKI lines of therapy, 4 [range: 1–8]. Ten pts had primary tumor size ≥ 15 cm, and 8 pts had mitotic index > 10/50 HPF at the time of diagnosis. Imatinib was the most common TKI used (n = 21); followed by sunitinib (n = 15), dasatinib (n = 8), sorafenib (n = 6), regorafenib (n = 4), nilotinib (n = 2) and pazopanib (n = 1). Imatinib was the first line TKI in 20 pts (91%). Only 1 (5%) pt responded to first-line TKI therapy (complete response to imatinib in a pt with residual disease following primary resection). Median PFS on first line TKI was 6.4 months. Median OS from initial diagnosis of GIST was 4.2 years. **Conclusions:** These results confirm and extend previous data suggesting that pts with advanced PDGFRα D842V GIST have a low response rate, and poor overall survival with currently available TKIs. To transform therapy for PDGFRa D842V GIST, novel TKIs that potently and selectively inhibit D842V mutant PDGFRα are needed.

11534 Poster Session (Board #279), Sat, 8:00 AM-11:30 AM

Immune microenvironment profiling of gastrointestinal stromal tumors (GIST). *First Author: Maria A. Pantaleo, Interdepartmental Centre of Cancer Research "Giorgio Prodi", University of Bologna, Bologna, Italy*

Background: GIST benefit from TK inhibitors but unfortunately can develop resistance or intolerance. Patients prolonged life expectancy associated with the complex biology involved in progressive disease led to a growing urgency and interest in developing new therapeutic strategies. Recently, few preclinical studies were conducted investigating the immunological profile in GIST. In the present study we analyzed GIST by whole transcriptome sequencing to estimate the gene expression signature, the presence of immune-infiltrate through in silico analysis, and to define the immunological profile of GIST as basis for immunotherapy . **Methods:** 18 fresh frozen GIST tumors (14 primary and 4 metastases) were analyzed. RNA-seq was performed with Illumina technology. Gene expression data was used to estimate the relative and absolute presence of 22 hematopoietic cell types in tumor microenvironment adopting CIBERSORT, an analytical tool suited to perform a deconvolution of neoplastic and tumor-infiltrating cells. The data were further processed to evaluate the enrichment of immune cell types, the correlation between cell subpopulations and to compare GIST microenvironment with other tumors. IHC tests for CD163, CD20, CD8 and TIA1 were performed and scored on FFPE samples. **Results:** A significant presence of immune-infiltrate in all GIST samples was confirmed, with a dominance of macrophages (M2 and M1), immediately followed by CD3+ T cells, both CD4+ and CD8+. Compared to other solid tumors, the immune profile of GIST appears similar to that of melanoma. The most relevant result is the high amount of CD8+ T-cells, suggesting that the adaptive immune response could be an immunotherapeutic target. The presence of CD8+ was confirmed by IHC that also showed the expression of citolytic markers (TIA1). Moreover the abundance of CD8+ T-cells correlated with the expression of IFN-gamma signature genes. Interestingly, the abundance of macrophages negatively correlates with T-cells presence (CD4+ and CD8+) supporting the dynamic balance between the immunosuppressive and active components of the immune-infiltrate. **Conclusions:** These findings represent a potential rationale to plan an immunotherapy approach along with TK inhibitors in GIST.

11535 Poster Session (Board #280), Sat, 8:00 AM-11:30 AM

LMTK3 to regulate the translation of oncogenic KIT in GIST regardless of imatinib sensitivity. *First Author: Lillian Rose Klug, Portland VA Health Care System and OHSU Knight Cancer Institute, Portland, OR*

Background: The majority of gastrointestinal stromal tumors (GIST) have been shown to be caused by somatic activating mutations in the receptor tyrosine kinase KIT. The major cause of death in patients with advanced *KIT*-mutant GIST is due to the development of KIT tyrosine kinase inhibitor-resistant (TKI-resistant) metastatic disease. Drug resistance arises almost exclusively from secondary mutations within KIT, highlighting the importance of KIT in the proliferation and survival of these tumors. **Methods:** We performed a human kinase siRNA screen in multiple *KIT*-mutant cancer cell lines, using viability as a read out. We defined candidate targets as those whose knockdown decreased viability in all cell lines. Validation and mechanistic studies were done using a library of *KIT*-mutant GIST cells. **Results:** We identified lemur tyrosine kinase 3 (LMTK3) as candidate target in three *KIT*-mutant cell lines. *LMTK3* silencing reduced the viability of all *KIT*-mutant GIST cells tested to date, including cell lines with KIT TKI-resistance mutations. Importantly, *LMTK3* silencing decreased the viability of *KIT*-mutant cells specifically, but not that of KIT-independent cells. LMTK3 knockdown also reduced tumor growth *in vivo* in a GIST xenograft model. Further, we found that decreased cell viability after *LMTK3* silencing was due to induction of apoptosis. Because these cells depend so heavily on KIT and the loss of KIT signaling results in cell death, we hypothesized that *LMTK3* silencing may affect this pathway. Indeed, *LMTK3* silencing decreased total KIT protein across all cell lines. The reduction in KIT protein was not the result of changes in KIT transcript or KIT protein stability, but translation rate of KIT was significantly reduced after LMTK3 knockdown. **Conclusions:** The protein kinase LMTK3 is an important translational regulator of oncogenic KIT expression in *KIT*-mutant GIST regardless of drug sensitivity and represents a novel, tractable target, particularly in drug-resistant tumors.

11536 Poster Session (Board #281), Sat, 8:00 AM-11:30 AM

Interrogating the sarcoma immune microenvironment (iME) using multiplex immunohistochemistry (mIHC). *First Author: Andrew Silverman, Columbia University Medical Center, New York, NY*

Background: Soft tissue sarcoma (STS) is a heterogeneous malignancy including more than 50 molecularly distinct subtypes. Undifferentiated pleomorphic sarcoma (UPS) and leiomyosarcoma (LMS) are common subtypes with limited treatment options. LMS can be divided into two distinct subsets: uterine (uLMS) and retroperitoneal (rpLMS). STS subtypes have differing levels of immune infiltration and show variable response to checkpoint blockade. We hypothesize that immune infiltration of cytotoxic T lymphocytes (CTLs) and macrophages will differ among subtypes of STS. **Methods:** 30 patients with sarcoma, naïve to systemic treatment, were identified, 10 cases each: UPS, uLMS and rpLMS. 5μm slides were stained using qmIF protocol for DAPI, CD3 (T cells), CD8 (CTLs), CD68 (macrophages), vimentin (tumor marker), HLA-DR (activation) and PD-L1 (immune suppression). Tumor areas were chosen by a pathologist, multiplex images acquired using Vectra, then processed and analyzed using inForm software. Genomic analysis to be performed using nanoString. **Results:** All cases have been stained and are now being analyzed. Preliminary analysis was performed by qualitative grading of stains (Table 1). We find increased CTL infiltration and HLA-DR expression in UPS as compared to either LMS group. uLMS appears to exhibit higher CTL infiltration and HLA-DR expression than rpLMS. QmIF and genomic analysis is ongoing. **Conclusions:** Qualitative analysis of UPS, uLMS, and rpLMS immune TME finds that UPS appears to have higher levels of CTLs and PD-L1 expression, consistent with results from other studies using conventional immunohistochemistry. Subtypes of LMS harbor distinct immune TME features, as uLMS as higher CTL and HLA-DR expression than rpLMS. These findings could have therapeutic implications. This study is currently ongoing; multiparameter immune phenotyping, spatial localization, and genomic analysis will be reported at the meeting.

Quantitative qmIF analysis.

Group	CD3	CD8	CD68	HLA-DR	PD-L1
rpLMS	+	-	+	++	++
UPS	++	++	++	+++	+++
uLMS	++	+	++	+++	++

- no cells, + few cells, ++ some cells, +++ many cells

11537 Poster Session (Board #282), Sat, 8:00 AM-11:30 AM

Phase II trial of continuous dosing of regorafenib in patients with metastatic or recurrent gastrointestinal stromal tumors (GISTs) after failure of imatinib and sunitinib. *First Author: Yoon-Koo Kang, Department of Oncology, Asan Medical Center, Seoul, Korea, Republic of (South)*

Background: Regorafenib in the standard intermittent dosing schedule (160 mg po per day for 3 weeks followed by 1week rest) was proven effective in the GRID trial in refractory gastrointestinal stromal tumors (GISTs). However, with this dosing schedule, frequent dose reduction was needed and progression of GIST tumors or tumor-related symptoms during the off-treatment period were also noted in some patients (pts).Therefore, we conducted this phase 2 trial to evaluate the efficacy and safety of regorafenib in lower dose continuous dosing schedule (NCT02889328). **Methods:** Pts with measurable, metastatic or recurrent GIST who failed both imatinib and sunitinib were eligible for this study. Regorafenib 100 mg po per day was administered continuously. The primary endpoint was disease control rate [DCR] (CR + PR + SD) lasting for at least 12 weeks by the RECIST v1.1. **Results:** From September 2016 to August 2017, a total of 25 pts were enrolled.The median age was 60 years (range, 42-74), and male was dominant (84%). Small bowel was the most common primary site (n = 15, 60%), followed by stomach (n = 7, 28%). The median treatment duration of imatinib and sunitinib was 40.5 months (range, 7.1–100.5) and 8.3 months (range, 0.7–37.5), respectively. Primary mutation was in kit exon 11 (n = 16, 64%) and 9 (n = 5, 20%), with 3 wild type (12%). The best response was PR in 2 (8%), SD in 16 (64%), and PD in 6 (24%) pts. DCR lasting for at least 12 weeks was 64% (16 of 25). With a median followup of 8.6 months (range, 2.3–14.6), the median PFS was 7.3 months (95% CI, 5.9–8.6), and the median OS was not reached with 1-year survival rate of 64.5%. Treatment was well tolerated. Ten pts (40%) experienced grade 3-4 toxicities including hand-foot skin reaction (n = 4, 16%), and elevation of alanine aminotransferase (n = 2, 8%). Only 5 pts (20%) needed dose modification with relative dose intensity of 91.8% for 8 cycles in all pts. **Conclusions:** With comparable efficacy and better safety profile compared to standard intermittent dosing schedule, regorafenib in this trial with lower dose continuous schedule might be an alternative treatment in GIST pts after failure of imatinib and sunitinib. Clinical trial information: NCT02889328.

11538 Poster Session (Board #283), Sat, 8:00 AM-11:30 AM

Impact of proton pump inhibitors (PPIs) on sunitinib (SU) pharmacokinetics (PK) and activity in GIST patients (pts). *First Author: Olivier Mir, Gustave Roussy Cancer Campus, Villejuif, France*

Background: PPIs alter the PK of several oral drugs, either through a decrease in absorption due to higher GI tract pH, or the induction of efflux pumps such as ABCB1. The PK of SU is well correlated with its activity in GIST. Previous works have suggested a deleterious impact of PPI intake on SU activity in mRCC, but sunitinib PK was unchanged in pts with previous gastrectomy. Overall, the impact of PPI intake on SU PK and activity in GIST remains to define. **Methods:** Steady-state plasma concentrations of SU were determined in 57 GIST pts treated in the 2nd line setting over 10 years (2008-2017), at the dose of 50 mg/day 4 weeks/6, or 37.5 mg daily, according to their performance status (PS) and co-morbidities, at the discretion of the treating physician. PK data were analyzed with a nonlinear mixed-effect modeling approach, using the Monolix software. For the population PK model, covariates included lean body mass (LBM, estimated using CT-scan) and PPI intake. PFS was analyzed using the Kaplan-Meier method. **Results:** 18 pts (32%) received PPIs troughout SU treatment. SU PK was satisfactorily described by a one-compartment model with a zero-order absorption. SU CL/F and V/F were increased by a 1.55 factor when co-administered with PPI, resulting from a decreased relative bioavailability. Covariate modeling showed that PPI intake decreased the fraction of dose absorbed by ~40%, and LBM was better related to the CL and V inter-subject variations than weight, supporting a major role of the non-fat mass in the elimination and distribution parameters. Overall, the covariate effects explained approximately half of the CL/F between subject variability. Median PFS was 3.0 months (95%CI: 2.5-3.2) vs. 7.7 months (95%CI : 6.1-11.2) in pts receiving PPIs, or not, respectively. Mutational status had no impact on PFS. **Conclusions:** Our results suggest that SU plasma concentrations in pts receving PPis could be sub-optimal, leading to early anti-tumor treatment failure. In this setting, either PPI discontinuation or SU dose escalation (up to 75 mg daily, in lack of limiting toxicity) should be considered.

11539 Poster Session (Board #284), Sat, 8:00 AM-11:30 AM

Utility of circulating tumor DNA (ctDNA) in the management of patients with gastrointestinal stromal tumor (GIST): Analysis of 152 patients. *First Author: Junaid Arshad, Jackson Memorial Hospital, Miami, FL*

Background: GIST is the most common sarcoma of the GI tract. Management of GIST is determined by KIT, PDGFR, or other genomic alterations. Tissue diagnosis has been the mainstay of the biomarker assessment but next generation sequencing (NGS) - based analysis of ctDNA is a novel, effective and non-invasive alternative. **Methods:** DNA sequencing of the circulating tumor DNA (ctDNA) was perfomed on blood samples from 152 patients. Samples were collected, shipped at room temperature and centrifuged to isolate plasma. DNA was extracted, concentrated, and quantified. **Results:** Of 152 unique patients, 72 (47%) females and 80 (52%) males with a median age of 59. 41 (27%) patients did not test positive for either KIT or PDGFRA while 111 (73%) had either KIT or PDGFRA mutation. 6 patients were positive for both KIT and PDGFRA mutations. Of these 6, 1 had KIT amp plus PDGFRA amp, then only a KIT point mutation 6 months later. 2 had KIT plus PDGFRA point mutations. Most of the imatinib resistance mutations were missense mutations and were found in males (p = .005). There were 3 (2%) patients positive for PDGFRA D842V with resistance to imatinib. Mutations other than KIT or PDGFRA included EGFR 8(7%), ERBB2 8 (7%), NF1 7 (6%), PIK3CA 7(6%), ARID1A 6(5%), FGFR2 6(5%), KRAS 6(5%), BRCA2 5 4%), MET 5 (4%), PTEN 5(4%), MYC 4(3%), NTRK1 4(3%). Overall, the average number of mutations at first test: 3 (range 1-11). The average highest MAF: 4.74% (RANGE 0-52.98%), MEDIAN 0.72%. Of the the 25 patients with clinical annotation 15 (10%) had treatment impacted, 20 (13%) identified resistance mutations, and and 30 (20%) of patients were found to harbor additional mutations. **Conclusions:** Digital DNA sequencing from ctDNA provides a reliable picture of the genomic profile in GIST. However, there is limited information related to resistance, prognosis or predictive role along with the effect of chemotherapy. Further validation and evaluation of clinical utility is warranted.

11540 Poster Session (Board #285), Sat, 8:00 AM-11:30 AM

Activity and safety of crizotinib in patients with advanced, metastatic alveolar soft part sarcoma (ASPS) with rearrangement of *TFE3:* European Organization for Research and Treatment of Cancer (EORTC) phase 2 trial 90101 CREATE. *First Author: Patrick Schoffski, Department of General Medical Oncology Leuven Cancer Institute, University Hospitals Leuven, KU Leuven, Leuven, Belgium*

Background: ASPS is an orphan disease associated with rearrangement of transcription factor E3 (*TFE3*), leading to abnormal *MET* expression. We assessed crizotinib in pts with ASPS (NCT01524926). **Methods:** Eligible pts with reference pathology-confirmed ASPS received crizotinib 250 mg bid. By central FISH assessment of *TFE3* rearrangement , pts were attributed to *MET*+ or *MET*- sub-cohorts. Primary endpoint was objective response rate (ORR; RECIST 1.1) according to local investigator. Secondary endpoints included duration of response (DOR), disease control rate (DCR), progression-free survival (PFS), progression-free rate (PFR), overall survival rate (OSR), overall survival (OS) and safety. **Results:** Among 53 consenting pts with confirmed diagnosis of ASPS, 48 were treated and 45 were evaluable. Among 40 *MET*+ pts, 1 achieved a confirmed partial response (PR) lasting 215 d and 35 had stable disease (SD) (ORR: 2.5%, 95%CI: 0.6-80.6%). Further efficacy endpoints in *MET*+ cases were: DCR 90.0% (76.3-97.2%); 1-year PFR 37.5% (22.9-52.1%); 1-year OSR 97.4% (82.8-99.6%). Among 4 *MET*- pts, 1 achieved a PR lasting 801 d and 3 had SD (ORR: 25.0%, 0.6-80.6%) for a DCR of 100% (39.8-100.0%). The 1-year PFR in *MET*- cases was 50% (5.8-84.5%); 1-year OSR was 75% (12.8-96.1%). One pat with unknown *MET* status (technical failure) achieved SD but progressed after 17 cycles. Shrinkage of target lesions was seen in 17 pts, both in *MET*+ and - cases. The most common related AEs were nausea (34/48 [70.8%]), vomiting (22/48 [45.8%]), blurred vision (22/48 [45.8%]), diarrhea (20/48 [41.7%]) and fatigue (19/48 [39.6%]). **Conclusions:** According to EORTC efficacy criteria for sarcoma, our data suggest that crizotinib has activity in *TFE3* rearranged ASPS. While objective responses were infrequent, we observed tumor shrinkage in a significant proportion of pts, excellent DCR and good survival. We present very mature and reliable prospective PFS and OS estimates as reference for future research in pts with ASPS. Clinical trial information: NCT01524926.

11541 Poster Session (Board #286), Sat, 8:00 AM-11:30 AM

Anti CXCR4 antibody combined with activated and expanded natural killer cells for sarcoma immunotherapy. *First Author: Maria Vela, Hospital La Paz Institute for Health Research (IdiPAZ), Madrid, Spain*

Background: Metastasis occurs in 20-55% of sarcoma patients and remains the main cause of death. We propose a novel immunotherapeutic approach based in anti CXCR4 antibody MDX1338 (Bristol Myers Squibb) in combination with Activated and Expanded Natural Killer (NKAE) cells therapy. CXCR4 is upregulated in 33.3-73.3% sarcomas. Its signaling blockade by MDX1338 may reduce tumor growth and metastatic burden. NKAE cells have shown cytotoxicity against osteosarcoma and Ewing sarcoma. **Methods:** Expression of CXCR4 by different sarcoma cell lines was analyzed by flow cytometry. Its migration and invasion capacity towards CXCL12 was tested using Transwell plates and Matrigel. NKAE cells were obtained coculturing healthy donors' peripheral blood mononuclear cells with K562-mb15-41BBL cells and IL-2. Rhabdomyosarcoma cells were inoculated intravenously in immunodeficient NSG mice to generate an *in vivo* model of metastatic sarcoma. Four treatment arms were established: MDX1338; NKAE; MDX1338+NKAE; vehicle. Luminiscent tumors were monitored and subsequently micrometastasis were identified and quantified: by qRT-PCR; by immunohistochemistry; and by fluorescence *in situ* hybridization. **Results:** Alveolar rhabdomyosarcoma RH30 cell line showed the highest CXCR4 expression, concomitant with highest migration and invasion index. Both MDX1338 and NKAE efficiently reduced *in vitro* RH30 cells migration and invasion, but only the combination of both agents completely abrogated it. In *in vivo* assays, NKAE treatment was enough to completely prevent RH30 tumor implant. Nontheless, qRT-PCR analysis found RH30 lung micrometastasis in NKAE-treated mice group. Again, the combination of both MDX1338 and NKAE was necessary to completely eliminate it. Immunohistochemical and *in situ* hybridization analysis further confirmed these results. **Conclusions:** Our *in vitro* and *in vivo* studies show a complementary role of anti CXCR4 antibody MDX1338 and NKAE cell therapy to prevent rhabdomyosarcoma cells migration, invasion, tumor implant and lung metastasis formation. These preclinical results constitute a first evidence of the efficacy of this combined immunotherapy to prevent sarcoma disease dissemination.

11542 Poster Session (Board #287), Sat, 8:00 AM-11:30 AM

Phase 1b/2 study of olaratumab plus gemcitabine and docetaxel for the treatment of advanced soft tissue sarcoma (STS) (ANNOUNCE 2): Phase 1b results. *First Author: Victor Manuel Villalobos, University of Colorado, Denver, CO*

Background: Olaratumab (O) is an antibody against platelet-derived growth factor receptor alpha. In a randomized phase 2 study, O in combination with doxorubicin (dox) demonstrated a significant improvement of overall survival (OS) over dox alone in patients (pts) with advanced STS. Here we report the safety, tolerability and recommended phase 2 dose (RPTD) of O plus gemcitabine (G) and docetaxel (D) (O + G/D). **Methods:** This dose-escalation study enrolled pts with advanced/metastatic STS, $\leq$2 prior lines of systemic therapy, no prior G, D or O, and ECOG PS 0-1. Pts received O on Days 1 and 8 at 15 mg/kg (cohort 1) or 20 mg/kg (cohort 2) with G (900 mg/m^2 Days 1 and 8) and D (75 mg/m^2 Day 8) on a 21-day cycle. The primary objective was to determine the RPTD of O + G/D, with a dose-limiting toxicity (DLT) occurring in Cycle 1 at a rate below 33%. Secondary objectives included safety and pharmacokinetics (PK). **Results:** 54 pts (cohort 1/2 = 21/33) received at least one dose of treatment. No DLT occurred in cohort 1. In cohort 2, 5 pts (15.2%) experienced 6 DLTs (ALT increase, bacteremia, neutropenia [2 pts], and thrombocytopenia [2pts]). Treatment-related adverse events (TRAEs) reported for cohorts 1 and 2 included all grades (90.5% and 93.9%), Gr 3 (14.3% and 42.4%), Gr 4 (0 and 18.2%), and serious AEs (9.5% and 15.2%), respectively. Common TRAEs (all grades, Gr $\geq$3) occurring in $\geq$ 25% of pts were fatigue (66.7%, 11.1%), anemia (61.1%, 18.5%), thrombocytopenia (35.2%, 18.5%), nausea (29.6%, 0%) and diarrhea (27.8%, 3.7%). 1 pt discontinued due to a study-related AE of fatigue (cohort 1). Following 2 deaths unrelated to study treatment, cohort 2 was expanded to 33 pts. The PK profile of O + G/D was similar to that of O in combination with other chemotherapies. **Conclusions:** Both dose levels were tolerated with a higher incidence for known toxicities of G/D in cohort 2. Based on safety and exposure-response analyses across O studies, the RPTD for O + G/D is 20 mg/kg at Days 1 and 8 in Cycle 1, followed by 15 mg/kg at Days 1 and 8 thereafter. The randomized, double-blinded phase 2 part of the study is enrolling and will compare OS of pts with STS receiving G/D + O vs G/D + placebo (ANNOUNCE 2). Clinical trial information: NCT02659020.

11543 Poster Session (Board #288), Sat, 8:00 AM-11:30 AM

CDKN2A deletion as a prognostic marker: A clinico-genomic analysis of sarcoma patients. *First Author: Nam Bui, Stanford Cancer Institute, Palo Alto, CA*

Background: Sarcomas are a heterogeneous group of tumors with variable tendencies for aggressive behavior. Molecular markers for prognosis are needed to help risk stratify patients and potentially identify those who may benefit from more intensive therapeutic strategies. **Methods:** We analyzed somatic tumor genomic profiles in 152 soft tissue (STS) and bone sarcoma (BS) patients as part of 1,282 oncologic patients sequenced at Stanford Cancer Institute. We also examined 206 STS patients with whole exome and RNAseq from The Cancer Genome Atlas (TCGA). **Results:** Compared to all other histologies, sarcomas were found to be driven by copy number and fusion alterations with the highest relative percentage of amplifications/deletions/fusions (BS 53%, STS 57%, lung cancer 34%, melanoma 26%) and the lowest average SNV count (BS 1.7, STS 1.8, lung cancer 3.4, melanoma 6.1) The most common genomic alterations were TP53 mutation (34%), CDKN2A deletion (21%), RB1 deletion (11%), TP53 deletion (8%), MDM2 amplification (8%), and PIK3CA mutation (6%). When all genomic alterations were tested for prognostic significance in the cohort of localized STS (n = 96), only CDKN2A alterations (n = 22) correlated significantly with prognosis with a hazard ratio (HR) of 2.83 for overall survival (p = 0.01). There was a trend towards earlier recurrence for CDKN2A patients (p = 0.08) and no difference in chemotherapy time to treatment failure (p = 0.26), suggesting that CDKN2A alterations portend a more aggressive course but not necessarily any additional chemo resistance. These findings were validated in the TCGA dataset where CDKN2A altered patients (n = 24) had significantly worse overall survival with a HR of 2.55 (p = 0.004). Gene Ontology enrichment analysis revealed upregulation of pathways involved in RNA processing, protein translation, and catabolic processes. **Conclusions:** This is the first study to suggest that CDKN2A deletion is a poor prognostic marker in STS. Further research is warranted towards novel agents that affect the CDKN2A pathway and whether aggressive adjuvant therapy can attentuate the poor prognosis. We are undertaking further study towards the correlation of loss of p16 expression as an IHC biomarker for CDKN2A deletion.

11544 Poster Session (Board #289), Sat, 8:00 AM-11:30 AM

Multi-institutional European phase I/II trial of trabectedin plus radiotherapy in metastaticsoft tissue sarcoma (STS) patients. A Collaborative Spanish (GEIS), Italian (ISG) and French (FSG) Sarcoma Groups study. *First Author: Javier Martin Broto, Virgen del Rocio University Hospital, Institute of Biomedicine Research (IBIS)/CSIC/Universidad de Sevilla, Seville, Spain*

Background: Patients (pts) with advanced STS who require tumor shrinkage beyond first line, have very limited options since the approved drugs exhibit less than 10% of RECIST response. Trabectedin (T) had shown preclinical synergy with radiotherapy (RT). Low-dose RT concurrent with T was conducted in a phase I/II trial as a proof-of-concept of synergy. We present here data from the phase I (pulmonary metastatic cohort) **Methods:** Pts received T along with RT (30 Gy) in 10 fractions (3Gy/fr). Dose Levels for T were: -1 (1.1 mg/m^2), 1 (1.3 mg/m^2) and 2 (1.5 mg/m^2). Dose level 1 was expanded for a better cardiotoxicity assessment. Dose-limiting toxicity (DLT) were defined as grade $\geq$3 events excluding G3/4 neutropenia lasting $<$ 5 days, G3 transaminitis if not led to T delay and G3-4 nausea/vomiting due to inadequate prophylaxis. Primary endpoint was response rate according to RECIST **Results:** From 04/2015 to 06/2017, 18 pts were enrolled. Histologies were: synovial sarcoma in 10 (56%) pts, UPS in 3 (17%), myxoid liposarcoma, dedifferentiated liposarcoma, G3 NOS sarcoma, leiomyosarcoma and MPNST in 1 pts each. Median previous lines 1 (0-3). Twelve pts received T at dose level 1 and 6 pts at level 2. Overall, G 3/4 AEs were: neutropenia (8), ALT elevation (2), GGT elevation (2), anemia (2), febrile neutropenia and pneumonitis (1 each). There were two DLTs: Transient G4 ALT elevation in level 1 and G4 neutropenia ($>$ 5 days) in level 2. Based on central radiological review and 17 evaluable pts, 2 pts achieved CR (12%), 3 PR (18%), 6 SD (35%), 6 PD (35%). On local review, we found 2 CR (12%), 5 PR (29%), 4 SD (24%), 6 PD (35%). On the irradiated lesions, 4 CR (24%), 8 PR (47%), 4 SD (24%) and 1 PD (5%) were found. With a median FU of 18 m, median PFS was 2.83 (2.3-3.3). Thirteen pts (72%) have died, with a median OS of 8.77 m (3.6-13.9) and 12-month OS rate of 48% **Conclusions:** T concurrent with RT was feasible in pts with pulmonary metastatic STS regardless of histologic subtype. T at 1.5 mg/m^2 is the recommended dose for phase II part. We confirmed the synergy of T+RT, with 71% of the irradiated lesions showing long-lasting dimensional responses. Clinical trial information: NCT02275286.

11545 Poster Session (Board #290), Sat, 8:00 AM-11:30 AM

Clinical and pathological analysis of eleven adult patients with inflammatory myofibroblastic tumor. *First Author: Xin Liu, Department of Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: Inflammatory myofibroblastic tumor (IMT) is a rare mesenchymal malignancy which occurs primarily in children and adolescents. Complete surgical resection is the major treatment, and conventional chemotherapy and radiotherapy are usually invalid. In this study, we retrospectively analyzed the clinical and pathological features of eleven patients with adult IMT. **Methods:** A total of eleven patients with adult IMT were enrolled into this study between February 2013 and November 2017. The clinical, pathological data, treatment and prognosis were analyzed. **Results:** Among the eleven patients with adult IMT, five patients were male (45%), six patients were female (55%), and the median age was 39 (24-74 years). The primary tumor was located in two patients (18%) in the lung and two cases (18%) in the retroperitoneum, and seven cases (64%) in the abdominopelvic region. Four cases were abdominal epithelioid inflammatory myofibroblastic sarcoma. The positive rate of anaplastic lymphoma kinase (ALK) immunohistochemical expression was 82% (9/11), and the positive rate of ALK translocation was 86% (6/7). Seven patients with ALK-positive advanced disease received the treatment of ALK inhibitor crizotinib, the response rate was 86%, and the median progression free survival (PFS) was 20.8 months (95% confidence interval: 7.6 months-34.0 months). Two patients were treated with the more potent ALK inhibitor ceritinib after progression of disease on crizotinib and both of them showed significant and durable partial responses. **Conclusions:** The treatment of crizotinib in adult patients with ALK-positive advanced IMT resulted in a very high response rate and a long-term PFS, and the patients still responded to the next generation of ALK inhibitor after the failure of crizotinib in our study, which suggested that ALK signaling pathway may play an important role in the development of adult IMT. Further studies are warranted to clarify the effects of ALK signaling pathway and the mechanism of ALK inhibitor resistance in adult patients with IMT.

11546 Poster Session (Board #291), Sat, 8:00 AM-11:30 AM

Efficacy and safety of apatinib in advanced soft tissue sarcoma: A multi-center, open-label phase II clinical trial. *First Author: Wenxi Yu, Affiliated Sixth People's Hospital, Shanghai Jiaotong University, Shanghai, China*

Background: Soft tissue sarcomas (STSs) are a heterogeneous group of mesenchymal tumors, accounting for $<$ 1% of all adult malignancies. Although surgery combined with radiation results in high local control rates in localized STSs, high-risk patients (pts) have only 50% 5-year survival. Moreover, chemotherapy has been shown to be lack of consistent overall survival benefit in clinical trials. The vascular endothelial growth factor (VEGF) signaling mediated tumor growth plays an important role in the pathogenesis of several STSs subgroups. This study aimed to explore the efficacy and safety of apatinib, an oral tyrosine kinase inhibitor targeting VEFGR-2, in pts with advanced STS after failure of prior chemotherapy preliminarily. **Methods:** This is a prospective, open-label, single-arm, multi-center phase II study, with planned sample size of 53. All pts with histologically confirmed STSs experienced failure of prior chemotherapy in the last 6 months. Oral apatinib (500 mg) was given to pts daily in cycles of 28 days until disease progression, death or unacceptable toxicity. The primary outcome was 6-month progression-free survival (PFS) rate. **Results:** 35 pts were enrolled as of January 16, 2018. The top 3 subtypes of STSs were alveolar soft tissue sarcoma (20%), leiomyosarcoma (17%) and liposarcoma (12%). The 6-month PFS rate was not reached. Of 35 pts, 23 were available for response evaluation: 6 achieved partial response, 15 had stable disease, and 2 had progressive disease, resulting in an overall response rate of 26.1% and a disease control rate of 91.3%, at primary response. 33 pts were eligible for safety evaluation. The incidence of adverse events (AEs) was 93.9%. The most common AEs were hypertension (63.6%), proteinuria (60.6%), and hand-foot syndrome (54.6%). The incidence of Grade 3-4 AEs was 42.2%, and hypertension (30.0%) was the most common Grade 3-4 AEs. **Conclusions:** Current results demonstrated encouraging signs of anti-tumor activity, and well-tolerated toxicity of apatinib in previously treated advanced STSs. Clinical trial information: NCT03064243.

11547 Poster Session (Board #292), Sat, 8:00 AM-11:30 AM

A phase II trial of axitinib plus pembrolizumab for patients with advanced alveolar soft part sarcoma (ASPS) and other soft tissue sarcomas (STS). *First Author: Breelyn A. Wilky, Sylvester Comprehensive Cancer Center, Miami, FL*

Background: Inhibition of programmed-death 1 (PD1) by pembrolizumab (P) produced overall response rates (ORR) of 19% in advanced STS [SARC028]. Vascular endothelial growth factor (VEGF) suppresses the immune microenvironment and may contribute to checkpoint inhibitor resistance. Axitinib (Ax) is a pan-VEGFR inhibitor that prolongs progression-free survival (PFS) in advanced STS [Axi-STS], with striking antitumor activity in combination with P in renal cell carcinoma. We report toxicity, efficacy, and correlative endpoints of combination Ax/P for patients (pts) with advanced STS. **Methods:** NCT02301039 is an open-label Phase II trial of Ax/P in 30 pts with advanced or metastatic STS, requiring RECIST 1.1 progressing disease, adequate end-organ function and performance status. Pts received Ax 5 mg PO twice daily with concurrent P 200mg IV q21 days. Primary endpoint: 3-month PFS rate (PFS_{3mo}); secondary endpoints: toxicity, ORR and clinical benefit rate (CBR) by RECIST 1.1, and overall survival. Tumor biopsies and peripheral blood samples were obtained for correlative studies of TIL and PBMC at baseline, 3 months on treatment, and at progression. **Results:** 33 pts received at least one dose of study drugs, with 30 pts evaluable for primary endpoint. Enrolled subtypes: ASPS (36%), UPS (15%), LMS (18%), other (30%). PFS_{3mo} was 70.3% [95% CI 50.7-83.3], with median PFS of 5.4 months [95% CI 3.02-11.6]. Best ORR was 21.9% [95% CI 5.9-33.5]. PFS_{3mo} in ASPS pts was 90.9% [95% CI 50.8-98.7], with best ORR of 45.5% [95% CI 18.1-75.4] and CBR of 72.7% [95% CI 39.3-92.7]. Ax/P was well-tolerated, with similar immune-related toxicity rates to prior studies. Correlative markers were analyzed by a penalized logistic regression model with bootstrapping to predict PFS_{3mo}. Baseline high plasma angiogenic activity, circulating neutrophil:lymphocyte ratio $<$ 4.1, low naïve fraction $CD4^+$ TIL, and low $PD1^+CD8^+$ PBMC were associated with lack of progression (AUC 0.878 [95% CI 0.743-1, p = 0.0002]). **Conclusions:** Combination Ax/P is well-tolerated with promising activity in ASPS pts. Identified immune correlates associated with PFS should be validated in prospective immunotherapy trials. Clinical trial information: NCT02301039.

11548 Poster Session (Board #293), Sat, 8:00 AM-11:30 AM

Characteristics and clinical outcomes of French patients diagnosed with advanced soft tissue sarcoma (aSTS) in real-life setting: Data from the European sarcoma biological and clinical data banking (ESBCB). *First Author: Jean-Yves Blay, Centre Léon Bérard, Lyon, France*

Background: This study describes clinical characteristics of a large cohort of aSTS patients (pts) and effectiveness of chemotherapy (CT) based on real world data. **Methods:** Multicenter retrospective cohort analysis using data from the French centers of the ESBCB (Conticabase.org) with an extraction in 2017. This study included adult pts with a diagnosis of sarcoma (WHO2013) between 2010 and 2013 in soft tissue or viscera, excluding GIST and Kaposi's sarcoma. **Results:** 2747 pts were included with a diagnosis of STS. 34.6 % of them had an aSTS and were described in this study. Among them were 608 with secondary (metachronous) metastasis, 299 metastatic at diagnosis (synchronous) and 61 pts with locally aSTS, not amendable to surgery. The mean age at diagnosis was 59.3 years (+/- SD 16.9), 52.3% of pts were female and 21.2% had cancer of viscera. Most frequent sarcoma subtypes were undifferentiated sarcoma (24.9 %), leiomyosarcoma (23.8%) and miscellaneous sarcoma (14.7%). Sarcoma were grade 1 for 4.4%, 2 for 27.3% and 3 for 55.0 %, missing for 13.3%. Surgery for primary tumor was more frequent in the metachronous metastasis group than in the synchronous metastatic one (89.6% vs 41.5% respectively). At least one line of CT was administered to 56.9% and 61.2% pts with synchronous and metachronous metastasis, respectively. Anthracyclin-containing CT regimen were delivered in 63.6% of pts treated by first-line chemotherapy. Responses rates to first line chemotherapy were 30.6 % for pts with synchronous metastasis and 19.1 % for those with metachronous metastasis. For the entire aSTS population, the median overall survival was 1.45 years (95% CI : [1.23; 1.63]). The rates of overall survival (OS) at 3 years were 35.7% [22.2%; 49.3%] for pts with locally advanced disease, 29.4% [23.8%; 35.2%] for the pts with metachronous metastasis and 21.1 % [15.2%; 27.7%] for pts with synchronous metastasis. **Conclusions:** In this large nationwide database, therapeutic strategies and OS differed across groups of cancer diagnosis dates. These data are useful to provide real world treatment patterns and outcomes in a hard to study disease.

11549 Poster Session (Board #294), Sat, 8:00 AM-11:30 AM

Genomic alterations in the homologous recombination pathway in soft-tissue sarcomas. *First Author: Nathan David Seligson, Division of Pharmacy Practice and Science, College of Pharmacy, The Ohio State University, Columbus, OH*

Background: Soft-tissue sarcomas (STS) describe a heterogeneous group of tumors with limited treatment options available to patients. Targeted therapy exists for tumors with alterations in *BRCA1/2* as well as other homologous recombination (HR) pathway genes; however, their prevalence has yet to be fully described in STS. We hypothesized that tumors with these alterations may represent a targetable cohort with the advent of poly (ADP-ribose) polymerase (PARP) inhibitors. Here we assess the frequency of *BRCA1/2* and HR alterations in STS. **Methods:** DNA sequencing data was aggregated from The Cancer Genome Atlas (n = 255), Genomics Evidence Neoplasia Information Exchange (n = 583), and The Ohio State Sarcoma Registry (n = 398). Deleterious genomic alterations were defined as in ClinGen. Clinical data from three patients with somatic *BRCA2* loss who were treated with PARP inhibitors were collected for analysis. **Results:** *BRCA1* and HR somatic alterations were more common in leiomyosarcoma (LMS) subtype compared to other STS (LMS 17%, liposarcoma 9.8%, other 8.9%, p = 0.001). A disproportionate number of *BRCA2* losses were detected in uterine LMS (uLMS) with 85.7% of tumors harboring *BRCA2* loss identified in this STS subtype ($p < 0.001$). When considering uLMS, 9.8% of tumors had a loss of *BRCA2* (0.9% in non-uterine LMS, 0.5% in all other STS). Tumors with *BRCA2* loss often exhibited a poor differentiated histology (57.1% of *BRCA2* loss *vs* 38.8% BRCA2 intact; p = 0.59) and tended to have a higher mitotic count (10.7 count/HPF *BRCA2* loss *vs* 3.3 count/HPF *BRCA2* intact; p = 0.10). Retrospective evaluation of three uLMS patients with somatic *BRCA2* loss treated with PARP inhibitors demonstrated a median progression-free survival of nine months highlighting the potential targetability of *BRCA2* loss in uLMS. **Conclusions:** Here we assess the frequency of *BRCA1/2* and HR alterations and their clinical phenotype in STS. We identify somatic *BRCA2* loss in a subset of patients with uLMS and describe three patients with uLMS harboring *BRCA2* loss who were treated with PARP inhibitors. Our data suggests that patients with uLMS should be screened for *BRCA2* alterations. Prospective trials are needed to confirm the efficacy of PARP inhibition in this cohort of patients.

11550 Poster Session (Board #295), Sat, 8:00 AM-11:30 AM

A phase II study of pazopanib with oral topotecan in patients with metastatic and non-resectable soft tissue and bone sarcomas. *First Author: Mark Agulnik, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: Topotecan and pazopanib (PAZ) individually have clinical benefit in patients (pts) with sarcomas. PAZ is a multi-tyrosine kinase inhibitor and topotecan affects endothelial cells, and inhibits HIF-1, an upstream regulator of VEGF expression. The utilization of PAZ with topotecan is anticipated to produce anti-tumor synergism in pts with sarcomas. **Methods:** A phase II study of PAZ/topotecan in pts with metastatic and non-resectable bone and soft tissue sarcomas (STS) was conducted by the Midwest Sarcoma Trials Partnership. Age > 18, ECOG ≤ 1, adequate organ function, measurable disease and 1 prior therapy were required. Pts were treated with PAZ 800mg oral daily, Topotecan 8mg orally day 1, 8, 15 on a 28-day cycle until disease progression or unacceptable toxicity. Pts enrolled in 3 cohorts: 1. STS non-liposarcoma 2. osteosarcoma 3. liposarcoma. Primary endpoint: progression-free rate (PFR) at 12 weeks in cohort 1. Secondary endpoints: overall response rate (ORR), clinical benefit rate (CBR), OS, median progression free survival (PFS), PFR at 12 weeks in cohort 2 and 3, and safety and tolerability. Lab correlates evaluated PFR and OS to levels of VEGFR2 and PDGF. Simon 2-stage design was used for cohort 1. **Results:** A total of 139 pts were enrolled at 6 sites, with 121 evaluable for response. Data per cohorts 1,2, and 3: # of pts- 103, 17 and 19; mean age- 56, 41, 57; % female- 63, 53, 32%; 1-2 prior therapies- 75, 65, 84%. PFR at 12 weeks is 57.5%, 62.5%, 31.3% with a median PFS of 4.4, 4.5, 1.4 months and OS of 9.8, 11.1, 12.3 months. ORR is 8,6,0 % and CBR is 74, 88, 38%. Grade 3-4 adverse events (%): neutropenia (42), thrombocytopenia (29), hypertension (16) and anemia (12). Pts in cohort 1 who progressed within 6 weeks received 61% of prescribed PAZ dose vs. 67% for those with did not progress. Histologies in cohort 1- LMS (49%), UPS (15%), synovial (10%). Correlative data will be presented. **Conclusions:** The combination of PAZ/topotecan produced identical results to historical data for PAZ alone in pts with STS, except with a worse toxicity profile. For pts with osteosarcoma, the combination proved extremely promising and cohort 2 will be expanded. The combination was ineffective in liposarcoma. Clinical trial information: NCT02357810.

11551 Poster Session (Board #296), Sat, 8:00 AM-11:30 AM

Targeted tumor profiling and actionable somatic variants in sarcoma. *First Author: Eytan Ben Ami, Dana-Farber Cancer Institute, Boston, MA*

Background: The impact of next generation sequencing data on treatment decision and clinical outcome in sarcoma remains under investigation. **Methods:** We queried the Dana Farber Cancer Institute database to identify soft-tissue and bone-sarcoma patients (pts) who underwent targeted sequencing under a research protocol. We searched for mutations and somatic copy number alterations (SCNA) and evaluated clinical outcomes in cases bearing actionable genetic abnormalities (eligible for NCI-MATCH/ASCO-TAPUR studies). **Results:** 613 pts with 38 sarcoma histologies were evaluated. Leiomyosarcoma (LMS, 23.8%), liposarcoma (LPS, 13.2%), undifferentiated pleomorphic sarcoma (9.4%) and solitary fibrous tumor (4.7%) were the common histologies. Frequent mutations were observed in *TP53* (30.1%), *ATRX* (12.1%) *KMT2D* (11.1%), *NF1* (8%) and *ATM* (7.3%) genes. Common SCNA included homozygous deletions in *RB1* (10%) and *CDKN2A* (8.1%), and high copy number gains in *MDM2* (13.6%), *CDK4* (11.5%), *GLI1* and *MYC* (3%). 123 pts (20%) had 145 actionable somatic variants (59 mutations, 86 SCNA). Actionable mutations, observed in 52 pts, frequently involved the *PI3K/Akt/mTOR* pathway (*PI3K3CA*, *TSC1/2* and *AKT1* genes; 25% of actionable mutations), *BRCA1/2* (15.2%), and *IDH1/2* (17%, exclusively in chondrosarcoma) genes. Actionable SCNA, observed in 82 pts, comprised mostly of homozygous deletions in *CDKN2A* (51% of actionable SCNA) and *PTEN* (15.1%), and high copy number gain, not associated with LPS, in *CDK4* (12.8%). Of 72 metastatic pts with actionable alterations and clinical data, 12.5% (9 pts) received matched therapies. Tumor responses were observed in 6 pts, including durable responses (6-28 months) in dedifferentiated chondrosarcoma (*IDH2* mutation), inflammatory myofibroblastic tumor (ALK rearrangement), LMS (*TSC2* mutation), spindle cell sarcoma (*NTRK1* rearrangement), and chordoma (*CDKN2A* deletion). **Conclusions:** As many as 20% of sarcoma pts may harbor actionable genetic alterations. We observed durable tumor responses with matched therapies in several sarcoma histologies and further research is needed to understand the proportion of patients who may benefit from this approach. Mutations and SCNA incidence by histology will be presented at the meeting.

11552 Poster Session (Board #297), Sat, 8:00 AM-11:30 AM

Outcome of 91 clear cell sarcoma tumor patients: A retrospective study from the French Sarcoma Group (GSF-GETO). *First Author: Nelly Firmin, Institut du Cancer de Montpellier, Montpellier, France*

Background: Clear-Cell Sarcoma (CCS) is a rare soft tissue sarcoma poorly documented, with poor prognosis. Primary objective was to study the characteristics and outcomes of CCS patients (pts). **Methods:** Retrospective study from the nation-wide French sarcoma network (NetSarc) from 1991 to 2017. Inclusion criterion was CCS central pathological review. Endpoints were local recurrence-free survival (LRFS), metastatic-free survival (MFS), disease-free survival (DFS) and overall survival (OS). **Results:** 91 pts from 16 centers were included (molecular biology confirmed in 53% pts). Pts were aged 41 years (18-73), 57.1% men. The median tumor size was 4 cm (3-17). Patients were divided in 3 groups: localized (L) (61.5%), locally-advanced (LA) (15.4%), metastatic (M) (23.1%). Presurgical biopsy was performed in 50.7% of pts. All L and LA CCS pts underwent surgery, which was conservative in 70.6% pts. R0 resection was achieved in 71.9% of pts with 42.4% surgical revision to obtain clear margins. After a median follow-up of 6.5 years (95% CI: 4.5-9), 16 (22.9%), 37 (52.9%), 45 (64.3%), 29 (41.4%) events for LRFS, MFS, DFS and OS, were reported. Prognostic factors of the univariate analysis in L and LA pts are presented in Table 1. (Neo)Adjuvant radiotherapy and chemotherapy were performed in 54.4% and 30.9% pts, respectively, with no impact on OS or DFS. The 5-year OS rate for the 91 pts was 53.8% (95% CI: 41.70-64.22). For M pts, median OS was 12.7 months (95% CI: 10.4-21.5). Poor prognostic factors found in univariate analysis were male gender, delay between diagnosis and metastatic stage < 24 months, metastases other than pulmonary, and no surgery for metastatic disease. **Conclusions:** It's the largest study on CCS since the 1990s, with a large proportion of molecular biology confirmation. Stage, tumor necrosis, tumor size and localization are poor prognosis factors.

Endpoint	Variable		Hazard Ratio (95% CI)	p
OS	Stage	Localized	1	**0.0128**
		Locally Advanced	2.76 [1.2 ; 6.37]	
	Tumor Size (mm)	< 50	1	**0.0171**
		≥50	2.82 [1.16 ; 6.85]	
DFS	Stage	L	1	**0.0253**
		LA	2.21 [1.08 ; 4.53]	
	Tumor necrosis	Yes	1	**0.0473**
		No	2.30 [1.00 ; 5.36]	
	Tumor Size (mm)	< 50	1	**0.0304**
		≥50	2.18 [1.06 ; 4.49]

11553 Poster Session (Board #298), Sat, 8:00 AM-11:30 AM

Primary pulmonary sarcomas (PSRC): A comprehensive genomic profiling (CGP) study. *First Author: Sophie Beaucaire-Danel, Institut Curie, Paris, France*

Background: In an exploratory study to find biomarkers for both targeted and immunotherapy treatments, we performed CGP on a series of PSRC to search for novel therapy options for patients with clinically advanced disease. **Methods:** Hybrid capture-based CGP was performed on 21 cases of PSRC, with 17 PSRC also undergoing RNA sequencing to enable expanded gene fusion detection. Tumor mutational burden (TMB) was determined on 1.1 Mbp of sequenced DNA and microsatellite instability (MSI) was determined by principal components analysis of optimal homopolymer loci. **Results:** There were 10 sarcoma NOS, 5 pulmonary artery intimal sarcomas, 4 pleomorphic/MFH sarcomas, 1 primary inflammatory myofibroblastic tumor (IMT) and 1 primary solitary fibrous tumor (SFT) cases. There was 1 stage I, 1 stage II, 9 stage III and 10 Stage IV tumors. The patients had a median age of 58 years (range 33 to 81 years). There were 7 female and 14 male patients. The mean number of genomic alterations (GA) per sarcoma was 5.8. Notable alterations not considered presently actionable included *TP53* (47%), *CDKN2A* (36%), *CDKN2B* (25%) and *RB1* (13%). Clinically relevant GA (CRGA) affected *PDGFRA*, *RICTOR*, *CDK4* and *KIT,* all at 11%. When considering additional CRGA in *EGFR*, *TSC2, ALK* and *BRAF* (each at 5%), a total of 10 (48%) PSRC featured ≥1 CRGA. The case with an *ALK* fusion represents an IMT initially localized to the lung and diagnosed as a primary lesion. The mean TMB in the PSRC was 8.3 mutations per Mb with 14% having TMB of > 10 mut/Mb and 10% having TMB > 20 mut/Mb. MSI status was available for 9 (43%) of the PSRC cases, and the remainder were all microsatellite stable. Assessment of therapeutic intervention and responses to targeted and immunotherapies is ongoing. **Conclusions:** PSRC is characterized by a relative high frequency of GA, including driver mutations or fusions in tyrosine kinases and cell cycle regulatory genes. In addition, this study identified a significant proportion of PSRC that feature an intermediate or high TMB, indicating the potential for use of immunotherapies for these patients. Further study of CGP to assist in management of patients suffering from this rare form of pulmonary malignancy appears warranted.

11554 Poster Session (Board #299), Sat, 8:00 AM-11:30 AM

Systemic therapy regimen outcomes in metastatic phyllodes tumors of the breast. *First Author: Amanda Marie Parkes, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Phyllodes tumors of the breast (PT) account for < 1% of all primary breast neoplasms. Metastatic PT (MPT) are less common, limiting development of standardized treatment approaches. We sought to characterize the largest group of MPT thus far reported, evaluating outcomes with systemic therapy regimens. **Methods:** Adult MPT patients followed at MD Anderson Cancer Center from 1954-2015 were selected for retrospective chart review. Systemic therapy was sorted into five categories: Adriamycin/Ifosfamide (AI), other anthracycline regimens (A), other ifosfamide regimens (I), gemcitabine regimens (G), and other (O). Given one patient may have received > 1 regimen, we assumed that the effects of each regimen were independent. Descriptive statistics, response to treatment, and survival analyses were performed. **Results:** We identified 50 MPT patients. Most patients had metachronous metastases (47/50, 94%) and lung was the most common site of metastasis at time of MPT diagnosis (35/50 patients, 70%). Thirty-one of 50 MPT patients received 61 systemic regimens (range: 1-4 regimens per patient, median: 1). Overall response rate (ORR) was highest in AI (10/19 patients, 53%), followed by A (5/13, 38%), I (2/8, 25%), G (3/13, 23%), and O (1/8, 13%). Median overall survival (OS) was 10.7 months (95% CI: 8.67, 16.5). Sixty regimens had complete information available for progression free survival (PFS) analyses. Table 1 details median PFS by regimen. After adjusting for tumor size, comparing other therapies to AI, risk of progression/mortality was significantly higher with G, A, and O (Table 1). There was no statistically significant difference between AI and I. **Conclusions:** MPT patients are a unique population with limited characterization. Our study demonstrates superiority of AI, with I showing similar risk of progression/mortality, but lower ORR.

Median PFS and risk of progression/mortality using multivariate cox regression.

Systemic regimen	Cases	Total	Median PFS (95% CI) (months)	HR (95% CI)	P-value
AI	16	19	9.10 (5.03, 14.2)	Ref	
I	8	8	5.10 (0.67, 12.1)	2.29 (0.88, 5.96)	0.090
A	12	12	3.65 (1.17, 7.90)	3.19 (1.38, 7.40)	0.007
G	12	13	2.80 (1.83, 4.60)	3.09 (1.31, 7.25)	0.010
O	6	8	1.67 (1.13, 7.77)	7.74 (2.42, 24.8)	< .001

11555 Poster Session (Board #300), Sat, 8:00 AM-11:30 AM

Early metabolic response as predictor for treatment outcome of pazopanib in patients with metastatic soft tissue sarcomas (the PREDICT study). *First Author: Winette T.A. Van Der Graaf, Institute of Cancer Research and The Royal Marsden NHS Trust Foundation, London, United Kingdom*

Background: Pazopanib is the first approved targeted treatment for non-GIST soft tissue sarcoma (STS) pts. In the PALETTE study 23% of pts had progressive disease as best response. This study correlates early metabolic response evaluated by FDG-PET/CT to treatment outcome assessed by RECIST and investigates the relation between metabolic response and pazopanib pharmacokinetics. **Methods:** Twenty STS pts recruited from sarcoma clinics in Radboud University Medical Centre Nijmegen and the Netherlands Cancer Institute Amsterdam, underwent FDG-PET scans at baseline, and 2 and 8 weeks after start of pazopanib. Blood samples were collected for pharmacokinetic (PK) assessment (C_{trough} levels and $AUC_{0\text{-}24h}$). We investigated the relation between early metabolic response after 2 weeks of therapy and pazopanib exposure at 2 weeks, and the relation between early metabolic response and treatment response assessed by RECIST1.1 at 8 weeks. The study was registered at ClinicalTrials.gov (NCT01995981) and approved by the regional medical ethics committee. All patients gave written informed consent. **Results:** After 8 weeks of therapy, 14 out of 20 pts had discontinued pazopanib due to radiological tumor progression ('non-responders' n = 12) or toxicity (n = 2). Quantitative FDG-PET scoring according to PERCIST guidelines at 2 weeks identified 25% (3 of 12) of all non-responders versus 42% (5 of 12) with visual response analysis by an independent evaluation from a nuclear medicine physician. No patient was incorrectly labeled as non-responder. PK results were not related to metabolic response. **Conclusions:** In this heterogeneous STS patients' cohort we did not see a relation between pharmacokinetics and pharmacodynamics of pazopanib, but we did show that FDG-PET/CT identified a substantial part of pazopanib non-responders. The results of this study warrant a larger study, to enable future early and cost-effective decision making in STS pts treated with pazopanib. Funding: This academic investigator-initiated study was supported by a grant from GlaxoSmithKline/ Novartis to the institute. Clinical trial information: NCT01995981.

11556 Poster Session (Board #301), Sat, 8:00 AM-11:30 AM

FAP-related desmoid tumours treated with low dose chemotherapy: Results from a multicentre retrospective analysis. *First Author: Bruno Vincenzi, Department of Medical Oncology, University Campus Bio-Medico of Rome, Rome, Italy*

Background: Desmoid tumours (DTs) are monoclonal neoplasms with fibroblastic-myofibroblastic differentiation and they represent the most common extra-intestinal manifestation of familial adenomatosis polyposis (FAP). DTs are often multifocal and, even in the absence of a metastatic potential, they represent the first cause of death in FAP patients after colectomy. Data on the activity of chemotherapy in FAP-associated DTs are limited. We specifically examined the activity of chemotherapy with low-dose methotrexate (MTX) + vinca alkaloids. **Methods:** We retrospectively reviewed data from all patients treated with MTX + vinca alkaloids for FAP-associated DTs in 5 reference centres and cases included into the National rare cancer network were also reviewed and included if sufficiently informative for the study purposes. Radiological responses were assessed using both RECIST and CHOI criteria. **Results:** We identified 28 patients treated with MTX + vinca alkaloids. All patients had progressive disease before chemotherapy; 17 patients and 9 patients had previously received respectively surgery and/or systemic treatments (i.e. hormone therapy, NSAIDs). Chemotherapy was administered for a median duration of 11 months. According to RECIST criteria (CHOI evaluation is ongoing) complete response, partial response, stable disease, and progressive disease were observed in 1, 17, 10, and 0 patients, respectively. The median progression-free survival (PFS) was 78 months; it was 124 months in responding patients. After chemotherapy withdrawal, MTX + vinca alkaloids rechallenge was offered to 11 patients with progressive disease. In these patients, we obtained a control rate of 100%, resulting in a median second PFS of 64 months. **Conclusions:** To the best of our knowledge, this is the largest series on the activity of low dose chemotherapy in FAP-related DTs. Our data suggest a tremendous activity of low dose chemotherapy in this very rare subset of patients.

11557 Poster Session (Board #302), Sat, 8:00 AM-11:30 AM

A multicenter phase II study of pazopanib in patients with unresectable or recurrent dermatofibrosarcoma protuberans (DFSP). *First Author: Julie Delyon, AP-HP Hôpital Saint-Louis, Paris, France*

Background: DFSP is a tumor accounting for 6% of soft-tissue sarcoma, with a high risk of local infiltrative dissemination. Wide local excision is the standard treatment. The identification of the *COL1A1-PDGFB* translocation activating the PDGF pathway in > 90% of DFSP had led to the use of the kinase inhibitor imatinib in locally advanced or metastatic DFSP, with a response rate of 36-57%. Pazopanib (pazo) is a multitargeted tyrosine kinase inhibitor (VEGF, PDGF, KIT) approved in severe pretreated soft-tissue sarcomas. We sought to evaluate the efficacy and safety of pazo in the treatment of DFSP. **Methods:** We conducted an open-label phase II trial in patients with histologically proven unresectable primary, recurrent or metastatic DFSP. Patients received pazo 800 mg qd. The primary study endpoint was the objective response rate defined as the reduction of the biggest diameter of the tumor ≥ 30%(RECIST) at 6 months(mo) or at surgery if performed before 6 mo. Pharmacodynamics analyses were performed on tumor biopsies and blood samples at baseline, month 1-3-6 and progression (*PDGF*, *PDGFR*, *VEGF*, *VEGFR* mRNA and downstream signaling pathway components). **Results:** 23 patients were included from Jul 2010 to Feb 2014 (9 centers, France). 18 had primary, 4 recurrent and 1 metastatic DFSP. The median follow up was 6.2 mo (interquartile range 5.6-7.8). 5 patients (22%, 95% CI: 7-22%) among 23 evaluable had response according to the primary endpoint. The best objective response rate was 30% (7/23, 95%CI 13-53%). 18 patients had surgery, including 12 with free margins. One patient with metastatic DFSP died. Median treatment duration was 3.8 mo (2.1-6.0); 9/23 patients discontinued for AEs; 11(48%) patients had dose reduction. Grade 3-4 AEs were transaminitis(5), cholestasis(3), hemolytic and uremic syndrome(1), nephrotic syndrome(1). No drug-related death occurred. Using FISH the *COL1A1-PDGFB* translocation was identified in 18 patients(5 not evaluable). High plasma level of soluble VEGFR2 was associated with tumor response (p = 0.01). **Conclusions:** Our results suggest that pazo is a therapeutic option in DFSP. As compared to previous studies with imatinib, we did not observe an improved response rate. Clinical trial information: NCT01059656.

11558 Poster Session (Board #303), Sat, 8:00 AM-11:30 AM

Short, full-dose neoadjuvant chemotherapy in localized high-risk adult soft tissue sarcomas (STS): An exploratory subgroup analysis on responding patients in a randomized controlled trial comparing 3 neoadjuvant versus 3 neoadjuvant + 2 adjuvant cycles of full dose anthracycline and ifosfamide chemotherapy at a 10yr median FU. *First Author: Silvia Stacchiotti, Department of Cancer Medicine, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: We already reported (*Cancer 2012;118:5857*) the correlation of Choi criteria (Choi) and RECIST with outcome of pts affected by high-risk STS entering a multicentric Italian/Spanish Phase 3 trial comparing 3 vs 5 cycles of (neo)adjuvant CT with full-dose epirubicin + ifosfamide (*JCO 2012; 30:850; Ann Oncol 2016; 27:2283*). We investigated whether the non inferiority of 3 vs 5 cycles held also in the subgroup of patients responsive to preoperative treatment. **Methods:** Patients were randomized to receive 3 cycles of preoperative CT with epirubicin 120 mg/m2 and ifosfamide 9 g/m2 (Arm A) or to receive the same 3 cycles of preoperative CT followed by 2 further cycles of post-operative CT (Arm B). Radiotherapy could be delivered in the preoperative or in the post-operative setting. Non-inferiority of the primary end-point, overall survival (OS), was assessed by the confidence interval of the hazard ratio (HR; Arm A/Arm B) derived from Cox model. Response was assessed by RECIST and Choi. **Results:** Between January 2002 and April 2007, 160 pts were assigned to Arm A and 161 to Arm B, 158 patients received preoperative RT (Arm A = 77; Arm B = 81). At a median FU of 117 months (IQR 103-135 months), 123 deaths were recorded, 58 in Arm A and 65 in Arm B. Ten-year OS was 61% for the entire group of patients, 64% in Arm A and 59% in Arm B (HR 0.92, 90% confidence interval [CI] :0.68–1.23). Of 243 patients evaluable for RECIST, 208 achieved a partial response (PR) or stable disease (SD), 93 in Arm A and 115 in Arm B. Ten year OS was 62% in Arm A and 59% in Arm B (HR 1.02; 90% CI 0.70-1.48). Of 166 pts evaluable for Choi, 135 achieved a PR, 60 in Arm A and 75 in Arm B. Ten-year OS was 60% in Arm A and 66% in Arm B (HR 1.29; 90% CI 0.80-2.07). **Conclusions:** In this (neo)adjuvant trial, the non inferiority of 3 vs 5 cycles of full dose anthracycline and ifosfamide /neo) adjuvant chemotherapy was confirmed also in the subgroup of patients with evidence of radiologic response to the preoperative treatment Clinical trial information: 2004-003979-36.

11559 Poster Session (Board #304), Sat, 8:00 AM-11:30 AM

Gemcitabine re-challenge in metastatic soft tissue sarcoma: A therapeutic option for selected patients. *First Author: Ana Sebio, Hospital de la Santa Creu i Sant Pau, Medical Oncology Department, Barcelona, Spain*

Background: Treatment options for patients with metastatic sarcoma are limited. Gemcitabine-based schedules have shown activity and in selected patients, re-challenge with a previously successful gemcitabine-based regimen is common practice. There are no published data to support this practice. This study evaluates the efficacy and safety of gemcitabine re-challenge in advanced soft tissue sarcoma. **Methods:** A retrospective search of a prospectively maintained database was performed to identify patients re-challenged with gemcitabine-based chemotherapy (GBC) from 2003 to 2015. Baseline clinical characteristics, progression-free and overall survival were obtained from clinical records and response evaluation was performed by RECIST 1.1 criteria. **Results:** 29 patients were identified. The most frequent histology was leiomyosarcoma (n = 25, 86%). In the first GBC treatment, 86% (n = 25) of patients received gemcitabine-docetaxel and the others gemcitabine monotherapy. 38% (n = 11) of the patients received the first GBC as 1st treatment line, 45% (n = 13) as 2nd line and 17% (n = 5) as 3rd or further. The re-challenge GBC consisted of gemcitabine-docetaxel in 66% (n = 19) of the patients, gemcitabine monotherapy in 31% (n = 9) and gemcitabine-DTIC in 3% (n = 1) of the cases. Re-challenge GBC was administered as 2nd treatment line in 21% (n = 6) of the patients, as 3rd line in 34% (n = 10) and 45% (n = 13) of the patients received it in 4th or further line. In the evaluable patients (n = 28) the first GBC yielded a 55% response rate and after re-challenge GBC 26% (n = 6) of the evaluable patients (n = 23) responded. Progression-free survival was 11.1 months (95% CI, 7.2-11.9) for the first GBC and 5.3 months (95% CI, 2.0-7.5) in the re-challenge setting. Overall survival following gemcitabine re-challenge was 12.2 months (95% CI, 7.0-18.2). Regarding toxicity, 46 % of the patients (n = 12 of 26 evaluable) treated with re-challenge GBC presented grade 3-4 adverse events (CTCAE 4.03) and 31% of the patients needed a dose reduction. **Conclusions:** In selected sarcoma patients, re-challenge with a gemcitabine-based regimen can be considered as a treatment option in advanced disease at the expense of increased toxicity.

11560 Poster Session (Board #305), Sat, 8:00 AM-11:30 AM

First prospective observational study in diffuse-type tenosynovial giant cell tumors. *First Author: Monique Mastboom, Leiden University Medical Center, Leiden, Netherlands*

Background: Tenosynovial giant cell tumor (TGCT) is a rare, benign, but potentially locally aggressive and often recurrent disease. Its impact on patient quality of life and ability to work is not well defined. This is the first prospective registry detailing economic impact, management and burden of TGCT. **Methods:** This international, multicenter, prospective, non-interventional observational registry enrolled patients with histologically proven diffuse-TGCT. Patient data was collected at baseline (time of patient enrolment) and at follow up data collection points, performed at 12 and 24 months. **Results:** This snapshot analysis included 88 TGCT patients with complete baseline data from six active international sites between November 2016 and September 2017: 58% female; mean age at enrolment 45 years (standard deviation [SD] 14 years). Most (73%) patients had tumors located in the knee. Fifty six (64%) patients with a primary diagnosis of TGCT were included, 32 (36%) with recurrent disease. Mean time from first symptoms until diagnosis was 42 months (median 21 months) and the most commonly reported symptom was pain (78%). A total of 63 (72%) patients had surgery, primarily open synovectomy (54%). Thirty eight (43%) patients received systemic therapy, pexidartinib [55%] and imatinib [42%]. Over 12 months, 44 (50%) patients reported that TGCT compromised their ability to work with a mean of 51 days of work (median 21 days) missed due to TGCT. Eight (9%) patients were fully unemployed due to TGCT, 2 (2%) were partially unemployed and 1 (1%) patient had retired prematurely. On average, a clinically significant impairment of physical function at baseline was observed as compared with the reference population based on PROMIS Physical Function score (42 [SD 7] vs 50 [SD 10]). Mean EQ-5D-5L at baseline was 0.75 (SD 0.19). **Conclusions:** This disease-registry in six sites, with a two-year recruitment period and two-year follow-up per patient, showed that TGCT has a major impact on daily living in a relatively young and working population. Clinical trial information: NCT02948088.

11561 Poster Session (Board #306), Sat, 8:00 AM-11:30 AM

Characterization of tumor microenvironment in extraskeletal myxoid chondrosarcoma (EMC). *First Author: Valentina Indio, Interdepartmental Centre of Cancer Research "Giorgio Prodi", University of Bologna, Bologna, Italy*

Background: EMC is a rare sarcoma mostly originating from soft tissues. EMC carries a specific translocation, involving NR4A3, which is fused more often with EWSR1 and less frequently with other partners, including TAF15. We investigated EMC tumor microenvironment to define the differential immune-profile of NR4A3-EWSR1 and NR4A3-TAF15 EMC subtypes and to evaluate if EMC could be good candidate to immunotherapy. **Methods:** RNA-seq was performed on 12 naïve tumors with Illumina technology. The gene expression was quantified and, after normalization, the tool CIBERSORT was adopted to evaluate the presence of 22 hematopoietic population within the tumor-infiltrating environment. Absolute and relative abundance were used to estimate the correlation between infiltrating cell types. Moreover, the EMC immune-profile was comparatively evaluated between two subgroups of EMC based on the rearrangement type EWSR1-NR4A3 (7/12) and TAF15-NR4A3 (5/12). Immunohistochemistry, for CD3, CD20, CD14, CD163, CD56, HLA ABC, PDL1(22C3), and CD1a was performed and scored on available FFPE specimens (3/12). **Results:** The analysis showed in all cases the existence of gene signatures related to the presence of immune-infiltrate. Globally, M2 macrophages were the most enriched cell type, followed by CD4+ memory resting, and M0 macrophages; B-cell and mast cell were also moderately observed. The correlation analysis showed that the abundance of M2 macrophages negatively correlated with the presence of CD3+ T-cells. Comparative analysis showed that the EMC with TAF15 fusion had a significantly lower level of CD4+ memory resting cells ($p = 0.042$), lower NK cells and a trend to a higher enrichment of mast cells compared to EWSR1+ EMC. IHC analysis confirmed the presence of an immune-infiltrate, with both a macrophagic and a lymphocytic component. **Conclusions:** Our results showed that EMC is marked by the presence of a macrophagic and, to a less extent, a CD4+ T cells immuno-infiltrate. Interestingly, the immune-profile differed between the 2 molecular subtypes, highlighting that the high degree of diversity that marks sarcomas is reflected also in their immune-profile. EMC looks to be a potential interesting candidate for immune-therapy.

11562 Poster Session (Board #307), Sat, 8:00 AM-11:30 AM

Phase 1b study of selinexor, a first in class selective inhibitor of nuclear export (SINE) compound, in combination with doxorubicin in patients (pts) with locally advanced or metastatic soft tissue sarcoma (STS). *First Author: Eoghan Ruadh Malone, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Selinexor is a first-in-class SINE compound with single-agent activity in STS. We undertook this study to determine the safety, tolerability and efficacy of selinexor when combined with doxorubicin in pts with locally advanced or metastatic STS. **Methods:** This phase 1b study was conducted using a modified toxicity probability index (mTPI) design. Patients with locally advanced or metastatic STS received selinexor at two dose levels (60 or 80mg weekly PO) plus doxorubicin (75mg/m^2 IV q21 days, max 6 cycles). Pts with stable disease or better (per RECIST 1.1 criteria) after 6 cycles of combination treatment received selinexor monotherapy until disease progression or unacceptable toxicity. Disease assessments were made with standard imaging after every 2 cycles. Limited pharmacokinetic (PK) data was collected for the first 3 pts at each dose level. **Results:** 13 pts (11F/2M, ECOG 0/1: 5/8, median age 63 years [range 51-73]) were enrolled. Disease subtypes included leiomyosarcoma (n = 6), undifferentiated pleomorphic sarcoma (n = 2; UPS), liposarcoma (n = 2) and other sarcomas (n = 3). Three pts at 60mg selinexor and 10 pts at 80mg selinexor have been treated. The most common G3 drug related adverse events (AEs) were hematological, including neutropenia n = 6 (46%), anemia n = 3 (23%). There were two dose-limiting toxicities (febrile neutropenia and unresolved fatigue lasting more than 7 days), both at the 80mg dose level. Of the 13 evaluable pts (median follow-up of 15 weeks [range 5-31]), partial response was seen in 3 pts (23%, n = 1 for UPS, malignant peripheral nerve sheath tumor and myxofibrosarcoma) and stable disease was seen in 7 (54%). PK analysis of selinexor did not demonstrate changes compared to single agent profile. **Conclusions:** Our initial data demonstrate that the combination of selinexor and doxorubicin appears to be tolerable and safe. There was no exposure changes oberserved for selinexor in this combination regimen. Updated toxicity, safety and efficacy data will be presented at the meeting. Clinical trial information: NCT03042819.

11563 Poster Session (Board #308), Sat, 8:00 AM-11:30 AM

Discovery and characterization of novel, recurrent, targetable ALK fusions in leiomyosarcoma. *First Author: Lara Emily Davis, Oregon Health & Science University, Portland, OR*

Background: Leiomyosarcoma (LMS), a type of soft tissue tumor that originates from smooth muscle, is the second most common type of sarcoma. Despite multimodal treatment including surgery, chemotherapy and radiation, locally advanced or metastatic LMS portends poor prognosis. We hypothesize that discovery and validation of oncogenic drivers and cognate targeted therapies holds the potential to dramatically impact LMS patient outcomes. **Methods:** To discover putative kinase fusions, we analyzed existing genomic or transcriptomic data from LMS clinical samples. We functionally validated the oncogenic potential and targetability of discovered kinase fusions through biochemical, cell-based and *in vivo* tumor modelling approaches. Multiple independent cell-based (Ba/F3, NIH3T3 and murine smooth muscle cell) model systems were utilized. **Results:** We identified ALK rearrangements in 7 of 280 (2.5%) LMS patients, including a novel KANK2-ALK fusion and a recurrent ACTG2-ALK fusion. KANK2-ALK and ACTG2-ALK operate as dominant oncogenes in Ba/F3 or NIH3T3 model systems, and KANK2-ALK is tumorigenic when introduced in smooth muscle cells, the cell of origin for leiomyosarcoma. Oral monotherapy with the targeted ALK kinase inhibitor lorlatinib significantly inhibited tumor growth and prolonged survival in a murine model of KANK2-ALK leiomyosarcoma. **Conclusions:** These results provide the first validation of a targetable oncogenic kinase fusion as a driver in a subset of leiomyosarcomas. Overall, these findings suggest that some soft tissue sarcomas may harbor previously unknown kinase gene translocations, and their discovery may propel new therapeutic strategies in this treatment-refractory cancer.

11564 Poster Session (Board #309), Sat, 8:00 AM-11:30 AM

Sarcomas in patients over 90: Natural history and treatment—A nationwide study over 6 years. *First Author: Clemence Basse, Centre Léon Bérard & University Claude Bernard Lyon I, Lyon, Lyon, France*

Background: Soft tissue sarcomas (STS) are rare tumors accounting for less than 1% of human cancers. While the highest incidence of sarcomas is observed in elderly, this population is often excluded or very poorly represented in clinical trials. The present study reports on clinicopathological presentation, and outcome of sarcoma patients over 90 recorded in the Netsarc French national database. **Methods:** Information of soft tissue and visceral sarcoma patients registered from January 1st 2010 to December 31st 2016 in Netsarc were collected, analyzed and compared with younger ($<$ 90-years old) patient population. **Results:** Patients with sarcomas aged $>$ 90 have almost exclusively sarcomas with complex genomics (92·0% vs 66·3%), are less frequently metastatic (5·3% vs 14·7%) at diagnosis, have more often superficial tumours (39·8% vs 14·7%), as well as limbs and head and neck sites (75·2% vs 38·7%) (all $p < 0·001$). Optimal diagnostic procedures and surgery were less frequently performed in patients over 90 (all $p < 0·001$). However, local relapse free, metastatic relapse free, and relapse-free survival were not significantly different from those of younger patients, in the whole cohort, as well as in the subgroup of operated patients. As expected overall survival was worse in patients over 90 ($p < 0·001$). Patients over 90 who were not operated had a worse overall survival than younger patients (9·9 vs 27·3 months, $p < 0·001$). **Conclusions:** Patients with STS diagnosed after 90 have distinct clinicopathological features, but comparable relapse free survival, unless clinical practice guidelines recommendations are not applied. Standard management should be proposed to these patients if oncogeriatric status allows.

11565 Poster Session (Board #310), Sat, 8:00 AM-11:30 AM

Identification of leiomyosarcoma circulating tumor DNA through ultra-low passage whole genome sequencing and correlation with tumor burden: A pilot experience. *First Author: Matthew Louis Hemming, Dana-Farber Cancer Institute, Boston, MA*

Background: Detection of circulating tumor DNA (ctDNA) has emerged as a new approach for identifying oncogenic mutations, measuring disease burden, clinical prognostication, and assessing response to therapy. Most ctDNA assays detect single-nucleotide variants (SNVs) that are highly recurrent in carcinomas. Though there are few recurrent SNVs in leiomyosarcoma (LMS), LMS is characterized by numerous chromosomal copy-number alterations (CNAs). We therefore evaluated plasma from patients with LMS for the presence of ctDNA using an ultra-low passage whole genome sequencing (ULP-WGS) approach designed to detect somatic chromosomal CNAs. **Methods:** We identified 30 tumor/plasma pairs from patients with advanced LMS. Ten pairs have undergone ULP-WGS, with an additional 20 pairs currently in process. Of the 10 pairs evaluated, 7 were of uterine and 3 of extrauterine origin. DNA from plasma samples was subjected to ULP-WGS and compared to tumor DNA. Differences in genome-wide sequencing coverage were used to identify chromosomal amplification or deletion and ichorCNA software was used to estimate tumor fraction of each sample. Identified CNAs from tumor specimens were used to confirm the specificity of ULP-WGS to detect CNAs in plasma. Clinical data were reviewed to assess disease burden and progression status. **Results:** ctDNA was identified in 5 of 10 cases including 5 out of 6 patients with progressive disease. None of the patients with no evidence of disease (NED) or with stable disease had detectable ctDNA. We identified ctDNA in patients with both metastatic uterine LMS and extrauterine LMS. CNAs in plasma correlated with CNAs detected in matched tumor samples. **Conclusions:** Identification of plasma ctDNA by ULP-WGS is feasible in patients with advanced LMS and correlates with tumor burden/progression. An additional 20 cases will be presented. These preliminary results support further investigation of ULP-WGS as a novel blood-based assessment of tumor burden in LMS. Future experiments will assess the utility of ULP-WGS in detecting residual disease following surgery, surveillance for disease recurrence, and monitoring response to therapy.

11566 Poster Session (Board #311), Sat, 8:00 AM-11:30 AM

Impact of pathological stratification of advanced well differentiated/dedifferentiated (WD/DD) liposarcoma (LPS) on the response to trabectedin (T). *First Author: Roberta Sanfilippo, Medical Oncology Unit 2, Medical Oncology Department, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: Recently, we showed that the FNCLCC grading system can prognosticate the outcome of retroperitoneal LPS. We aimed to explore the impact of pathological stratification using the FNCLCC grading system on the response to Trabectedin (T) of advanced/metastatic WD/DD LPS. **Methods:** We analyzed patients (pts) with advanced WD/DD LPS and treated with T at our Institution for whom formalin-fixed paraffin-embedded (FFPE) tumor samples were available. Histologically, samples were categorized according to the 2013 WHO classification, complemented by Evans' refinements. The "cellular subvariant" (CS) was diagnosed in the presence of a non-lipogenic area with a mitotic count $<$ 5/10HPF. In cases in which the mitotic count was $\geq$5/10 HPF, the diagnosis was DDLPS and graded as 2 or 3 according to the FNCLCC grading system. Patients were divided into two subgroups: WDLPS/CS and G2/G3 DDLPS. Response rate (RR) and progression-free survival (PFS) were compared using the Fisher's exact test and the log-rank test, respectively. **Results:** We included a total of 39 pts with advanced WD/DD LPS treated with T from April 2003 up to present. In 21 pts the sample analyzed was the primitive tumor prior to starting any systemic treatment. In 18 pts we analyzed the sample obtained at the closest date to T initiation. Four patients had a WDLPS, 7 a CS, 21 a G2 DDLPS and 7 a G3 DDLPS. In the subgroup of 11 WDLPS/CS, 5 partial responses, two minor responses and two stable diseases were observed, while in the subgroup of 28 G2/G3 DDLPS we observed one PR and 13 SD. RR was 45% for WDLPS/CS versus 4% for G2/G3 DDLPS (p = 0.0165). Median PFS was 14 months for WDLPS/CS and 3 months for G2/G3 DDLPS (HR 0.28; 95% CI 0.14-0.59; p = 0.0006). **Conclusions:** In this series, sensitivity to T was higher in WDLPS/CS. If what suggested by this limited retrospective case series analysis were confirmed on larger series, WD/CS vs G2/G3 DD histologies could serve as predictive factors for T in advanced WD/DD LPS.

11567 Poster Session (Board #312), Sat, 8:00 AM-11:30 AM

Nodal involvement and survival in synovial, clear cell, angio, rhabdo, and epithelioid sarcoma. *First Author: Haotong Wang, Massachusetts General Hospital, Boston, MA*

Background: Synovial, Clear cell, Angiosarcoma, adult Rhabdomyosarcoma and Epithelioid sarcoma is often referred to by the mnemonic SCARE as soft tissue sarcoma subtypes with higher risk of lymph node involvement(LNI). This study is to identify the incidence of LNI, prognosis and predictors of LNI, treatment and patterns of failure. **Methods:** We identified 829 patients with the diagnosis of the above 5 histologies who were treated in our institution and retrospectively reviewed 343 patients who were diagnosed from 2000 to 2017. Statistical significance was assessed with Chi-square and Wald tests. Kaplan-Meier analysis was used to analyze survival outcomes. **Results:** Primary SCARE sarcoma sites include head and neck(71, 21%), upper extremity(57, 17%), lower extremity(90, 26%), thorax, abdomen and pelvis(47, 14%), trunk and retroperitoneum(44, 13%), GU, GYN and other(34, 10%). 152 present with Stage 2 and 109 with Stage 3 disease (AJCC7). Primary tumor size was = $<$ 5 cm in 123, 5-10 cm in 77 and $>$ 10 cm in 57. LNI was found in 54(16%) patients, of whom 48 were positive at diagnosis and 6 were found during follow up. LNI rates differed significantly (table 1). Tumor size(p = 0.05), histology(p $<$ 0.001), metastasis(p $<$ 0.001) were found as predictors of LNI. 282(82%) patients underwent resection with R0 in 177 patients. Sentinel lymph node biopsy was performed in a limited number of patients. 171(50%) patients received chemotherapy. 247(72%) patients received radiation therapy. Median follow up is 26.5 months. 5-year overall survival (OS) in SCARE histology is 72.7, 41.3, 34.5, 30.8, 45.4% respectively. Synovial sarcoma(SS) has better survival compared to others(p $<$ 0.001). LNI was associated with worse OS (p = 0.001) and DFS(p = 0.001). Multivariate analysis identified LNI(HR = 1.89, p = 0.005), large tumor size (HR = 1.05 per cm, p = 0.003), metastasis(HR = 3.31, p $<$ 0.001) as significant factors affecting OS. **Conclusions:** LNI is significantly higher in clear cell, angiosarcoma, rhabdomyosarcoma and epithelioid sarcoma than SS, is predicted by larger tumor size, and has poorer prognosis.

	Synovial	Clear cell	Angiosarcoma	Rhabdomyosarcoma	Epitheloid Sarcoma
Overall: 343	125	18	78	73	49
LNI (p = 0.0015)	6%	28%	15%	21%	29%
M+ at presentation (N.S.)	10%	3%	23%	27%	24%

11568 Poster Session (Board #313), Sat, 8:00 AM-11:30 AM

Survival impact of surgical management in reference centers for retroperitoneal sarcoma: A nationwide study of FSG-GETO and NETSARC. *First Author: Sylvie Bonvalot, Institut Curie, Paris, France*

Background: Retroperitoneal sarcoma (RPS) are complex to treat. We previously reported that management and surgery in a reference center are independent prognostic factors for relapse free survival (RFS) in sarcoma. Here, we investigated the impact of the surgery in a reference center on RFS and overall survival (OS) in the nationwide NETSARC study. **Methods:** NETSARC (netsarc.org) is a network of 26 reference sarcoma centers, funded by the French NCI. Since 2010, second pathological review are mandatory for sarcoma patients (pts) facilitating exhaustive collection. Pts characteristics and follow-up are collected in a database regularly monitored. From 2010 to 2016, RPS represented 10.0% (range 8.3-10.5%) of all sarcomas included in Netsarc. **Results:** 1286 RPS (M/F ratio: 1.09, median age 63, range 20-94) are reported in NETSARC from 01/2010 to 12/2016. WD/DDDLPS (63.7%), LMS (21,3%), UPS (6,3%) were the most frequent histotypes. 155 (12%) pts had metastasis (met) at diagnosis. 699 (54%) and 587 (46%) were presented to one of the 26 NETSARC multidisciplinary board before and after initiation of treatment. 477 (37%) and 809 (63%) were operated within vs outside a NETSARC reference center. The former group had larger tumor size, p $<$ 0.0001, but no difference of age, grade, histotypes. More pts treated in NETSARC centers had documented imaging (92% vs 80%) and preoperative biopsy (81% vs 63%, p $<$ 0.0001 both). Quality of final surgery was R2 or unknown, in 24% vs 69% in NETSARC vs non NETSARC centers (p $<$ 0.0001). In univariate analysis on non met patients, surgery within a reference center was associated with a better OS (median not reached: 30-months OS 84% vs 63% respectively, logrank p $<$ 0.001). Local RFS and RFS were significantly better for pts operated in reference centers (p $<$ 0.0001). Surgery in reference center was an independent good prognostic factor for OS (HR: 0.23), LRFS (HR:0,56), RFS (HR:0,79) using Cox model (p $<$ 0.001 all). **Conclusions:** In this nationwide unselected population of RPS over 7 years period, surgery in reference center is associated with a major reduction of the risk of relapse and death.

11569 Poster Session (Board #314), Sat, 8:00 AM-11:30 AM

Upfront isolated limb perfusion (ILP) in untreated patients with unresectable non-metastatic primary soft-tissue sarcomas (STS) of the limb: The Gustave Roussy experience. *First Author: Tarek Assi, Gustave Roussy Cancer Campus, Villejuif, France*

Background: Options for limb-preserving surgery in locally advanced (LA) STS include chemotherapy and/or radiotherapy (RT), or ILP with tumour necrosis factor-alpha (TNFa) + melphalan, if the tumour is confined to an extremity. The aim of this study is to evaluate the benefit of upfront ILP in untreated unresectable patients (pts). **Methods:** All pts with unresectable non-metastatic primary LA STS of the limb treated at Gustave Roussy with exclusive ILP as induction treatment between 2003 and 2016 were included in this study. Demographic, clinical and long-term characteristics were obtained from the electronic medical records and retrospectively analyzed. **Results:** 41 pts were identified, with a median age of 51 yrs [range: 21-76]. Liposarcoma and undifferentiated pleomorphic sarcoma were the most common subtypes (27% and 22 % respectively) with tumors classified as FNLCC grade 3 in 11 pts, grade 2 in 16 and grade 1 in 13. Acute regional toxicities after ILP (Wieberdink classification) were grade 2 in 35 pts (85%), and grade 3 in 2 (5%). No grade IV-V were observed. Objective response rate and disease stabilization were observed in 22% (including 2 CR) and 65% respectively. 8 pts were not operated (4 had exclusive RT, 1 pt progressed, 2 pts were in CR and 1 pt died after 3 months after ILP of a massive pulmonary embolism). 1 patient had early amputation due to PD after ILP. Out of 41 pts, 32 patients had conservative resection (78%). 2 pts (6%) experienced pathological CR, 17 (53%) had pathological PR ($\geq$ 50% necrosis) while 13 (41%) were considered refractory ($<$ 50% necrosis). All but 5 pts (84 %) received post-operative RT. After a median follow-up (FU) of 43 months 18 pts (47%) relapsed; one locally, 13 at distance (62% in the lung) and 4 in both sites. Median disease-free survival after surgery was 6.7 yrs. The 1-yr, 5-yrs and 10-yrs DFS rates were 75%, 50% and 45% respectively. Median overall survival (OS) was not reached after median FU of 6.3 yrs.1-yr, 5-yrs and 10-yrs OS rates were 90%, 63% and 55%. **Conclusions:** This study suggests that upfront ILP in unresectable STS pts is a potentially curative limb saving procedure and is well tolerated without affecting OS.

11570 Poster Session (Board #315), Sat, 8:00 AM-11:30 AM

Treatment of angiosarcoma with pazopanib and paclitaxel: Results of the phase II trial of the German Interdisciplinary Sarcoma Group (GISG-06 EVA) study. *First Author: Daniel Pink, Helios Klinikum Bad Saarow, Bad Saarow, Germany*

Background: Angiosarcomas (AS) account for 2-3% of all soft tissue sarcomas. About 60% develop at the skin, and radiation-induced AS following breast cancer therapy represent a characteristic feature. In metastatic or locoregionally advanced AS paclitaxel may induce tumor response. Data also show positive effects of VEGF-inhibiting drugs in AS patients. Thus, the combined application of chemotherapy and TKI seems warranted. **Methods:** This multicentre, open, prospective, single-armed phase II trial (NCT02212015) evaluates efficacy and safety of combined pazopanib (800mg/d) and paclitaxel (70mg/msq d1, 8, 15 of a 28d cycle) in advanced or metastatic AS. Primary endpoint is PFS at 6 mos. after start of therapy. Statistical analysis looks for 6 m-PFS $>$ 35% using RECIST 1.1. The trial is conducted in two steps with an interim futility analysis. Twenty-six patients were recruited (23 f, 3 m, median age 60.5 yrs), ECOG 0/1: n = 20/6 (80%/20%), 5 pts had local tumor progression, 21 pts (80.8%) showed metastatic disease, tumor description see table 1. **Results:** At interim analysis, the full analysis set consisted of 26 pts who received study medication at least once. The number of successes (6-m PFS yes) was n = 12 (46%). We had to adapt type-I-error for overrunning the pre-specified interim sample size, prompting a boundary of 17/26 pts with 6-m PFS, which the study did not meet (2-sided Clopper-Pearson CI). The formal decision was to stop the trial for futility. Analysing the non-responders showed that none of pts with hepatic involvement and 2nd AS after total body irradiation (TBI) did profit from study therapy. **Conclusions:** Combined paclitaxel and pazopanib is an active treatment in AS particularly in tumors located superficially. Patients with visceral metastases and those with hepatic angiosarcoma after TBI did not respond. The study protocol is about to be amended with refined inclusion citeria. Clinical trial information: NCT02212015.

Location of AS: skin.	17 (65.4%)
Loc. of AS: visceral/deep	12 (46.2%)
of loc. skin: chest/chest wall	13 (76.5%)
of loc. visc/deep: liver	5 (41.7%)
of loc. visc/deep: other	6 (50.0%)
Haemangiosarcoma	22 (84.6%)
Lymphangiosarcoma	4 (15.4%)
1ry AS	13 (50.0%)
2ndary AS	13 (50.0%)

11571 Poster Session (Board #316), Sat, 8:00 AM-11:30 AM

Inherited BRCA2 mutations and tumor hemi/homozygosity of metastatic soft tissue sarcoma in up to one-third of the 55 patients with shorter survival time. *First Author: Katsuhito Takahashi, International University of Health and Welfare, Mita Hospital, Sarcoma Center, Tokyo, Japan*

Background: Soft tissue sarcoma (STS) is well-known rare cancer with few therapeutic options. Although recent comprehensive genomic analyses of adult STS revealed few somatic mutations and many copy number variations (CNVs), the pathogenesis, prognostic markers and drug sensitivity mechanisms remain to be understood. **Methods:** We recruited 55 patients (50 female and 5 male, mean age 49) with a confirmed metastasis, information on familial cancer burden and detailed sarcoma pathology under written informed consent approved by IRB. Whole-exome sequencing was performed on the illumina HiSeq 2500 with the mean coverage depth of 178x in tumor and 68x in germline samples. In order to find CNVs and germline contributions in tumor, we used Strelka and Virmid analysis software filtering all mutations with allele frequencies more than 80%. CNVs and specific mutations in the BRCA2 locus identified were validated by multiplex ligation-dependent probe amplification (MLPA) and Sanger sequencing. **Results:** Among the somatic mutations, TP53, MED12, ATRX and RB1 are most frequently affected under mean total mutation numbers 1.26/Mb. All patients show MSS phenotype. Of the 72 genes with heritable cancer risk evaluated by Ballinger et al.(2016) in sarcoma germline, 25 have mutations with tumor bialletic loss of wild type sequence in 44/55 (80%) patients. Of these, six BRCA2 missense mutations recognized as variants of unknown significance (VUS) are most frequently found in 15/55 patients (27%, 12/37 LMS, 1/9 LPS, 1/1 MPNST, 1/1 AS) in both female and male. CNVs analysis by MLPA showed complete deletion of wild type BRCA2 locus, leading to hemizygosity of the VUS. Kaplan-Meier analysis revealed that patients with the BRCA2 mutations (N = 15) significantly reduced the 5-year survival rate as compared with patients with normal sequence or mutations in heterozygosity (N = 40) (48% vs 93%, P = 0.00272). **Conclusions:** Our results unveiled a different landscape of STS genomics from previous studies, indicating more germline and CNVs contributions in prognosis. Tumor loss of wild type allele and hemizygosity in BRCA2 implicates defective HRR as a potential therapeutic target in STS.

11572 Poster Session (Board #317), Sat, 8:00 AM-11:30 AM

Effect of JS001, a monoclonal antibody targeting programed death-1 (PD-1), on responses and disease control in patients with advanced or refractory alveolar soft part sarcoma: Results from a phase 1 trial. *First Author: Sheng Yang, Department of Medical Oncology, Beijing Key Laboratory of Clinical Study on Anticancer Molecular Targeted Drugs, National Cancer Center/ Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China*

Background: Alveolar soft part sarcoma (ASPS) is a rare and lethal malignancy mainly affecting youth, with no effective standard systemic treatment. Checkpoint inhibitors has showed efficacy in a variety of tumors, but its role in ASPS remains elusive. Here we report data of JS001, a humanized IgG4 anti-PD-1 antibody developed by Shanghai Junshi Biosciences Co., Ltd., China, in advanced or refractory alveolar ASPS from a phase 1 trial. **Methods:** After a dramatic tumor shrinkage with a single injection of JS001 in a patient with ASPS, we decided to expand a cohort in this tumor. Following patients(pts) were planned to receive JS001 at 3mg/kg or 10mg/kg, repeated every 2 weeks (up to 6 doses). The diagnosis was confirmed with central histological review. PD-L1 and CD8 IHC were performed when tissue sample available. **Results:** From October 2016 to June 2017, 12 pts were enrolled and all are efficacy-evaluable. One achieved CR and 2 had PR, with a response rate of 25%. Two additional pts had some degree of tumor shrinkage. Response heterogeneity was common: some lesions enlarged while others reduced in a same patient. In three pts with responses, the time to responses were 5.7, 7.7 and 23.9 weeks, respectively and the durations of response were 48.3, 31.1+ and 36.0+ weeks, respectively. Six pts remained under disease control at 6 months, and 4 at 12 months. The estimated median progression-free survival was 12.4 months. Toxicities were mostly grade 1-2. Grade 1 pneumonia and hepatitis, each in 1, were considered immune-related. No DLT or treatment-related death occurred. Tissue samples were available in 10 pts. In 4 PD-L1 positive cases, there were 2 PR, 1 SD and 1 PD; while in 2 pts with minimal CD8+ T-cell infiltration, there were 1 SD and 1 PD. In-depth biomarker analysis is in progress. **Conclusions:** In this first prospective cohort of PD-1 antibody in ASPS, JS001 showed satisfactory response rate and prolonged disease control. Responses heterogeneity highlights the importance of biomarker and microenvironment study in ASPS. Our findings may prelude a new option for advanced ASPS. Clinical trial information: NCT02836834.

11573 Poster Session (Board #318), Sat, 8:00 AM-11:30 AM

Prognostic role of HMG proteins in a series of 301 advanced soft tissue sarcoma patients: A Spanish Group for Sarcoma Research Study (GEIS). *First Author: Nadia Hindi, Institute of Biomedicine Research (IBIS)- Universitary Hospital Virgen del Rocio/CSIC/Universidad de Sevilla, Sevilla, Spain*

Background: High Mobility Group (HMG) proteins act as architectural transcription factors and can influence the expression of many genes. The role of promoting an undifferentiated pluripotent stem-like cell state makes HMGA proteins attractive for sarcoma research. Overexpression of HMGA1 and HMGA2 have been correlated with poor prognosis in some epithelial tumors but there is hardly any data on the prognostic role of HMGA in soft tissue sarcoma (STS). We present the analyses of protein expression of HMGA1/2 and B1 as prognostic factor in STS. **Methods:** Selection criteria were: advanced STS (at diagnosis or at any time from then on), paraffin block available, treated with at least 2 lines in advanced disease (one of them with trabectedin) and ethic committee's approval. A TMA was set up for nuclear expression of HMGA1 (Abcam), HMGA2 (Sigma-Aldrich) and HMGB1 (Abcam) with block from diagnostic time. An expert blinded pathologist reviewed and classified the intensity staining into negative, weak or strong and the extension as high (at least 50% of stained cells) or low ($<$ 50%) for each protein. Kaplan–Meier was used for time-to-event variables and the log-rank test was used to compare groups. **Results:** A series of 301 patients was studied, median age 52, 53% females and median follow-up from metastasis (M1) of 42 m. Strong and high expression were distributed as follows: HMGA1 24% and 18%, HMGA2 58% and 63%, HMGB1 69% and 75%, respectively. Strong expression of HMGA1 showed significant worse prognosis for OS from M1 time (31 vs 22 m; p = 0.007) and for PFS of trabectedin line (3.8 vs 2.6 m; p = 0.002). Similar results were obtained with high HMGA1 expression. In multivariate analyses, age ($>$ 60y) HR 1.52 (1.10-2.09) p = 0.009, short lapse to metastases ($<$ 10 months) HR 1.44 (1.08-1.92) p = 0.013, and strong expression of HMGA1 HR 1.45 (1.06-1.48) p = 0.018 showed to be independent prognostic factors for worse survival from M1. **Conclusions:** Protein expression of HMGA1 exhibited a significant prognostic role in a series of advanced STS. Validation studies are ongoing to confirm its prognostic and potential predictive role. These results could open new target in STS.

11574 Poster Session (Board #319), Sat, 8:00 AM-11:30 AM

Doxorubicin plus dacarbazine (DoDa), doxorubicin plus ifosfamide (DI) or doxorubicin alone (Do) as first line treatment for advanced leiomyosarcoma (LMS): A retrospective study from the EORTC Soft Tissue and Bone Sarcoma Group (STBSG). *First Author: Lorenzo D'Ambrosio, University of Torino, Department of Oncology, Torino, Italy, Torino, Italy*

Background: LMS is one of the most common soft tissue sarcoma histotypes that may arise in any site of the body. In advanced disease, first line treatment is still based on Do alone or in combination. Previous retrospective data suggested limited activity of ifosfamide (Sleijfer 2010), whereas Da showed interesting results in limited series. DoDa, DI and Do regimens were retrospectively evaluated as first line treatment in advanced LMS. **Methods:** Inclusion criteria: confirmed histological diagnosis, treatment between 1/2010 and 12/2015, measurable disease (RECIST 1.1), ECOG performance status (PS) $\leq$2, age $\geq$18 years, no major comorbidities. Endpoints: progression-free survival (PFS), overall survival (OS), overall response rate (ORR), toxic death (TD) rate. **Results:** 303 patients, 87 males (29%), median age 58 (range 20-87), were enrolled from 18 EORTC STBSG sites and were distributed as follows: 117 DoDa (39%), 71 DI (23%), 115 Do (38%). No significant differences were detected between treatment arms in terms of dose reductions $>$ 10%, delays $>$ 72h, G-CSF use, or TD. Median PFS was 9.4 (95% CI 6.1-9.7), 6.8 (4.5-9.5), 5.4 months (3.8-6.8), and ORR was 36.8%, 21.5%, and 25.9%, for DoDa, DI and Do, respectively. When attempting to adjust for lack of randomization by balancing baseline characteristics among arms, a non-significant trend for PFS and ORR in favor of DoDa was observed. Shorter median follow-up was observed in DoDa (32 months; IQR 23-47) compared to DI (50; 37-73) and Do arms (46; 31-58), weakening a direct comparison of OS. Subsequent treatments were well balanced across arms. **Conclusions:** To our knowledge, this is the largest retrospective study on the first line treatment of advanced LMS. Acknowledging the limitations of such retrospective analysis and the unbalanced follow up, DoDa may favorably compare with both DI and Do showing interesting activity in advanced LMS in terms of both ORR and PFS similar to previous single center-based experiences. Consistency of both DI and Do arms outcomes with EORTC 62012 trial results increases the reliability of these results.

11575 Poster Session (Board #320), Sat, 8:00 AM-11:30 AM

Subgroup analysis of elderly patients treated within the randomized phase 3 doxorubicin versus doxorubicin plus evofosfamide (SARC021) trial. *First Author: Eugenie Younger, Royal Marsden Hospital, London, United Kingdom*

Background: Approximately 50% of patients diagnosed with soft tissue sarcoma (STS) are aged $\geq$65 years (yrs). The management of elderly STS patients ($\geq$65yrs) is challenging and there are few prospective data on the outcome of those with advanced disease. This study aims to document the safety and efficacy of first-line chemotherapy in elderly patients within the SARC021 trial and provide a benchmark for future research. **Methods:** SARC021 randomized patients to receive first-line doxorubicin (Dox) or doxorubicin + evofosfamide (DE) with overall survival as the primary end point. The eligibility criteria have been described previously. Patients aged $\geq$65yrs were identified from the trial database. **Results:** Of 640 participants, 209 (33%) elderly were treated (Dox: n = 103, median age 70 [65-84] yrs. DE: n = 106, median age 69 [65-89] yrs). There was no significant difference in OS, PFS or response rate (RR) for elderly patients between the 2 arms (OS: median OS Dox 517 days {95%CI 393-628} vs DE 494 days {95%CI 351-701}, p = 0.99. PFS: median PFS Dox 185 days {95%CI 142-218} vs DE 197 days {95%CI 150-250}, p = 0.28. RR: Dox 19{18%} vs DE 27{25%}, p = 0.22). Non-hematological toxicity was significantly more common in the DE arm (Dox 53{51%} vs DE 78{74%}, p = 0.001). Differences in hematological, cardiac and $\geq$grade 3 toxicities were not significant. In 431 patients aged $<$ 65yrs the median OS (whole cohort) was 614 days (95%CI 515-708) compared to 509 days for those $\geq$65yrs (p = 0.057). No significant differences were observed for PFS ($<$ 65yrs 183 days {95%CI 154-194} vs $\geq$65yrs 191 days {95%CI 176-218}, p = 0.14) or RR ($<$ 65yrs 103{24%} vs $\geq$65yrs 46{22%}, p = 0.596). Patients $\geq$65yrs had significantly more hematological (208{48%} vs 141{67%}, p $<$ 0.0001), non-hematological (215{50%} vs 131{63%}, p = 0.0097) and $\geq$Grade 3 toxicity (299{69%} vs 178{85%}, p = 0.0002). Significantly more patients $\geq$65yrs (22{5%} vs 30{14%} p = 0.0001) stopped therapy due to toxicity. **Conclusions:** For elderly patients no significant difference in outcome was observed between those treated with Dox or combination DE. Elderly outcomes were similar to those $<$ 65yrs, however considerably more toxicity was observed in patients $\geq$65yrs.

11576 Poster Session (Board #321), Sat, 8:00 AM-11:30 AM

Genomic subtypes of angiosarcoma: A comprehensive genomic profiling (CGP) study. *First Author: Vinod Ravi, Department of Sarcoma Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Angiosarcomas (AS) arise from the vascular endothelium of skin and other visceral organs and from such diverse etiologies as exposure to carcinogenic agents or therapeutic radiation. We used CGP to sub-classify AS and to identify genomic alterations (GA) linked to responsiveness to targeted therapy and immune checkpoint inhibitor (ICPI) therapies. Median overall survival of metastatic AS is only 13.1 months. **Methods:** Hybrid capture based CGP including RNA-seq in a subset of cases was performed on 278 cases of AS including 53 breast angiosarcomas (BA) and 207 soft tissue (STA). Tumor mutational burden (TMB), was calculated from 1.1Mb of sequenced DNA and UV exposure signature was determined. **Results:** For all AS, the most commonly altered genes were *TP53* (38%), *MYC* amplification (22%), *CDKN2A* (17%), *KDR* (12%) and *PIK3CA* (8.6%). 4q12 (*KIT/KDR/PDGFRA*) amplifications were increased in STA relative to BA (p = 0.18). *MYC* amplifications were more frequent in BA than STA (p $<$ 0.001) likely due to radiation associated BA. Three genomic subsets were identified within BA: *MYC* amplified (mean 60 copies, range 16-277) with increased age (p $<$ 0.0001), *KDR* altered mutually exclusive to *MYC* amplified (p $<$ 0.05) and *MYC/KDR* wildtype, 42% of which have *PI3K* pathway alterations. A subset (19%) of STA had a UV signature (UV-STA) with a median TMB of 21. We identified 14 AS cases (5%) with *KDR* T771R none of which harbor other *KDR*, *MYC* or tyrosine kinase mutations. **Conclusions:** Broadly assessing GA in AS has potential benefit from matched therapy and correlates with anatomic and etiologic origin. AS patients may benefit from matched TKIs to kinase fusions, 4q12amp and *KDR* GAs. *KDR* T771R defines a new class of AS which should be investigated for a unique non-radiation etiology. The high TMB UV-STA cases suggest potential benefit from ICPI and indicates cutaneous non-melanocytic, non-squamous neoplasms can arise from UV damage.

Type (n)	Median age	Median TMB	4q12 amplified (%)	MYC amplified (%)
AS (278)	64 (5-88)	2.5 (0-151)	4	22
STA (207)	64 (10-88)	3.2 (0-151)	4.8	18
UV-STA (39)	72 (33-86)	21 (2.4-151)	5.1	2.6
BA (54)	61 (19-88)	2.4 (0-8.9)	0	46
BA-*MYC* (25)	72 (19-88)	3.2 (0.8-8.9)	0	100
BA-*KDR* (10)	36 (22-66)	2.4 (0.8-6.45)	0	0
BA-*KDR/MYC*wt (19)	49 (23-71)	1.6 (0-8.1)	0	0

11577 Poster Session (Board #322), Sat, 8:00 AM-11:30 AM

Identification of novel intra-genic deletions of *CTNNB1* gene in WT desmoid-type fibromatosis. *First Author: Milena Urbini, Interdepartmental Centre of Cancer Research "Giorgio Prodi", University of Bologna, Bologna, Italy*

Background: Desmoid-type fibromatosis (DT) are characterized by molecular alterations of *CTNNB1* or *APC* genes. These abnormalities have been described in ~85% of DT using Sanger sequencing. Recently, whole-exome sequencing allowed to detect molecular aberrations in *CTNNB1* or *APC* in approximately 95% of DT. In order to characterized the true WT DT, we performed this study on DT WT Sanger-sequenced samples. **Methods:** Deep sequencing of *CTNNB1* and of *APC* was performed using TruSeq Custom Amplicon Low Input kit (Illumina) on 11 WT FFPE DT samples from patients treated with surgery. Whole Exome sequencing (WES) was performed using Nextseq500 (Illumina, CA) sequencer. Mutations were validated through Sanger sequencing, and expression of *CTNNB1* mutated alleles was evaluated through RT-PCR. **Results:** *APC* mutation was found in 2 cases, while low-frequency *CTNNB1* mutations were discovered in 5 samples (45%) (mean of 16% reads) and 4 cases remained WT. WES was performed in 6 cases (3 *CTNNB1* WT and 3 with low frequency mutations). Through in-depth analysis of reads spanning exon 3 of *CTNNB1*, 2 large intra-genic deletions were detected in 2 cases, one carrying also a T41A low frequency mutation. Both deletions were approximatively of 190bp and led to the loss of the T41 codon hotspot of mutation. In one case, the deletion led to the loss of the second half of exon 3 and part of intron 3, in the other it involved part of intron 2 and the 5' part of exon 3 losing the splicing acceptor site. We demonstrated that even if the acceptor splicing site was lost, the deleted allele of *CTNNB1* was expressed, with the retention of 32 bp of intron 2 in the mature mRNA. Moreover, we demonstrated that, at mRNA level, low frequency T41A mutated allele was the prevalent isoform expressed with respect to the WT allele. The importance of these molecular alterations in the natural history of DT needs further investigations. **Conclusions:** A minority of DT is WT for either *CTNNB1*, *APC* or any other gene involved in the WNT pathway. In this subgroup novel and hard to be detected molecular deletions of *CTNNB1* were discovered, contributing to explain a portion of the allegedly WT DT cases.

11578 Poster Session (Board #323), Sat, 8:00 AM-11:30 AM

Doxorubicin (D), gemcitabine (G), ifosfamide (I) and the EZH2 inhibitor EPZ-011989 in epithelioid sarcoma (ES): A comparison of different regimens in a patient-derived xenograft (PDX) model. *First Author: Nadia Zaffaroni, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: ES is a rare soft tissue sarcoma with two variants, i.e., the proximal and the distal. Retrospective data on the activity of anthracycline- and G-based regimens are available. EZH2 inhibitors, which target the INI1 pathway that is inactivated in ES, are currently being tested in clinical trial. Comparisons of these agents are not available and unlikely to be prospectively evaluated. We comparatively assess these agents in a proximal-type INI1-deleted ES PDX. **Methods:** A PDX model (ES-1) was established by subcutaneously xenotransplanting into immunodeficient (SCID) mice tumor fragments obtained from a patient with primary, proximal-type, INI1 deleted ES of the forearm. After tumor propagation in SCID mice for three consecutive passages, the PDX was considered established. Mice were randomized to receive D and I, as single agents or in combination (D+I), G and the EZH2 inhibitor EPZ-011989 (E) (8 mice/experimental group). Drug activity was assessed in terms of tumor volume inhibition (TVI%). RNA-seq was performed on samples obtained from patient primary tumor and from ES-1 before and after treatment with E. **Results:** As single agents, both D and I showed a modest antitumor effect. Conversely, D+I induced an almost complete tumor growth inhibition (max TVI: 94%). A comparable antitumor activity was caused by G (max TVI: 98%). E initially induced a tumor growth stabilization, followed by a progressive reduction of tumor volume starting from end of treatment (max TVI: 89%). Consistently with its mechanism of action, E inhibited trimethylation and increased acetylation of H3K27, as detected by Western Blot in tumor samples at different intervals from the end of mouse treatment. Analysis of RNAseq data is ongoing. **Conclusions:** Our preclinical results in a proximal-type ES INI1-deleted PDX model showed a strong and comparable antitumor activity for D+I, G and E. These data support clinical use of G and D+I and confirm that EZH2 is a therapeutic target in proximal-type ES. Experiments with D and G combined to E are planned. To which extent these preclinical findings can be extended to distal ES subtype is left to be defined.

11579 Poster Session (Board #324), Sat, 8:00 AM-11:30 AM

Frequency of genomic biomarkers of response to immunotherapy in sarcoma. *First Author: Sally E. Trabucco, Foundation Medicine, Inc, Cambridge, MA*

Background: Recent data (D'Angelo et al, 2018) has suggested possible benefit for a subset of sarcoma patients from immune checkpoint inhibitors (ICPI). We assessed a large sarcoma population for genomic alterations (GA) suggesting benefit from ICPI including high tumor mutational burden (TMB-H) [> = 20 mutations/mb (m/mb)], presence of microsatellite instability (MSI-high) and genomic amplification of *PDL1*. **Methods:** Hybrid capture based comprehensive genomic profiling including RNA-seq in a subset of cases was performed on > 6100 cases of sarcoma and included TMB and MSI status. UV exposure signature was determined as previously described (Zehir et al, 2017). **Results:** TMB was distributed throughout sarcoma cases with a median of 1.7 (range 0-160) and 2% TMB-H. The sarcomas frequently TMB-H were skin atypical fibroxanthoma (86%, 6/7), skin sarcoma NOS (50%, 3/6), and lung sarcoma (14%, 2/14). Presence of a fusion gene, such as the frequent fusions EWSR1:FLI1, SS18:SSX1, and STAT6:NAB1, were mutually exclusive with TMB-H, *PDL1* amplification and MSI-high ($p < 0.0001$). MSI-high cases (0.23%), with median TMB of 26 (11-67), were predominantly a subset of TMB-H. 0.83% of sarcoma cases had *PDL1* amplification (6/51 TMB-H), most frequently soft tissue sarcoma NOS (35% of *PDL1* amplified cases). 2% of sarcoma cases have a UV signature, with median TMB of 36 (2.4-160), and make up 72% of TMB-H sarcomas. Notably, 14% of angiosarcomas have a UV signature; these cases have median TMB of 19 m/mb (2.4-148). Of sarcomas with a UV signature, 26% harbored GA associated with melanoma (*BRAF* V600x, *NRAS* or *KIT* mutation) and 27% were assayed from a cutaneous specimen. An index case of high grade sarcoma with an initial intrabdominal presentation was identified as harboring high TMB and a UV signature on CGP. **Conclusions:** Identification of one or more of TMB-H, *PDL1* amplification and/or MSI-high is detected in 2.8% of unselected sarcoma cases, which may be more likely to benefit from ICPI and such cases lack oncogenic fusions. Notably, 72% of the TMB-H cases harbored a UV signature which may raise the possibility of an alternative diagnosis of melanoma, particularly desmoplastic melanoma.

11580 Poster Session (Board #325), Sat, 8:00 AM-11:30 AM

Management and outcome of patients with neo-adjuvant chemotherapy (CT) in locally advanced soft-tissue sarcoma (LASTS): The Gustave Roussy experience. *First Author: Sarah Naomie Dumont, Gustave Roussy Cancer Campus, Villejuif, France*

Background: Neo-adjuvant CT with anthracyclines plus ifosfamide (AI) is a therapeutic option in patients (pts) with marginally LASTS, aiming at a local benefit, facilitating surgery, in addition to the systemic one (ESMO guidelines 2017). **Methods:** We retrospectively reviewed all consecutive pts with LASTS who received AI (doxorubicin 60 mg/m2 plus ifosfamide 9g/m2) regimen treated from 1996 to 2015 in neo-adjuvant setting in our institution. Clinical, biological, imaging and pathology data were collected from patient files. Survival curves were calculated according to Kaplan-Meier and compared with the log-rank test or a Cox proportional hazard model, using R 3.4.3. **Results:** The data of 161 pts (89 males, 72 females) was collected. The median age was 45 years and the median tumor size was 10 cm (range 3-27 cm). LASTS were located in the extremities (67%), trunk (17%) and retroperitoneal (8%). The main histotypes were UPS 73 (45%), L-sarcomas 36 (23%), and synovial sarcoma 26 (16%). Fifty-eight % of pts had a grade 3, 38% a grade 2 and 4% a grade 1 disease. The median number of cycles of CT administered was 3 (range 1-6). The clinical benefit rate was 87 % pts (49.5%) (partial response and stable disease according to RECIST). All patients were subsequently operated, including 5 amputations, 85% R0 and 15% R1 resections. Eighty percent of pts received adjuvant radiation therapy and 10% received adjuvant CT. Twenty-one pts experienced a local relapse and 48 developed distant metastases. After a median follow-up of 57 months, the 5-yr-DFS was 56% (CI 95% [47-65]) and the 5-yr OS was 70% (CI 95% [61-79]) . There was a quasi-linear significant relationship between the rate of residual identifiable cells (RIC) and both DFS and OS, with the most discriminating cut-off being 35% (respectively for OS and DFS, $p = 0.012$ and $p = 0.0054$); each additional percent worsening the prognosis. Grade was correlated to a good histologic response ($p = 0.00019$). A R0 resection was significantly related to a better DFS ($p = 0.025$) with a trend on OS ($p = 0.058$). **Conclusions:** Neo-adjuvant CT with AI regimen in LASTS facilitates surgery, with a R0 resection achieved in 85% of pts. The rate of RIC correlates to outcome.

11581 Poster Session (Board #326), Sat, 8:00 AM-11:30 AM

Genomic amplification of CDK4 in dedifferentiated liposarcomas as a predictive biomarker for microtubule disrupting agents. *First Author: Bryce Demoret, Ohio State University, Columbus, OH*

Background: Dedifferentiated liposarcoma (DDLPS) represents a common but morbid subtype of sarcoma. Microtubule disrupting agents (MDA), including eribulin and taxanes, disrupt the cell cycle and have modest clinical activity in patients with DDLPS. Unfortunately, no clinically validated biomarkers exist to predict MDA response in this population. DDLPS is characterized by amplification of *cyclin-dependent kinase 4* (*CDK4*), which regulates the cell cycle. We hypothesized that *CDK4* amplification may predict response to MDAs. **Methods:** 25 DDLPS trial patients (NCT01574716) who received docetaxel as part of their therapy and for whom tissue was available were profiled using DNA next generation sequencing (NGS) to quantify *CDK4* copy number alteration. Patients were divided into *CDK4*-high and -low cohorts based on median amplification level. Progression-free survival (PFS) was calculated using Kaplan-Meier analysis. Patient derived DDLPS cell lines (LPS246, LPS815, LPS863) were analyzed for *CDK4* amplification level via NGS. Sensitivity to MDA (eribulin and docetaxel) was quantified using cell viability assays. CDK4 activity was attenuated using palbociclib and drug synergy was ascertained via Chou-Talalay algorithm. **Results:** DDLPS patients treated with MDA revealed patients' *CDK4* levels greater than median had improved median PFS compared to patients with *CDK4* levels lower than median (19.7 vs 11.1 m, $p = 0.03$). This suggested improved biologic activity of MDAs in *CDK4*-high tumors, and was further investigated using in vitro models. DDLPS cell lines were characterized for sensitivity to eribulin and docetaxel. LPS246 had the highest *CDK4* gene copy number vs. LPS815 and LPS863 (1373, 533, 563 transcripts per cell, respectively) and showed a greater sensitivity to both docetaxel and eribulin compared to LPS815 and LPS863 in cell viability assays. Pharmacologic inhibition of CDK4 demonstrated drug antagonism (avg. CI > 1.3). **Conclusions:** These data suggest that MDA sensitivity in DDLPS may be associated with levels of *CDK4*. Prospective clinical trials are needed to confirm whether CDK4 expression levels may predict response to eribulin and other microtubule disrupting agents.

11582 Poster Session (Board #327), Sat, 8:00 AM-11:30 AM

Combination of CDK and Bcl-2 inhibitors in the treatment of soft-tissue sarcomas. *First Author: Xavier Garcia del Muro, Instituto Catalan de Oncologia de Hospitalet, Barcelona, Spain*

Background: Soft tissue sarcomas (STSs) present high mortality rates when metastatic and therefore identification of new active therapies is needed. Dinaciclib is a promising CDK inhibitor under evaluation in clinics, targeting principally CDK1 and CDK9 (involved in cell cycle and transcription regulation). BH3-mimetics are a promising new class of pro-apoptotic drugs for cancer treatment. **Methods:** We analyzed the response to Dinaciclib in a series of different STSs established cell lines, as apoptotic induction visualized in Flow Cytometry. Cell lines were categorized as Dinaciclib-sensitive and Dinaciclib-tolerant. Differences were studied by relevant protein expression changes during treatment leading to hypothesis proposal for key regulators. Validation of targets was performed by siRNA technology prior to engage in drug combination testing. *In vivo* experiments encompassed drugs safety and effectivity. **Results:** Dinaciclib induced apoptotic cell death, with important differences in the extent and timing among cell lines. Liposarcoma 402-91 was the most sensitive (cell death $> 75\%$ after 72 h), whereas leiomyosarcoma SK-LMS-1 was highly tolerant to Dinaciclib (cell death $< 25\%$). Major partners in cell cycle and apoptosis induction signaling networks were affected by Dinaciclib treatment. The inhibition status of anti-apoptotic protein Bcl-x_L was identified as the main determinant of the rhythm and extent of apoptosis triggering. *In vitro* combination of Dinaciclib with chemical Bcl-x_L inhibitors (ABT-747 and A-1331852) overcame tolerance and triggered massive cell death in cultures (95% of cell death after 24 h). Once safely scalated to mice experimentation, drug combination effectiveness on mice engrafted tumors is currently ongoing. **Conclusions:** CDK inhibitors are active in STSs cell lines. The inhibition status of Bcl-x_L can be considered as a predictor of Dinaciclib sensitivity in STS. Combinatorial strategies with CDK inhibitors and BH3-mimetics are worth examination as a new proposal for STS treatment.

11583 Poster Session (Board #328), Sat, 8:00 AM-11:30 AM

Identification of histone deacetylase 2 (HDAC2) as a novel target for MDM2 directed therapies in dedifferentiated liposarcoma. *First Author: Colin W Stets, The Ohio State Comprehensive Cancer Center, Columbus, OH*

Background: Dedifferentiated liposarcoma (DDLPS) is a common, but morbid mesenchymal tumor driven by amplifications in the mouse double minute 2 homolog (MDM2) gene. Prior studies have indicated that pan-HDAC inhibition may be able to lower MDM2 levels in vitro. However, there are multiple HDAC isoforms and pan-HDAC inhibitors used in the clinic have significant toxicities. We hypothesize that isoform specific HDAC inhibition may achieve modulation of MDM2 and limit the toxicities associated with pan-HDAC inhibition. We report here that HDAC2 is sufficient to lower the expression of MDM2 and improve tumor response to doxorubicin in DDLPS *in vitro* and *in vivo*. **Methods:** Bioinformatics analysis of RNA-Seq data from DDLPS cell lines was used to identify HDAC proteins associated with MDM2 expression. Potential targets were validated using shRNA mediated knockdown and pharmacologic agents. We examined and quantified MDM2 protein expression via immunoblotting. Cytotoxicity was determined using XTT reagents *in vitro*. Synergy calculations were performed using the Chou-Talalay algorithm on *in vitro* cytotoxicity assays. *In vivo* response was measured using mouse xenograft models. **Results:** Small molecule pan-HDAC inhibitor AR42 and HDAC2 specific inhibitor Mi-192 decreased MDM2 expression (2.5-fold and 7.1 fold decrease, respectively) and induced a 6500-fold increase in the expression of the tumor suppressor P21. HDAC2 shRNA knockdown further corroborated the HDAC2 specific effect on MDM2 expression (5-fold reduction). *In vitro* synergism with doxorubicin in DDLPS (cooperativity index < 0.7) was observed across a range of HDAC2i concentrations. In mouse xenograft model, MI-192 significantly reduced tumor volume ($p = 0.02$) without the induction of MDM2 mRNA expression. **Conclusions:** HDAC2 specific inhibition lowers MDM2 expression and synergizes with doxorubicin in DDLPS cell lines and slows tumor growth *in vivo*. Prospective clinical studies are necessary to confirm these findings.

11584 Poster Session (Board #329), Sat, 8:00 AM-11:30 AM

Immune signature in sarcoma with prognostic and predictive implications. *First Author: Shailaja KS Raj, Wake Forest School of Medicine and VAMC, Winston-Salem, NC*

Background: While immunotherapy has established its benefit in the management of many solid tumors, its efficacy in sarcoma is still not well understood. In this study, we sought to evaluate the protective effects of intrinsic anti-tumor immunity in sarcoma by analyzing genomic measures of immune response and tumor immunogenicity in a multi-institutional convenience cohort of sarcoma patients. **Methods:** Publicly available RNAseq and exome mutation data were assembled from The Cancer Genome Atlas (TCGA) sarcoma cohort ($n = 259$). For each tumor, a relative measure of abundance of tumor-infiltrating effector immune cells was estimated using three previously published immune gene signatures, reflective of T-cells, cytotoxic T lymphocytes and/or natural killer cells derived from co-expressed, leukocyte-specific genes (named CYT, CD8T and T/NK). Tumor mutational burden (TMB), expressed as the rate of non- synonymous mutations per megabase of sequenced DNA, was used as a measure of tumor immunogenicity. Interactions between immune infiltration, tumor immunogenicity and patient overall survival (OS) were assessed by Cox regression and Kaplan-Meier analysis. **Results:** In the full cohort, the 3 immune signatures were highly correlated with one another and univariately associated with patient OS (T/NK; $p < 0.001$; CYT; $p < 0.001$ and CD8; $p = 0.004$ Cox regression). A single immune signature T/NK, selected for further analyses was associated with OS in TMB-high tumors ($p < 0.001$) but not TMB-low tumors ($p = 0.129$). Univariable and multivariable survival analysis of T/NK with significant variables included age, and tumor size, that were significant. **Conclusions:** Our findings fit a model where patients whose tumors were characterized by a TMB-high genotype and elevated effector immune infiltration exhibited the highest survival rates ($p < 0.035$). In the full cohort multivariable analysis we showed that T/NK remained a significant prognostic factor independent of age, tumor size, radiation therapy, margin status, tumor necrosis and subtype analysis indicating that the T/NK signature provided additive prognostic information and can utilized in the future for therapeutic stratification.

11585 Poster Session (Board #330), Sat, 8:00 AM-11:30 AM

Lack of cardiac toxicity in patients treated with aldoxrubicin with doxorubicin equivalent doses beyond 1000mg/m2. *First Author: Kamalesh Kumar Sankhala, Sarcoma Oncology Center, Santa Monica, CA*

Background: Aldoxrubicin is classical Doxorubicin with a linker which rapidly binds to albumin on IV administration. Doxorubicin, either alone or in combination with ifosfamide, is still considered standard therapy for sarcomas. Aldoxorubicin alone or in combination with ifosfamide have been shown to improve antitumor activity and lack of cardiac toxicity. The allowable maximum cumulative lifetime dose of doxorubicin is 550 mg/m2. We report on the evaluation of cardiac function in patients who received aldoxorubicin with Doxorubicin equivalent at doses beyond 1000 mg/m2. **Methods:** Fifty-two patients enrolled in a Phase 1/2 study of aldoxorubicin and ifosfamide/mesna and a Phase 3 study using aldoxorubicin alone were treated for at least 6 cycles of aldoxorubicin at either 250 mg/m2 or 350 mg/m2 per dose i.v. every 3 weeks. Cardiac function using 2D echocardiogram was evaluated at regular intervals every two cycles of aldoxorubicin until end of treatment and every six months after completion of the treatment. **Results:** In eleven patients, the median cumulative doxorubicin dose prior to aldoxorubicin treatment was 158 (range: 64-360) mg/m2. The cumulative aldoxorubicin dose ranged from 1000 to 7500 mg/m2. No patient developed any sign or symptom of clinical congestive heart failure. Ventricular ejection fractions ranged from 45-74% baseline, and 50-77% at end of treatment, median being 60% both at the beginning and end of treatment. **Conclusions:** Aldoxorubicin lacks cardiotoxicity in these patients treated with aldoxorubicin alone or in combination with ifosfamide/mesna. We did not find any evidence of cardiac toxicity of aldoxorubicin up to doxorubicin equivalent dose of 7500mg/m2. Clinical trial information: NCT# 02235701.

TPS11586 Poster Session (Board #331a), Sat, 8:00 AM-11:30 AM

A phase I trial of pomalidomide in combination with liposomal doxorubicin in the treatment of advanced or refractory Kaposi sarcoma in individuals with or without HIV. *First Author: Ramya Ramaswami, HIV/AIDS Malignancy Branch, CCR, NCI, Bethesda, MD*

Background: Kaposi sarcoma (KS) is a multicentric angioproliferative tumor caused by the gammaherpesvirus Kaposi-sarcoma herpesvirus (KSHV, or human herpesvirus 8 [HHV-8]) that is commonly seen among people living with HIV. KSHV also contributes to the pathogenesis of multicentric Castleman disease (KSHV-MCD) and KSHV inflammatory cytokine syndrome (KICS). Advanced KS can occur alone or in combination with KSHV-MCD or KICS. KS can be difficult to treat when it occurs with KSHV-MCD or KICS and can result in high mortality rate. Pomalidomide is an orally available third generation thalidomide analog with immunomodulatory and antiangiogenic properties that has been shown to be safe and to have activity in patients with KS with or without HIV. Liposomal doxorubicin (LD) is a preferred treatment for KS. The tolerability and activity of pomalidomide in combination with LD with advanced KS or KS and concurrent KSHV-MCD or KICS are unknown. **Methods:** The primary objective is to evaluate the safety, tolerability and pharmacokinetics of pomalidomide (in escalating dose levels I - 2mg, II - 3mg, or III- 4mg) in combination with liposomal doxorubicin in two groups of patients: Group I) KS requiring systemic therapy; Group II) KS with concurrent KSHV-associated MCD or KICS. Patients will receive LD intravenously on day 1 of a 28-day cycle combined with pomalidomide once a day, days 1 to 21 at a specific dose level. Dose escalation of pomalidomide for each cohort will stop when 2 or more dose-limiting toxicities (DLTs) occur (in a cohort of 3 or 6 patients). Assessment of the KS antitumor effect, using a modified AIDS Clinical Trials Group KS response criteria; effects on manifestations of KSHV-MCD or KICS in those patients with these diseases; and changes in quality of life in patients receiving pomalidamide and LD will be evaluated. Patients with confirmed cutaneous, pulmonary or visceral KS are eligible. Adherence to combination antiretroviral therapy for 1 month is required for participants in Group I except for those with progressive disease or end-organ disease. The study began enrollment in January 2016. Clinical trial information: NCT02659930.

TPS11587 Poster Session (Board #331b), Sat, 8:00 AM-11:30 AM

PEMBROSARC combination of MK3475 and metronomic cyclophosphamide (mCP) in patients (pts) with advanced sarcomas a multicentre phase II trial with 3 new combination strategies. *First Author: Maud Toulmonde, Institut Bergonié, Department of Medical Oncology, Bordeaux, France*

Background: PD-L1 is expressed in soft tissue sarcomas (STS) but PD-1 inhibition alone has limited activity. This primary resistance may partly be explained by IDO pathway activation. Epigenetics modifications have also been recognized as mechanisms of resistance to PD-1 inhibition. We hypothesized that the association of MK3475 (PZ) + mCP, either alone or with IDO inhibitor Epacadostat (EP), TLR4 agonist G100 or EZH2 inhibitor Tazemetostat (TZ) could have a synergistic activity with good safety in pts with advanced STS, with a focus on Undifferentiated Pleomorphic Sarcoma (UPS). **Methods:** This is a multicenter, prospective open-labeled single-arm phase II trial with ten independent strata assessing: PZ 200 mg IV on day 8 of a 3 weeks cycle, mCP 50 mg b.i.d. orally one week on /one week off: - in leiomyosarcoma (stratum 1), UPS (stratum 2), other STS (stratum 3), osteosarcoma (stratum 4) and GIST (stratum 5) - + EP orally 100 mg b.i.d. in UPS (stratum 6) and other STS (stratum 7) - + G100 intratumor at 20 μg once weekly for 6 weeks in STS (stratum 8) - + TZ orally 800 mg b.i.d. in UPS (stratum 9) and other STS (stratum 10) Main eligibility criteria are - adult pts with metastatic or unresectable locally advanced, histologically confirmed sarcoma by central review, - measurable progressive disease (RECIST v1.1) – no more than 2 previous lines of systemic treatment – PDL1 and/or IDO expression on immune cells $>$ 1% on $<$ 3 months old tumor sample (strata 6 and 7) Primary endpoint is 6-month non progression as per RECIST v1.1. Secondary endpoints encompass toxicity according to NC-CTCAE v4.03, best overall response RECIST v1.1, 1-year progression-free survival and overall survival, growth modulationi, pharmacodynamics on mandatory collection of blood and tumor samples at baseline and on treatment. Each strategy will follow a 2-stage Simon's design. PZ+mCP + either EP, G100 or TZ will be considered promising if at least 8 non-progressions at 6 months are observed among 29 evaluable pts. In this regards, 32 pts will be recruited in each stratum. Strata 1-3, 5 have been reported. Stratum 4 is on hold for intermediate analysis. Opening of strata 6-10 is awaited by June 2018. Clinical trial information: NCT02406781.

TPS11588 Poster Session (Board #332a), Sat, 8:00 AM-11:30 AM

SU2C-SARC032: A phase II randomized controlled trial of neoadjuvant pembrolizumab with radiotherapy and adjuvant pembrolizumab for high-risk soft tissue sarcoma. *First Author: Yvonne Marie Mowery, Duke University Medical Center, Durham, NC*

Background: Radiotherapy (RT) and surgical resection achieve local tumor control for most large, high-grade soft tissue sarcomas (STS) of the extremity. However, many patients (pts) subsequently develop metastatic disease that is associated with median survival $<$ 2 yr. SARC028 (NCT02301039), a phase II clinical trial of pembrolizumab (pembro) for metastatic sarcoma, showed promising results with PD-1 blockade with RECIST 1.1 responses in 40% of undifferentiated pleomorphic sarcoma (UPS) pts and 20% of liposarcoma (LPS) pts. RT can augment the anti-tumor immune response and synergize with immune checkpoint blockade. We hypothesized that anti-PD-1 therapy with concurrent RT will stimulate a host immune response to eliminate micrometastatic deposits of STS, preventing progression to metastatic disease. To test this hypothesis, we opened SU2C-SARC032 (NCT03092323) in July 2017. This multi-institutional (11 of 12 US sites open; 5 international sites planned) randomized phase II trial is examining the safety and efficacy of neoadjuvant pembro with RT and adjuvant pembro for high-risk STS. **Methods:** Eligible patients for SU2C-SARC032 are adults with non-metastatic UPS or dedifferentiated/pleomorphic LPS of the extremity or limb girdle (FNCLCC grade 2 or 3, tumor $>$ 5 cm; stage III). Patients are randomized to neoadjuvant RT (50 Gy/25 fractions) then surgical resection vs neoadjuvant pembro and RT followed by surgical resection and adjuvant pembro. Pts receive 200 mg pembro Q3 wk for 3 neoadjuvant cycles (before, during and after RT) and up to 14 adjuvant cycles (1 yr of pembro). The primary endpoint is 2-yr disease-free survival (DFS). Target enrollment is 110 pts to achieve 51 evaluable pts/arm. This provides 80% power with a = 0.05 to distinguish between a null hypothesis of 50% 2-yr DFS and alternative hypothesis of 75% 2-yr DFS using a logrank test. Tumor specimens (pre- and post-neoadjuvant therapy) and blood will be collected for correlative studies including immunophenotyping, whole exome sequencing, RNAseq, and circulating tumor DNA analysis. Four pts have accrued. A planned toxicity evaluation is ongoing for the first 3 pts on pembro. Clinical trial information: NCT03092323.

TPS11589 Poster Session (Board #332b), Sat, 8:00 AM-11:30 AM

Mutational analysis and safety/efficacy in a phase 2 multi-center investigation of ABI-009 (*nab*-rapamycin) in patients with advanced malignant perivascular epithelioid cell tumors (PEComa). *First Author: Andrew J. Wagner, Dana-Farber Cancer Institute, Boston, MA*

Background: PEComas are rare mesenchymal tumors with a female predominance, composed of epithelioid cells that show a focal association with blood vessel walls and usually express both melanocytic and smooth muscle markers. The prognosis of advanced malignant PEComa is poor, with a median survival of 12-17 months. There have been no prospective trials for PEComa. Case reports have shown that PEComas are often associated with the loss of tumor suppressor genes *TSC1* or *TSC2* which results in downstream activation of the mTOR complex, making mTOR inhibition a promising therapeutic strategy. ABI-009, albumin-bound rapamycin nanoparticle, is a novel mTOR inhibitor that can utilize albumin-mediated transport pathways to achieve enhanced tumoral drug delivery. This is the first prospective open-label multicenter study to assess mutational status and safety/efficacy of an mTOR inhibitor for advanced PEComa. **Methods:** At least 30 patients naive to mTOR inhibitors, with pathologically confirmed malignant PEComa that is either metastatic or locally advanced and for which surgery is not a recommended option, will be enrolled. ABI-009 at 100 mg/m^2 IV, is given weekly for 2 out of 3 weeks (21-day cycle) until disease progression or unacceptable toxicity. The primary endpoint is overall response rate (ORR) assessed with CT/MRI scans via RECIST v1.1. This sample size will be sufficient to exclude an inactive regimen ($<$ 15% ORR) with 95% confidence. Secondary endpoints are duration of response, 6-month progression-free survival (PFS), median PFS, median overall survival, and safety. Patient tumor mutational analysis, including exome sequencing of 300 genes including TSC1/2 and mTOR pathway genes, and circulating DNA analysis, will be performed. Exploratory endpoints include PK/PD relationships for safety and/or efficacy endpoints, and correlative studies with baseline TSC mutational analysis and tumor biomarkers. The study is ongoing as of February 2018. Clinical trial information: NCT02494570.

TPS11590 Poster Session (Board #333a), Sat, 8:00 AM-11:30 AM

TAPPAS: An adaptive enrichment phase 3 trial of TRC105 and pazopanib versus pazopanib alone in patients with advanced angiosarcoma. *First Author: Vinod Ravi, Department of Sarcoma Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Angiosarcoma (AS) is an aggressive soft tissue sarcoma (STS) of endothelial origin with reported median OS of 8-12 months. Pazopanib (P) is approved for treatment of advanced STS refractory to an anthracycline. In a retrospective study of 40 AS patients treated with single agent P, median PFS was 3.1 months and median OS 9.9 months with a low response rate and no complete responses. Endoglin is an essential angiogenic receptor expressed on AS that is upregulated following VEGF inhibition. TRC105, an endoglin antibody, combined with P achieved durable complete responses in two of 18 AS patients, with median PFS of 7.8 months in chemotherapy-refractory and P-naïve patients enrolled in a Phase 1/2 trial. The TAPPAS Phase 3 trial was initiated following protocol assistance from the EMA and Special Protocol Assessment from the FDA. **Methods:** TAPPAS (NCT02979899) is a randomized multicenter study of TRC105/P vs P alone actively enrolling cutaneous and non-cutaneous AS patients at $>$ 25 sites in the United States and Europe, and incorporates an adaptive enrichment design. Key inclusion criteria: 0, 1 or 2 prior lines of therapy, ECOG $\leq$ 1. Primary endpoint is PFS. Secondary endpoints include ORR and OS. The initial sample size of 124 patients, followed until 95 PFS events, provides more than 80% power to detect a hazard ratio of 0.55. At the time of interim analysis, projected to occur upon the occurrence of 40 events in approximately 70 patients, the trial will be classified as belonging to either the favorable, promising, enrichment or unfavorable zones, based on conditional power. Sample size and PFS events will be unchanged in the favorable and unfavorable zones, and will be increased to a total of 200 patients followed for 170 events in the promising zone. The trial will enroll a total of 135 patients with cutaneous disease followed for 110 events in the enrichment zone. An independent Data Monitoring Committee will follow the trial for safety and futility and recommend sample size or population adaptation. The adaptive design permits enrollment of fewer and more responsive patients over a shorter time compared to a fixed sample size design, while preserving type-1 error. Clinical trial information: NCT02979899.

TPS11591 Poster Session (Board #333b), Sat, 8:00 AM-11:30 AM

Phase 1/2 study of safety/efficacy using trabectedin, ipilimumab and nivolumab triple therapy as first line treatment of advanced soft tissue sarcoma. *First Author: Erlinda Maria Gordon, Sarcoma Oncology Center, Santa Monica, CA*

Background: Sarcoma cells are most immunogenic at the onset of cancer when the immune system can recognize and destroy them (Schreiber 2011). Hence, immune checkpoint inhibitors would be most effective when given as first line therapy. Objectives: Primary: To investigate the maximum tolerated dose of trabectedin, an alkylating agent, when given sequentially with ipilimumab, a CTLA4 inhibitor, and nivolumab, a PD-1 inhibitor, in advanced STS. Secondary: To investigate the objective response rate (ORR), progression free survival (PFS) and overall survival (OS). Exploratory: To correlate PFS with PD-L1 and other biomarker expression in patients' tumors. **Methods:** Forty patients $\geq$18 years of age with advanced STS will be enrolled. This is an open label, dose-seeking phase $^1/_2$ study using a defined dose of ipilimumab (1 mg/kg i.v. q 12 weeks), nivolumab (3 mg/kg i.v. q 2 weeks), and escalating doses of trabectedin (1.0, 1.3, 1.5 mg/m^2 i.v. q 3 weeks). I. Dose Escalation Phase 1 (previously treated patients): The study will employ the standard "cohort of three" design. The maximum tolerated dose is defined as the highest safely tolerated dose, where not more than one patient experienced DLT, with the next higher dose level having at least two patients who experienced DLT. II. Expansion Phase 2 (previously untreated patients): An additional 22-28 patients will receive trabectedin at the MTD and defined doses of ipilimumab and nivolumab to assess overall safety and potential efficacy in a greater number of patients. Patients may continue treatment until significant disease progression or unacceptable toxicity occurs. Statistical Considerations: NIH CTCAE v4.03 and RECIST v1.1 will be used. Categorical variables will be summarized by the n and percent in each category. Point estimates for efficacy endpoint incidences will be accompanied by a 2-sided 95% exact binomial CI. Time to event endpoints will be summarized descriptively using the KM method. The analyses of all study objectives will be descriptive and hypothesis generating, for planning Phase 2/3 studies. Clinical trial information: NCT 03138161.

12000 Oral Abstract Session, Tue, 8:00 AM-11:00 AM

Association of high tissue TMB and atezolizumab efficacy across multiple tumor types. *First Author: Fatema A. Legrand, Roche/Genentech, South San Francisco, CA*

Background: PD-L1 expression has limitations as a biomarker for checkpoint immunotherapy (CI). Prior atezolizumab (atezo) monotherapy studies suggest improved efficacy in high tissue tumor mutational burden (tTMB-H) cohorts. We report a large retrospective analysis associating tTMB with neoantigen load (NAL) and CI efficacy across multiple studies, tumor types and lines of therapy. **Methods:** Tissue TMB was evaluated by the FoundationOne (F1) assay across 7 atezo monotherapy studies: NSCLC n= 342 (FIR, BIRCH, POPLAR, OAK), metastatic urothelial carcinoma (mUC) n=400 (IMvigor210, 211), and other advanced solid tumors n=245 (PCD4989g). Pooled data yielded a biomarker evaluable population (BEP) of 987 patients (pts); 175 (17.7%) had TMB-H defined as ≥16 mutations/megabase (mut/Mb). Efficacy endpoints were overall response rate (ORR) and duration of response (DoR). Survival analysis is ongoing. Neoantigen load (NAL) was calculated by whole-exome sequencing (WES) and RNA-Seq. **Results:** tTMB was associated with efficacy across tumor types and lines of therapy. In the BEP, ORR was 16.4% (95% CI 14.2, 18.9), vs. 29.7% (95% CI 23.1, 37.1) in tTMB-H (≥16 mut/Mb, N=175), and 13.5% (95% CI 11.3, 16.1) in tTMB-Low (<16 mut/Mb, N=812). DoR benefit was also observed: median DoR=29.0 mths (95% CI 18.6, NA) in tTMB-H vs. 16.6 mths (95% CI 13.8, 23.1) in BEP and 13.8 mths (95% CI 12.5, 17.4) in tTMB-Low cohorts. This association was not seen in control cohorts of randomized studies OAK, POPLAR, and IMvigor211. Pooled ORR in controls was 14.9% in BEP, 14.4% in tTMB-H and 15.1% in tTMB-Low. Survival analysis by tTMB is ongoing. tTMB-H also identified a population independent of PD-L1 status. tTMB by F1 was positively correlated with WES-based NAL in mUC (Pearson=0.85, N=218) and NSCLC (Pearson=0.78, N=70). NAL was associated with atezo ORR in mUC (p=2.7 x 10-9). **Conclusions:** High tTMB (≥16 mut/Mb) is associated with improved atezo response and DoR across NSCLC, mUC and melanoma and lines of therapy. tTMB-H by F1 may serve as a surrogate biomarker for NAL and may complement PD-L1 expression in providing predictive value. Ongoing studies are prospectively evaluating both tissue TMB and blood-based TMB for efficacy with CI. Clinical trial information: NCT02008227 NCT01903993 NCT02031458 NCT01846416 NCT02951767 NCT02302807 NCT01375842.

12001 Oral Abstract Session, Tue, 8:00 AM-11:00 AM

Prospective clinical evaluation of blood-based tumor mutational burden (bTMB) as a predictive biomarker for atezolizumab (atezo) in 1L non-small cell lung cancer (NSCLC): Interim B-F1RST results. *First Author: Vamsidhar Velcheti, Taussig Cancer Institute, Cleveland Clinic, Cleveland, OH*

Background: TMB in both tissue and blood has shown promise in selecting for patients (pts) who clinically benefit from PD-L1/PD-1 inhibitors. In the randomized, 2L NSCLC Phase III OAK and Phase II POPLAR studies, high bTMB enriched for a PFS benefit in patients treated with atezo monotherapy. Here we report interim results from the single-arm, 1L NSCLC Phase II B-F1RST atezo monotherapy trial, which prospectively evaluated bTMB as a predictive biomarker for atezo using an NGS-based panel. **Methods:** Of 78 treated pts in the interim analysis population (IAP), 58 had adequate blood samples with sufficient detection of circulating tumor DNA (MSAF≥1%) and comprised the biomarker-evaluable population (BEP). A bTMB score of 16 (prevalence, 19% [11/58]) was prespecified to evaluate clinical efficacy in the BEP (bTMB high, ≥16; bTMB low, < 16). Statistical tests were 2-sided at a 0.1 level and 90% confidence interval. **Results:** Baseline characteristics were similar in the IAP and BEP. With a minimum follow-up of 6 mo, median PFS was 9.5 vs 2.8 mo for bTMB high vs low; HR, 0.49 (90% CI, 0.23, 1.04; *P*= 0.11). PFS HRs improved as bTMB scores increased (Table). In the BEP, the ORR was 12.1% (7/58) and disease control rate was 25.9% (15/58). In the bTMB high vs low groups, the ORR was 36.4% (4/11) vs 6.4% (3/47); odds ratio, 8.38 (90% CI, 2.02, 34.79; *P*= 0.02). Treatment-related serious AEs and treatment-related grade 3/4 AEs occurred in 14.1% and 16.7% of pts, respectively; 15.4% experienced AEs leading to discontinuation. **Conclusions:** PFS by various bTMB scores show preliminary utility of bTMB as a predictive biomarker for PFS and ORR, and further support bTMB selection of patients in the ongoing 1L BFAST study (NCT03178552). The safety profile in B-F1RST is consistent with the known AE profile for atezo. Additional biomarker and clinical data will be reported. B-F1RST is ongoing and has completed enrollment at 153 patients. Clinical trial information: NCT02848651.

PFS (mo) by bTMB cutoff scores (BEP, n = 58).

bTMB Score	bTMB High Median (n)	bTMB Low Median (n)	HR	90% CI
12	3.0 (22)	3.2 (36)	0.95	0.55, 1.63
14	3.4 (14)	3.2 (44)	0.73	0.39, 1.39
16	9.5 (11)	2.8 (47)	0.49	0.23, 1.04
20	9.5 (8)	2.7 (50)	0.23	0.08, 0.62

12002 Oral Abstract Session, Tue, 8:00 AM-11:00 AM

Multiplexed analysis of myeloid cell (MC) markers to characterize the innate immune composition and clinical features of human non-small cell lung carcinomas (NSCLC). *First Author: Brian S. Henick, Yale School of Medicine, New Haven, CT*

Background: Despite innate immunity's prominent role in the anti-tumor response, little is known about the MC composition of human NSCLC. We used multiplexed quantitative immunofluorescence (QIF) to determine MC subtypes' distribution, functional state and clinical significance in large cohorts. **Methods:** We established a novel QIF panel to map distinct MC subsets in fixed human NSCLC including DAPI for all cells, pancytokeratin for tumor-epithelial cells, CD11b for all MCs, CD68 for M1-type macrophages and HLA-DR to interrogate maturation state/antigen-presenting potential. We interrogated 834 NSCLC represented in 5 tissue microarray-based cohorts: #1 (Yale, n = 55) with patient-matched NSCLC and morphologically-normal lung tissue; #2 (Yale, n = 379) and #3 (Greece, n = 230) with different/mixed NSCLC subtypes; #4 (Yale, n = 138) with molecularly annotated lung adenocarcinomas (ADC); and #5 (Yale, n = 32) including baseline samples from anti-PD-1-treated patients. We examined associations between marker levels, MC-profiles, clinicopathologic/molecular variables and survival. **Results:** Stromal CD11b-levels were significantly higher in tumor than in non-tumor lung tissues. HLA-DR was consistently higher in MCs from tumors with elevated CD68 expression, supporting a more mature phenotype. Stromal CD11b was significantly higher in squamous-cell carcinomas (SCC) than ADC across the cohorts. In SCC, increased stromal CD11b or HLA-DR expression was associated with shorter 5-year survival. EGFR-mutated lung ADC had significantly lower CD11b levels than KRAS-mutant ADC. In a limited sample set/preliminary analysis, MC markers did not significantly stratify clinical benefit to PD-1 axis inhibitors (cohort #5). **Conclusions:** NSCLCs contain more tumor-associated MCs than non-tumor lung and exhibit distinct myeloid compositions across histologies and presence of major oncogenic driver-mutations. ADC lacking EGFR variants and SCC display higher stromal MC content associated with worse outcome. Studies with larger datasets are ongoing to confirm the role of MC markers for prediction of sensitivity/resistance to PD-1 axis blockers.

12003 Oral Abstract Session, Tue, 8:00 AM-11:00 AM

Prevalence of clonal hematopoiesis of indeterminate potential (CHIP) measured by an ultra-sensitive sequencing assay: Exploratory analysis of the Circulating Cancer Genome Atlas (CCGA) study. *First Author: Charles Swanton, Translation Cancer Therapeutics Laboratory, The Francis Crick Institute, London, United Kingdom*

Background: CHIP is defined by the presence of age-dependent acquired mutations in hematopoietic progenitor cells and has been reported to occur in up to 30% of individuals 60-70 years of age. CHIP is a risk factor for hematologic malignancies and cardiovascular disease; its biological mechanisms and clinical significance are just now being studied. Using an assay ~100X more sensitive than exome sequencing, we determined the prevalence and features of CHIP in the CCGA cohort, and the impact on interpretation of cell-free DNA (cfDNA) somatic variants. **Methods:** Blood was prospectively collected (N = 1627) from 749 controls (no cancer, C) and 878 participants (pts) with newly-diagnosed untreated cancer (20 tumor types, all stages) for WBC and cfDNA isolation. Paired white blood cell (WBC) and cfDNA targeted sequencing (507 genes, 60,000X median coverage) identified somatic single nucleotide variants/indels. Unique molecular barcodes and a machine learning-based noise model achieved a specificity of 1 false positive variant call per Mb of genome targeted at a limit of detection of ~0.1% variant allele frequency (VAF). **Results:** 1412 samples were eligible and evaluable (576 C, 836 pts; 18 solid tumor types, all stages). Of somatic cfDNA variants matched in WBC (CHIP), 7% of individuals had CHIP with VAF > 10%, 39% had CHIP with VAF > 1%, and nearly all pts (92%) had a somatic mutation with VAF > 0.1%. The rate was similar between C and pts (median age 62, 60), increasing in prevalence by 160% per decade, such that we observed 2.5 variants/Mb at age 60. Of CHIP variants identified, 92% were unique to individual patients, most of which were present at low VAF. Genes impacted by CHIP included *DNMT3A* (40%), *TET2* (27%), and *TP53* (10%), consistent with previous reports in patients with solid tumors. **Conclusions:** An ultra-sensitive sequencing assay demonstrated that CHIP signal in WBC and cfDNA is much more common than previously appreciated. The clinical significance of CHIP warrants further study and must be accounted for when interpreting cfDNA variants for both early cancer detection and tumor genotyping (liquid biopsy). Clinical trial information: NCT02889978.

12004 Oral Abstract Session, Tue, 8:00 AM-11:00 AM

Confounding effects of clonal hematopoiesis in clinical genomic profiling of solid tumors. *First Author: Ahmet Zehir, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Clonal hematopoiesis (CH) is the somatic acquisition of genomic alterations in hematopoietic stem/progenitor cells, leading to clonal expansion. While a few reports showed CH-derived mutations can contaminate solid tumor sequencing results, a comprehensive analysis has not been reported before. Here, we set out to identify and quantify CH-related mutations in patients with solid tumors using matched tumor-blood sequencing, and to establish the proportion that would be misattributed to the tumor from unmatched analysis. **Methods:** We retrospectively selected 17,469 solid tumor patients that underwent prospective clinical sequencing of DNA isolated from tumor tissue and matched peripheral blood using the MSK-IMPACT assay between January 2014 and August 2017. We identified the presence of CH-related mutations in each patient's blood leukocytes by performing mutation calling in the blood and genotyping the tumor DNA at the mutated positions. We then considered variants passing our detection thresholds for somatic mutation calling in tumor NGS data to quantify the prevalence of CH alterations detected in solid tumor specimens. **Results:** We identified 7,608 CH-associated mutations in the blood of 4,628 (26.5%) patients. 14% of CH-associated mutations (n = 1,075) were also detectable in the matched tumor above established thresholds for calling somatic mutations. In total, 5% of the patients (n = 912) would have had at least one CH-associated mutation erroneously called as tumor-derived in the absence of matched blood sequencing. 99% of these mutations were absent from population scale databases of germline polymorphisms (ExAC and gnomAD) and therefore would have been challenging to filter informatically. Of these, 534 were identified as oncogenic or likely oncogenic based on OncoKB database and 3% of the oncogenic mutations were associated with clinical actionability. **Conclusions:** Our results demonstrate how CH-derived mutations could lead to erroneous reporting and treatment recommendations when tumor-only sequencing is employed.

12005 Oral Abstract Session, Tue, 8:00 AM-11:00 AM

Whole exome sequencing (WES) to define the genomic landscape of young lung cancer patients (pts). *First Author: Xiaoliang Wu, West Virginia University Cancer Institute, Morgantown, WV*

Background: Previous studies have identified specific genomic driver alterations in non-small cell lung cancer (NSCLC). However, the causative molecular mechanisms that underlie the pathogenesis of most lung cancers in young patients (pts) remain largely undefined. We hypothesized that the key driving molecular events underlying lung cancer in young pts differ from that in older pts. **Methods:** We identified 45 pts diagnosed with NSCLC at an age $\leq$45 (median: 41; range: 21-45), at Cleveland Clinic, USA (2000-12) (n = 17) and Sun Yet-sen University Cancer Center, China (2007-13)(n = 28), with primary tumors or metastatic lesions sufficient for WES. Tumor histology was adenocarcinoma (n = 29), squamous cell (n = 13), mucous epidermoid (n = 2) and large cell (n = 1). Thirty two pts were female (71%). There were 34 non/never smokers, while others had a median smoking history of 30 pack-year. Genomic DNAs from both FFPE tumors and paired-normal lung tissues/peripheral blood were analyzed by WES (Illumina HiSeq2000). Sequencing reads were cleaned and then aligned to the human genome using the BWA algorithm. The aligned data were sorted, validated and indexed. Somatic variants were identified using GATK (genome analysis toolkit)(https://gatkforums.broadinstitute.org/gatk) and the Mutect 2 algorithms. The location and predicted functional impact of the somatic variants was identified using SnpEff. Pathway enrichment analysis was performed with Enrichr (http://amp.pharm.mssm.edu/ Enrichr). **Results:** Unique mutations associated with young NSCLC but not with other types of lung cancer were identified by comparison with The Cancer Genome Atlas (TCGA) lung cancer mutations in pts $>$ 65 years. Among the 426 unique mutated genes identified in young pts, 125 mutations were predicted to be highly disruptive to protein structure and/or function. Bioinformatic pathway enrichment analysis revealed a number of trending pathways including oxidative ethanol and nicotine degradation pathways (both $p < 0.05$), and TGF-beta receptor signaling enrichment ($p < 0.05$). **Conclusions:** Our study nominates novel biologically relevant candidate genes/pathways involved in young lung cancer pathogenesis that merit further analysis.

12006 Oral Abstract Session, Tue, 8:00 AM-11:00 AM

Application of a real world endpoint to identify and characterize genetic profiles of patients (pts) with poor prognosis in advanced non-small-cell lung cancer (aNSCLC). *First Author: Gracy Crane, Roche Products Ltd., Welwyn, United Kingdom*

Background: There is an unmet need to identify and characterize pts who rapidly progress on currently available therapies. Recent availability of linked clinico-genomic information offers an opportunity to characterize genetic profiles of rapid progressors to increase treatment options available to these patients. **Methods:** Pts diagnosed with NSCLC (n=2,139) within the Flatiron (FIH)-Foundation Medicine (FMI) linked database (Jan 2011–Dec 2016) were grouped by treatment class: cancer immunotherapy (CIT), targeted therapy (TKIs) or chemotherapy (CT). A composite real world endpoint of time to treatment failure (rwTTF) $<$2 months was created using the earliest of: a) time to next treatment, or b) real world progression (based on abstraction of clinician's assessment in electronic health records), or c) death within 60 days. A rwTTF $<$2 months was used to define rapid progressive (RPD). Baseline characteristics, overall survival (OS) and genetic profiles by NGS (using FMI) were analyzed for pts with RPD vs non rapid progressive disease (NRPD) by treatment class. **Results:** Baseline characteristics were mostly balanced. Median OS was substantially longer in pts with NRPD vs RPD across treatment classes confirming that the rwTTF definition can be used to identify RPD in real world databases. In CIT median OS was 4.4m (3.32–5.72) in the RPD vs 17.1m (14.26–NA) in the NPRD. In addition, higher tumor mutational burden (TMB) correlated with higher likelihood of response to CIT (median TMB was 9.9 (3.60–15.31) in NRPD patients vs. 5.4 (2.70–9.91) in RPD patients). This difference was not observed in the TKI or CT groups. In the CIT group, *HER2* and *EGFR* mutations were suggestive of an association with RPD status; however, *EGFR* and *BRAF* mutations were suggestive of an association with NRPD in the CT group. In the TKI group, CDKN2A/CDKN2B copy number variants were suggestive of an association with NRPD status. **Conclusions:** Applying a real world endpoint, we identified and characterized genetic profiles of pts with rapid progression. Rapid advances in data capture and linkage availability and quality can help with optimal management of patients at the point of care.

12007 Oral Abstract Session, Tue, 8:00 AM-11:00 AM

Liquid biopsy to predict benefit from rechallenge with cetuximab (cet) + irinotecan (iri) in RAS/BRAF wild-type metastatic colorectal cancer patients (pts) with acquired resistance to first-line cet+iri: Final results and translational analyses of the CRICKET study by GONO. *First Author: Daniele Rossini, Department of Translational Research and New Technologies in Medicine and Surgery, Unit of Medical Oncology 2, Azienda Ospedaliera Universitaria Pisana, Istituto Toscano Tumori, Pisa, Italy*

Background: CRICKET (NCT02296203) was designed to investigate the activity of the rechallenge with cet and iri as 3rd-line treatment in *RAS/BRAF* wild-type mCRC pts with acquired resistance to 1st-line cet- and iri-based therapy. The role of liquid biopsies as a tool to identify pts more likely to benefit from this strategy was investigated. **Methods:** Eligibility criteria included *RAS/BRAF* wild-type status on tissue samples; prior 1st-line iri-based, cet-containing regimen with at least RECIST partial response (PR), 1st-line PFS $\geq$6 months, and progression within 4 weeks after the last cet; prior 2nd-line oxaliplatin- and bevacizumab-based treatment. Pts received 3rd-line cet + iri until PD. The primary endpoint was response rate (RR) according to RECIST v1.1. With p0 = 5%, and p1 = 20%, 1-sided-α and β errors of 0.05 and 0.20, 27 pts were required. The null hypothesis can be rejected if responses are observed in $\geq$ 4 pts. Liquid biopsies were collected at the rechallenge baseline. ctDNA was analyzed with ddPCR for specific *RAS/BRAF* mutations (mut), and then by ultra-deep NGS with Ion Torrent S5 XL. **Results:** Between Jan 2015 and Jun 2017, 28 pts were enrolled in 9 centres. The primary endpoint was met. Six PRs (two unconfirmed) and 9 disease stabilizations (RR: 21%,95%CI: 10-40%, disease control rate: 54%,95%CI: 36-70%) were reported. *RAS* mut were found in liquid biopsies collected at the rechallenge baseline in 12 (48%) out of 25 evaluable pts (6 KRAS G12D, 5 KRAS G12V with 1 harboring also Q61H and 1 NRAS Q61L). No *RAS* mut were detected in samples from pts who achieved a confirmed PR. Pts with *RAS* wt ctDNA, had significantly longer PFS than those with *RAS* mut ctDNA (mPFS: 3.9 vs 1.9 mos; HR: 0.48 [95%CI 0.20-0.98], p = 0.048). No *BRAF* or *PIK3CA* mut were found. **Conclusions:** This is the first prospective demonstration of the activity of rechallenge with cet + iri in some mCRC pts initially sensitive and then resistant to first-line iri- and cet-based therapy, with no *RAS/BRAF* mut in pre-treatment liquid biopsies. Partially funded by Merck Serono SpA. Clinical trial information: NCT02296203.

12008 Oral Abstract Session, Tue, 8:00 AM-11:00 AM

Evolution of genomic instability in metastatic cancer. *First Author: Eric Yang Zhao, BC Cancer Agency, Vancouver, BC, Canada*

Background: Although metastasis underlies up to 90% of cancer-related mortality, genomic instability and mutation signatures are mostly studied in primary tumours. Mutation signatures are patterns of somatic mutation resulting from specific mutational processes (i.e. tobacco/UV exposure) and often evolve over time. Recent studies suggest that certain mutation signatures may predict chemotherapy response. Understanding mutational processes in metastatic cancers could uncover actionable targets and refine the understanding of progression and drug resistance. **Methods:** As part of the BC Cancer Agency Personalized Oncogenomics Project, mutation signatures were deciphered from 571 metastatic whole genomes from 12 cancer types totalling 13,249,678 somatic mutations. We created a novel Bayesian hiearchical model named SignIT (github.com/eyzhao/SignIT) to track temporal evolution of mutation signatures. Using real and simulated data, we showed that SignIT decomposes signatures and their temporal evolution more accurately than comparable methods. Previous chemotherapy treatments were catalogued for all patients by retrospective review. **Results:** We discovered 21 distinct mutation signatures, including 9 novel signatures (numbered M1-M9). Mutational processes associated with aging and cigarette smoke were early-arising. Signature 17 and M2 were consistently late-arising across cancer types and metastatic sites. Prior treatment with platinum-based chemotherapy was associated with depression of the homologous recombination deficiency signature 3 ($p = 0.03$). Platinum exposure was also associated with late elevation of signature 17. **Conclusions:** To date, this is the largest study of metastatic cancer whole genomes. Our findings revealed 9 novel mutation signatures, including potential markers of late disease and metastasis. We also observed temporal evolution of mutation signatures correlated with chemotherapy exposures. The association of decreasing signature 3 activity with platinum exposure suggests the restoration of homologous recombination as a resistance mechanism. These findings highlight the complexity of metastatic cancers, and the variety of factors which impact their mutagenesis.

12009 Clinical Science Symposium, Mon, 9:45 AM-11:15 AM

Characterisation of the TCR repertoire in NSCLC to reveal the relationship between TCR heterogeneity and genetic heterogeneity that is influenced by mutational load and is associated with disease recurrence. *First Author: Kroopa Joshi, Cancer Immunology Unit, University College London Cancer Institute, London, United Kingdom*

Background: The lung TRACERx study is a prospective study exploring the cancer genome evolution of NSCLC. Data analysis from the first 100 patients enrolled into the study has shown an increased risk of recurrence or death associated with intratumoural genomic heterogeneity. The importance of the phylogenetic clonality of cancer neoantigens in predicting overall survival in NSCLC and response to checkpoint blockade is previously reported. **Methods:** We hypothesised that mutational burden and genomic heterogeneity is reflected in the intra-tumoural T cell receptor (TCR) repertoire. We utilised quantitative high throughput sequencing of α and β chains to explore the TCR repertoire from multi-region tumour specimens, normal lung and PBMC samples from patients within the lung TRACERx study. **Results:** We observed that the TCR repertoire across multi-region tumour specimens was distinct to that observed in normal lung and PBMC. Intratumoural TCR repertoire heterogeneity was found to reflect genomic heterogeneity and was influenced by the tumour mutational load highlighting the potential importance of antigenic dosing in anti-tumour immunity. Moreover, we observed diversification of the TCR repertoire in late stage tumours and disease recurrence was associated with a heterogeneous intra-tumoural TCR response. Alpha and beta chain TCRs re-constructed from single cell RNA sequencing data obtained from T cells reactive to a truncal neoantigen were distributed across all regions of the tumour. **Conclusions:** Taken together, these findings demonstrate a heterogeneous spatial distribution of tumour infiltrating lymphocytes amongst patients with NSCLC. Moreover, our data suggest that TCR clones present across multiple regions of the tumour may expand in response to the presence of truncal neoantigens. The observations described are indicative of a dynamic intra-tumoural T cell response related to the diverse mutational landscape observed in NSCLC.

12010 Clinical Science Symposium, Mon, 9:45 AM-11:15 AM

NRG Oncology/NSABP B-31: Stromal tumor infiltrating lymphocytes (sTILs) and outcomes in early-stage HER2-positive breast cancer (BC). *First Author: Rim S. Kim, KU Leuven - University Hospitals Leuven, Leuven, Belgium*

Background: Stromal tumor infiltrating lymphocytes (sTILs) in HER2-positive and triple-negative breast cancer (BC) are associated with prognosis and treatment response. NSABP B-31 evaluated chemotherapy (C) *v* C + trastuzumab (CT) for early-stage HER2-positive BC. **Methods:** Based on International Immuno-Oncology Working Group (IIOWG) guidelines, sTILs were assessed by RSK in 1581/2016 eligible B-31 cases with available slides for H&E review, and as a semi-continuous variable (SCV) in 10% intervals. RSK and five pathologists from the IIOWG reviewed 100 of the cases as a consensus study. sTILs as an SCV and with a predefined lymphocyte-predominant BC (LPBC as $>$ 50% sTILs) were correlated with disease-free survival (DFS), the primary endpoint of B-31. sTILs were also correlated with clinicopathological characteristics, genotyping, intrinsic subtype, gene expression, and mutation profiling. Cox proportional hazard models were used, with p-values < 0.05 considered significant. **Results:** In both the C and CT arms, increases in sTILs, defined either as a SCV (combined arms HR 0.42, 95% CI 0.27-0.64, $p < 0.01$) or as LPBC (combined arms HR 0.65, 95% CI 0.49-0.86, $p = 0.003$), were significantly associated with improved DFS. However, there was no association of sTIL levels with degree of trastuzumab benefit (interaction $p = 0.556$). ER status by IHC was inversely associated with sTILs ($p < 0.01$). High sTILs were significantly associated with basal- and HER2- enriched intrinsic subtypes, and the high-benefit group by 8-gene expression model. None of the PIK3CA mutations or genotyping of Fc gamma receptors were associated with sTILs. The mean concordance between RSK and the other pathologists was 90.8%. **Conclusions:** sTILs were significantly associated with improved DFS in pts with early-stage HER2-positive BC treated with chemotherapy on B-31. However, sTILs were not associated with degree of trastuzumab benefit. sTILs may have utility as a prognostic biomarker to help to define pts with HER2-positive early BC, at low risk for recurrence. Pooled analysis in this clinical context is warranted. SUPPORT: U10CA180868, -180822, UG1-189867, U24-196067, PA DOH; Breast Cancer Research Foundation

12011 Clinical Science Symposium, Mon, 9:45 AM-11:15 AM

WINTHER: An international WIN Consortium precision medicine trial using genomic and transcriptomic analysis in patients with advanced malignancies. *First Author: Jordi Rodon, Vall d'Hebron Institute of Oncology, Barcelona, Spain*

Background: Precision medicine has focused mainly on matching drugs to tumor DNA alterations. However, not all individuals have tractable genomic alterations.We initiated the WINTHER trial to navigate patients to therapy based on either next generation sequencing (NGS) or transcriptomic analysis that compared tumor to normal tissue. **Methods:** Genomics (Arm A) was performed by NGS (N = 236 genes) (Foundation Medicine); transcriptomics (Arm B), by Agilent oligo-arrays (from fresh biopsies). A matching score was calculated for each patient (based on drugs received): for Arm A, number of alterations matched/total number of alterations; for RNA, by adding the reciprocals of the ranks of expression-matched drugs (using a transcriptomic algorithm). The clinical management committee (CMC) (lead investigators from the participating centers in 5 countries) suggested therapies, prioritizing genomic matches if available. The treating physician determined therapy given. **Results:** Overall, 303 patients consented; 107 (35%) received therapy consistent with CMC recommendations: 69 patients (64.5%) on Arm A (DNA-guided); 38 (35.5%), Arm B (RNA-guided). The median number of prior therapies was 3; median age = 59; median performance status = 1 (did not differ between arms). The most common diagnoses were colon, head/neck, and lung cancers. Adverse events after biopsy occurred in 1.2% of patients (1, (unrelated) convulsion; 2, pneumothorax). The rate of stable disease (SD) $\geq$ 6 months plus partial and complete response was 26.2%: Arm A, 23.2%; Arm B, 31.6%. Median progression-free survival (PFS) was 2.1 months (Arm A, 1.9; Arm B, 2.4). In multivariate analysis (hazard ratio (HR), 95% confidence interval (CI)), fewer prior therapies (0.63, 0.40-1.00, $p = 0.048$), better performance status (0.59, 0.37-0.92, $p = 0.020$) and a higher matching score (0.52, 0.33-0.82, $p = 0.005$) correlated with PFS. Higher matching score was also significantly associated with better overall survival (OS). ($p = 0.012$). **Conclusions:** Genomic and transcriptomic analysis were both useful for therapy selection. Higher degrees of DNA and RNA matching independently associated with longer PFS and OS. Clinical trial information: NCT01856296.

Association of loss of adaptive PD-L1 expression with upregulation of PBRM1 chromatin regulator in melanoma. *First Author: Daniel Sanghoon Shin, University of California Los Angeles Medical Center, Los Angeles, CA*

Background: Primary resistance to anti-PD-1 through genetic mechanisms is rare and may be mediated by loss-of-function (LoF) mutations in *JAK1/2* or antigen presentation. 3 out of 48 human melanoma cell lines with complete loss of adaptive PD-L1 expression upon interferon (IFN)-γ exposure, two harbored LoF mutations in *JAK1/2*. The third had intact IFN-γ signaling pathway without LoF mutations. We therefore sought to determine whether an epigenetic mechanism that may result in loss of adaptive PD-L1 expression in this cell line might be an underlying cause of primary resistance in some patients. **Methods:** Human melanoma cell lines that represent good, poorly and non-responding to IFN-γ were analyzed by flow cytometry, gene expression, ChIP-seq and ATAC-seq upon IFN-γ exposure. **Results:** The M412b human melanoma cell line showed no PD-L1 expression in response to IFN-γ exposure despite increased expression of IRF-1, STAT1 and STAT-3. ChIP-seq analysis for IRF-1 in M412B cell line showed no significant enrichment at the PD-L1 promoter compared to three others. ATAC-seq in M412b showed little signal at the PD-L1 promoter, suggesting that M412b cell line lost adaptive PD-L1 expression due to a promoter inaccessible to transcription factors. Peng et al (*Science*, 2018) demonstrated that the PBAF form of the SWI/SNF chromatin remodeling complex is associated with resistance to checkpoint blockade immunotherapy in the B16 murine melanoma model. Miao et al (*Science*, 2018) reported increased response to checkpoint blockade immunotherapy when patients with advanced renal cell carcinoma harbored LoF mutations in the PBRM1 gene. Consistently, M412b cell line displayed the highest PBRM1 and ARID2 expression among 48 human melanoma cell lines, suggesting that constitutive high expression of this chromatin remodeling complex may prevent access to PD-L1 promoter by transcription factors that would otherwise activate the gene in response to IFN-γ signaling. We are now testing this model. **Conclusions:** Lack of adaptive PD-L1 expression upon IFN-γ is associated with increased expression of the PBAF chromatin remodeling complex, which may be an epigenetic mechanism of primary or acquired resistance to anti-PD-1 therapy.

Role of CD4 cells in the complete anti-tumor response to PD1 blockade in a syngeneic murine melanoma model with activated WNT signaling. *First Author: Siwen Hu-Lieskovan, UCLA's Jonsson Comprehensive Cancer Center, Los Angeles, CA*

Background: Recent data suggested a correlation of active WNT signaling and tumor T cell exclusion. We developed a syngeneic *BRAF^{V600E}/PTEN$^{-/-}$*melanoma model YUMM2.1 (Y2.1) that has partial response (PR) to anti-PD1 (Homet, 2016), and an inducible cre/lox system to stabilize ß catenin. We hypothesized that WNT activation would alter the efficacy of anti-PD1 therapy in this model. **Methods:** Y2.1 cells were treated with tamoxifen (4HT) *in vitro* and ß catenin stabilization was confirmed (Y2.1 4HT1). C57BL/6 mice were implanted Y2.1 4HT1 tumors sc, followed by ip anti-PD1 (RMP1-14) or Isotype q3d for 3wks when tumors reach 5-8mm. For *in vivo* depletion, antibodies (a) against CD4, CD8, NK1.1, CD40L was given starting 1d prior to anti-PD1 x2d then WKly x 3. Tumors were harvested for flow, RNAseq. **Results:** WNT activation rendered a partial response to anti-PD1 w Y2.1 to complete regression of Y2.1 4HT1 tumors by wk 8 in majority of treated mice (median vol 180 vs 48 mm3 in WK6, p = 0.02). This enhanced anti-tumor effect is seen in additional 4HT treated Y2.1 (Y2.1 4HT2-6), but not YUMM1.1 (resistant to anti-PD1), but is lost in Y2.1 4HT1 BCKO (ß catenin gene knocked out by CRISPR, median vol ISO 587 vs aPD 560 mm3 in WK6, p = 0.65). Depletion studies showed complete abrogation of anti-tumor response with CD4 depletion but only partial with CD8 depletion, aCD40L or in *IFNg-/-* mice (Table 1), and no effect w NK depletion. Flow Cytometry and RNAseq showed increased T cells, IFNg, granzyme B with anti-PD1 in Y2.1 4HT1 tumor. CD4 depleted tumors also have increased CD8 but w/o effector functionality, and a global downregulation of immune related genes by hierarchical clustering. **Conclusions:** WNT signaling activation results in complete response to anti-PD1 therapy, w increased T cell infiltration and CD4 cells being essential for this anti-PD1 mediated anti-tumor response.

Facile single cell profiling and clonotype analysis of NSCLC immune microenvironments. *First Author: Ameen Abdulla Salahudeen, Stanford University, Stanford, CA*

Background: Immunotherapies acting upon tumor infiltrating lymphocytes (TILs) generate deep and durable responses in NSCLC patients. However, the clonality, cell phenotype, and signaling states of TILs remain poorly defined in clinical specimens. In addition, current in vitro model systems do not typically preserve both the tumor epithelium and microenvironment as an intact syngeneic unit thus hindering conceptual and therapeutic advances. **Methods:** We developed 3-dimensional organoid cultures of surgically resected NSCLC specimens that intrinsically retained diverse tumor microenvironmental cellular components without requiring reconstitution. We then profiled TIL clonotypes and gene expression phenotypes in varying histologies of NSCLC with a 5' based scRNA-seq platform capable of pairing alpha beta T cell receptor (TCR) sequence identity with 5' based transcriptomes. **Results:** Fresh clinical samples were viably dissociated into single cell suspensions and droplet based scRNA-seq was carried out in a rapid and reliable manner. Correct, full length, and paired TCRA/TCRB clonotypes were detected at expected ratios and demonstrated a detection sensitivity of clonal expansion with a sensitivity of 1% for 1000 cells observed. In addition, paired transcriptome analysis facilitated phenotypic categorization of each unique clonotype, including cytotoxic and helper T, B, Treg, as well as TIL exhaustion. Furthermore, examination of NSCLC tumor microenvironments with varying patient smoking history and tumor histology exhibited differences suggesting a potential link between immune microenvironments and cancer etiology. **Conclusions:** Organoid cultures faithfully recapitulate tumor microenvironment diversity within NSCLC histologic types, and scRNA-seq profiling of clonotype TIL dynamics may elucidate underlying immune microenvironment dynamics in NSCLC patients. Further studies in this human preclinical model coupled with scRNA-seq may advance our understanding of tumor immunology within NSCLC subtypes as well as facilitate the discovery of novel immunotherapies.

Expression and clinical significance of antigen presentation components beta-2 microglobulin, HLA class I heavy chains, and HLA class II in non-small cell lung cancer (NSCLC). *First Author: Ila Datar, Yale School of Medicine, New Haven, CT*

Background: Defective antigen presenting machinery (APM) limits tumor recognition by cognate T cells mediating resistance to immune checkpoint inhibitors (ICIs). The expression frequency, biological context and prognostic value of major APM components in NSCLC are poorly characterized. **Methods:** Using multiplexed quantitative immunofluorescence we measured levels of Beta-2 microglobulin (B2M, clone-D8P1H), HLA-B, C heavy chains (HLA-I, clone HC10), HLA Class-II (HLA-II, clone LGII-612.14) and pancytokeratin (CK, clone AE1/AE3) protein in 754 stage I-IV immunotherapy-naïve NSCLCs represented in tissue microarrays: Cohort#1 Yale (n = 423), Cohort#2 Greece (n = 284) and cohort# 3 Yale (n = 137) with molecularly annotated lung adenocarcinomas (ADCs). Targets were measured in tumor/stroma by fluorescence colocalization with tumor-specific CK. Associations with clinicopathological variables, T-cell infiltration, driver mutations and survival were studied. **Results:** B2M, HLA-I heavy chains (HCs) and HLA-II were expressed in tumor cells in 86.7%, 83.1% and 77.9% of NSCLCs, respectively. The markers showed significant positive association with each other in CK^- stromal cells (R^2= 0.27-0.33, $P < 0.05$) but not in CK^+ tumor cells (R^2= 0.002-0.14, $P > 0.05$). Tumors lacking B2M had significantly lower HLA-I, -II and $CD3^+$ infiltrating T cells than cases with B2M expression. No consistent association was seen between the targets and major clinicopathological variables across cohorts. Comparable levels of the markers were seen in KRAS/EGFR mutant and wild type lung ADCs. Tumor B2M downregulation was associated with worse outcome in both cohorts, but was significant only in cohort#1 and showed clear trend in #2. **Conclusions:** B2M, HLA-I HCs and HLA-II are downregulated in 12-22% of primary, immunotherapy-naïve NSCLCs. Reduced B2M expression associates with an immune "cold" phenotype characterized by low HLA-I, -II levels, low T cell infiltration and poor prognosis. Our results support an immunomodulatory role of APM downregulation in NSCLC and underscore its possible involvement in primary resistance to ICIs and potential as a biomarker.

Whole exome sequencing (WES) in hormone-receptor positive (HR+) metastatic breast cancer (MBC) to identify mediators of resistance to cyclin-dependent kinase 4/6 inhibitors (CDK4/6i). *First Author: Seth Andrew Wander, Dana-Farber Cancer Institute, Boston, MA*

Background: Combining CDK4/6i with endocrine therapy results in prolongation of disease control in HR+ MBC, though resistance invariably occurs. There is a critical need to understand mechanisms governing response and resistance to these agents. **Methods:** WES was performed on 51 baseline metastatic tumor biopsies obtained at treatment initiation with CDK4/6i in combination with various anti-estrogens. Tumor samples were classified as sensitive (S, from patients with clinical benefit) or intrinsically resistant (IR, from patients without clinical benefit). WES was also performed in 11 acquired resistance (AR) specimens obtained from responding patients after progression. In 6 patients, WES was performed on matched pre-treatment S and post-progression AR specimens. Putative resistance drivers were introduced into HR+/HER2- breast cancer cells (T47D, MCF7) via lentiviral infection or knockout via CRISPR. Sensitivity of the modified cell lines to anti-estrogens and CDK4/6i was characterized. **Results:** WES of 62 tumors revealed multiple potential mechanisms of resistance to CDK4/6i (Table), including biallelic *RB1* inactivation, *AKT1* mutation (mut) and/or amplification (amp), *RAS* mut, *AURKA* amp, *IGF1R* amp, *ERBB2* mut, and *FGFR2* mut and/or amp. Introduction of candidates into HR+ breast cancer cells conveyed resistance to CDK4/6i *in vitro*, including loss of Rb and overexpression of AKT1, AURKA, FGFR2, mut-KRAS, and mut-ERBB2. Additional sequencing efforts and characterization of variants is ongoing and will be presented. **Conclusions:** These results provide new insight into the diverse spectrum of genomic events driving resistance to CDK4/6i and set the stage for additional mechanistic studies. For patients with AKT1, RAS, AURKA, IGF1R, ERBB2, and FGFR2-dependent resistance, clinical trials incorporating novel combinations of targeted therapies could be designed to circumvent or overcome resistance.

Phenotype	S	IR	AR	IR+AR (%)
Tumor samples (n)	21	30	11	41
RB1 biallelic inactivation	0	3	1	4 (10)
IGF1R amp	0	2	1	3 (7)
RAS mut	0	2	1	3 (7)
AKT1 mut or amp	1	3	2	5 (12)
FGFR2 mut or amp	0	3	0	3 (7)
AURKA amp	0	7	4	11 (27)
HER2 mut	1	1	3	4 (10)

Analysis of tumor samples from SOLO2: Concordance of *BRCA* mutation (*BRCA*m) detection in tumor vs. blood and frequency of *BRCA*-specific loss of heterozygosity (LOH) and loss of function somatic mutations. *First Author: Darren R. Hodgson, AstraZeneca, Cambridge, United Kingdom*

Background: The PARP inhibitor olaparib is approved for maintenance treatment of platinum-sensitive relapsed ovarian cancer (PSR OC) in the USA based on pivotal studies (Study 19, SOLO2) that demonstrated a progression-free survival benefit of olaparib (Ledermann et al 2012, 2016; Pujade-Lauraine et al 2017). Patients (Pts) with *BRCA*m benefit most from olaparib, but questions remain on the functional equivalence of germline (g) and somatic *BRCA*m and the frequency and impact of *BRCA*-gene-specific LOH (Dougherty et al 2017; Maxwell et al 2017). **Methods:** Blood and tumor samples from 241 pts with g*BRCA*m in a Phase III trial of olaparib maintenance monotherapy (300 mg bid tablets; SOLO2; NCT01874353) were analyzed. A concordance analysis of g*BRCA*m and tumor *BRCA*m (t*BRCA*m) status was conducted; gene-specific LOH for *BRCA1* and *BRCA2* and assessment of homologous recombination deficiency (HRD) using Myriad HRD score (Tumor BRACAnalysis CDxTM test) was also determined. **Results:** t*BRCA*m testing was evaluable in 241/289 g*BRCA*m pts. There was 98% and 100% concordance between pts' *BRCA1*m and *BRCA2*m status, respectively, in t*BRCA*m vs g*BRCA*m. 13/241 (5.4%) of g*BRCA*m were due to large rearrangements (exonic insertions or deletions), of which 4 involving *BRCA1* were not detected in the tumor. A further deleterious somatic mutation in *BRCA1* was identified in 1/241 pts with g*BRCA*m tumors. This was a large rearrangement in *BRCA1*, causing an exon 1–22 deletion that likely constituted the second 'hit' in this tumor. Of 210 evaluable LOH samples, 144/144 (100%) g*BRCA1*m and 65/66 (99%) g*BRCA2*m tumors had gene-specific LOH. The pt without *BRCA2* LOH had an HRD score of 53, was progression-free for 911 days and remained on olaparib at data cut-off. **Conclusions:** Very high concordance between t*BRCA* and g*BRCA* testing is demonstrated, supporting wider implementation of t*BRCA* testing in addition to availability of g*BRCA* testing to determine *BRCA*m status in OC. Deleterious somatic *BRCA*m almost never arises in g*BRCA*m tumors, in keeping with *BRCA* loss being a driver of tumorigenesis in OC. In PSR g*BRCA*m pts, gene-specific LOH in tumors is almost universal. Clinical trial information: NCT01874353.

Mass spectrometry biomolecular omics profiling and imaging to dissect the initial emergence of molecular drug resistance in *ALK*-positive (ALK+) lung cancer. *First Author: Xiaoliang Wu, West Virginia University Cancer Institute, Morgantown, WV*

Background: ALK tyrosine kinase inhibitors (TKIs) yield a significant tumor response in advanced *ALK*+ non-small cell lung cancer (NSCLC), that is often rapid and remarkable. Nonetheless, acquired drug resistance invariably develops. Currently, the mechanisms for the initial emergence of molecular drug resistance in the responders are still not fully understood. **Methods:** *ALK*+ H3122 and Ma-ALK001.S (patient-derived cell line) lung adenocarcinoma in vivo xenograft models were investigated under drug treatment with/without ALK-TKI (TAE684 or Alectinib) for 0, 7 and 14 days. Mass spectrometry imaging (MSI) and biomolecular profiling were carried out on FFPE or fresh frozen tissues to compare peptide/lipid/metabolite profiles among the tumors using a histology-guided MS (HGMS) approach. Full section MSI was also performed to determine the intratumoral drug distribution. Cells were subjected to both Matrix Assisted Laser Desorption/Ionization (MALDI)-MS and Laser Ablation Electrospray Ionization (LAESI)-MS profiling. Statistical analyses were performed using SCiIS and MarkerLynx, respectively. **Results:** ALK-TKIs precision treatment engendered an early emergence of drug resistant escape in the ALK+ tumor cells within the initial 14 days of treatment. Direct MS/MS fragmentation verified that ALK-TKIs were detected within the drug-dosed tumors undergoing early drug-escape. We identified unique peptide landscape changes emerging under ALK-TKI treatment. Most significant peak differences were observed between day 0 and day 14 (677) in the H3122 group, and also between day 0 and day 14 (341) in the Ma-ALK001.S group. Interestingly, day 7 peptide signatures in these models were more similar to day 14 than to the day 0 control. Overall, biomolecular profiling (peptides, lipids and metabolites) of *ALK*+ lung tumor cells using combined MALDI and LAESI-MSI analysis was successful. **Conclusions:** MSI technology facilitates interrogation of the biomolecular changes occurring within drug persister tumor cells under precision treatment. An ALK drug resistant proteomics signature emerges as early as day 7 under precision inhibitor treatment.

Development of diagnostic method for bone and soft tissue sarcomas of various histological subtypes using serum microRNA profiles. *First Author: Naofumi Asano, Department of Orthopaedic Surgery School of Medicine, Keio University, Tokyo, Japan*

Background: Diagnosis of sarcomas is considered to be quite difficult because of the rarity and diversity of the disease. The development of a novel diagnostic test for sarcoma is eagerly awaited. The aim of this study is to address whether serum miRNA profiles can be used to detect only malignant cases (sarcomas) of bone and soft tissue tumors regardless of histological subtypes. **Methods:** The case-control study included 1,002 patients with bone and soft tissue tumors representing more than 43 histological subtypes, including sarcomas, intermediate, and benign tumors. As controls, 275 healthy and 240 patients with other cancers were enrolled. MiRNA levels were measured using microarray. Patients were divided into three cohorts: a discovery to identify differentially expressed miRNAs; a training to establish a diagnostic index; and a validation to validate the utility of the index. An exploratory cohort was used to evaluate the index in recurrent sarcomas, intermediate tumors, and other cancers. **Results:** Circulating serum miRNA profiles, determined by microarray analysis, in malignant cases of bone and sarcomas, were clearly distinct from those in benign and healthy controls. A promising molecular detector, diagnostic index II, was developed using the serum levels of three miRNAs. Diagnostic index II also clearly separated sarcomas from benign and healthy controls with remarkable high sensitivity (94%), specificity (90%), and accuracy (91%). **Conclusions:** Comprehensive analysis of serum miRNA profiles in approximately 1000 cases of bone and soft tissue tumors identified a promising classifier, diagnostic index II, calculated using the serum levels of three miRNAs with remarkable performance for the detection of sarcoma. The present data overcome a serious problem associated with sarcoma diagnosis and provide the basis for the development and implementation of miRNA-based strategies for diagnostic purposes in the clinic.

PRC-2 epigenetic chromatin reprogramming in ALK-positive (ALK+) lung cancer initial emergence of precision drug resistance. *First Author: Patrick C. Ma, WVU Cancer Institute, West Virginia University, Morgantown, WV*

Background: Despite remarkable upfront response to ALK tyrosine kinase inhibitors (TKIs) in ALK+ lung cancer, acquired resistance eventually develops. Molecular mechanisms of the initial emergence of drug resistance are poorly understood. **Methods:** ALK+ H3122, H2228 and a patient-derived Ma-ALK001.S NSCLC cell lines were used in our study. In vitro MTS viability and murine in vivo xenograft assays were performed. siRNA knockdown and CRISPR/cas9 gene knockout were used for mechanistic studies. ChIP-qPCR was conducted to analyze HOXB3 epigenetic marks. RNA-seq was also performed for transcriptome analysis. Tumor microarray (TMA) biomarker study was adopted for outcome analysis of the polycomb repressive complex-2 (PRC-2) in NSCLC. **Results:** Our study revealed a rapid-onset emergence of adaptive drug-resistant ALK+ lung cancer cells within the first 14 days upon TKI treatment initiation. The expression of stem cell transcription factors, most notably HOXB3, was induced adaptively within the tumor cells undergoing drug escape. Similarly, tumoral TGFβ2 autocrine expression both at mRNA and protein levels were significantly elevated, and it regulated the downstream HOXB3 expression and mitochondrial prosurvival BCL-2/BCL-xL signaling, cancer stemness and EMT markers. RNA-seq revealed a rapid-onset adaptive global transcriptome reprogramming in the drug-escaping persister tumor cells. ChIP-qPCR showed resistance emerged via epigenetic regulation of the untreated bivalent HOXB3 promoter closed chromatin state transforming to stem-like open state during drug-escape, based on H3K4me3/H3K27me3 methylation mark balance. Findings were validated via CRISPR/cas9-EZH2 knockout studies. AQUA-TMA biomarker and survival outcome analysis confirmed the clinical relevance of EZH2/UTX of PRC-2. Finally, direct EZH2 inhibition or knock-out promoted ALK-TKI drug resistance, while UTX inhibition enhanced drug sensitivity. **Conclusions:** ALK+ lung cancer achieves initial rapid-onset emergence of adaptive drug escape through PRC-2 epigenetic chromatin reprogramming to regulate cancer plasticity-EMT/stemness interplay via the TGFβ2-EZH2/UTX-HOXB3-BCL-2/BCL-xL cascade.

Development of a comprehensive cell-free DNA (cfDNA) assay for early detection of multiple tumor types: The Circulating Cell-free Genome Atlas (CCGA) study. *First Author: Eric A. Klein, Cleveland Clinic Glickman Urology and Kidney Institute, Cleveland, OH*

Background: Globally most cancers are detected at advanced stages with high treatment burden and low cure rates. A noninvasive cfDNA blood test detecting multiple cancers at early stages when curative treatment is more likely to succeed is desirable. CCGA (NCT02889978) is a prospective multicenter observational study for development of a noninvasive cfDNA-based multi-cancer detection assay. **Methods:** Prospectively collected samples (N = 1627) from 749 controls (no cancer diagnosis, C) and 878 participants (pts) with newly diagnosed untreated cancer (20 tumor types, all stages) were analyzed in a preplanned substudy. 3 prototype sequencing assays were performed: paired cfDNA and white blood cell (WBC, 60,000X) targeted sequencing (507 genes) for single nucleotide variants/indels; paired cfDNA and WBC whole genome sequencing (WGS, 30X) for copy number variation; cfDNA whole genome bisulfite sequencing (WGBS, 30X) for methylation. For each assay a detection model was developed for all cancer pts; sensitivity was estimated at 95% specificity. **Results:** Pts w/cancer and C had similar age, smoking status and gender. WGBS had the highest sensitivity and is reported here; results were consistent across assays. Detected (sensitivity [95% CI]) cancers (stage I-III) included 28 colorectal (66% [48-84]), 19 esophageal (63% [38-84]), 5 head and neck (56% [21-86]), 5 hepatobiliary (80% [28-99]), 73 lung (59% [47-70]), 17 lymphoma (77% [50-93]), 11 multiple myeloma (73% [39-94]), 10 ovarian (90% [56-99]), and 10 pancreatic (80% [44-98]). Breast cancer-specific assay results are reported separately. Cancers with low signal ($<$ 10% sensitivity) include low gleason score prostate cancer, thyroid, uterine, melanoma, and renal. Comparison to tumor WGS and multi-assay classification will be reported. **Conclusions:** A cfDNA-based blood test detected multiple cancers at various stages with high specificity, indicating this approach is promising as a multi-cancer screening test, including for lethal unscreened cancers where stage shift can impact mortality. Further assay and clinical development of a multi-cancer cfDNA test in an asymptomatic population is ongoing. Clinical trial information: NCT02889978.

Cell-free circulating tumor DNA somatic alteration burden and its impact on survival in metastatic cancer. *First Author: Seyed Saeed Pairawan, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Prognostication has been a challenging subject in patients with metastatic disease. Physicians are expected to assess prognosis of patients with advanced disease both for determining suitability for clinical trials and for patient counseling. Increasingly, cell-free circulating tumor DNA (cfDNA) sequencing is being performed for clinical decision-making. We sought to determine whether somatic alteration burden (SAB) in cfDNA is associated with prognosis. **Methods:** We performed a retrospective analysis of 298 patients with metastatic disease who underwent clinical comprehensive cfDNA analysis at a single tertiary care institution. Our primary objective was to determine the influence of SAB (defined as maximum mutant allele frequency) on overall survival (OS). Secondary objectives included the association between the number of nonsynonymous mutations (NSM) and OS, and of site of primary malignancy on mutation detection and SAB. **Results:** CfDNA mutations were detected in 240 (80%) patients. SAB was classified by quartiles, Q1 lowest, Q4 highest SAB. Median follow-up was 8.4 months after cfDNA testing; we observed 116 deaths (39%) among 298 patients. Median OS was 11.5 months. Higher SAB levels had a statistically significant impact on overall survival in SAB Q3 (HR 2.3, p = 0.0069) and SAB Q4 (HR = 3.8, p $<$ 0.0001) on univariate analysis. On multivariate analysis, SAB Q4 (HR = 2.6, p = 0.0033), male sex (HR = 1.59, p = 0.0033) and albumin level $>$ 3.9 g/dl (HR = 0.40, p = 0.00011) were independent predictors of OS. CfDNA mutation detection, SAB, and number of NSM significantly differed between tumor types (p $<$ 0.0001, p = 0.0013, and p = 0.0001 respectively), being lowest in appendiceal cancer and highest in colon cancer. Having more than one NSM detected was associated with significantly worse overall survival (HR = 2.3, p $<$ 0.0001). **Conclusions:** Higher levels of cfDNA SAB and higher number of NSM were associated with worse OS in patients with metastatic disease. Further study is needed to determine optimal SAB thresholds for clinical decision-making and the utility of SAB across different tumor types.

12023 Poster Discussion Session; Displayed in Poster Session (Board #136), Mon, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Mon, 4:45 PM-6:00 PM

Assessment of the genomic stability and molecular landscape of patient-derived xenograft (PDX) models from NCI's Patient-Derived Models Repository (PDMR). *First Author: Bishwajit Das, Frederick National Laboratory for Cancer Research, Frederick, MD*

Background: Patient-derived xenografts (PDXs) are a powerful tool for cancer translational research. However, it is unclear if early passage PDXs faithfully recapitulate the molecular profiles of the corresponding patient tumors. The National Cancer Institute (NCI) has developed a Patient-Derived Models Repository (PDMR; www.pdmr.cancer.gov) of PDXs with clinical annotation and comprehensive genomic data. We used this data set, which represents 13 broad categories of tumor types, to conduct an in-depth investigation of the genomic stability of PDXs with early passaging. **Methods:** Tumors (biopsy or resection), including some from metastatic sites, were used to establish 211 PDX models from 206 patients. Whole Exome Sequencing and RNA-Seq were performed on 2-9 mice per model. Passages represented include the original clinical sample, P0, P1, P2, and less frequently $>$ P2. **Results:** By several metrics, genomic profiles of a large majority of PDMR models were stable with early passaging: (1) transcriptome profiles of mice from different passages in a model were found to always cluster together; (2) 75% of PDXs maintained similar copy number alteration profiles compared with the original clinical sample, with no significant differences between passages; (3) the allele frequency (AF) of clinically relevant mutations remained consistent across passages, with only 20% of models having $>$ 15% AF range from the median. Moreover, genomic features of PDMR models were broadly comparable to those in large public patient data sets. For example, melanoma models had the highest tumor mutation burden and a 55% prevalence of BRAF V600X; 11% of colon adenocarcinoma models were MSI-H, with APC (65%), TP53 (59%) and KRAS (53%) being most frequently altered. **Conclusions:** In this large and histologically diverse PDMR data set, PDXs exhibited genomic stability with early passaging. The molecular landscape of PDMR models is faithfully comparable to large public patient data sets. As the PDMR collection expands additional in-depth analyses will be performed. The PDMR thus represents a valuable resource for researchers interested in pre-clinical drug or other studies.

12024 Poster Session (Board #137), Mon, 1:15 PM-4:45 PM

First-in-human phase I trial of BI 836880, a vascular endothelial growth factor (VEGF)/angiopoietin-2 (Ang-2)-blocking nanobody, given every 3 weeks (q3w) in patients (pts) with advanced/metastatic solid tumors. *First Author: Christophe Le Tourneau, Institut Curie, Paris, France*

Background: VEGF and Ang-2 inhibitors have demonstrated clinical activity in various tumor types. Given the overlap of the VEGF/VEGFR2 and Ang-2/Tie-2 signaling pathways there is a rationale for dual inhibition. BI 836880 is a humanized bispecific nanobody (engineered antibody fragment of variable antibody domains) that inhibits VEGF and Ang2 and has demonstrated preclinical activity in cancer models. **Methods:** Pts with solid tumors refractory after standard therapies/for whom no established treatment options were available received BI 836880 q3w (IV; starting dose 40 mg). Dose escalation followed a Bayesian logistic regression model with overdose control. The maximum-tolerated dose (MTD; primary endpoint) was evaluated based on dose-limiting toxicities (DLTs) in the first 21-day cycle. Treatment-related AEs (TRAEs) leading to dose reduction/discontinuation, exposure/disposition kinetic measures (both secondary endpoints) and best overall response were also assessed. **Results:** 29 pts were treated: median age 57 yrs (range 2879); 62% female. The MTD was determined as BI 836880 720 mg q3w (Table). All pts had at least 1 AE, most commonly (all grade/grade $\geq$3): hypertension 86%/34%, asthenia 48%/10%, nausea 45%/3% and vomiting 38%/3%. 23 (79%) pts had TRAEs; none led to dose reduction. One patient had a TRAE leading to discontinuation (pulmonary embolism DLT at 1000 mg). Two (7%) pts (nasopharyngeal [n = 1] and breast [n = 1] carcinoma) had a partial response and 9 (31%) pts had stable disease. PK/PD analysis of 14 evaluable pts showed dose-proportional plasma kinetics of BI 836880, complete peripheral target inhibition at doses $\geq$360 mg q3w and predicted required trough values at doses $\geq$720 mg q3w. Clinical trial information: NCT02674152. **Conclusions:** The MTD/recommended phase 2 dose of BI 836880 was determined as 720 mg q3w based on safety and PK/PD analyses. Early signs of antitumor activity were observed.

Dose, mg	Pts, n	Pts with DLT, n
40	3	0
120	2	0
360	2	0
720	17*	0
1000	5	1: G3 pulmonary embolism

*No DLT in first 2 pts; expanded to 7 after DLT at 1000 mg; 10 more patients enrolled after MTD determined at 720 mg.

12025 Poster Session (Board #138), Mon, 1:15 PM-4:45 PM

Monitoring microsatellite instability (MSI) in circulating tumor DNA by next-generation DNA-seq. *First Author: Adam Deng, Geneis(Beijing) Co.,Ltd., Beijing, China*

Background: Microsatellite instability (MSI) is a useful predictive biomarker for prognosis of patients with phase II colorectal cancer and clinical benefit from cancer immunotherapy. Conventional MSI testing is commonly performed with tumor tissues by a fluorescent multiplex PCR-based method, consisting of six mononucleotide microsatellite makers. Recently, next generation DNA sequencing (NGS) has been developed for detection of MSI status in tumor tissues. However, we are still curious about whether we could accurately monitor MSI in ctDNA by NGS to achieve the non-invasive diagnosis. **Methods:** We collected plasma, matched tumor tissue and blood samples from 200 cancer patients. ctDNAs extracted from plasma and genomic DNAs extracted from tumor tissue and blood were used to perform MSI testing by conventional PCR methodand amplicon-based NGS. Six regular mononucleotide microsatellite makers (NR-27, NR-21, BAT-26, BAT-25, NR-24, MONO-27) were analyzed in two methods, and blood was compared as the normal control for MSI evaluation. MSI-H or MSI-L/MSS patients were primarily distinguished by conventional PCR method. Further we performed MSI detection in plasma, matched tumor tissue and blood by NGS and designed an algorithm for evaluating MSI status. **Results:** In 200 cancer patients, we primarily identified 13 patients with MSI-H (6.5%) and the others with MSS by conventional PCR method. Interestingly, we found that MSI testing in plasma was not performed by conventional PCR assay, namely that MSI could not be precisely monitored by conventional method. However, both MSI testing in plasma and in tumor tissue could be performed well by NGS. Compared the results of MSI testing in tumor tissue by two methods, there was high consistency. Importantly, we found that all 13 MSI-H patients were correctly identified by MSI testing in circulating tumor DNA(ctDNA), in concordance with the results of MSI testing in tumor tissue. The sensitivity of MSI testing was 100%. **Conclusions:** In our study, the MSI status of cancer patients could be accurately monitored in circulating tumor DNA(ctDNA) by amplicon-based NGS. It provides the possibility of non-invasive MSI testing for cancer patients in clinical diagnosis.

12026 Poster Session (Board #139), Mon, 1:15 PM-4:45 PM

The prognostic and predictive value of AR-V7 quantification in mCRPC. *First Author: Adam Sharp, The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Sutton, United Kingdom*

Background: Androgen receptor splice variant-7 (AR-V7) is associated with resistance to abiraterone/enzalutamide treatment in metastatic castration resistant prostate cancer (mCRPC). **Methods:** We determined CTC status and AR-V7 RNA quantification from mCRPC patient blood (Adnagen assay; AG). Reproducibility, clinical significance, and comparison to CellSearch CTC (CS_CTC) enumeration and biopsy AR-V7 protein quantification (Immunohistochemistry; IHC) was investigated. **Results:** To-date 218 blood samples from 130 patients have been analysed. AG reproducibility was determined from 84 samples run in triplicate with high concordance (70% of samples); poor concordance was seen in samples with low AR-V7 RNA expression supporting the identification of a cut-off for negative AR-V7 testing. CS_CTC enumeration was available for 109 samples; AG_CTC^{neg} samples had lower CS_CTC counts (p = 0.0001). AG_CTC^{pos}/AR-V7^{neg} samples had lower CS_CTC counts than AG_CTC^{pos}/AR-V7^{pos} samples (p = 0.006). CS_CTC counts in AG_CTC^{pos}/AR-V7^{pos} samples positively correlated with AR-V7 RNA expression (p = 0.0002). Contemporaneous mCRPC biopsies were available for 56 samples. All 25 AG_CTC^{pos}/AR-V7^{pos} samples, 12/16 AG_CTC^{pos}/AR-V7^{neg} samples and 9/15 AG_CTC^{neg} samples were AR-V7 IHC positive. Finally, AG_CTC^{pos}/AR-V7^{pos} patients had a worse prognosis than AG_CTC^{pos}/AR-V7^{neg} and AG_CTC^{neg} patients (median OS 6.9 vs 14.4 vs 30.8 mo; p $<$ 0.0001). In addition; only patients with AG_CTC^{pos}/AR-V7^{neg} (5/11) and AG_CTC^{neg} (1/5) samples, not AG_CTC^{pos}/AR-V7^{pos} (0/5) samples, before either enzalutamide/abiraterone therapy had a 50% PSA response. **Conclusions:** We confirm that AG_AR-V7 RNA analyses can be conducted as a continuous variable, and determine a cut-off for negative tests and show that this is prognostic and predictive. Furthermore, we show that AG_AR-V7 RNA expression may be associated with higher CS_CTC counts and more advanced disease. Finally, we demonstrate that patients with AG_CTC^{neg} and AG_CTC^{pos}/AR-V7^{neg} samples had mCRPC biopsies positive for AR-V7 protein expression; the clinical significance of this requires further interrogation to identify whether these patients derive less benefit from enzalutamide/abiraterone therapy.

12028 Poster Session (Board #141), Mon, 1:15 PM-4:45 PM

Re-visiting *EGFR* amplification as a target for anti-EGFR therapy: Analysis of cell-free circulating tumor DNA in patients with diverse cancers. *First Author: Shumei Kato, Moores Cancer Center, La Jolla, CA*

Background: To date, evidence for tissue *EGFR* amplification (amp)/overexpression as a biomarker for anti-EGFR efficacy has been weak. We investigated the relationship between elevated *EGFR* copy numbers in cell-free circulating tumor DNA (cfDNA) and the role of anti-EGFR drugs in achieving response. **Methods:** We evaluated *EGFR* amp status amongst 1,435 patients with diverse cancers using clinical-grade next generation sequencing (NGS) of cfDNA (Guardant Health) (detects single nucleotide variants [54-73 genes], amp, fusions and indels in selected genes) and analyzed treatments used (NCT02478931). **Results:** Overall, 6.0% of patients (86/1,435) had *EGFR* amp on initial cfDNA evaluation (copy numbers, 1+: 2.13-2.39 [N = 40], 2+: 2.40-3.99 [N = 40], 3+: $>$ 4.00 [N = 6]). *EGFR* amp was most frequent among small cell lung (30.0% [3/10]), breast (11.9% [13/109]) and colorectal cancer (11.0% [14/127]). All patients had co-existing alterations, most commonly in other tyrosine kinase family genes (70.9% [61/86]), MAPK signaling pathway (59.3% [51/86]) or cell cycle-associated genes (53.5% [46/86]). Nine evaluable patients with *EGFR* amp were treated with anti-EGFR-based regimens. Fifty-six percent (5/9) achieved partial responses, including 2 patients treated with dual anti-EGFR agents (small molecule inhibitor plus antibody) (adenocarcinoma of unknown primary [-44%, 4 months] and gastroesophageal cancer [-70%, 17+ months]. Responses were seen across different degrees of *EGFR* amp (1+ [N = 1], 2+ [N = 2], 3+ [N = 2]) and included patients with colorectal cancer. Two of 5 responders had tissue NGS showing *EGFR* amp; 1 of 3 non-responders with tissue NGS showed EGFR amp. Two-month landmark analysis showed median PFS of 3.9 versus 0.57 months among responders versus non-responders (P = 0.11); overall survival, 4.8 versus 0.6 months (P = 0.04). **Conclusions:** *EGFR* amp was detected in cfDNA among 6.0% of diverse cancers. Most patients had co-existing alterations. Responses were observed in 5 of 9 patients who received EGFR inhibitors, including 3 who were negative for *EGFR* amp in tissue. Incorporating EGFR inhibitors in regimens given to patients with *EGFR* amp in cfDNA merits further study. Clinical trial information: NCT02478931.

12029 Poster Session (Board #142), Mon, 1:15 PM-4:45 PM

Correlation between natural killer cell activity and treatment effect in patients with disseminated cancer. *First Author: Torben Hansen, Department of Oncology, Vejle Hospital, Institute of Regional Health Research, University of Southern Denmark, Vejle, Denmark*

Background: Prediction of treatment effect remains an unsolved problem in patients with malignant tumors. The aim of the present study was to analyze the possible correlation between Natural Killer (NK) cell activity as measured by the NK Vue assay and treatment effect in patients with different tumors. **Methods:** The study included four different trials encompassing palliative treatment to patients with prostate, ovarian and colorectal cancer. The current results are based on 93 patients with mature data on treatment effect. Blood samples were collected at baseline and prior to each treatment cycle into NK Vue Promoca tubes and placed in an incubator at 37°C within 15 minutes of sampling. Following 24 hours of stimulation the level of interferon-gamma (IFNγ) in the plasma was measured by ELISA (NK Vue Gold) as a surrogate for NK cell activity. Response rates (RR) and progression free survival (PFS) were endpoints. **Results:** The relationship between NK cell activity and treatment response was similar across tumor types and treatment, and data were consequently pooled for analyses. The outcome suggested a classification into three groups. During the first two months of treatment the IFNγ dropped to an abnormal level (< 200 pg/mL) in group 1 or remained at an abnormal level (n = 35). In group 2 (n = 30) the level remained within a normal range (> 500 pg/mL), while in group 3 (n = 28) it increased from an abnormal to a normal level. The RR were 29%, 47%, and 82%, respectively, p = 0.0001. The median PFS was 2.6 months (95% confidence interval (CI) 2.1-3.9), 10.0 months (95% CI 6.5-11.1), and 8.3 months (95% CI 6.5-8.7), respectively, $p < 0.0001$ (log-rank). **Conclusions:** The results suggest a correlation between NK cell activity and treatment effect across different tumor types and treatments. Patients lacking the ability to mount an immune response during the first two months of treatment have a very poor prognosis and clinical benefit of the treatment is questionable.

12030 Poster Session (Board #143), Mon, 1:15 PM-4:45 PM

Extracellular matrix (ECM) circulating peptide biomarkers as potential predictors of survival in patients (pts) with untreated metastatic pancreatic ductal adenocarcinoma (mPDA) receiving pegvorhyaluronidase alfa (PEGPH20), nab-paclitaxel (A), and gemcitabine (G). *First Author: Song Wang, Halozyme Therapeutics, Inc., San Diego, CA*

Background: Hyaluronan (HA) and collagens are major constituents of the ECM. HA accumulation in the tumor microenvironment may result in elevated interstitial fluid pressure, vascular compression, and reduced drug delivery and immune cell access. PEGPH20 degrades HA, increasing tumoral access for therapeutics and immune cells. Liquid biopsies reflecting ECM remodeling may provide a non-invasive approach to identify pts most likely to benefit from PEGPH20 therapy. **Methods:** Peptide markers of ECM remodeling (C3M, PRO-C3, PRO-C6, and VCANM) were measured using baseline plasma samples from Stage 1 (n=94) and Stage 2 (n=95) of HALO-109-202 (NCT01453153), a Phase 2, open-label, randomized study of PEGPH20 + A + G (PAG) *vs* AG in previously untreated pts with Stage IV PDAC. Univariate and ratio analyses were conducted to correlate biomarker levels with survival outcomes (PFS, OS). **Results:** The ratio of C3M (MMP degradation fragment of type-III collagen) *vs* PRO-C3 (N-terminal pro-peptide of type-III collagen) predicted for PFS benefit in PEGPH20-treated pts in Stage 1. The predictive value of this ratio for PFS and OS of PEGPH20-treated pts was further validated in Stage 2. **Conclusions:** This supports development of a liquid biopsy-based companion diagnostic for selecting pts that may benefit from PEGPH20.

Biomarker levels and survival outcome.

			PFS								
			Median (mths)		Log-rank, P	HR (95% CI)

12031 Poster Session (Board #144), Mon, 1:15 PM-4:45 PM

Role of serum thymidine kinase-1 (TK1) activity in patients (pts) with hormone receptor positive (HR+) advanced breast cancer (ABC) treated with endocrine therapy (ET) in the EFECT trial. *First Author: Luca Malorni, Sandro Pitigliani Medical Oncology Department, Hospital of Prato, Prato, Italy*

Background: TK1 plays a critical role in DNA synthesis and cell proliferation. The DiviTum assay measures serum TK1 activity (sTKa), reflecting cancer cell proliferation. Recent studies suggest this assay may provide real time prognostic information in ABC. However, its role in HR+ ABC needs further validation. **Methods:** EFECT (n = 693) was a double-blind, randomized trial of fulvestrant 250mg versus exemestane after progression on nonsteroidal aromatase inhibitor therapy for ABC. 58% of pts had received > 1 prior ET for ABC. sTKa was retrospectively assessed with DiviTum on serum samples from pts in the EFECT cohort. Samples were collected before start of ET (T0), after 3 (T3) and 6 (T6) months of ET, and at disease progression (PD). Pts were categorized as High/Low sTKa at T0 based on the median value. On-treatment sTKa changes were calculated from T0 to the next available time-point within 3 months from randomization (T3, or PD for those pts with early progression - ePD), accounting for a coefficient of variation of 10%, and defined as follows: Drop (T3 or ePD $<$ T0); Increase (T3 or ePD $>$ T0); No change (T3 or ePD = T0). Analyses were conducted regardless of study arms. **Results:** All available samples were successfully tested for sTKa (586 samples from 244 consenting pts). Median sTKa at T0 (n = 227), T3 (n = 135), T6 (n = 80) and PD (n = 137) was 97, 57, 57.5 and 132 Du/L, respectively. Median time to progression (mTTP) for pts with Low T0 sTKa (n = 111) was 5.03 months (m) (95% CI 3.91-5.89) vs 2.57 (95% CI 2.04-3.52) for pts with High T0 sTKa (n = 110) ($p < 0.001$). On-treatment sTKa changes from T0 were analysed in 159 pts (T3 = 116; ePD = 43). mTTP in pts with TK1 Drop (n = 53) was 5.4 m (95% CI 3.7-7.7) vs 3.4 (95% CI 2.1-4.1) in pts with Increase (n = 68) ($p < 0.018$). mTTP in pts with No change (n = 38) was similar to those with Drop. After adjustment for major prognostic factors, sTKa remained an independent marker. **Conclusions:** sTKa is a potential circulating prognostic marker in pts with ABC treated with ET, and may represent a tool for upfront identification of ET-resistant pts, and non-invasive monitoring of response to ET. Independent validation of these results is warranted.

12032 Poster Session (Board #145), Mon, 1:15 PM-4:45 PM

Combining circulating tumor cells and circulating cancer associated macrophage-like cells for accurately predicting responsiveness of new line therapies in late stage cancers. *First Author: Daniel Adams, Creatv MicroTech, Inc., Monmouth Junction, NJ*

Background: The discovery of cancer associated macrophage like cells (CAMLs) as independent prognostic indicators of survival has highlighted the need for more in depth analysis of blood based diagnostics. As CTCs & CAMLs are isolated in parallel from a single blood sample and both are prognostic for therapy response, we hypothesized that monitoring CTCs & CAMLs before and after initiation of therapy might increase their prognostic value in a large array of cancer subtypes. **Methods:** A prospective 2 year blind multi-institutional study was undertaken to evaluate CTCs & CAMLs before, and after, induction of a new line therapy. Patients with breast (n = 12), esophageal (n = 20), NSCLC (n = 23), prostate (n = 12), and SCLC (n = 7) in Stage III (n = 45) or Stage IV (n = 30) disease were recruited. A baseline (BL) blood sample was taken prior to induction of a new therapy and a 2nd sample (T1) taken after initiation of systemic therapy (~30 days). Blood was filtered by CellSieve filtration. The quantities and subtypes of CTCs & CAMLs were analyzed based on OS hazard ratios (HRs) by censored univariate & multivariate analysis. **Results:** CTCs were identified in 16% of patients at BL, with a single CTC being prognostic for OS (HR = 4.8 95%CI1.5-14.9, p = 0.018). Further, CTCs were found in 19% of samples at T1 and also prognostic for OS (HR = 4.3 95%CI1.7-10.7, p = 0.005). However, CTCs were rare in lung (7%), esophageal (5%) and prostate cancers (17%), but common in breast (58%). In contrast, CAMLs were found in 97% of BL, with $\geq 50\mu$m CAMLs being a prognostic for OS (HR = 2.8, 95% CI 1.3-5.9, p = 0.011). At T1, the OS prognostic value of $\geq 50\mu$m CAMLs increased (HR = 3.1 95% CI 1.5-6.6, p = 0.005). Further, after induction of systemic therapy, the presence of both, > 5 CTCs or a $\geq 50\mu$m CAML was 92% accurate at predicting survival of patients within 24 months, with OS HR = 3.4 95%CI1.6-7.2, p = 0.002. **Conclusions:** Our data suggests that simultaneous measurement of both CTCs and CAMLs may increase the prognostic value of blood based diagnostics and may be predictive of benefit of subsequent therapies.

12033 Poster Session (Board #146), Mon, 1:15 PM-4:45 PM

Dynamic change of PD-L1 expression on circulating tumor cells in advanced gastrointestinal tumor patients undergoing PD-1 blockade therapy. *First Author: Chunyan Yue, National Center for Nanoscience and Technology of China, Beijing, China*

Background: Tumor PD-L1 levels have predictive value in PD-1/PD-L1 checkpoint blockade therapies, yet biopsies can only provide baseline information. Whether PD-L1 expression on circulating tumor cells (CTCs) could serve as an alternative biomarker is of great interest. **Methods:** We established an immunofluorescence assay for semi-quantitative assessment of the PD-L1 expression levels on CTCs with four categories (PD-L1^{negative}, PD-L1^{low}, PD-L1^{medium} and PD-L1^{high}). 35 patients with advanced gastrointestinal tumors were enrolled in a phase 1 trial of a PD-1 inhibitor, IBI308. The CTC numeration and the PD-L1 expression levels were analyzed prior the treatment and at the time of therapeutic evaluation. **Results:** Prior the treatment of PD-1 inhibitor, 97% (34/35) patients had CTCs, ranging from1 to 70 (median 7). 74% (26/35) had PD-L1^{positive} CTCs, and 60% (21/35) had at least one PD-L1^{high} CTCs. The disease control (DC) rate in PD-L1^{high} patients (48%) is much higher than the others (14%). The group with at least 20% abundance of PD-L1^{high} CTCs had even higher DC rate of 64% (9/14), with only 14% DC rate for the rest (3/21). We also observed that the count changes of total CTC, PD-L1^{postive} CTC and PD-L1^{high} CTC correlate quite well with disease outcome ($P < 0.001$, $P = 0.002$ and 0.007, respectively). In addition, the abundance of PD-L1^{high} CTCs at baseline had predicative significance for progression free survival (PFS). **Conclusions:** We revealed that the abundance of PD-L1^{high} CTCs at baseline might serve as a predictor to screen patients for PD-1/PD-L1 blockade therapies and measuring the dynamic changes of CTC could indicate the therapeutic response at early time. Clinical trial information: NCT02937116.

12034 Poster Session (Board #147), Mon, 1:15 PM-4:45 PM

Theoretical model and clinical validation of blood tumor mutation burden (bTMB) detection for cancer immunotherapy. *First Author: Jianchun Duan, Department of Medical Oncology, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China*

Background: Tumor mutational burden(TMB) measured by whole exome sequencing (WES) or cancer gene panel (CGP) sequencing, has been identified to be associated with clinical outcome to anti-PD1/PDL1 treatment. However, a considerable proportion of patients(pts) with advanced lung cancer cannot acquire enough tumor tissue for TMB detection. Here, we defined an optimal gene panel for TMB estimation and validated the availability of blood TMB (bTMB) from circulating tumor DNA (ctDNA) in predicting therapeutic efficacy of anti-PD1/PDL1. **Methods:** A theoretical model of measuring TMB by CGP was established including 9205 WES-measured samples of 33 tumor types based on TCGA database. We further designed a panel (CT150) including 62 hotspot genes and 88 lung-cancer related genes, and built a robust bTMB detection pipeline. Correlation of CT150-measured bTMB and WES-measured TMB from paired tumor tissue in 30 NSCLC patients was analyzed to validate our model. Public clinical dataset and an independent clinical cohort were used to evaluate the association of bTMB with the efficacy of anti-PD1/PDL1 treatment. **Results:** Our model demonstrated that at least 100 genes need to be included in CGP when estimating WES based TMB, which was identified being influenced by the choice of hotspot genes, the weight of nonsynonymous mutations and the sequencing depth. In most tumor types, the CT150-measured TMB is highly correlated with WES-measured TMB. The bTMB and WES-based tumor TMB (tTMB) in 30 NSCLC patients is highly correlated. pts with high TMB estimated by CT150 had a significantly longer median progression free survival (mPFS) (14.5 vs 4.1 months, $p = 0.01$) than those with low TMB in the published Rizvi cohort ($N = 34$) . In a pilot study of 12 NSCLC pts treated with PD1/PDL1 inhibitors, pts with bTMB-high (designated as≥8 muts) had higher durable clinical benefit (DCB) rate and longer mPFS than those of bTMB-low (DCB %: 100% vs 42.9%, mPFS: 9.9 vs 2.9 months, $p = 0.03$). **Conclusions:** The designed CT150 panel can be utilized to estimate the TMB in the majority of cancer types. The bTMB estimated by this panel might provide a noninvasive biomarker assay to identify NSCLC pts benefitting from PD1/PDL1 inhibitors.

12035 Poster Session (Board #148), Mon, 1:15 PM-4:45 PM

Correlation of peripheral T cell receptor repertoire with response to neoadjuvant chemotherapy plus trastuzumab in early-stage HER2-positive breast cancer. *First Author: Wenna Wang, Department of Medical Oncology, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College (CAMS & PUMC), Beijing, China*

Background: The immune microenvironment of tumor is now emerging as an indicator of responses to anticancer treatment in HER2-positive breast cancer. However, the peripheral blood (PB) TCR repertoire and its interaction with early-stage HER2-positive breast cancer patients treated with chemotherapy plus trastuzumab have not been systemically studied. **Methods:** We investigated the TCR repertoire using next-generation deep sequencing of the complementarity determining region 3 (CDR3) of the TCR β chain in the PB samples from 26 treatment-naïve hormonal receptor (HR)-negative HER2-positive breast cancer patients before and after 2 cycles of chemotherapy plus trastuzumab and 26 age- and gender-matched healthy volunteers. The patient population was obtained from a single-center prospective study between January 2014 and June 2017 (ClinicalTrials.gov, NCT02041338). **Results:** The TCR repertoire in the pre-treatment PB of patients was markedly different from that of healthy volunteers, exhibiting higher TCR density ($P = 0.0001$) and lower evenness ($P = 0.01$). Patients who achieved a pCR ($n = 11$) had a lower TCR density in their pre-treatment PB ($P = 0.0147$) and a higher degree of overlap between the pre- and post-treatment PB TCR repertoires ($P = 0.0488$) than patients who achieved a non-pCR ($n = 15$). The sequences of V segments of the TCR β chain demonstrated significantly lower frequencies of TCR β variable (TRBV) 3-1, TRBV4-2, TRBV12-3, TRBV12-5, TRBV15, TRBV6-2, and TRBV7-7 genes in the pre-treatment PB samples of the pCR group than in the non-pCR group. There were no significant differences in TCR density, diversity, clonality or evenness between pre- and post-treatment PB samples. **Conclusions:** Based on the current study, the TCR repertoire in pre-treatment PB may be used as a predictor of response to neoadjuvant chemotherapy plus trastuzumab in HR-negative HER2-positive breast cancer patients and as a new approach to select patients who will benefit from neoadjuvant therapy.

12036 Poster Session (Board #149), Mon, 1:15 PM-4:45 PM

Circulating tumor DNA as a potential indicator of tumor load during interventional therapy of unresectable hepatocellular carcinoma. *First Author: Yong Li, Center of Intervention radiology, Zhuhai Precision Medicine Center, Zhuhai People's Hospital,Jinan University, Zhuhai,Guangdong 519000, P.R. China, Guangdong, China*

Background: Hepatocellular carcinoma (HCC) is a common malignant tumor, causing high morbidity and mortality. Interventional treatments have improved survival in unresectable hepatocellular carcinoma. Imageology and serologic biomarkers are major methods to evaluate therapeutic efficacy but limited in radiation exposure and accuracy. This study aims to assess feasibility of ctDNA as a potential biomarker to monitor therapeutic response during interventional treatments of HCC. **Methods:** We enrolled 30 HCC patients from 2016 to 2017. Tumor biopsies and matched pretreatment peripheral blood samples were collected. We implemented target capture NGS to identify somatic variants with a panel of 1021 cancer related genes. Blood tumor mutation burden (bTMB) analysis interrogated single nucleotide variants, small insertion and deletion, with VAF ≥0.5 %. **Results:** Somatic genomic alterations were identified in 29 of 30 tumour biopsies (96.7%). TP53 (%), TERT (37.9%), CTNNB1 (13.8%) mutated most frequently in this cohort. Mutations in TP53 was commonly detected at codon 249(R249S). In matched plasma samples, we identified 28 of 30 (93.3%) patients to be positive before interventional treatment. A consistence of detected mutation between ctDNA and tumors is 90% and presented positive relation with tumour load (Pearson $r = 0.48$, $p = 0.01$). Compared with AFP, ctDNA abundance showed a positive correlation with tumour load ($r = 0.61$, $p = 0.0005$). In addition, TP53-mutated samples showed higher bTMB than TP53-wild samples (5.5 vs 2.4 mut/Mb, $p = 0.03$), suggesting a potential better effect when received treatment of immune checkpoint inhibitors. **Conclusions:** Liquid biopsy can reveal the mutation profile of patients of HCC. CtDNA can be used as a potential tool to reflect the tumor load and guide more precise interventional treatments.

12037 Poster Session (Board #150), Mon, 1:15 PM-4:45 PM

Correlation of expression of TK1 in plasma-derived exosomes with clinical response to CDK4/6 inhibitors in breast cancer. *First Author: Marzia Del Re, Clinical Pharmacology and Pharmacogenetics Unit, Department of Clinical and Experimental Medicine, Pisa, Italy*

Background: Cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) improve PFS in patients with hormone receptor positive (HR+) advanced breast cancer (1). In order to better characterize the response to these agents and increase our knowledge on the pharmacogenetic profile of CDK4/6i, the aim of this study was to analyse the expression of targets relevant to the activity of CDK4/6i in plasma-derived exosomes. **Methods:** Blood samples were collected from patients affected by HR+, HER2- advanced breast cancer receiving a palbociclib in association with hormonal therapy. Three ml of plasma were taken at the beginning of treatment (baseline) and at the first clinical evaluation (after 3 months). Objective responses were defined following the RECIST criteria v.1.1. RNA from plasma-derived exosomes was extracted by the ExoRNeasy kit (Qiagen) and analysed for the expression of thymidine kinase 1 (TK1), CDK 4, 6 and 9 by digital droplet PCR (BioRad). Mann-Whitney test was applied. **Results:** Thirty-eight metastatic breast cancer patients were prospectively enrolled in this study. The comparison of mRNA levels of TK1, CDK4, 6 and 9 between baseline and the first clinical evaluation was available in 5 patients treated with letrozole + palbociclib and 11 patients given fulvestrant + palbociclib. Eight patients had newly diagnosed advanced breast cancer while 9 patients received $>=1$ line of treatment. Objective responses were: 2 (12%) PR, 12 (70%) SD and 3 (18%) PD. The comparison of the expression between TK1, CDK 4, 6 and 9 at baseline and at first evaluation was statistically significant for TK1 (PR+SD vs PD $p = 0.048$). No association was found between the baseline levels of TK1, CDK 4, 6 and 9 and best response or number of disease sites. **Conclusions:** Exosomal TK1 expression may be useful to early identify patients who are likely to respond to CDK4/6i. **Reference:** Finn RS, et al. Analysis of single circulating tumor cells (CTCs) to identify resistance mutations to ALK-inhibitors in both ALK-gene and bypass oncogenic pathways. *First Author: Emma Pailler, Gustave Roussy, Université Paris-Saclay, "Circulating Tumor Cells" Translational Platform, CNRS UMS3655 – INSERM US23 AMMICA, Villejuif, France*

Background: Non-invasive methods including CTCs are crucial to develop for the implementation of precision medicine in the treatment of NSCLC. *ALK*-rearranged NSCLC patients develop resistance to ALK-inhibitors which manifest by genetic alterations either in the *ALK*-gene itself or in by-pass signaling pathways. Here, we evaluated whether resistance mutations to first-generation ALK-inhibitor crizotinib and third-generation lorlatinib could be identified using individual CTCs. **Methods:** The study included 17 patients at resistance to crizotinib or lorlatinib. Matched tumor-biopsies were available for 3. Two CTC isolation strategies were used. A process including Ampli1 whole-genome amplification, quality controls, multiplex PCR with two panels (Ampli1 CHPCustomBeta cancer panel and a home-made panel targeting the 13 known *ALK* mutations) and Ion Torrent next-generation sequencing was established. Single CTCs or pools of 2-10 CTCs and one $CD45^+$ cell pool were analyzed for each patient. A specific bioinformatic workflow was developed to identify somatic variants including determination of positive predicted value (PPV), allele drop-out (ADO), false-positive rate (FPR). **Results:** PPV, ADO and FPR means were respectively $> 95\%$, 19% and 6.10^{-4} in the seven first patients. A limited number of shared mutations between CTCs and matched tumor-biopsies were identified. Several CTC-private (exclusively present in CTCs and not in matched biopsies) hotspots mutations were identified including in *ALK*-gene such as the F1174L, F1174C or G1202R. Potential by-pass signaling pathways in other oncogenic drivers such *TP53, PIK3CA* and *BRAF* genes were also identified. A much higher degree of mutational diversity was observed in CTCs compared to tumor-biopsies. **Conclusions:** Using a rigorously qualified workflow, we report for the first time that resistance mutations to ALK-inhibitors can be identified in individually isolated CTCs of *ALK*-rearranged patients. Our data demonstrate that both "on-target" and "off-target" resistance mechanisms can be detected in individual CTCs highlighting their important mutational diversity in *ALK*-rearranged patients.

12039 Poster Session (Board #152), Mon, 1:15 PM-4:45 PM

Integration of lymphocyte ratios (LRs) and circulating tumor cells (CTCs) characterization: The interplay between immunity and metastatic breast cancer (MBC). *First Author: Lorenzo Gerratana, Department of Medicine-Hematology and Oncology, Feinberg School of Medicine, Northwestern University; Department of Medicine (DAME), University of Udine; Department of Oncology, University Hospital of Udine, Udine, Italy*

Background: The detection of CTCs in MBC is associated with worse prognosis and metastases development. We evaluated the integration of immunity biomarkers such as monocyte, neutrophil and platelets LRs (MLR, NLR, PLR) with CTCs data to identify new clues about the interaction between MBC and the immune system. **Methods:** The study enrolled 44 MBC patients (pts) at the University Hospital of Udine, Italy, between 2013 and 2015, regardless of the line of treatment. $CD45^{neg}$ circulating cells (CC) were sorted through the DEPArray microfluidic system, based on a multiparametric fluorescence analysis. The $CD45^{neg}$ CC phenotypes were defined as epithelial (E CTC), mesenchymal (MES) and transitional (EM CTC). MLR, NLR and PLR cut-offs were previously obtained through ROC analysis using propensity score-matched healthy controls (Gerratana et al 2018). The association between LRs and $CD45^{neg}$ CC was explored through Kruskal Wallis test. CC subtypes were analyzed both as a percentage of total $CD45^{neg}$ CCs and as absolute values. **Results:** In luminal-like MBC pts, both NLR and PLR were significantly associated with EM CTC ($P = 0.016$), while a trend was observed in respect to MLR. In pts with HER2 positive MBC, PLR was significantly associated with E CTC ($P = 0.042$). Notably, only MLR was associated with EM CTC in the total population ($P = 0.02$). Pts with visceral involvement had higher EM CTC and E CTC when MLR^{high} ($P = 0.036$ and $P = 0.031$, respectively) and E CTC when PLR^{high} ($P = 0.025$), while MES was significantly lower when MLR^{high} ($P = 0.001$). In particular, in case of liver localizations, the MLR^{high} subgroup showed higher E CTC ($P = 0.022$) and lower MES ($P < 0.001$). Pts with bone localizations had lower MES when MLR^{high} ($P = 0.004$). Interestingly, MLR^{high} pts with 2 or more sites of distant involvement, had higher EM CTC and lower MES ($P = 0.015$ and $P < 0.001$, respectively). **Conclusions:** MLR is associated with $CD45^{neg}$ CC subtypes proportions. Particularly intriguing is the direct correlation with EM CTCs suggesting an interlink between CTC and immunity in MBC pathogenesis and progression. Moreover, these findings highlight the need to explore more granular classifications for $CD45^{neg}$ CC.

12040 Poster Session (Board #153), Mon, 1:15 PM-4:45 PM

Circulating tumor cells enumeration (CTCs) and circulating tumor DNA (ctDNA): Clinical and molecular features of "rapidly progressing" stage IV disease (Stage IV_{prog}). *First Author: Lorenzo Gerratana, Department of Medicine-Hematology and Oncology, Feinberg School of Medicine, Northwestern University; Department of Medicine (DAME), University of Udine; Department of Oncology, University Hospital of Udine, Chicago, IL*

Background: Liquid biopsy technologies, including CTCs and ctDNA, have a growingly paramount role in the management of advanced breast cancer (ABC) and are potentially capable to convey different types of information. **Methods:** This retrospective study analyzed 62 ABC patients (pts), characterized with paired CTCs and ctDNA assessments. CTCs were isolated through CellSearch and ctDNA was analyzed using the Guardant360 NGS assay. The previously reported cut-off of 5.7 was used for ctDNA percentage (%ctDNA) (Gerratana et al 2018), while 5 count was used for CTCs. Matched pairs variations in %ctDNA and CTCs at baseline (BL), at the 1st evaluation (E1) and at progression (PD) were tested through Wilcoxon test and associations with clinical variables were tested through Kruskal-Wallis test. Their prognostic impact was explored through Cox regression for progression-free survival (PFS), overall survival (OS) and PFS after E1 (E1_PFS). **Results:** CTCs and %ctDNA were comparable in respect to age at BL, while CTCs were marginally higher in luminal ABC ($P = 0.07$). Pairwise %ctDNA varied significantly between BL and E1 ($P = 0.0012$) and E1 and PD ($P = 0.0016$), but not between BL and PD. No significant variations were observed regarding CTCs, apart from triple negative ABC ($P = 0.035$). Both BL %ctDNA and CTCs had an impact in terms of PFS (HR 1.9, $P = 0.02$ and HR 3.4, $P = 0.003$ respectively) and OS (HR 3.5, $P = 0.021$ and HR 16.6, $P = 0.011$; respectively) but only BL CTCs retained its impact on E1_PFS (HR 3.5, $P = 0.015$). On the other hand, both E1 %ctDNA and CTCs had a prognostic impact on E1_PFS (HR 3.2, $P = 0.009$ and HR 3.2, $P = 0.012$; respectively). Pts with an increased ≥ 5.7 %ctDNA or stable ≥ 5.7 %ctDNA between BL and E1, experienced a worse E1_PFS in respect to pts with stable %ctDNA < 5.7 (HR 9, $P = 0.009$ and HR 3.1, $P = 0.043$; respectively); with a median time to progression after E1 of 22 days and 2.53 months each. **Conclusions:** The study suggests that both CTCs and ctDNA provide non-overlapping information about prognosis and treatment benefit. CTCs describes the underlying metastatic biology, while ctDNA gives a more, quantitative, *real-time* assessment of tumor burden and treatment benefit.

12041 Poster Session (Board #154), Mon, 1:15 PM-4:45 PM

Landscape of kinase rearrangements (kRE) detected in circulating tumor DNA (ctDNA). *First Author: Ben C. Creelan, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

Background: kRE are established oncogenic drivers and therapeutic targets across advanced cancers. Increasingly, clinical activity targeting kRE across tumor types has been reported, largely based on tissue analysis. We sought to describe the pan-cancer landscape of predicted driver kRE identified in ctDNA. **Methods:** Blood samples from 8,567 cancer patients underwent hybrid capture-based genomic profiling of ctDNA. We evaluated rearrangements in 6 genes (*ALK, EGFR, FGFR3, PDGFRA, RET, ROS1)* for which selected introns are baited, and 7 others (*BRAF, ERBB2, FGFR1, FGFR2, MET, PDGFRB, RAF1).* Only samples with detectable ctDNA were included in analysis (N = 6,571). **Results:** kRE were observed in 4.9% of lung cancer (LC) cases (N = 2,709) and 2.4% of non-lung (nLC) (N = 3,862), including 223 unique cases (3.4% overall) with 254 kRE events (Table). The most commonly rearranged kinases were *ALK (45%), RET (15%), ROS1* (15%), *FGFR3 (8%), FGFR2* (5%), and *EGFR (4%).* The frequency of kinases altered by kRE varied by anatomic origin, with *FGFR2* events identified only outside lung cancer ($p < 0.001$) (Table 1). Top recurrent kRE were *EML4-ALK* (61 LC + 7 nLC), *FGFR3-TACC3* (7 + 11), *KIF5B-RET* (9 + 2), *CD74-ROS1* (9 + 1), and *CCDC6-RET* (5 + 3). Comparison with > 70,000 tissue genomic profiles analyzed over the same time period showed *ALK*, *RET*, or *ROS1* kRE in 4.3% of ctDNA and 4.9% of tissue LC samples, and 1.3% of nLC ctDNA and 0.4% of tissue nLC. 65% of kRE detected in ctDNA were also detected in paired tissue samples (N = 43), including 9 of 11 collected < 30 days apart. **Conclusions:** Kinase fusions and rearrangements exist across tumor types and can be detected by liquid biopsy. Comparison of genomic profiles of ctDNA to tissue suggest similar frequencies of *ALK*, *RET* or *ROS1* kRE in lung, but a higher frequency of kRE in non-lung samples by ctDNA vs tissue, perhaps reflecting greater heterogeneity.

ctDNA-detected kRE across solid tumors.

Cancer	Total N	N with kRE	%	*ALK*	*RET*	*ROS1*	*FGFR2*	*FGFR3*	*EGFR*
Lung	2709	134	4.9%	78	20	19		7	4

12042 Poster Session (Board #155), Mon, 1:15 PM-4:45 PM

Circulating tumor DNA as biomarker in mutant malignant melanoma. *First Author: Jan Braune, Department of Hematology and Oncology, University Medical Center, Freiburg, Germany*

Background: Available biomarkers LDH and S100B possess limited sensitivity and specificity to predict outcome in melanoma. In this pilot study we evaluated the use of circulating tumor (ct)DNA harboring BRAF and NRAS mutations as a predictive biomarker for treatment response and progression-free survival (PFS) in patients with locally advanced or metastatic melanoma. **Methods:** We analyzed 168 retrospective plasma samples from 40 unselected pts, and 311 samples from 33 pts included in a prospective trial (DRKS00009507). We included stage III disease with planned resection or stage IV disease before initiation or change of medical treatment. Blood samples were taken at baseline at d +8, d +28, and thereafter at 3 months intervals for up to two years. We developed hydrolysis probe based, Locked Nucleic Acid assays to detect BRAF, NRAS and wild type ctDNA by droplet digital PCR. Results were correlated with LDH, S100B and PFS. **Results:** Sensitivity of the specific assays was 0.01% with a limit of Blank of 0.28 copies/well. Of 37 stage IV pts with retrospective samples, 29 were positive for ctDNA at least once (78%). Out of eight negative pts, three were in CR, three had SD, and two were negative despite measurable disease. Positive pts had a mean of 9 (range: 1-17) and 283 (range: 0.1-16,388) ctDNA copies/mL for stage III and stage IV respectively. The presence of ctDNA one month after therapy initiation indicated poor PFS (hazard ratio [HR] 1.9, 95% CI 0.85-4.44). No measureable increase in ctDNA was a favorable prognostic factor for PFS for all therapies (hazard ratio [HR] 0.30, 95% CI 0.05-2.56) with a median PFS of 4.5 vs. 3.1 months (range 0.9-17.5 vs. 1.5-9.1) and particularly for those receiving Immunotherapy (hazard ratio [HR] 0.07, 95%CI 0.007-0.68) with a median PFS of 8.8 vs. 2.6 (range 1.8-17.5 vs 1.5-3.1). Based on 290 measurement pairs, ctDNA strongly correlated with S100 (r = 0.73) and LDH (r = 0.52). **Conclusions:** Residual ctDNA early after change or institution of treatment predicted tumor progression at first clinical response assessment. A positive to negative conversion or a decrease indicated a more favorable course especially for those receiving immunotherapy. These data support the use of ctDNA as an early predictive marker for treatment response. Clinical trial information: DRKS00009507.

12043 Poster Session (Board #156), Mon, 1:15 PM-4:45 PM

Predictive tools for bevacizumab therapy in patients with aggressive HER 2-negative metastatic breast cancer: 2-years results from an observational study. *First Author: Encarnación González Flores, H. Virgen de las Nieves, Granada, Spain*

Background: The determination of monitoring Circulating Tumor Cells (CTC) in patients (pts) with metastatic breast cancer (MBC) is a well-established prognostic marker of efficacy/tolerance. We aimed to determine the predictive value of the normalization of CTC in terms of clinical benefit. **Methods:** Multicenter, prospective, observational study in pts with aggressive HER2-negative MBC amenable to receive first-line treatment with chemotherapy plus bevacizumab. A 18-month follow-up is planned. CTC levels were determinated in baseline (BL) and after the first cycle. The Spearman correlation coefficient was calculated to CTC and biomarkers. Interim analysis of 2-years with data on the correlation and progression free survival (PFS). **Results:** At database cut, 111 evaluable pts were enrolled: median (range) age 54.1 (46.4-61.3) years; ECOG 0/1: 50.5/39.6%. Median (range) time from diagnosis was 2.9 (0.8-7.2) years, and 28.8% of pts were "di novo" MBC. Neoadjuvant and/or adjuvant therapy was received by 70.3% pts and 73.0% underwent surgery. Histological grade III found in 49.3% of pts; ER-positive in 74.6% and PR-positive in 50.8%. Metastases were mainly located in liver (62.2%), bone (57.7%) and lung (40.5%). Mean (SD) CTC levels: 83.4 (333.8)/7.5 mL BL and 3.6(10.3)/7.5 mL after first cycle. According to this change, 89.5% were sensitive. Discontinuation in 28 pts (75.0% exitus; 3.6% progression). A 3.5% had complete response, 50.6% partial response and 25.9% stable disease. Median follow-up was 8.2 (5.3-12.9) months. The median PFS was 11.0 (6.6-15.4) months. Median overall survival was not reached. BL CTC levels had a significant correlation with CEA ($p < 0.05$) and CA 15.3 ($p < 0.001$). Overall, 79.3% pts presented at least one toxicity. Most common grade III/IV toxicities were hypertension (8.1%), peripheral neuropathy (3.6%), neurotoxicity (3.6%) and neutropenia (2.7%). Two grade V toxicities reported abdominal sepsis and pain upper. **Conclusions:** The preliminary data shows a correlation with CTC levels and other tested biomarkers. No safety concerns were addressed.

12044 Poster Session (Board #157), Mon, 1:15 PM-4:45 PM

A priori filtering of post-operative (post-op) circulating tumor DNA (ctDNA) to predict recurrence in post-metastasectomy colorectal cancer patients (CRC pts) without knowledge of tumor genotype. *First Author: Michael J. Overman, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: ctDNA in post-op CRC pts correlates with molecular residual disease and may be useful to guide adjuvant therapy. However, initial studies employed clinically impractical assays indexed to individual pt-specific tumor tissue-defined mutations or were confounded by non-tumor-associated somatic alterations, including variants related to clonal hematopoiesis. **Methods:** 51 CRC pts undergoing curative intent metastasectomy were prospectively recruited at a single institution. Pre and post-op (1-17 days) plasma was sequenced to high depth using a 23-gene NGS panel with 96% theoretical sensitivity for CRC. Tumor tissue was sequenced using this panel or local testing. ctDNA profiles from 4000 CRC pts (Guardant Health) were used to train a variant classifier to predict truncal CRC mutations. **Results:** At median follow up of 10 months (range 1.2-57.7), 37 of 51 pts recurred (median 7.8 months, range 1.2-34.5). Based on post-op mutation detection alone, ctDNA was identified in 31 of 36 recurrent (sensitivity 86% [71-96%]) and 9 of 15 non-recurrent pts (specificity 60% [32-84%]). When restricted to variants detected in tumor tissue, ctDNA was identified in 14 of 31 recurrent (sensitivity 38% [27-64%]) and 0 of 10 non-recurrent pts (specificity 100% [69-100%]). When filtered by the variant classifier, post-op ctDNA was found in 18 of 36 (sensitivity 50% [33-67%]) recurrent pts and 0 of 15 non-recurrent pts (specificity 100% [78-100%]). Median somatic allelic fraction was similar after tumor tissue- and classifier-based filtering (median 0.48% vs. 0.65%, range 0.02-20.0%). **Conclusions:** Recurrence prediction using post-op somatic variant detection alone is fraught by a high clinical false positive rate. Filtering using tumor tissue is effective but reduces sensitivity substantially and is clinically impractical. However, filtering using a variant classifier without knowledge of tumor genotype eliminated false positives and maintained clinical sensitivity in this cohort. *A priori* variant classification may enable clinically feasible ctDNA diagnostics for adjuvant decision making in early-stage disease.

12045 Poster Session (Board #158), Mon, 1:15 PM-4:45 PM

Mutation count, a potential surrogate for tumor mutation load, of circulating tumor DNA (ctDNA) using targeted panel sequencing correlates with clinical outcomes in late stage lung adenocarcinoma and small cell lung cancer. *First Author: Stephanie Yaung, Roche Sequencing Solutions, Pleasanton, CA*

Background: Studies show that mutation count can be used as a biomarker to predict whether or not a patient may respond to immunotherapy or chemoradiation therapy. However, mutation count is usually determined by whole exome sequencing or large targeted panel sequencing of tumor tissue DNA. Tissue biopsy is often inaccessible for many late stage lung cancer patients. **Methods:** We assessed mutation count using the AVENIO ctDNA Surveillance Kit, a targeted next-generation sequencing panel of 198 kilobases, on pre-treatment plasma samples from a prospective, observational study, where 43 late stage lung adenocarcinoma and 72 late stage small cell lung cancers (SCLC) treated with first-line chemo or chemoradiation therapies were initially assessed. Synonymous and prevalent driver mutations were filtered out from the detected somatic mutations prior to calculating a mutation count per megabase. Subjects were classified as high mutation count if the filtered somatic mutation count was above the bottom tertile of their cancer type. **Results:** We detected somatic variants in all 43 lung adenocarcinoma and 72 SCLC subjects with a median mutation count of 9 and 14, respectively. Lung adenocarcinoma subjects with low mutation count showed better survival in terms of overall survival (OS) (18.3 vs 7.8 mo, HR 0.41, p = 0.026) and progression free survival (PFS) (6.2 vs 4.3 mo, HR 0.51, p = 0.042). SCLC subjects with low mutation count had shorter OS (9.3 vs 14.1 mo, HR 1.75, p = 0.034) and a similar trend in PFS. **Conclusions:** We were able to derive a ctDNA-based mutation count from a panel the size of one-fifth of a megabase and identified an association between low mutation count and better prognosis in subjects with late stage lung adenocarcinoma treated with chemo or chemoradiation therapy. In late stage SCLC, however, high mutation count correlated with better prognosis. Our findings suggest differences in lung cancer histology are key to understanding measurements of mutation count and their potential to predict outcome on chemotherapy. Studies to further validate these results are ongoing.

12046 Poster Session (Board #159), Mon, 1:15 PM-4:45 PM

Use of cell-free DNA for management of breast and lung cancer by academic and community providers. *First Author: Roby Antony Thomas, University of Pittsburgh Medical Center, Pittsburgh, PA*

Background: Next-generation sequencing of cell-free DNA (cfDNA) can assess presence of somatic genomic alterations in patients with cancer without an invasive biopsy. Results may guide therapeutic decision-making. We evaluated use of cfDNA test results for management of breast and lung cancer in a major healthcare system with academic and community-based practices. **Methods:** Retrospective review of cfDNA tests (Guardant360) ordered for patients with breast or lung cancer at the University of Pittsburgh Medical Center between 8/2014 and 3/2017 was performed. For patients with actionable results (lung: alterations with FDA-approved or NCCN-recommended targeted therapy; breast: ERBB2, ESR1 or PIK3CA alterations), information on clinical care was abstracted. Differences in clinical use of test results were evaluated between academic and community providers. **Results:** In total, 230 tests were ordered for 218 subjects; 128 by academic and 102 by community providers. Community providers ordered significantly ($P < 0.05$) more tests for lung cancer patients than academic providers (78% vs. 47%) and their patients were older (mean age: 65.5 vs. 60.3 yrs.). Actionable alterations were identified in 82 subjects (38%; 48 breast, 34 lung). Six were excluded from further analyses because their mutations had been known previously. For 32 (42%) of the remaining 76 subjects, actionable results led to a change in therapy, for the other 44 it did not. Reasons for not changing therapy included: patient died or lost to follow up, palliative care elected, treatment targeted a different molecular finding, targeted therapy recommended but cost prohibitive, and patient currently stable but results could guide therapy at progression. Actionable results significantly more often resulted in a management change for lung cancer than breast cancer (63% vs. 28%). Use of test results differed significantly between academic and community providers (result led to change: 31% vs. 61%) **Conclusions:** Results of cfDNA tests were used to guide therapy changes, especially for patients with lung cancer. Community practice-based providers appear to act on actionable results more often than academic center-based providers in this health care system.

12047 Poster Session (Board #160), Mon, 1:15 PM-4:45 PM

Liquid biopsies (LB) across treatment of 29 metastatic colorectal cancer (mCRC) patients (pts) to reveal driver mutations and tumor evolution with anti-EGFR therapy: Experience in a GI oncology clinic at Fox Chase Cancer Center. *First Author: Pooja Ghatalia, Fox Chase Cancer Center, Philadelphia, PA*

Background: LB captures dynamic genomic alterations (alts) across mCRC therapy and may complement tissue biopsy (TB). We sought to describe the utility of LB and better understand mCRC biology. **Methods:** We identified 29 pts with mCRC who underwent LB (Guardant360; 2016-17). We used non-parametric methods to measure correlations between alts, highest allelic fraction (maxpct) and clinical variables. We used Kendall's tau to describe correlations. **Results:** Of 29 pts, 14 (48.2%) were women; 17 (58.6%) had colon and the rest rectal cancer. Pts received a median of 2 (range 0-7) lines of therapy before LB. 15 pts had limited testing on TB (*RAS/RAF/TP53/APC*), 11 had extended NGS and 2 no TB. Of 3 pts with 0 alts in LB, only 1 had NED on CT. LB was performed due to inability to get TB in 5 pts and to assess mutation load or targetable alterations in 24 pts. Median maxpct was 11% (range 0-83.9%). Median number of alts was 5 (range 0-43). One pt with MSI-H on TB had LB 11 alts while a pt with 27 alts was MSS. MSI status was not done in 1 pt with 43 LB alts. Maxpct and alts correlated with CEA ($p = 0.002$, $p < 0.001$, respectively). In 3/5 pts with serial LB, CEA correlated with maxpct trend and CT tumor burden. In 6 pts mutant *RAS* was seen in LB only; 5/6 had received anti-EGFR therapy prior to LB, suggesting *RAS* alts developed post-therapy. In 2 pts *RAS*-mutated by TB, no *RAS* alts were detected on LB, due to low disease burden on CT at time of LB that also did not reveal *APC* or *TP53* alts. In 1 pt with serial LB, a *KRAS* alt was found in TB and the first LB but subsequent LB showed no *KRAS* alts post-treatment. Mean number of alts was higher post anti-EGFR LB (n = 12) vs anti-EGFR naïve LB (n = 24) (10.6 vs 5.3, p = 0.009). More alts were also noted in post anti-EGFR therapy LB vs *KRAS* wt anti-EGFR-naïve LB (n = 8) (10.6 vs 4.9, p = 0.055) and *KRAS* mutant anti-EGFR-naïve LB (n = 16) (11.6 vs 5.6, p = 0.056). 1 pt had LB pre- and post-anti-EGFR therapy but alts remained the same. **Conclusions:** LB across mCRC therapy detects driver mutations, monitors disease burden, and identifies sub-clonal alts that reflect drug resistance, tumor evolution and heterogeneity.

12048 Poster Session (Board #161), Mon, 1:15 PM-4:45 PM

Duvelisib inhibition of chemokines in patients with CLL (DUO study) and iNHL (DYNAMO study). *First Author: David T. Weaver, Verastem, Inc., Needham, MA*

Background: Duvelisib (IPI-145) (DUV) is an oral dual inhibitor of phosphoinositide 3-kinase (PI3K)-δ and PI3K-γ being developed to treat B-cell malignancies. PI3K-δ inhibition directly targets proliferation and survival of malignant leukemia and lymphoma cells, while PI3K-γ inhibition modulates the tumor microenvironment (TME) through key support cells, including tumor-associated macrophages, nurse-like stroma and T cells, and via soluble factors stimulating tumor growth, survival and migration. The Phase 3 DUO study in relapsed/refractory (RR) CLL/SLL and the Phase 2 DYNAMO study in RR iNHL both met their primary endpoints (Flinn, ASH 2017; Zinzani EHA 2017). **Methods:** DUO (NCT02004522) pts were randomized to DUV (n = 160) or ofatumumab (OFA) (n = 159). DYNAMO (NCT01882803) pts (n = 129) received DUV. Serum from baseline and C2D1 was used for correlative studies of 24 chemokines, cytokines and serum factors. Bonferroni-Holm adjustment for multiple comparisons was applied. **Results:** In DUO, CCL1, CCL17, CXCL9, CXCL10, CXCL11, and IL-10 were reduced in pts treated with DUV (median % inhibition = 43.8%) but not in those treated with OFA ($p \leq 0.0009$). Eight chemokines were reduced in both treatment arms, but the level of reduction was significantly greater for DUV pts (median % inhibition, DUV 64.6% vs OFA 26.8%; $p \leq 0.001$). Many of the chemokines inhibited following DUV treatment are associated with the TME, including TNFα, IL-10, IL2Rα, IL12P40, CCL1, CCL17, CCL19, CXCL9, CXCL10, CXCL11, and CXCL13. In DYNAMO, 13 corresponding chemokines were also inhibited ($p \leq 0.008$), including TME factors. Reductions occurred rapidly (by C2D1) in both studies. In DUO, there was a correlation between duration of response and reduction (highest quartile) of the following chemokines: CCL17 (19.4 mo. Q4 vs 10.4 mo. Q1-3), CXCL11 (14.9 mo. Q4 vs 10.9 mo. Q1-3) IL-6 (16.6 mo. Q4 vs 10.9 mo. Q1-3), TRAIL (24 mo. Q4 vs 10.3 mo. Q1-3), VEGF_D (24 mo. Q4 vs 10.9 mo. Q1-3), TPO (14.9 mo. Q4 vs 10.9 mo. Q1-3). **Conclusions:** Pts with CLL and iNHL treated with DUV monotherapy showed significant reduction of chemokines potentially derived from the tumor cells and TME. Further investigation of the effects of DUV on TME pharmacodynamic markers is warranted. Clinical trial information: NCT02004522; NCT01882803.

12049 Poster Session (Board #162), Mon, 1:15 PM-4:45 PM

Immunoprofiling in intrahepatic cholangiocarcinoma (IHCC). *First Author: Roberto Carmagnani Pestana, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Molecular profiling has become important in directing therapy for IHCC, while not much has been described about the immune environment of this disease. Understanding the immune milieu could highlight potential options for immunotherapy (IT). **Methods:** We performed a retrospective institutional review of 99 surgically resected IHCC from February 2007 to November 2016. Immunohistochemistry was performed using 13 immune antibodies including CD3, CD4, TIM-3, PD-1, and ICOS. Overall survival (OS) was defined as the time from surgery to death date or last follow-up (f/u). OS was estimated by Kaplan-Meier method, and differences were assessed by two-sided log-rank tests. Cox proportional hazards regression models were used to assess association between pt characteristics and OS. **Results:** Median age: 62 yrs (range, 24-83), females (61%), T stage (T1/T2; 75%), w/o metastasis (90%), and w/o neoadjuvant chemotherapy (NACT) (73%). Median f/u among survivors :3.0 yrs (range 0.04 to 9.1). Median OS was 6.3 yrs (95% CI: 3.6 – NE). Among B- and T-lymphoid cells, $CD3^+$ T-cells represented the dominant population and were predominantly located in the invasive margin (IM). Positivity for PD-1 was seen in 4.7 centrally located, tumor infiltrative lymphocytes (CL-TI)/mm^2 and 14.2 CL-TI/mm^2 were positive for TIM-3. Univariate Cox analysis revealed that longer OS was significantly associated w/ a high number of CL-TI CD3+ (HR 0.78; p=.044) and CD4+ (HR 0.76; p=.05) immune cells, and lower CL-TI TIM-3+ cells (HR 0.87; p=.01). *Multivariate Cox analysis* demonstrated *that* lower number of CL-TI TIM-3+ cells (HR 0.87; p=.01) was an independent predictor of improved OS. Expression of CL-TI TIM-3+ cell was significantly associated with higher CL-TI CD3+ ($p<.001$), CD4+(p=.003), and PD1+ ($p<.001$) immune cells. Expression of a membrane-bound form of B7-H4 was significantly increased in pt that received NACT (p=.013). **Conclusions:** Our findings identify CL-TI CD3+/CD4+ and TIM-3 expression as independent prognostic factors following surgical resection in IHCC and shed light on changes in immune markers with NACT. This study represents one of the largest analyses of the immune environment of IHCC and suggests potential targets for drug development with IT in this disease.

12050 Poster Session (Board #163), Mon, 1:15 PM-4:45 PM

Immunologic and clinical implications of CD73 expression in non-small cell lung cancer (NSCLC). *First Author: Lee Chun Park, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: CD73, known as ecto-5'-nucleotidase and encoded by the *NT5E* gene, is a pivotal enzyme that converts extracellular adenosine monophosphate (AMP) into adenosine, which promotes tumor growth by impairing anti-tumor T cell immunity. Several preclinical studies noted that the pharmacologic inhibition of CD73 led to improved immune response and thus highlighted the value of CD73 as a therapeutic target for cancer immunotherapy. **Methods:** CD73 expression was explored from The Cancer Genome Atlas (TCGA) database including patients with adenocarcinoma (n = 517) and squamous cell carcinoma (n = 501) of the lung. We stratified samples based on mRNA expression level (low, low-intermediate, intermediate-high, high). Immune profiling (immune cell infiltration, immune checkpoints, and cytokines), tumor mutational burden (TMB), neoantigen burden, and survival outcome were analyzed between the CD73 high group (CD73-H) and CD73 low group (CD73-L). The tumor immune landscape was analyzed using the signatures derived from 812 'immune metagenes' that predict the immune infiltration of 31 distinct immune cells for each tumor sample (Angelova, M. *et al*, 2015). **Results:** In NSCLC, CD73-H showed significantly lower infiltration of activated CD4 and CD8 T cells compared with CD73-L (41% vs 20%, $P< 0.01$; 47% vs 28%, $P< 0.01$ respectively). In addition, PD-L1 (*CD274*), *ICOS*, *TGFB1*, and *IL1B* expression positively correlated with CD73 expression. However, TMB and neoantigen burden demonstrated no significant differences between the two groups. CD73-H had significantly shorter overall survival (OS) and disease free survival (DFS) compared with CD73-L (OS median 62 vs 44 months, $P< 0.01$; DFS median 83 vs 34 months, $P< 0.01$). Additionally, CD73 expression was significantly increased in samples with EGFR mutations when compared with wild type (mean z-score 0.77 vs -0.06, $P= 0.03$). **Conclusions:** This is the first report to illustrate an inverse association between CD73 expression and tumor infiltration of activated CD4 and CD8 T cells, as analyzed in over 1,000 human lung cancer samples. In addition, CD73-H demonstrated unfavorable survival outcome compared with CD73-L. CD73 remains a promising target for cancer immune modulation.

12052 Poster Session (Board #165), Mon, 1:15 PM-4:45 PM

TP53 mutations and programmed cell death ligand-1 expression in solid tumors: Associations with clinical factors and outcomes. *First Author: Ed Kheder, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The regulation of Programmed cell death ligand-1 (PD-L1) expression remains poorly understood. Preclinical data suggest that TP53, via microRNA-34, regulates PD-L1 expression in lung adenocarcinoma cell-line. We aimed to estimate the correlation between TP53 mutations and PD-L1 expression in solid tumors. **Methods:** We reviewed pathology, immunohistochemical (IHC) and mutational analysis reports of patients who were diagnosed with advanced solid tumors and treated at MD Anderson Cancer Center. We used Kaplan-Meier, logistic regression, and Cox PH regression, for statistical analysis. Survival was computed from date of biopsy used for mutational analysis. **Results:** We analyzed data from 302 patients [136(45%) female, 163 (55%) male; median age: 57 years, range (16-83); median OS: 43 month]. One hundred and three (34%) patients had TP53 mutations, 105 (35%) patients had PD-L1 $\geq$ 1%, and 50 (18%) had both. Tumor types (%): GI 41 (14%); GU 36 (12%); non-small cell lung cancer (NSCLC) 54 (18%); melanoma 40 (13%); sarcoma 27 (9%); head and neck (HNC) 21 (7%); others 83 (27%). The association between TP53 mutations and tumoral PD-L1 expression was significant across all patients [OR: 2.47, 95%CI (1.5-4.07). p = 0.0003], but changed significantly with tumor type (p = 0.021): OR: 5.3 sarcoma; 5.2 "other"; 3.6 NSCLC; 1.4 melanoma; 1.1 GU; 0.7 GI. The odds of PD-L1 expression increased with age [30 year increase OR: 1.84, 95%CI (1.01, 3.38). p = 0.044], but not sex [OR: 1.0, 95%CI (0.6, 1.7). p = 0.87]. TP53 mutation was associated with worse OS [HR = 1.6, 95% CI (1.1, 2.2). p = 0.010] and PD-L1+ with better OS [HR = 0.6, 95% CI (0.4, 0.8). p = 0.0042]. The effect of PD-L1 on OS did not depend on TP53 mutation status (p = 0.37). Among PD-L1+ and PD-L1- patients, OS was related to tumor type ($p < 0.004$). One-year survival rate of patients treated with PD-1 or PD-L1 inhibitors in phase I trials was independent of PD-L1/TP53 status (p = 0.53). **Conclusions:** PD-L1 expression is multifactorial. TP53 mutations are highly associated with PD-L1 expression across solid tumors but association significantly varies among tumor types.

12053 Poster Session (Board #166), Mon, 1:15 PM-4:45 PM

GBR1302: Effect of CD3-HER2, a bispecific T cell engager antibody, in trastuzumab-resistant cancers. *First Author: Jonathan Back, Glenmark Pharmaceuticals SA, La Chaux-De-Fonds, Switzerland*

Background: Current therapies targeting HER2 overexpressing cancers, such as Herceptin (trastuzumab) and Kadcyla (T-DM1), have proven beneficial but therapeutic benefit is limited by many resistance mechanisms. Checkpoint inhibition therapies demonstrate the potential of mobilizing T cell activities to elicit anti-tumor responses, but these T cell tumor-specific immune responses are highly immune contexture-dependent. Using Glenmark's BEAT platform, we developed GBR 1302, a T cell redirecting antibody targeting CD3 and HER2, as an alternative way of leveraging T cell potency against tumor cells, independently of existing tumor immune response. **Methods:** In vitro cytotoxic assays. In vivo tumor models. Ex vivo assay recreating native TME, including immune compartment, stroma and vasculature. **Results:** Preclinical pharmacology studies demonstrated that GBR 1302 can trigger a potent killing of HER2 positive (IHC3+) as well as HER2 equivocal (IHC2+) cancer cells while maintaining an acceptable therapeutic window on cells expressing normal levels of HER2. In vitro assays, as well as in vivo tumor models comparing the potency of GBR 1302 to trastuzumab or T-DM1 demonstrated a superior cytotoxic potential for GBR 1302 against a variety of tumor cells and that GBR1302 is effective in trastuzumab resistant tumors in vitro and in vivo. To further translate these observations into a clinically relevant human context, we studied the effects of GBR1302, as a single agent and combination partner, in a patient derived tumor microenvironment matched ex vivo assay with co-culture of autologous immune system and tumor tissue from 50 subjects with varying levels of HER2 expression ranging from 3+ to 1+. GBR 1302 treatment arm was compared to trastuzumab and to a combination of GBR 1302 + a PD-1 inhibitor on metastatic breast, gastric and gastro-esophageal cancers. GBR 1302 is currently in a phase 1 dose escalation clinical trial in HER2 positive and equivocal cancers. Preliminary data from peripheral blood biomarkers indicate that GBR 1302 triggers relevant T cell activation and cytokine production.

12054 Poster Session (Board #167), Mon, 1:15 PM-4:45 PM

Isolation of CD4$^+$ T cells specific for neoantigens created by recurrent driver mutations in non-small cell lung cancer (NSCLC) and melanoma. *First Author: Joshua Veatch, Hutchinson Cancer Rsrch Ctr, Seattle, WA*

Background: T cells specific for neoantigens encoded by mutated genes are increasingly recognized as mediators of tumor destruction after immune checkpoint inhibitor therapy or adoptive cell transfer. Unfortunately, almost all neoantigens result from random mutations that are patient-specific. Here, we describe CD4$^+$ T cell responses one melanoma patient and two NSCLC patients that are specific for recurrent driver mutations in their cancers. **Methods:** Neoantigen-reactive T cells were expanded and cloned by peptide stimulation of the peripheral blood from cancer patients. **Results:** The melanoma patient had a CD4$^+$ T cell response to the peptide encoded by the BRAF V600E mutation found in 40% of melanoma, and obtained a complete response following adoptive transfer of tumor infiltrating lymphocytes (TIL). The BRAF V600E specific cells showed a Th1 memory phenotype, were preferentially localized to the tumor at the time of resection, and expanded and persisted in blood greater than 2 years after TIL therapy. Gene transfer of the BRAF V600E-specific T cell receptor (TCR) conferred recognition of class II MHC positive cells expressing the BRAF mutation. A CD4$^+$ T cell response specific for KRAS G12V that is present in 5% of NSCLC and 10% of colon cancer was detected in one NSCLC patient. A second NSCLC patient had a CD4$^+$ T cell response specific for the Her2 internal tandem duplication (ITD) found in 4% of NSCLC, and deep sequencing of TCR genes showed the mutation-specific T cell clone was enriched in a tumor resection sample, relative to the non-adjacent lung. The CD4$^+$ T cells specific for the BRAF V600E, KRAS G12V, and Her2 ITD epitopes only recognized the mutant and not the wild-type peptide and were restricted by common class II HLA alleles found in 10-25% of the population. The neoantigen reactive Her2 and KRAS reactive TCRs are currently being cloned. **Conclusions:** This study greatly expands the number of driver mutations with known T cell responses, and suggests that adoptive transfer or vaccination strategies targeting recurrent driver mutations could help interrogate the role of CD4$^+$ T cells in human anti-tumor immunity, and could have clinical activity across multiple patients.

12055 Poster Session (Board #168), Mon, 1:15 PM-4:45 PM

Synergy of TLR4 agonist GSK1795091, an innate immune activator, with agonistic antibody against co-stimulatory immune checkpoint molecule OX40 in cancer immunotherapy. *First Author: Hua-Xin Gao, GSK, Collegeville, PA*

Background: GSK1795091 (aka, GSK'091) is a synthetic glycolipid toll-like receptor 4 (TLR4) agonist. TLR4 is a Pattern Recognition Receptor for host defense against bacterial infection, expressed on innate immune cells monocytes, macrophages, dendritic cells. GSK'091 is a potent and selective TLR4 agonist and is being evaluated for use in combination with other immunotherapies to treat cancer **Methods:** To understand the antitumor activity and pharmacologic effects of intravenously administered GSK'091, *in vivo* studies were performed in murine syngeneic tumor models. Pharmacodynamic (PD) effects of GSK'091 was examined in peripheral and tumor infiltrating lymphocytes (TILs) using multicolor flow cytometry assays. Additionally, TCRβ sequencing, Nano string and multiplex cytokine assays were employed to understand the molecular and cellular mechanisms induced by this molecule **Results:** GSK'091 potently activated the immune system and modulated the tumor microenvironment by inducing an array of proinflammatory cytokines, enhancing antigen presentation, activating T cells, and reducing T regulatory cells. At doses sufficient to induce systemic cytokines in mice, GSK'091 inhibited tumor growth and resulted in long term survival in tumor model. When administrated with OX86, a murine surrogate OX40 agonist monoclonal antibody (mAb), the combination induced a robust PD response as demonstrated by a significant increase in Th1 cytokines, expression of interferon regulated genes, higher tumor infiltration by leucocytes, increase in T cell activation , proliferation and increase in the CD8: Treg ratio. Additionally, GSK'091 when combined with anti-OX40 induced clonal expansion of T-cells and drove synergistic interferon and T-cell dependent anti-tumor response **Conclusions:** The current study demonstrated that GSK'091 activates key initiating immune pathways and can induce robust anti-tumor efficacy when combined with agonistic antibodies directed against the OX40 receptor. This novel combination provides a strong rationale and supports evaluation of GSK'091 in combination with immuno-oncology agents in clinical trials

12056 Poster Session (Board #169), Mon, 1:15 PM-4:45 PM

Dependency of radiotherapy and combinatorial radio-immunotherapy responses on the systemic t cell immune response. *First Author: Kevin Lee Min Chua, National Cancer Centre Singapore, Singapore, Singapore*

Background: Combinatorial immune checkpoint blockade (ICB) with radiotherapy (RT) potentiates anti-tumour response via modulation of the immune microenvironment. However, detailed host-specific mechanisms underpinning dramatic clinical responses of RT-ICB are poorly understood. Here, we performed deep characterization of the systemic immune response in circulating T cells following treatment with RT and RT-ICB. **Methods:** We recruited a cohort of 29 patients with biopsy-proven metastatic cancers (10 prostate, 10 EBV+ nasopharynx, 9 others) who underwent RT (N = 13) or RT-ICB (N = 16; anti-PD1/-PDL1/-CTLA4), under a prospective observational study protocol. All patients received ablative RT (8-50 Gy in 1-5 fractions). Patient blood samples were longitudinally collected at following timepoints: baseline, 2 d, 7 d, and 14 d post-RT/RT-ICB. Circulating T cells were profiled by a customized CyTOF panel of 41 T cell surface markers, and analyzed using the t-SNE method (ACCENSE v3.0). **Results:** Median follow-up was 3.6 mo (0.5–8 mo). At time of reporting, 26 of 29 patients had evaluable lesions; response of any kind was observed in 9 of 12 cases in the RT cohort and 12 of 14 cases in the RT-ICB cohort. However, we observed increased complete response rates at 1 mo in the RT-ICB than RT group (50% vs 8%). Additionally, we observed abscopal responses in 2 of 14 RT-ICB cases. We detected significant shifts in the CD8+ and CD4+ T cells that peaked 7 d post-RT ($P < 0.001$). Interestingly, the majority of responses (67%) involved the expansion of a distinct immunophenotype of elevated Tbet^{Dim}CD28^{high} effector memory CD8+ and CD4+ T cells post-RT. These responses were reproduced in the RT-ICB cohort; in particular, CD28^{high}CD27^{high} CD4+ T cells were increased in the exceptional responders ($P = 0.027$). Lastly, for a patient with abscopal response, this was associated with a 25% reduction of TH2 CD4+ T cells. **Conclusions:** Here, we characterized the systemic immune repertoire of circulating CD8+ and CD4+ T cells in response to RT, either alone or in combination with immunotherapy. Our data suggests that expansion of a distinct CD28^{high}CD27^{high} CD4+ T cell population may account for the dramatic responses to RT-immunotherapy.

12057 Poster Session (Board #170), Mon, 1:15 PM-4:45 PM

Association of Akt inhibition with change in immunophenotype of tumor microenvironment (TME) in breast cancer (BC). *First Author: Douglas Kanter Marks, Columbia University Medical Center, New York, NY*

Background: The PI3K/Akt/mTOR pathway is a known regulator of oncogenic growth in BC. In addition, this pathway also modulates host immune function and may indirectly affect tumorigenesis. Clinicopathologic studies have demonstrated that tumor infiltrating lymphocyte density is predictive of chemosensitivity and improved prognosis in BC, while myeloid infiltration has been hypothesized to play a deleterious role. To define the impact of Akt inhibition on the TME, we analyzed tumor tissue from patients (pts) with early-stage BC treated with MK-2206, an Akt inhibitor, as part of a pre-surgical trial (NCT01319539). **Methods:** Transcriptomic analysis was performed on surgical specimens to assess if differences exist in mRNA expression of tumor-associated and immune genes between pts treated with MK-2206 (n = 6) and untreated matched controls (n = 5) (nanoString). Quantitative immunofluorescence (qmIF) was performed for CD3, CD8, CD4, FOXP3, CD68, Pancytokeratin on 4uM sections from biopsy and surgical specimens of both groups. Images acquired using Vectra (PerkinElmer), allowing for multiparameter phenotyping. Statistical analysis performed using t-Test and Z- test. **Results:** mRNA expression supports in vivo activity of MK-2206 with decreased expression of cell cycle, proliferation and antiapoptotic genes (CTNNB1, CCND2, BAX, $p < 0.05$) and a numerical decrease in FasL ($p = 0.12$) in MK-2206 treated pts. Additionally, MK-2206 was associated with marked decrease of expression of myeloid markers (CSF1R, CD163, TGFBR2, CLEC7A) in post-treatment tissue ($p < 0.05$). On qmIF analysis, MK-2206 treated pts exhibited a significant increase in median CD3+CD8+ cell (CTL) density between pretreatment biopsy and surgical excision specimens, as compared to the control pts (87% vs.0.2%, $p < 0.05$). **Conclusions:** Combined mRNA and qmIF analysis suggest that Akt inhibition, may decrease myeloid infiltration and increase recruitment of CTLs. Thus, Akt inhibition may promote a favorable TME. At present, there are both FDA approved and investigational agents that target the PI3K pathway. Further investigation is warranted to understand the impact of Akt inhibition on the TME and its potential therapeutic implication.

12058 Poster Session (Board #171), Mon, 1:15 PM-4:45 PM

Tumor PD-L1 heterogeneity in non-small cell lung cancer: Does biopsy size and volume matter? *First Author: Monica Khunger, Cleveland Clinic, Cleveland, OH*

Background: Although patients with high tumor programmed death ligand-1 (PD-L1) expression benefit from PD-1/PD-L1 axis inhibitors, many studies have highlighted that a fraction of patients respond to these agents despite lacking detectable PD-L1 expression. Heterogeneity of tumor PD-L1 expression within the tumor has been postulated to be contributing to the limited performance of PD-L1 as a predictive biomarker. We evaluated the PD-L1 expression heterogeneity by comparing the percentage of PD-L1 positive tumor cells as a measure of tumor PD-L1 proportion scores (TPS) using fluorescence immunohistochemistry in paired whole tissue sections (WTS) and tissue microarray (TMA) cores from surgical non-small cell lung cancer (NSCLC) specimens. **Methods:** WTS and two 0.6mm TMA cores localized at least 3mm apart from each other were prepared from each formalin-fixed, paraffin-embedded surgically resected tumor specimens of 451 patients with stage I-III NSCLC. Using quantitative immunofluorescence with the E1L3N anti-PD-L1 antibody, TPS were generated in TMA and corresponding WTS and classified as 0%, 1-49% and ≥50%. **Results:** There was a high discordance between the TPS scores of PD-L1 expression among the WTS and TMA cores (discordance rate = 40.6%, 95% CI, 35.4%-45.9%; k = 0.26). Moderate discordance was observed between the TPS of PD-L1 expression among the two TMA cores (discordance rate = 10.2%, 95% CI, 7.6%-13.5%; k = 0.609). **Conclusions:** Discrepancies among the PD-L1 expression between WTS and TMA core as well as between TMA cores themselves represents intratumoral heterogeneity of PD-L1. Small needle aspirations or biopsies during endobronchial or CT-guided biopsy, which can be equated to TMA core, may not be representative of the true tumor PD-L1 expression. It is imperative to obtain bigger or multiple needle biopsies to identify patients with true positive tumor PD-L1 expression and maximize the number of patients who could benefit from PD-1/PD-L1 axis inhibitors.

12059 Poster Session (Board #172), Mon, 1:15 PM-4:45 PM

PD-1/PD-L1 interaction and CD25/FOXP3+ t cells to predict survival benefit from adjuvant chemotherapy in early stage non–small-cell lung cancer (ES-NSCLC). *First Author: Jennifer Bordeaux, Navigate BioPharma Services, Inc, Carlsbad, CA*

Background: Adjuvant chemotherapy (ACT) for ES-NSCLC provides only a modest improvement in survival and is associated with serious adverse effects. Thus, identifying subgroups of ES-NSCLC patients who will benefit from ACT is of high clinical relevance. Utilizing novel digital pathology algorithms, we evaluated relationship between pre-treatment tumor immune microenvironment and survival benefit from ACT in ES-NSCLC patients. **Methods:** 451 tissue sections of formalin-fixed, paraffin embedded surgical resection specimens from ES-NSCLC patients with/without ACT were tested with multiplexed fluorescence immunohistochemistry assays designed to detect key immune cell markers such as PD-1, PD-L1, CD4, CD8, CD25, FOXP3 and Ki67. Fluorescence Images were acquired on the Vectra platform (Perkin Elmer) and analyzed with novel AQUA algorithms designed to accurately measure the co-localization of PD-1 and PD-L1 (the Interaction Score), regulatory (CD25+/FOXP3+) and activated (Ki67+) T cell subsets. **Results:** High PD-1/PD-L1 Interaction Scores (≥ 643) and regulatory T cell burden (≥ 1%) in pre-treatment tumors exhibited significant correlations with improved recurrence free ($p = 0.003$) and overall survival ($p = 0.004$) in patients receiving ACT after surgery, whereas no difference in survival was observed for patients who received surgery alone ($p > 0.5$). Median RFS was not reached in signature positive patients vs 93.2 months in signature negative patients. Interestingly, the levels of PD-1 or PD-L1 alone did not predict survival for surgery + ACT or surgery alone patient populations. **Conclusions:** PD-1/PD-L1 Interaction Score and CD25/FOXP3 positive T cells are predictive of benefit from ACT in patients with ES-NSCLC. Future studies will determine if these biomarker signatures can be used to select patients that may be spared chemotherapy without compromising outcome.

12060 Poster Session (Board #173), Mon, 1:15 PM-4:45 PM

Exploring effects of MEK inhibition in tumor microenvironment in non-small cell lung cancer (NSCLC) pre-clinical models. *First Author: Tarik Silk, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: NSCLCs often harbor mutations in the KRAS oncogene and require improved treatment to provide durable disease control. Targeted therapy via MEK inhibition shows promising but temporary control of tumor growth but ultimately fails with a quick rebound of tumor growth. As the RAS-RAF-MEK-ERK pathway is evolutionarily conserved in most cells, MEK inhibition may cause broader effects in the tumor microenvironment. **Methods:** We examined the effect of novel pulsatile versus standard continuous MEK inhibition on lymphocytes and myeloid cells. KRAS tumor bearing mice were treated with selumetinib and T cells were analyzed for phenotypic changes. Tumor progression and survival with and without the addition of checkpoint blockade therapy was also monitored. In vitro experiments were also conducted with murine bone marrow-derived macrophages subsequently exposed to pulsatile or continuous selumetinib treatment. **Results:** MEK inhibition in T cells shows significant effects on T cell activation and proliferation. CD8+ T cell phenotypes increased CTLA-4, Ki67 and 4-1BB expression when treated with pulsatile compared to continuous MEK inhibitor, suggesting greater activation and proliferation status. Pulsatile MEK inhibitor therapy with CTLA-4 checkpoint blockade showed improved overall survival compared to continuous treatment in a mouse model of Kras mutant lung cancer. We extended our investigation to other tumor microenvironment components particularly myeloid cells. In vitro experiments revealed that pulsatile versus continuous treatment with the clinical MEK1/2 inhibitor selumetinib differentially effects macrophage viability and pro-inflammatory cytokine production. **Conclusions:** Pulsatile MEK inhibition improves T cell activation and prolongs survival in combination with anti-CTLA-4, compared with continuous treatment. It also has a modulating effect on myeloid cells compared to the standard continuous dosing. Optimizing MEK inhibition scheduling to target cancer cells and activate immune infiltrates will provide the best therapy for KRAS mutant NSCLC. These data will contribute to informing design immune modulation with targeted therapies in patients.

12061 Poster Session (Board #174), Mon, 1:15 PM-4:45 PM

Computer extracted features of cancer nuclei from H&E stained tissues of tumor predicts response to nivolumab in non-small cell lung cancer. *First Author: Xiangxue Wang, Case Western Reserve University, Cleveland, OH*

Background: Immune checkpoint inhibitors have recently been FDA-approved for use in advanced stage non-small cell lung cancer (NSCLC). These drugs target the PD-1 receptor or its ligand PD-L1, but treated patients only have a response rate of about 20%. It is thus crucial to identify which patients will derive maximal benefit from such treatments, especially since the current gold standard biomarker, detection of tissue-based PD-L1 expression, has been shown to be inadequate. Previous studies have shown that computer extracted features of nuclear shape and texture are predictive of recurrence in early stage NSCLC. The goal of this work is to evaluate the role of features of nuclei shape and arrangement in the tumor in predicting response to Nivolumab for NSCLC. **Methods:** The study included 56 patients with NSCLC from two different institutions who had had pre-treatment tumor biopsies and were treated with Nivolumab. The patients were split into two categories, responders and non-responders, that were determined by clinical improvement and radiologic assessment through RECIST criteria. The 245 features from tumor nuclei included standard measures used to characterize shape and texture of nuclei as well graph based features that capture the distinct spatial arrangement of the nuclei. Features were extracted from tumor regions manually annotated on digitized H&E images by two expert pathologists. **Results:** A statistical feature selection method determined the top five tumor nuclear features from the training set. These features included the spatial arrangement of nuclei and variance in nuclear shape and chromatin structure. A machine learning classifier trained with these top five features yielded an AUC = 0.65 on the training set (n = 32) and an AUC = 0.6 on the independent validation set from a separate institution. (n = 24). **Conclusions:** Computer extracted features of cancer nuclei were found to distinguish between patients who did and did not respond to Nivolumab immunotherapy. Validation is needed on larger cohorts from multiple different sites.

12062 Poster Session (Board #175), Mon, 1:15 PM-4:45 PM

Upfront next generation sequencing in NSCLC: A publicly funded perspective. *First Author: Kirstin Perdrizet, University of Toronto, Toronto, ON, Canada*

Background: A growing number of actionable targets in non small cell lung cancer (NSCLC) have led to the need for molecular profiling beyond the standard of care (SOC) *EGFR/ALK*. Here we present actionable targets, impact on patient treatment, clinical trial opportunities and costs using the Illumina TruSight Tumour 15 panel (TST15) for NSCLC samples. **Methods:** In addition to immunohistochemistry for ALK and PDL-1, tissue-based next generation sequencing using the TST15 was reflexively performed on all new non-squamous NSCLC specimens at the University Health Network (Toronto, Canada) between February and December 2017. The panel identifies hot spot mutations in *KRAS*, *EGFR*, *TP53*, *PIK3CA*, *BRAF*, *ERBB2*, *FOXL2*, *GNA11*, *GNAQ*, *KIT*, *NRAS*, *PDGFRA*, *RET*, *AKT1* and *MET*, but not fusions, copy number variations (CNV) nor *MET* exon 14 skipping mutations. Patient age, stage, pathologic subtype and genotyping results were collected prospectively. Treatment changes as a result of TST15 and clinical trial opportunities (using clinicaltrials.gov) were identified. Incremental testing costs were based on direct laboratory costs, but not personnel and administration costs. **Results:** Testing included 284 samples from 282 patients. The TST15 panel identified 343 mutations from 284 samples. Sample demographics include: male/female 53/47%, stage 1/2/3/4 33/7/16/44%. Incremental actionable targets beyond *EGFR* and *ALK* were identified in 2.6% of specimens (*ERBB2* 1.7%, *BRAF* V600E 0.9%). Most mutations occurred in *TP53* (43%), *EGFR* (25%) and *KRAS* (24%), with co-mutations in 31% (*TP53*, *KRAS*, *EGFR*). To date, one patient has had a treatment change as a result of TST15 beyond targeting *EGFR*. Above SOC clinical trial options were identified for 73% of stage IV and 25% of stage III patients. 3.6 samples were needed to identify one actionable mutation, predominantly in *EGFR*, at an estimated cost of $1919 CAD per target. **Conclusions:** Extended genotyping with TST15 in NSCLC identifies many actionable mutations and improves clinical trial options for patients. Despite this, impact on patient treatment beyond targeting *EGFR* is minimal. To enhance the number of targets and minimize costs, population-based comprehensive testing with a panel that includes fusions/CNV is needed.

12063 Poster Session (Board #176), Mon, 1:15 PM-4:45 PM

The role of dynamic susceptibility contrast perfusion- weighted MRI in the estimation of IDH mutation in gliomas. *First Author: Sotirios Bisdas, University College London, London, United Kingdom*

Background: The presence of mutation in the encoding gene of isocitrate-dehydrogenase (IDH) has been defined as a molecular biomarker in the diagnosis and differentiation of gliomas. Dynamic Susceptibility Contrast Perfusion- Weighted Imaging (DSC - PWI) is a relatively recently established technique for gliomas staging and its diagnostic accuracy may benefit when using sophisticated image analysis algorithms. In this study, we aimed to investigate whether DSC - PWI, enhanced by texture analysis and machine learning, can stratify gliomas according to their IDH mutation status. **Methods:** 208 patients (F/ M : 84 / 119, median age : 47 [range 21-81 years]) from a multicenter setting, who have have been immunohistopathologically diagnosed with gliomas (IDH positive / negative: 98 / 105) were prospectively included in our study. The raw data from DSC - PWI was processed on a dedicated workstation, using a fully adaptive Bayesian method, to create leakage-corrected relative cerebral blood volume (rCBV) maps. Tumours were manually segmented and registered to rCBV maps. rCBV maps were used to generate distribution and rotational invariant Haralick texture features over the tumour mask. The predictive power of the extracted features in differentiating between IDH status was assessed in a 2-fold cross-validation setting of 1000 iterations using support vector machine and multinomial ordinal regression, respectively. **Results:** Overall sensitivity and specificity rates for the rCBV for IDH stratification were 68% and 81%, respectively. All except one of the ten classical histogram statistics and 12 texture features appeared significantly different across mutation status ($p < 0.05$) when using non parametric Wilcoxon test. In the case of the classification across grading, the same features led to a distance error (difference between the real and predicted grade) inferior or equal to 1 in 88.6 % of the cases and an exact prediction in 57.2% of cases. **Conclusions:** Preliminary results are promising in the differentiation of gliomas with DSC- PWI on the basis of IDH mutation status, especially regarding the high specificity rates obtained using features from rCBV data.

12064 Poster Session (Board #177), Mon, 1:15 PM-4:45 PM

Resolving diagnostic uncertainty in bone-predominant metastases in cancer of unknown primary (CUP) using the 92-gene assay. *First Author: Kanwal Pratap Singh Raghav, Department of GI Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Bone-predominant metastases in patients (pts) with CUP pose diagnostic challenges in pathologic analyses, which may delay optimal therapy. The 92-gene assay is a validated gene expression profiling (GEP)–based cancer classifier with high accuracy in limited tissue. This study evaluated performance and clinical utility of the 92-gene assay in bone biopsies from bone-predominant CUP. **Methods:** A correlative database integrating 92-gene assay (CancerTYPE ID) results and de-identified patient data was developed under an IRB-approved protocol for 26,594 cases where the assay was performed in routine care. Database was queried using biopsy site of bone/skeletal designation (rib, pelvis, vertebrae, sacrum, femur). Descriptive statistics and Chi-square analyses were used. **Results:** 7% (n = 1834) of cases were bone specimens. With an analytical success rate of 70%, a molecular diagnosis was made in 94% cases, among which pancreaticobiliary (Pb; 19%), NSCLC (14%), and kidney (8.3%) were most frequently classified tumors. Kidney, sarcoma, liver, salivary gland, and thyroid were more prevalent with bone biopsies (all $p < 0.05$), while neuroendocrine, intestine, ovary, and endometrium were more frequent with non-bone cases (all $p < 0.05$). In Pb subtypes, gallbladder showed a higher proportion of bone cases ($p < 0.001$) compared to cholangiocarcinoma and pancreas. Higher frequency of immune-responsive tumor types was observed in bone vs non-bone biopsies (44% vs 35%), with kidney and liver predictions 2-3x more frequent in bone samples ($p < 0.0001$). **Conclusions:** The 92-gene assay is effective for molecular diagnosis in bone-predominant CUP. In this large cohort of bone biopsies, tumor type results matched previously reported frequencies of CUP putative primaries. A notable subset of bone-predominant CUP was identified as having a molecular diagnosis with an FDA-approved indication for immunotherapy. These results indicate a promising avenue for a GEP classifier to identify immune-responsive CUP subsets. Given the limited nature of bone samples, tissue-sparing GEP assay should be considered early in the diagnostic workup to direct biomarker testing and treatment selection.

12065 Poster Session (Board #178), Mon, 1:15 PM-4:45 PM

Whole genome sequencing in metastatic breast cancer: Lessons learned from the BC Cancer personalized oncogenomics program. *First Author: Nathalie LeVasseur, British Columbia Cancer Agency, Vancouver, BC, Canada*

Background: The emerging interest in precision medicine has lead to the genomic profiling of breast cancer, with the intent of identifying therapeutically targetable alterations. The clinical relevance of whole genome sequencing (WGS) and RNA-sequencing as compared to targeted next generation sequencing (NGS) remains uncertain. Moreover refined data is needed to identify which patients benefit most from molecular profiling. **Methods:** Informative and actionable findings from WGS in metastatic breast cancer patients between 2012-2017 were reviewed and compared to FoundationOne and MSKCC-IMPACT targeted panels. The data providing rationale for informative and actionable findings was compiled using an RNA/DNA heatmap. Comparison of signal nucleotide variants (SNVs) mutation signatures and mutational burden was compared across histological and molecular subtypes and between aging-driven and non-aging driven tumours. **Results:** WGS of 139 metastatic breast cancer patients revealed that 77% of actionable items arose from expression data, 60% from mutations, 45% from copy number changes, 28% from mutation signature, mutation burden, or homologous recombination deficiency (HRD) and 5% from structural variants (SV). The majority (7616/7998, 95%) of mutations were only detected by WGS, representing mostly passenger mutations, whereas driver mutations were also identified with the genes included in the FoundationOne (339/7998, 4%) and MSKCC-IMPACT panels (201/7998, 3%). No significant differences in mutation burden were identified among subtypes, although tumors whose somatic mutagenesis was driven predominantly by aging-related processes displayed lower mutation burdens. More frequent elevation of HRD-associated mutation signatures of SNV/SV were identified in triple-negative/basal-like tumors. **Conclusions:** While most actionable mutations were covered by pre-existing targeted panels, expression data represents a significant proportion of actionable information obtained from WGS. Mutational burden did not vary significantly among subtypes. Signature properties and their relation to molecular subtypes remains an interesting arena for clinical application.

12066 Poster Session (Board #179), Mon, 1:15 PM-4:45 PM

Clinical significance of enterocyte-specific gene polymorphisms as candidate marker of oxaliplatin-based treatment for metastatic colorectal cancer. *First Author: Mitsukuni Suenaga, USC Keck School of Medicine Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: An enterocyte subtype of the Colorectal Cancer (CRC) Assigner classifier has shown to confer benefit from oxaliplatin in adjuvant treatment for stage III CRC. *MS4A12* belongs to the enterocyte subtype-specific gene, whose expression is regulated by endogenous CDX2. We tested whether single nucleotide polymorphisms (SNPs) in enterocyte-related genes predict oxaliplatin efficacy in first-line treatment for metastatic CRC (mCRC). **Methods:** Three different cohorts of mCRC patients (pts) (total 603) were included in this study: discovery cohort receiving FOLFOX ± bevacizumab (BV) (n = 146, median age = 61, median follow-up = 45.0 mos); validation cohort receiving FOLFOXIRI + BV (n = 230, TRIBE arm B, median age = 60, median follow-up = 46.5 mos); and control cohort receiving FOLFIRI + BV (n = 228, TRIBE arm A, median age = 60, median follow-up = 49.3 mos). SNPs were analyzed by PCR-based direct sequencing. Progression-free survival (PFS) and overall survival (OS) were analyzed using Kaplan-Meier curves, log-rank test, and Cox proportional hazards regression. **Results:** Among the SNPs tested in the discovery cohort, *MS4A12* rs4939378 and *CDX2* rs3812863 were extracted as potential markers of efficacy. In the validation cohort, any G allele in *MS4A12* rs4939378 was associated with longer PFS than the A/A variant in univariate analysis (12.4 vs. 10.9 mos, HR 0.70, 95% CI: 0.49-0.99, *P*= 0.033) and multivariable analysis (HR 0.65, 95%CI: 0.44-0.97, *P*= 0.035). The findings were more evident in the *KRAS* mutant than *KRAS* wild-type pts. In contrast, *KRAS* wild-type mCRC pts with the G/G variant in *CDX2* rs3812863 had a longer PFS than those with any A allele (32.3 vs. 10.3 mos, HR 0.39, 95%CI: 0.19-0.81, *P*= 0.004), and the trend remained in multivariable analysis though without statistical significance (HR 0.48, 95%CI: 0.21-1.09, *P*= 0.08). These findings were not confirmed in the control cohort. **Conclusions:** The enterocyte subtype might affect the antitumor activity of oxaliplatin in not only early stage but also metastatic disease in CRC. Genetic variants in *MS4A12* and *CDX2* gene polymorphisms may serve as potential predictive marker of oxaliplatin-based treatment in mCRC pts.

12067 Poster Session (Board #180), Mon, 1:15 PM-4:45 PM

Poly-ligand profiling (PLP) to differentiate pancreatic cancer patients who benefit from gemcitabine+evofosfamide versus gemcitabine+placebo treatment. *First Author: Valeriy Domenyuk, Caris Life Sciences, Phoenix, AZ*

Background: The MAESTRO trial randomized 693 locally advanced or metastatic pancreatic cancer patients to gemcitabine (G) + placebo vs G + evofosfamide (GE). OS hazard ratio (HR) was 0.84; p = 0.059. We developed a PLP assay that identifies patients most likely to benefit from GE vs G alone. By capitalizing on ssDNA aptamer binding properties, PLP measures network changes in tumors, including those that predict drug response. **Methods:** FFPE tissues of pancreatic cancer patients from the MAESTRO trial with good (OS > 13 mos) or poor (OS < 7 mos) outcome from GE were used for PLP assay development. Assay cut-points were determined using a training set (n = 12) and performance metrics were then determined using an independent blinded test set (n = 172). The study population enrolled in MAESTRO was divided into four cohorts based on treatment and benefit (cut-point = 240 days). The assay performance from the blinded test set was used to generate 1000 different possible patient subsets. Each simulation represents one possible trial outcome if the PLP assay had been used to enroll patients. We used the average value of the simulated median increase in OS from the 1000 random selections to estimate the impact the PLP assay would have had on MAESTRO. **Results:** 97% of the simulations yielded log-rank p < 0.05. Compared to MAESTRO, the average median OS increase for GE improved by 116±38% (simulation s.d.) with an average HR of 0.72±0.04. Moreover, the sample size in the simulations was 49% smaller compared to the original study, reflecting the percentage of test positive patients in the blinded test set. When only data from primary tumors were used, 100% of the permutations yielded log-rank p < 0.05 with an average median OS increase of 216±36% compared to MAESTRO and an average HR of 0.63±0.03. **Conclusions:** This retrospective study demonstrates that PLP, if prospectively applied, likely would have resulted in a successful study comparing GE to G pancreatic cancer patients. PLP is a powerful, flexible and facile platform warrants further study of additional therapies and in prospective trials.

12068 Poster Session (Board #181), Mon, 1:15 PM-4:45 PM

Identification of clonal hematopoiesis mutations in solid tumor patients undergoing unpaired commercial next-generation sequencing assays. *First Author: Catherine Callaghan Coombs, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Precision medicine is increasingly utilized for both prognostication and application of targeted therapies for oncologic patients (pts). Results from next-generation sequencing (NGS) assays ideally should reflect the burden of somatic tumor mutations (muts), yet challenges can arise from differentiation of germline muts and from contamination of biopsies by non-tumor tissue. Clonal hematopoiesis (CH), defined by the presence of somatic muts typically in leukemia-associated genes in hematopoietic cells, occurs in aging individuals, with an increased risk for hematologic cancers and shorter survival in pts with solid tumors (ST). Here we examine the prevalence of CH leading to false positive (FP) calls on commercial NGS assays. **Methods:** This is a multi-institution, retrospective cohort study of pts undergoing NGS of ST. All pts undergoing commercial NGS (Foundation Medicine) testing were examined (N = 768 at UNC and 989 at MCC). For a subset of pts (N = 64 at UNC and 30 at MCC), NGS of paired blood samples was performed to examine the prevalence of true CH events, defined as a variant allele frequency (VAF) in the blood exceeding the VAF in the tumor tissue. Germline events were defined by VAF > 35% in both tumor and blood. **Results:** Muts in genes that are frequently altered in CH (*DNMT3A*, *TET2*, *ASXL1*, *TP53*, *ATM*, *CHEK2*, *SF3B1*, *CBL*, *JAK2*) were identified in 65% of pts; excluding *TP53*, often mutated in ST, these events were seen in 35% of pts. A bimodal distribution of VAFs was seen for CH genes, with low VAF events most suggestive of true CH events. Using paired blood samples, we confirmed such muts as true CH events in 9.4% of ST pts in the UNC cohort. Across all genes, germline events were reported in 23% of UNC pts, of which 33% were known or likely pathogenic variants. MCC samples were enriched for pts with reported muts in CH genes; 33% of which (10/30) were confirmed as true CH events. The majority of *DNMT3A* muts (64%, 7/11) were CH; the minority of *TP53* muts (4%, 2/50) were CH. **Conclusions:** Muts in CH genes are commonly reported on unpaired clinical NGS testing of ST; some are true CH events as opposed to TS events. It is important to recognize CH as a possible FP when applying NGS results to pt care.

12069 Poster Session (Board #182), Mon, 1:15 PM-4:45 PM

Molecular subtypes of triple-negative breast cancer (TNBC) tumor samples obtained before and after neoadjuvant systemic therapy (NST) and relationship between immunomodulatory (IM) gene signature and intensity of tumor-infiltrating lymphocytes (TILs). *First Author: Hiroko Masuda, Department of Surgical oncology, Showa University, Tokyo, Japan*

Background: Lehmann et al have identified 4 molecular subtypes of TNBC [basal-like (BL) 1, BL2, mesenchymal (M), and luminal androgen receptor (LAR)] and an IM gene expression signature. Our group previously showed that response of TNBC to NST differs by molecular subtype, but whether NST affects TNBC subtype has not been studied. We hypothesized that certain TNBC subtypes change after NST. We also tested whether IM signature correlates with the intensity of TILs. **Methods:** From the World TNBC Consortium dataset, which contains TNBC samples from 4 institutions from 4 countries, we examined 68 formalin-fixed, paraffin-embedded tumor samples from patients treated with NST: 27 pairs of matched pre-NST and post-NST samples and 14 pre-NST samples. TNBC classification was performed with the Insight TNBCtype assay. We compared the molecular subtypes of TNBC samples obtained before and after NST. We used the Spearman correlation test to investigate the association between IM status and percentage of TILs in all 68 samples. **Results:** The distribution of TNBC subtypes before and after NST is shown in the Table. Of the 27 matched pairs, 14 (52%) showed a change in TNBC subtype after NST. Among the 14 matched pairs with a subtype change, all 7 cases of BL1 subtype before NST changed to M, and 4 of 5 cases of LAR subtype before NST converted to BL2 (one LAR changed to unclarified). As expected, a low residual cancer burden (RCB 1) was more common in patients with (4/14 [29%]) than in patients without subtype change (1/13 [8%]); however, subtype change and amount of residual cancer were not related statistically (p = 0.32), most likely due to the small sample size. There was a strong positive correlation (rho 0.95, p = 0.0008) between TIL intensity and IM gene signature positivity. **Conclusions:** TNBC molecular subtype frequently changed after NST. TIL intensity positively correlated with IM signature. We will validate our findings in a larger group of samples in the World TNBC Consortium dataset. Subtype Distribution

Subtype	Pre-NST (%)	Post-NST(%)
BL1	37	11
BL2	11	22
LAR	37	22
M	15	37
Unstable	—	8

12070 Poster Session (Board #183), Mon, 1:15 PM-4:45 PM

Novel platform for monitoring bladder cancer recurrence using expression analysis of small non-coding RNAs. *First Author: Ilija Aleksic, Albany Medical College, Albany, NY*

Background: Bladder cancer patients are routinely monitored after treatment by cystoscopy due to a high rate of recurrence. In the absence of an accurate non-invasive screening test to monitor recurrence, bladder cancer will remain the most expensive malignancy to manage. We have developed a non-invasive test that interrogates small non-coding RNAs (sncRNAs) present in urinary exosomes. Analyzing the urine exosome data with a novel statistical classification algorithm provides a platform that unequivocally differentiates between patients with no evidence of disease and those with recurrence. **Methods:** Urine samples were collected from patients previously treated for bladder cancer (n = 82) who are currently under routine surveillance cystoscopy. Patients without bladder cancer or without evidence of recurrent disease served as the control cohort. A Sentinel sncRNA signature specific for bladder cancer was generated by interrogation of urine exosomal RNAs on Affymetrix 4.0 arrays that probes for > 6600 sncRNAs. A customized platform to interrogate the most informative (~120) Sentinel sncRNAs, was then used to screen urine exosomal RNA derived from patients at risk for recurrent disease. Data were then analyzed using a statistical classification algorithm that provides the miR-BCPx (bladder cancer progression score). This novel analytical approach requires no *a priori* knowledge of the sncRNA function to generate an unbiased classification into those with stable disease versus those with recurrent tumor. **Results:** Bladder cancer patients have significantly elevated levels of exosomal RNA relative to control cohort. In a small blinded testing male cohort, comparison of the miR-BCPx score generated to the disease status demonstrates that the miR-BCPx identifies patients with recurrent tumor with 100% sensitivity (59/59) and 96% specificity (22/23). **Conclusions:** Implementation of the miR-BCPx as a surveillance screen for bladder cancer patients provides an affordable, non-invasive alternative to cystoscopy for monitoring disease stability, and can readily be deployed in the clinic to reduce the number of screening cystoscopies needed.

12071 Poster Session (Board #184), Mon, 1:15 PM-4:45 PM

Survival of patients treated by a Precision Oncology approach is determined by performance status and lines of therapy. *First Author: Bat-Ami Gordon, Sylvester Comprehensive Cancer Center, Miami, FL*

Background: Academic Medical Centers (AMC) and community practices are implementing Molecular Tumor Boards (MTB) to interpret next-generation sequencing (NGS) results and develop clinical guidelines for utilizing NGS results. Reports of MTB experiences from cancer centers nationally vary in their abilities to translate molecular test results to actionable recommendations for their patients. In these efforts, there is not yet a definition for parameters of patients who would benefit most from a Precision Oncology approach. **Methods:** Defining Platforms for Individualized Cancer Treatment (DePICT) is an IRB approved registry trial designed to monitor outcomes of Broward County, FL residents with late-stage refractory cancer (ECOG ≤2) who undergo NGS. After consent, the MTB used NGS results to match patients to targeted clinical trials and therapies. The patients are followed at 12 week intervals. DePICT has consented 141 patients, out of which 111 have had at least one follow up. We analyzed these cases to identify key characteristics of patients that benefit most from NGS testing and MTB review. Groups were defined as those who pursued targeted therapies versus those who pursued standard of care or palliative regimens. Kaplan Meier survival analyses were done in R 3.4.3. **Results:** Patients with ≤3 previous lines of therapy were more likely to pursue targeted therapy than patients with ≥4 lines of therapy (32% vs. 17%, p = 0.045). Only patients with an ECOG score 0 or 1 pursued targeted therapy. An analysis of this population (ECOG < 2, ≤3 lines of therapy) revealed that patients on targeted therapy performed better than their palliative care counterparts. Median overall survival (mOS) for patients who received targeted therapy is 84 weeks (95% CI 36-Not Reached (NR)) and the mOS for patients who did not undergo targeted therapies was 36 weeks (95% CI 36-NR). **Conclusions:** This analysis identifies patients who may benefit most from NGS testing. Patients with ECOG scores of 0 or 1 and 3 or fewer lines of therapy were more likely to go on targeted therapy, and have better outcomes. Patients should be evaluated by precision oncology approaches earlier in their cancer care continuum.

12072 Poster Session (Board #185), Mon, 1:15 PM-4:45 PM

A cell cycle-related RNA expression signature of neoantigen burden in lung adenocarcinoma. *First Author: Michael F Sharpnack, The Ohio State University, Columbus, OH*

Background: Tumor somatic mutation burden (TMB) and neoantigen burden (NB), are emerging therapeutic biomarkers for immune checkpoint blockade in NSCLC; however, these biomarkers are costly and require extensive expertise to measure. Cheaper, simpler surrogate biomarkers are necessary to keep up with current translational research findings. **Methods:** We curated RNAseq, NB, and clinical data from The Cancer Genome Atlas (TCGA) for lung adenocarcinoma (LUAD, n = 461) tumors. Gene-level RNAseq data was correlated with TMB and NB, and ontological enrichment of genes associated with these quantities are discovered using the enrichR tool. In addition, RNA expression and TMB data from lung adenocarcinoma cell lines were curated from the Cancer Cell Line Encyclopedia. Neural network and penalized linear regression methods were used to create and test RNA expression signatures of somatic mutation and neoantigen burden. The code for these methods was implemented in R. **Results:** 5199 genes' RNA expression are significantly correlated with NB (Spearman correlation, Benjamin hochberg q-value < 0.01). Genes positively associated with NB are highly enriched in cell cycle related genes (pathway database, corrected p-value < 0.01). Further, we correlated RNA expression with mutation burden in lung adenocarcinoma cell lines and found a similar enrichment of cell cycle related genes. We created RNA expression signatures of NB using two separate methods and tested their performance on TCGA LUAD tumors using a random cross validation approach. Neural network and penalized linear regression cross-validation experiments had mean AUCs of 0.74 and 0.68, respectively. The final signatures were selected based on consistent and accurate performance on LUAD tumors. 50 genes were selected for the final signature, including *YBX2*, *TDRKH*, *HDGF* and others. **Conclusions:** Cell cycle-related RNA abundances are strongly associated with NB in LUAD. We show that these genes can be incorporated into a biomarker of NB. We are in the process of validating this RNA signature's ability to predict NB with a NanoString RNA panel on a separate LUAD cohort and investigating its implication in lung cancer immunotherapy.

12073 Poster Session (Board #186), Mon, 1:15 PM-4:45 PM

Plasma sequencing of ctDNA in early stage breast cancer as part of the screening process. *First Author: Begona Jimenez Rodriguez, Unidad de Gestión Clínica Intercentros de Oncología, Hospitales Universitarios Regional y Virgen de la Victoria de Málaga, Malaga, Spain*

Background: Mammography is the current standard of care for breast cancer (BC) screening. However, not all cancers are detectable on mammography and not all mammographic findings represent cancer, moreover, the confirmatory biopsy is not always 100% informative due to the intrinsic intratumor heterogeneity. The aim of this study was to investigate the power of ctDNA to both confirm and interrogate disease status beyond mammography findings by comparing ctDNA mutation results to those obtained by tissue sequencing. **Methods:** Matched blood and fresh tissue biopsies were collected from 56 patients with BIRADS 4c/5 mammography findings and subsequent diagnosis of primary BC. The blood draw was performed immediately before the tissue biopsy. The NGS study on fresh frozen tissue samples was performed using a customized design of TruSeq Custom Amplicon Low Input Panel (Illumina), which includes the full region of PIK3CA, TP53, CDH1, GATA3, PIK3R1 and MAP2K4 genes (most commonly mutated ganes in early stage BC according to TCGA). Plasma sequencing was performed using Plasma SafeSeq (PSS). **Results:** At the time of this analysis, 29 matched samples were analyzed for TP53 and PIK3CA mutations. Median age was 64y(44-92), 56% of patients has mammographic lesions greater than 2cm, 35% of patients had grade 3 tumors and % of IHQ tumor subtypes was 52% LumA, 30.5% LumB, 13% TNBC and 4.5% Her2-enriched. At least 1 mutation was detected in each patient in the tissue analysis, with 10 *TP53* and 24 *PIK3CA* different mutations detected overall. PSS detected TP53 and PIK3CA mutations in 10 of these 29 patients. Concordance of plasma and tumor mutations was observed in 8 of 29 patients (27.6%) [3 TP53 (c.637C > T, c.398T > A,c.587G > C); 4 PIK3CA (c.3140A > G, c.1633G > A,C.1624G > A, C.3145G > C), 1 with both mutations (TP53 c.743G > T, PIK3CAC.3140A > T)]. Additionally, PSS revealed 4 plasma mutations that were not identified in the tissue (3 TP53, 1 PIK3CA). **Conclusions:** Mutations in ctDNA can be readily detected using a highly sensitive plasma sequencing method in early-stage breast cancer patients. These findings suggest that early ctDNA testing can provide critical clinical information that may improve patient diagnosis.

12074 Poster Session (Board #187), Mon, 1:15 PM-4:45 PM

Comparison of the prognostic performance between OncoMasTR and OncotypeDX multigene signatures in hormone receptor-positive, HER2-negative, lymph node-negative breast cancer. *First Author: Catherine Margaret Kelly, Mater Misericordiae University Hospital, Dublin, Ireland*

Background: Multigene prognostic signatures (MGPS) enable identification of early stage breast cancer (BC) patients requiring less aggressive treatment. OncoMasTR is a new MGPS found via a novel transcriptional network analysis method that identified genes – Master Transcription Regulators (MTRs) – that regulate previously identified prognostic biomarkers. The optimised OncoMasTR signature consisting of just 3 MTRs (OM) and incorporating clinicopathological information (OMclinical) has been clinically validated. We examined OncoMasTR's prognostic performance alone and in comparison to OncotypeDX. **Methods:** We measured MTR expression levels by RT-qPCR in tissue from Irish patients (n = 367) enrolled in the Trial Assigning Individualized Options for Treatment (TAILORx) study through Cancer Trials Ireland. OM and OMclinical numeric risk scores and risk category (high or low) were blindly calculated using the OncoMasTR algorithm. OncoMasTR scores and OncotypeDX recurrence scores (RS) were independently compared on measures of risk classification, BC recurrence (all, local and distant), correlation and concordance over 9 years of follow-up. **Results:** OM ($LR\chi^2$= 12.92, p = 0.0003) and OMclinical ($LR\chi^2$= 17.21, $p < 0.0001$) provided more prognostic information than RS ($LR\chi^2$= 4.74, p = 0.0294). OM classified 39% of samples as low risk (no local or distant recurrence, 0.0% recurrence) and 61% as high risk (9.0% recurrence; 4.5% local, 4.5% distant). OncotypeDX classified 17.3% of samples as low risk (1.9% recurrence; 1.9% local, 0% distant), 63.3% as intermediate risk (7.0% recurrence; 3.5% local, 3.5% distant), and 19.4% as high risk (8.0% recurrence; 3.2% local, 4.8% distant). There was moderate correlation between OM and RS numeric risk scores (r = 0.46, $p < 0.0001$) and low concordance between the OM and RS risk categories. Higher correlation and concordance were observed among high risk samples. **Conclusions:** OM, OMclinical and RS were significantly prognostic for recurrence in TAILORx samples. OM and OMclinical demonstrated exceptional sensitivity by classifying all patients who had any recurrence to the high risk category.

12075 Poster Session (Board #188), Mon, 1:15 PM-4:45 PM

Computer-extracted stromal features of African-Americans versus Caucasians from H&E slides and impact on prognosis of biochemical recurrence. *First Author: Hersh Kumar Bhargava, University of California, Berkeley, Department of Molecular and Cell Biology, Berkeley, CA*

Background: There has been recent interest in investigating differences in the prostate cancer (PCa) phenotype between African-Americans (AA) and Caucasian-Americans (CA). Separately, there is evidence that stromal morphology may be predictive of cancer aggressiveness. The objective of this work was to evaluate whether computer extracted measurements of stromal nuclei in PCa histology (1) were significantly different between AA and CA populations and (2) could be used to create more accurate, population-specific prognostic models for biochemical recurrence (BCR) following surgery. **Methods:** Radical prostatectomy specimens from 200 patients (93 AA, 93 CA, 73 BCR, 113 non-BCR) were reviewed (ethnicity self-declared). Patients were randomly partitioned into training (n = 124) and validation sets (n = 62). Image features from stromal nuclei were computed from scanned H&E slides and used with 3 machine learning (ML) models (random forest, top 4 features by t-test) to predict BCR in each population subset. We validated these models against the independent validation cohort and compared them with extant clinical recurrence risk prediction nomograms (KATTAN, CAPRA-S). **Results:** 23 stromal features had significantly differing distributions between the BCR and non-BCR cohorts ($p < 0.05$). These included descriptors of nuclear shape and arrangement. 31 features were significant in the AA cohort while only 4 were in the CA cohort. Our ML models based on these features significantly (log-rank $p < .005$) outperformed existing nomograms for AA patients and had an AUC of 0.82. **Conclusions:** Stromal nuclear features were predictive of PCa BCR in AA patients. Taking into account population-specific information significantly improves accuracy of computational pathology based prognostic models for AA PCa patients.

Comparison of our model with nomograms for AA validation cohort.

Classifier	Features	Statistics
Random Forest	4 descriptors of nuclear shape.	AUC: 0.82 Logf-rank p = 0.0046 Hazard ratio: 19.95
CAPRA-S	Clinical variables (PSA, grade, stage, age, etc.).	AUC: 0.61 Log-rank p = 0.4265 Hazard ratio = 0.5514
KATTAN	AUC: 0.64 Log-rank p = 0.3385 Hazard ratio = 0.54

Comprehensive detection of targetable fusions in lung adenocarcinomas by complementary targeted DNAseq and RNAseq assays. *First Author: Ryma Benayed, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: While *ALK*, *ROS1*, *RET* fusions, and *MET* exon 14 (*MET*ex14) alterations are routinely detected by hybridization capture-based DNASeq assays such as MSK-IMPACT, a genomic DNA-based approach may not identify all patients with such events. We evaluated the utility of targeted RNAseq for the identification of these alterations in MSK-IMPACT driver-negative lung cancers. **Methods:** MSK-IMPACT driver-negative tumors (defined in Jordan E *et al*, 2017, PMID 28336552), underwent further molecular profiling with the MSK-Fusion Solid panel, a custom RNAseq panel based on the Archer FusionPlex technology designed to detect fusions involving 62 cancer genes and *MET*ex14 skipping. Low tumor mutation burden (TMB) was assessed as a potential prioritization criterion for targeted RNAseq. **Results:** Between 01/01/2014 and 12/31/2017, 2502 lung adenocarcinomas were profiled using MSK-IMPACT; 201 (8%) gene fusions and 119 (5%) *MET* exon 14 alterations were identified (table). Among 276 driver-negative cases, 255 (92%) with available tissue were subjected to targeted RNAseq. A previously undetected alteration was identified in 36 of 255 (14%) cases by the MSK-Fusion Solid panel, 33 of which were actionable (27 in-frame gene fusions, 6 *MET*ex14 skipping events; table). Of these 33 patients, 11 were eligible for matched targeted therapies (the rest had early-stage disease or low KPS, or were on alternate therapies, on active observation, or deceased). All 11 patients received targeted therapy, 8 of whom (72%) derived clinical benefit. In the subset of 63/255 MSK-IMPACT driver-negative cases with low TMB (0-5 mt/Mb), 19 (30%) were positive for previously undetected gene fusions. **Conclusions:** Our results emphasize the importance of complementary targeted DNAseq and RNAseq assays to ensure robust and comprehensive detection of actionable gene fusions and *MET*ex14 alterations in clinical samples. Furthermore, we observed enrichment for gene fusions in driver-negative samples with low TMB, supporting the prioritization of such cases for complementary RNAseq analysis.

Longitudinal ctDNA analysis to enable early assessment of prognosis in lung adenocarcinoma in the absence of matched tissue biopsy. *First Author: Xiaoju Max Ma, Roche Molecular Syst, Pleasanton, CA*

Background: Longitudinal ctDNA monitoring using variants identified in tissue biopsies is an emerging method for disease management. However, tissue biopsy is often inaccessible for many late stage lung cancer patients. We hypothesized that variants found in baseline plasma ctDNA can also be used for monitoring, and that an early response assessed by changes in the level of ctDNA could predict treatment effect. **Methods:** We employed a 197-gene NGS assay, the AVENIO ctDNA Surveillance Kit, which allowed us to perform longitudinal ctDNA analysis and measure changes in the allele frequency (AF) of the variants identified in baseline plasma. Using this tissue-independent method, we evaluated the association between change in ctDNA levels and survival of advanced lung adenocarcinoma subjects treated with first-line chemo or chemoradiation therapies. Post-treatment AF values were compared with the lowest AF value (nadir) of all previous timepoints, including baseline. New variants were included if the AF was above the mean AF at baseline (b0). The algorithm was tested in a training cohort (44 subjects) and validated in an independent cohort from a prospective, observational study (40 subjects, all stage IV lung adenocarcinoma). **Results:** At b0, we identified variants in all subjects to enable ctDNA monitoring. From the training cohort, we defined the post-second treatment cycle (p2) as 30 to 60 days post-start of first treatment and compared AF value of each variant with the nadir value. Good responders at p2 were defined as having no significant increase in AF from the nadir. Applying this algorithm to the validation cohort, good early responders with samples collected within p2, 24/40 (60%), were associated with better progression-free survival (PFS) (6.1 vs. 3.8 mo, P = 0.0145; HR 0.43; 95% CI 0.21, 0.86) and overall survival (OS) (15.0 vs. 6.8 mo, P = 0.0032; HR 0.31; 95% CI 0.14, 0.70). **Conclusions:** Longitudinal ctDNA analysis in the absence of matched tissue biopsy may be feasible. No significant increase in post-treatment ctDNA levels measured by NGS was associated with better prognosis in advanced lung adenocarcinoma treated with first-line chemo or chemoradiation therapy.

12078 Poster Session (Board #191), Mon, 1:15 PM-4:45 PM

Cancer genomics-based screening of new therapeutic targets and biomarkers for lung cancer. *First Author: Yataro Daigo, Research Hospital, Institute of Medical Science, The University of Tokyo, Tokyo, Japan*

Background: As the number of lung cancer patients who show objective response to standard therapies is still small, development of new anti-cancer drugs with minimum risk of adverse events and highly sensitive and specific cancer biomarkers is urgently awaited. **Methods:** We have been screening new molecular therapeutic targets and their companion biomarkers for lung cancer as follows; i) To identify up-regulated genes in lung cancers by the gene expression microarray, ii) To verify the candidate genes for their low expression in normal tissues, iii) To validate the clinicopathological significance of their protein expression by tissue microarray covering 385 lung cancers, and iv) To verify their function for the growth/survival/invasion of cancer cells by siRNAs. **Results:** We identified various candidate oncoproteins and selected a serine/threonine phosphatase *LAPP1* (lung cancer-associated protein phosphatase 1). Immunohistochemical analysis revealed that LAPP1 was expressed in 253 of 385 (65.7%) lung cancer tissues but not in healthy lung epithelia. LAPP1 expression was significantly associated with poor prognosis for lung cancer patients ($P < 0.0001$), and multivariate analysis confirmed its independent prognostic value. Further analysis identified EF1D (a cadmium-responsive proto-oncogene) as a LAPP1-interacting protein that was highly expressed in lung cancers. Suppression of LAPP1 or EF1D expression by siRNAs inhibited cell growth, whereas exogenous expression of LAPP1 in EF1D(+) cells elevated the dephosphorylation of EF1D(+), and subsequent increase of active phospho-AKT. Blocking this interaction by a cell-permeable peptide corresponding to a leucine zipper motif in EF1D destabilized EF1D protein and inhibited cancer cell growth and invasion. **Conclusions:** Cancer genomics approach could facilitate the development of diagnostic and prognostic biomarkers as well as therapeutic targets for small molecules, monoclonal antibodies, nucleic acid drugs, and cancer vaccines.

12079 Poster Session (Board #192), Mon, 1:15 PM-4:45 PM

Chimeric antigen receptor T cells targeting the lambda light chain of human immunoglobulin as a viable target for B cell non-Hodgkin lymphoma. *First Author: Raghuveer Ranganathan, University of North Carolina-Chapel Hill, Chapel Hill, NC*

Background: Mantle Cell Lymphoma (MCL) is an uncommon and clinically aggressive subtype of B cell derived non-Hodgkin lymphomas (B-NHL) which continues to have poor outcomes of all B-NHLs. Chemotherapy plus CD20-targeting antibodies make remission possible, with fit patients consolidated with autologous stem cell transplant but effects are invariably short-lived and MCL continues to principally be incurable. Adoptive chimeric antigen receptor T cells targeting CD19 (CD19.CAR-T) has shown therapeutic promise for B-NHL. Targeting this antigen, however, does not distinguish between normal and malignant B cells and causes profound B-cell aplasia since CD19.CAR-T can persist long-term. MCL, along with many diffuse large B cell lymphoma (DLBCL) subsets, expresses surface immunoglobulin (Ig) that carries the lambda light chain. We explored targeting Ig-lambda with CAR-T, which would possibly spare B lymphocytes expressing the reciprocal kappa light chain, and consequently reduce the impairment of humoral immunity. **Methods:** We genetically modified CAR-T cells to target the tumor-associated immunoglobulin lambda light chain (CAR.λ). We conducted in vitro trials with B-NHL derived tumor cell lines expressing the lambda light chain, and in vivo experiments using a NOD-*scid* xenograft murine model injected with these same tumor cell lines. We also established a murine model that reconstituted human B lymphocytes within immunosuppressed NSG mice using CD34+ umbilical cord blood cells. We then measured the selective ability of CAR.λ cells to eliminate normal human B-lymphocytes. **Results:** We found that the CAR.λ showed high cytotoxic activity against Ig-lambda+ B-cell tumor cell lines in vitro and in vivo within the NOD-*scid* xenograft murine model. We also demonstrated the selective elimination by the CAR.λ of lambda light chain-expressing B lymphocytes, with sparing of kappa chain-expressing B lymphocytes, in a humanized murine model. **Conclusions:** Adoptive transfer of CAR-T targeting the lambda light chain can be a very useful immunotherapy approach to treating both MCL and DLBCL clinically, without entirely compromising humoral immunity.

12080 Poster Session (Board #193), Mon, 1:15 PM-4:45 PM

Successful generation of patient derived xenografts and patient derived 3D cultures as preclinical models for breast cancer. *First Author: Verena Imke Isabel Kiver, Charite Comprehensive Cancer Center and Department of Gynecology and Breast Center Charité Universitätsmedizin Berlin Campus Mitte, Berlin, Germany*

Background: The establishment of patient-derived preclinical models in breast cancer has been a challenge for many years. We report our successful experience in establishing breast cancer patient derived xenografts (PDX) and patient derived 3D cultures (PD3D). **Methods:** Tumor tissue samples (twice 3mm diameter) from breast cancer patients undergoing surgery were collected by a team of gynecologists and pathologists. Ischemia time was minimized. Small tumor fragments were transplanted to immunodeficient NOG mice. The other part was used to establish a cell culture on serum free organoid media in the presence of growth hormones and, in case of hormone receptor positive breast cancer, estradiol supplementation. To address the question whether the genetics features of the model have changed during the process of engraftment and expansion the established models are currently undergoing molecular profiling. **Results:** Since May 2017 28 breast cancer samples have been processed. The sample characteristics are summarized in the table. Currently we have one PDX established, 18 in passage and 9 have not engrafted. Breast cancer PD3D organoids had a take rate of 56% under our culture conditions. Moreover, hormone receptor positive breast cancer PD3D models were successfully established as PD3D with a take rate of 37.5%. **Conclusions:** A high take rate under improved culture conditions provided a versatile method of patient-derived preclinical model generation.

Take rates and distribution of breast cancer subtypes.

Role of PD-L1 expression in triple-negative breast cancer stem cells. *First Author: Massimo A. Di Nicola, Fondazione IRCCS Insituto Nazionale Tumori, Milan, Italy*

Background: Triple negative breast cancer (TNBC) is characterized by poor prognosis, lack of specific-targeted agents and is in need of new therapeutics. Immune checkpoint blockers have shown significant efficacy against various tumors, including TNBC. Recent evidences suggested that PD-L1 expression on cancer stem cells (CSCs) might induce immune evasion. We have investigated the role of PD-L1 expression on TNBC stem cells (TNBCSCs). **Methods:** Formalin-fixed, paraffin embedded (FFPE) samples from TNBC patients treated at our Institution and at Fundación Mexicana de Fomento para la Prevención Oportuna del Cáncer de Mama, were analyzed for PD-L1 and immune gene pathways expression and for cancer stemness features. TNBC cell lines (MDAMB231, MDAMB468, SUM149, SUM159, and BT549) and syngeneic high-grade mammary murine models (SN25A) were used to elucidate the mechanisms behind PD-L1 implication in TNBC stemness. **Results:** FFPE tumor samples from a total of 158 TNBC patients were sorted according to the high (79 cases; 50%) and low (79 cases; 50%) median level of PD-L1 transcript. In our series, PD-L1 expression was associated with the stemness-score ($p = 0.026$) and with the up-regulation of CSC-related WNT signaling pathway. Digital fluorescence microscopy analyses revealed a preferential PD-L1 expression in $ALDH^+$ and $CD44^+$ cells. This data was confirmed *in vitro*, being the significant and constitutive higher expression of PD-L1 associated with $ALDH^+$ and CD44-high TNBCSC subsets but not with their neg/low expressing counterparts. Also, $PD\text{-}L1^+$ TNBC cells had a significantly higher mammosphere-forming efficiency than $PD\text{-}L1^-$ TNBC cells. On the same line, XAV-939, a specific inhibitor of WNT, significantly impaired PD-L1 expression indicating their active cross-talk in sustaining stemness feature. *In vivo*, we observed that in syngeneic murine high grade mammary tumor models, Sca^+ and $PD\text{-}L1^{High}$ tumor elements took close contact with CD8 and CD3 T cells suggesting a direct interaction between CSCs and lymphoid cells. **Conclusions:** Our study shows that TNBCSCs up-regulate PD-L1 through the activation of the WNT pathway. Unveiling this new mechanism of TNBC immune modulation, we suggest of targeting the WNT pathway to overcome TNBC immune-evasion.

12082 Poster Session (Board #195), Mon, 1:15 PM-4:45 PM

Local drug activation technology to make cytotoxics safer for localized solid tumors. *First Author: Sangeetha Srinivasan, Shasqi Inc., San Francisco, CA*

Background: Only 1-2% of systemic chemotherapies actually reaches a localized tumor while the rest can result in severe off-target effects. There is a critical need to safely deliver cytotoxics directly to the tumor. **Methods:** Shasqi's Therapy (Shasqi Tx) is a bioorthogonal chemistry-based approach consisting of 1) a drug-activating gel and 2) a systemic prodrug. The biocompatible tetrazine (Tz)-modified gel is injected at tumor site and a *trans*-cyclooctene (TCO)-modified prodrug of a cytotoxic agent such as doxorubicin (Dox), with attenuated activity is given systemically. The prodrug concentrates through a covalent reaction between TCO and the Tz located at the gel. The active drug is spontaneously released over multiple days, directly in the tumor compartment. Remaining prodrug is rapidly cleared by systemic routes, minimizing off-target effects. This technology is reloadable and independent of biological processes. The attenuation of prodrug activity enables an increase in therapeutic index while reducing systemic side effects, as the active drug predominantly localizes to the gel site. **Results:** NSG-H mice injected with Tz-modified alginate gel and systemic TCO-doxorubicin (TCO-Dox; prodrug of Dox). The maximum tolerable dose (MTD) of single dose of TCO-Dox was >12x and as 5 daily doses was >38x of single MTD of Dox (control), without any adverse effects. Preliminary bioanalysis provides a basis for the improved safety of Shasqi Tx over traditional chemotherapy. Gel-injected BALB/c mice received TCO-Dox IV. In serum 5 min after injection > 90% of the circulating anthracycline remained as intact prodrug while ~7% was converted to Dox. Finally, we tested Shasqi Tx's safety in a pilot dog study with spontaneous local adenocarcinoma. Standard Dox therapy led to disease progression with a drastic drop in body weight. Then, multiple cycles of Shasqi Tx given at > 11x the lifetime MTD of Dox, reduced tumor size and led to stable disease for > 430d, body wt. gain without major side effects. **Conclusions:** Shasqi Tx enhances delivery of toxic drugs to a target site while limiting exposure in off-target tissues in small and large animals. Further, the increase in therapeutic index allows greater doses of cytotoxics to be delivered safely.

12083 Poster Session (Board #196), Mon, 1:15 PM-4:45 PM

Clinicopathologic characteristics and molecular features of BRG1-deficient non-small cell lung cancer (NSCLC). *First Author: Ibiayi Dagogo-Jack, Massachusetts General Hospital, Boston, MA*

Background: Genomic alterations (GA) in *SMARCA4*, the gene encoding the SWI/SNF complex subunit BRG1, have been observed in 10% of NSCLC. RNA-based analyses suggest that loss of BRG1 expression is frequently associated with frameshift/nonsense (F/N) *SMARCA4* GA. In preclinical studies, BRG1 deficiency sensitizes to enhancer zeste homolog 2 (EZH2) inhibition combined with chemotherapy (PMID: 25629630). To characterize the subset with *SMARCA4* GA, we reviewed 2 independent NSCLC datasets and analyzed BRG1 protein expression in cases with available tissue. **Methods:** To identify cases with *SMARCA4* GA, we examined the molecular profiles of 27,281 NSCLCs sequenced at Foundation Medicine (FM) and a separate cohort of 820 consecutive NSCLCs sequenced at Massachusetts General Hospital (MGH). We performed immunohistochemistry (IHC) using the Abcam rabbit BRG1 antibody (EPR3912) to assess BRG1 expression in NSCLCs with *SMARCA4* GA. **Results:** We detected *SMARCA4* GA in 73 (9%) and 3,188 (11%) patients (pts) in the MGH and FM datasets, respectively. *SMARCA4* GA were distributed throughout all protein domains. F/N GA comprised approximately one-third of *SMARCA4* GA in both groups (MGH: 32% and FM:36%). 40 pts (15 with F/N GA) in the MGH group had available tissue for IHC. Thirteen specimens—all from smokers with F/N *SMARCA4* GA— had loss of BRG1 expression. Median age of pts with absent BRG1 expression was 69.2 years. Loss of BRG1 expression was observed in 9 adenocarcinomas as well as 2 poorly-differentiated,1 sarcomatoid, and 1 neuroendocrine carcinoma(s). Ten of the 13 pts with BRG1-deficient NSCLC underwent PD-L1 testing. Eight tumors had no PD-L1 expression and one had ≥50% expression. With the exception of 5 (38%) pts with concurrent *KRAS* GA, we did not find driver GA in the BRG1-deficient specimens. As BRG1 loss was limited to F/N GA, we queried the FM dataset to identify genes frequently co-altered with F/N *SMARCA4* GA. F/N *SMARCA4* GA commonly co-occurred with *TP53* (74%), *CDKN2A* (38%), *STK11* (34%), and *KRAS* (26%) GA. **Conclusions:** *SMARCA4* GA are present in approximately 10% of NSCLC, but our data suggest that F/N GA may disproportionately lead to BRG1 loss. F/N *SMARCA4* GA occur in 3-4% of NSCLC and overlap with *KRAS* GA.

12084 Poster Session (Board #197), Mon, 1:15 PM-4:45 PM

Incidence of *Neuregulin1* (*NRG1*) gene fusions across tumor types. *First Author: Stephen V. Liu, Georgetown University Medical Center, Washington, DC*

Background: *NRG1* gene fusions are an emerging potential therapeutic target in non-small cell lung cancer (NSCLC). NRG1 is a ligand for the HER3 tyrosine kinase and *NRG1* fusions can activate oncogenic HER2/HER3 and PI3K-AKT signaling. The pan-ErbB inhibitor afatinib has been associated with durable response in patients with *NRG1*+ lung adenocarcinoma. *NRG1* fusions and the specific fusion partners have not been well characterized across different tumor types. **Methods:** Tumor samples submitted for profiling between 01/16 - 01/18 at a CLIA-certified genomics laboratory (Caris Life Sciences, Phoenix, AZ) were assayed with anchored multiplex PCR for targeted RNA sequencing with the ArcherDX fusion assay (Boulder, CO). Novel isoforms and fusions with high reads (defined as > 10% of total reads), high confidence after bioinformatics filtering and considered in-frame are included in this analysis. **Results:** In a cohort of 14,150 tumors successfully assayed, 31 cases (0.2%) harbored an *NRG1* fusion. The incidence of *NRG1* fusions varied by tumor type: 0.9% thyroid (1/116), 0.5% ovary (3/574), 0.5% cholangiocarcinoma (1/194), 0.4% pancreas(2/510), 0.3% NSCLC (20/5869), 0.2% breast (2/927), 0.2% sarcoma (1/475), and 1 case in sinonasal teratocarcinoma (SNTC). One of the 20 NSCLC cases (NRG1- SDC4) had squamous histology, the remaining were adenocarcinoma. No *NRG1* fusions were detected in colorectal cancer (0/1382) or glioblastoma multiforme (0/1200). In NSCLC, *NRG1* fusions were mutually exclusive with oncogenic alterations in *EGFR*, *ALK*, *ROS1*, *RET*, and *KRAS* with the exception of one case that co-occurred with a *KRAS* G12C mutation. Fusion partners are shown below. **Conclusions:** Gene fusions in *NRG1* can be identified in various tumor types though the highest number of events was in NSCLC. Consistent detection of *NRG1* fusions will need to account for multiple fusion partners. The optimal treatment of tumors harboring *NRG1* fusions needs to be established.

Tumor Type	NRG1 fusion partners
NSCLC	CD74 (n = 8), SDC4 (n = 3), ATPB1, DPYSL2, MRPL13, OAS2, PARP8, ROCK1, SLCA3, TNC, WRN (n = 1, each)
Ovary	ZMYM2, SETD4, TSHZ2 (n = 1, each)
Pancreas	CDH1, VTCN1 (n = 1, each)
Breast	ADAM9, COX10-AS1 (n = 1, each)
Thyroid	TRAF3IP2
Cholangiocarcinoma	NOTCH2
Sarcoma	WHSC1L1
SNTC	HMBOX1

12085 Poster Session (Board #198), Mon, 1:15 PM-4:45 PM

Effect of anti-PD-1 and anti-Id-1 combo on tumor response and survival in lung cancer. *First Author: Iosune Baraibar, Department of Oncology, Clínica Universidad de Navarra, Pamplona, Spain*

Background: PD-1/PDL-1 inhibitors are approved in advanced non-small cell lung cancer (NSCLC). Long-term survivals associated to PD-1/PDL-1 blockade have changed treatment paradigm. However, many patients do not benefit from PD-1/PDL-1 blockade. New therapeutic combinations are under investigation. Id1 is involved in proliferation, angiogenesis and immunosuppression. We described Id1 as a prognostic factor in NSCLC (Ponz-Sarvise, Clin Cancer Res 2011) and more recently showed Id1's role in lung cancer metastasis (Castanon, Cancer Letters 2017). Here we test a combined therapeutic strategy targeting PD-1 and Id1 in a murine lung cancer model. **Methods:** Three *in vivo* studies evaluated the impact of *Id1* inhibition in tumor cells, tumor microenvironment and in both, on tumor volumes and mice survival. A syngeneic tumor model using C57BL/6 and *Id1-/- Id3+/-* mice was created by subcutaneous injection of Lewis Lung Carcinoma (3LL) cells and *Id1* silenced 3LL (*Id1Sh*) cells. After injection, mice were treated with an anti-PD-1 (RMP-1-14) monoclonal antibody or PBS. Tumor volumes according to mice strain, *Id1* status in tumor cells and treatment were quatified. Mice's survival was calculated in those groups.Tumors PD-L1 expression and CD8+ and CD3+ TILs and CD68+ cells were quatified by specific immunostainings. **Results:** Id1 inhibition in the tumor environment and the injected tumor cells, combined with anti-PD-1 treatment, induced a significant tumor growth impairment ($p < 0.0001$) and increased survival ($p = 0.0051$). CD3+ and CD8+ TILs and tumor CD68 + cells were significantly higher in tumors from mice with the combined *Id1*-PD-1 blockade treated with the anti-PD-1 inhibitor compared to control animals suggesting that tumor increased immune-related cells infiltration exerts the effector phase of the antitumor immune response. Additionally, PD-L1 expression seemed to be higher when Id1 expression was absent in the immune microenvironment ($p = 0.04$). **Conclusions:** *Id1* and PD-1 combined blockade in our syngeneic murine lung cancer model significantly impaired tumor growth and increased survival. Increased tumor PD-L1 expression and CD3+ and CD8+ TILs and CD68+ cells may explain these findings.

12086 Poster Session (Board #199), Mon, 1:15 PM-4:45 PM

Novel ex vivo patient-derived 3D model as a powerful tool to apply precision medicine. *First Author: Kayla Simeone, Centre de recherche du CHUM, Montreal, QC, Canada*

Background: Among the several therapeutic options available to treat Castrate-Resistant Prostate Cancer (CRPC), choosing the most suitable option for an individual patient remains a clinical challenge. For this, our group has developed a novel ex-vivo model based on patient-derived micro-dissected tissues (MDT) cultivated in microfluidic devices to determine patient sensitivity profile in the presence of therapeutic agents. **Methods:** MDTs (~400 μm in diameter) derived from PC cell line xenografts (DU145 and LnCaP) were exposed to docetaxel (10 nM for 12 hours) or enzalutamide (10 μM for 24 hours) and analyzed after a 12-hour recovery period or immediately after exposure time. Cell fate was measured using flow cytometry techniques (Annexin V for apoptotic cells and DRAQ7 for dead cells) and by a technique based on formalin fixed paraffin embedding of MDTs within a microfluidic device creating a high-density MDT-Array (MDTA). Using MDTA we can monitor MDT viability (cleaved caspase-3), proliferation (Ki-67) and epithelial composition (CK 8/18) by immunohistochemistry (IHC) and immunofluorescence (IF). MDTs were also separately treated with TNF-α at a concentration of 10 ng/mL for 30 minutes and analyzed by MDTA. **Results:** We show that the microfluidic device does not affect the viability (> 85% by flow cytometry) or proliferative capacity (60% by IHC) of the MDTs during a culture period of 15 days in PC cell line xenograft models (N = 3 for LNCaP, N = 2 for DU145). Pharmacological responses to docetaxel showed 50% increase in caspase-3 activity by IF and 20% increase in cell death by flow cytometry compared to control MDTs. Enzalutamide response was dependent on the cells 2D hormone sensitivity profile. The nuclear translocation of p65 was also monitored in 80% of MDTs treated with TNF-α. **Conclusions:** Within less than 5 days, we can obtain treatment response analysis using our ex vivo drug response model, appropriate for clinical decision-making, The precise techniques developed within our lab, allows the characterization of molecular responses of cancerous cells in the presence of various therapeutic agents while conserving the natural tumor microenvironment.

12087 Poster Session (Board #200), Mon, 1:15 PM-4:45 PM

Genetic and chemical screens in 2-D vs. 3-D generate distinct leads for target and drug discovery. *First Author: Piyush Gupta, Whitehead Institute/MIT, Cambridge, MA*

Background: Oncology drug discovery programs commonly utilize genetic or chemical screens with cancer cell lines propagated on two-dimensional (2D) plastic surfaces. While convenient for high-throughput screens, such cultures do not incorporate the extracellular matrix (ECM) present in patient tumors, which plays a critical role in determining cancer cell signaling. This has led to significant concerns about the biological relevance of targets discovered using standard 2D cultures, but the extent to which performing assays in 3D ECM would alter the leads generated by screening is not known. **Methods:** We have recently developed 3D hydrogel scaffolds that replicate the physical and signaling characteristics of human tissues. We performed both high-throughput CRISPR and chemical screens, doing so in parallel either in standard 2D cultures or in 3D ECM. The CRISPR screen included 10 sgRNAs targeting each of 507 kinases in the human genome. The chemical screen was performed with 780 drugs approved by the FDA for oncology and other indications. **Results:** The CRISPR screen identified major differences in the kinase pathways utilized by cancer cells in 3D vs. 2D. We discovered 29 kinases that were essential for promoting growth in 3D tissues but had no phenotype when inhibited in 2D. In addition, 3 kinases were essential in 2D culture but were not essential in 3D ECM. The drug screen identified agents that inhibited cancer cell viability or invasion. Drugs that inhibited viability were strongly enriched for FDA-approved oncology drugs. By contrast, most of the 26 drugs that were potent inhibitors of cancer cell invasion in 3D were approved for non-oncology indications (22/26), identifying opportunities to 'repurpose' drugs to target cancer invasion. **Conclusions:** Our findings establish the importance of conducting target and drug discovery efforts in biomimetic 3D conditions that replicate the matrix content of human tissues. Continued use of standard 2D cultures poses a risk of generating both false-positives and false-negatives – identifying spurious leads that will not validate in follow up studies, or failing to identify novel leads that are promising candidates for follow-up validation.

12088 Poster Session (Board #201), Mon, 1:15 PM-4:45 PM

Early assessment of treatment effect in advanced lung adenocarcinoma via longitudinal ctDNA analysis. *First Author: Xiaoju Max Ma, Roche Molecular Syst, Pleasanton, CA*

Background: Despite routine use of chemotherapy in advanced non-small-cell lung cancer (NSCLC) patients, the knowledge of optimal prognostic methods is still limited to imaging-based methods. We hypothesized that an early response assessed by mutant molecules count in plasma could predict the treatment effect. **Methods:** We employed AVENIO ctDNA Surveillance Kit, a 197-gene NGS assay, which allowed us to perform longitudinal ctDNA analysis and measure the mutant molecules per milliliter-of-plasma (MMPM), which quantifies ctDNA at the variant level. The association between changes in ctDNA levels and survival was evaluated in advanced lung adenocarcinoma subjects. Post-treatment MMPM values were compared with the MMPM value at baseline and/or the previous treatment timepoint. **Results:** At baseline (b0), we identified variants in all (93/93) subjects to enable ctDNA monitoring. From the training cohort (50 subjects), we were able to set the cutoff of 40 for the mean MMPM at post-first treatment cycle (p1). Applying the MMPM cutoff of p1 to the validation cohort (43 subjects with stage IV lung adenocarcinoma, from a prospective, observational study) low levels of ctDNA toward the end of first treatment cycle was associated with better progression-free survival (PFS) (P = 0.0088 HR 0.4; 95% CI 0.20 - 0.83) and overall survival (OS) (P = 0.0026 HR 0.32; 95% CI 0.15 - 0.71). The prognostic value is increased by applying the Continuous Responder algorithm, defined by a continuous drop in ctDNA levels represented by mean MMPM reduction over time ($p2 < p1 < b0$), to a mean MMPM below 8 at p2. As a result, continuous responders 13/43 (30%) were associated with a better therapy response indicated by PFS (P = 0.028 HR 0.45; 95% CI 0.23 - 0.90) and OS (P = 0.0074 HR 0.3; 95% CI 0.12 - 0.77). The continuous responders demonstrated a median overall survival benefit of 11.25 months over the poor responders. **Conclusions:** A decrease in post-treatment ctDNA level measured by NGS was associated with better prognosis in advanced lung adenocarcinoma. An early assessment of treatment effect can be measured by mutant molecule counts in the plasma within 1 or 2 treatment cycles.

12089 Poster Session (Board #202), Mon, 1:15 PM-4:45 PM

Quantitative measurement of total erbB2 (H2T), p110 t-erbB2, and erbB2: erbB3 (H23D) heterodimer expression and p110 t-erbB2 in malignant progression from ductal carcinoma in situ (DCIS) to invasive ductal carcinoma (IDC). *First Author: Yu Zong, Stanford Cancer Institute, School of Medicine, Stanford University, Stanford, CA*

Background: We previously reported that human mammary epithelial cell lines stably expressing p110 t-erbB2, but not p95 nor erbB2 intracellular C-terminal fragment, significantly increased cell migration, invasion and xenograft formation – more than full length p185 erbB2 [Ward, *et al.*, Oncogene. 2013;32(19):2463-74]. Moreover, published frequency of erbB2 overexpression is higher in DCIS (41%) than IDC(~20%), suggesting erbB2 may play a role in tumor initiation, rather than progression to invasion. We hypothesized that p185 erbB2 in DCIS is insufficient to cause an invasive phenotype, and that enrichment of p110 t-erbB2 facilitates malignant progression to IDC. **Methods:** H2T, p110 t-erbB2, and H23D were quantified using the proximity-based HERmark and VeraTag assay technology (CLIA/CAP-certified conditions) in 67 DCIS and 70 IDC erbB2-amplified/overexpressed FFPE samples. Macrodissection ensured pure IDC or DCIS samples. Measurements were normalized to cell line standards of known H2T, p110 t-erbB2 and H23D levels, with cutoffs established as previously described [Huang W, *et al.*, Am J Clin Pathol. 2010;134:303-311; Sperinde J, *et al.*, Clin Cancer Res. 2010;16(16):4226-35]. **Results:** p110 t-erbB2 was higher in IDC than DCIS cases (p = 0.036). Level of H2T overexpression was strongly associated with high p110 t-erbB2 levels in IDC patients (R^2= 0.51, $p < 0.001$), but not in DCIS. p110 t-erbB2 difference between IDC vs. DCIS was more pronounced in the H2T overexpressed subset ($p < 0.001$). H2T and p110 t-erbB2 expression were in agreement with erbB2 IHC staining (H2T p = 0.002; p110 t-erbB2 p = 0.04, respectively); and inversely correlated with estrogen receptor levels (H2T p = 0.009; p110 t-erbB2 p = 0.004, respectively). In IDC, high expression of H23D levels were not significantly different between DCIS and IDC cases (p = 0.13). **Conclusions:** Our study is the first quantitative assessment of H2T, p110 t-erbB2 as well as H23D expression in both DCIS and IDC. These data suggest a potential pathophysiologic role of p110 t-erbB2 in driving progression of erbB2 positive DCIS to IDC.

12090 Poster Session (Board #203), Mon, 1:15 PM-4:45 PM

Towards a molecular algorithm predicting glioma treatment response and resistance: A biomarker analysis and path to real time profiling in N^2M^2. *First Author: Tobias Kessler, Neurology Clinic, DKFZ, DKTK, Heidelberg, Germany*

Background: Gliomas regularly evade current therapies through primary and acquired resistance and the effect of temozolomide is mainly restricted to the subgroup of *methylguanin-O6-methyltransferase promoter* (*MGMT)* hypermethylated tumors. Further resistance markers and pathways against chemotherapy, radiotherapy and targeted agents are unknown, but will be important in targeted warehouse studies like NCT Neuro Master Match (N^2M^2). **Methods:** The diagnostic pipeline involves clinical and molecular analysis of WHO grade III (n = 116) and WHO grade IV (n = 400) glioma patient samples focusing on methylation profiles as well as a prospective feasibility study of real time multilayer molecular profiling on various levels in 43 WHO grade IV patients with an unmethylated *MGMT* promoter. **Results:** *Isocitrate dehydrogenase* (*IDH)* wildtype glioblastomas mainly show three different methylation clusters (RTKI, RTKII and mesenchymal). Samples of Cluster 1 (RTKII) had higher prevalence of *MGMT* methylation, *TERT* methylation and *TERT* promoter mutation. *MGMT* methylation is only prognostic in this cluster, likely to be linked to *TERT* status. *TERT* promoter mutation is further associated with changes in the global methylation profile. DNA damage response (DDR) gene methylation patterns show association with survival in grade IIII and IV glioma, including *POLE4* linked to radiation response. The prospective N^2M^2 pilot study demonstrates feasibility of complex molecular profiling within four weeks and identified high confidence markers for targeted therapy in 35% of the patients. Furthermore, a therapeutic algorithm is proposed to allocate patients with high grade gliomas to the best possible treatment based on molecular biomarkers. This algorithm is ready to be adjusted by continues input from targeted clinical and preclinical studies and *in vivo* CRISPR screens. **Conclusions:** Multilayer molecular biomarker analysis for high grade glioma is feasible and can be implemented in a therapeutic algorithm estimating the most promising therapy according to current knowledge. Specifically, the TERT-DDR axis may be involved in resistance to chemo- and radiotherapy in high-grade glioma.

12091 Poster Session (Board #204), Mon, 1:15 PM-4:45 PM

***PBRM1* mutation and immunotherapy efficacy: A comprehensive genomic profiling (CGP) assessment.** *First Author: Gennady Bratslavsky, SUNY Upstate Medical University, Syracuse, NY*

Background: *PBRM1*, a member of the SWI/SNF family, is involved in chromatin remodeling. Recent evidence indicates that *PBRM1* inactivating mutations are associated with clinical benefit from immune checkpoint inhibitor treatments in clear cell renal cell carcinoma (ccRCC). **Methods:** CGP was performed on 140,411 specimens from solid tumors and hematologic malignancies using a hybrid capture-based NGS assay. Profiles were assessed for neoantigen load, tumor mutational burden (TMB), determined on 1.1 Mbp of sequenced DNA, and microsatellite instability (MSI) determined by principal components analysis of optimal homopolymer loci. Genomic alterations (GA) in *PBRM1* considered here were known loss-of-function GA or homozygous GA in the tumor. **Results:** *PBRM1* GA were identified in 3,674 (2.6%) cases. Compared to other tumor types, the *PBRM1* GA frequency was significantly higher in ccRCC at 45% ($P < 0.0001$); other tumor types with frequent *PBRM1* GA were renal cell carcinoma NOS (27%), site-specific mesothelioma (MESO) (7-20%), cholangiocarcinoma (CCA) (12%), and chordoma (11%). *PBRM1* GA were found in < 3% of highly prevalent tumors, including melanomas, carcinomas of lung, breast, colon and prostate, and all hematolymphoid malignancies. For ccRCC the most common co-altered genes with *PBRM1* were *VHL* (80%), *SETD2* (31%), *KDM5C* (15%), *PTEN* and *TP53* (13%), *TSC1* and *CDKN2A* (7%), *TERT*, *PIK3CA*, *BAP1* and *CDKN2B* (6%) and *MTOR* (5%). Top co-mutated genes in other tumors were *BAP1* (84%) and *NF2* (27%) in MESO; *ARID1A* (33%) and *IDH1* (30%) in CCA; and *PTEN* (11%) and *CDKN2A* (8%) in chordoma. Median TMB for *PBRM1*-mutated ccRCC was 2.5 mutations (mut)/Mb, with only one highly mutated sample (MSI-High and TMB ≥20 mut/Mb). These results were similar for *PBRM1* WT ccRCC (median 2.6 mut/Mb; no MSI-High or TMB ≥20 mut/Mb). Neoantigen load in ccRCC is significantly associated with *PBRM1* GA positivity ($p < 0.02$), but not TMB ($p < 0.50$). **Conclusions:** This study confirms *PBRM1* GA are significantly enriched in ccRCC, an immunotherapy responsive tumor type lacking high MSI or TMB. Further study of *PBRM1* GA in both renal and non-renal malignancies appears warranted, including evaluation of co-occuring GA that may predict ICPI efficacy.

12092 Poster Session (Board #205), Mon, 1:15 PM-4:45 PM

***PD-L1* genomic alterations (GA) in solid tumors and hematologic malignancies: A comprehensive genomic profiling (CGP) study.** *First Author: Laurie M. Gay, Foundation Medicine, Inc., Cambridge, MA*

Background: Amplification (AMP) of *PD-L1* (*CD274/B7H1*) has recently been linked to enhanced benefit from immune checkpoint inhibitor (ICPI) treatment. We used CGP to evaluate the *PD-L1* GA landscape in cancer. **Methods:** Specimens from 140,411 cancers representing > 450 individual disease ontologies were sequenced using a hybrid capture-based, next-generation sequencing assay. PD-L1 protein expression was measured by immunohistochemistry (IHC) in a subset of cases using the Dako 22C3 anti-PD-L1 antibody. **Results:** 1383 (0.9%) tumors had *PD-L1* GA (1414 GA): 879 (62%) AMP, 471 (33%) short variants (SV) and 60 (0.4%) truncating rearrangements (RE). *PD-L2* (*PDCD1LG2*) and *JAK2* were co-amplified in 94% and 82% of *PD-L1* AMP samples; other genes commonly altered with *PD-L1* AMP included *TP53* (77%), *CDKN2A/B* (28%/20%), *MYC* (21%), and *TERT* (13%). For samples with RE or SV, *PIK3CA* (19%; 21%) GA were common and *TERT* GA were in 7% or 14% of samples. Most SV GA were missense (88%), compared with truncating (10%) or splice site (2%) GA. Recurrent somatic variants of unknown significance (VUS) were observed, including frameshift and missense GA that may regulate PD-L1 stability. Of 10 common tumors, breast (213) and lung (210) carcinomas (CA) represented the most *PD-L1* AMP cases. Select cancers with notable *PD-L1* AMP frequencies were anaplastic thyroid CA (4%), head and neck squamous CA (HNSCC) (2.5%), cervical SCC (2.6%), and breast (1.4%), lung (0.7%) and bladder (0.6%) CA. Of common tumor types, such as colorectal, pancreatic, ovarian, or prostatic CA, melanoma and glioblastoma, ≤0.3% had *PD-L1* AMP. There was strong correlation between *PD-L1* AMP and PD-L1 expression by IHC in NSCLC, with 89% AMP positive samples showing > 50% IHC staining and 11% with positive but < 50% staining. Major clinical responses to ICPI therapies for tumors with *PD-L1* AMP will be presented. **Conclusions:** *PD-L1* AMP or other GA occur rarely across many cancer types. Many somatic PD-L1 GA are uncharacterized VUS. PD-*L1* AMP correlates with high membrane expression of PD-L1 measured by IHC and is linked to durable response to ICPI therapies. Further evaluation of *PD-L1* AMP as a potential biomarker for immunotherapy selection appears warranted.

12093 Poster Session (Board #206), Mon, 1:15 PM-4:45 PM

Dual MAPK inhibition (dMAPKi) as an effective therapeutic strategy for class II BRAF mutant (mt) metastatic melanoma (MM). *First Author: Matthew Dankner, McGill University, Montréal, QC, Canada*

Background: dMAPKi with BRAFi and MEKi improves survival in BRAF V600E/K mt MM, but the effects of these inhibitors on nonV600 BRAF mt MM is poorly understood. We sought to characterize nonV600/class II (enhanced kinase activity, dimerization dependent) BRAF mt MM and to investigate their responsiveness to MAPKi. **Methods:** We analyzed 3 MM datasets (PMH next generation sequencing (NGS) cohort, TCGA, GENIE) for clinicopathologic correlations and outcomes of nonV600 BRAF mt MM pts. Tumors from patients with BRAF WT, V600E (class I), and L597S (class II) MM were used to generate patient-derived xenografts (PDX); both were subjected to NGS analysis with the CANCERPLEX assay. We generated and obtained 8 MM cell lines with class IIa (activation segment) or IIb (p-loop) mt and compared these to BRAF WT and V600E/K MM cells. Cell lines and PDXs were treated with BRAFi (vemurafenib, dabrafenib, encorafenib) and MEKi (cobimetinib, trametinib, binimetinib), or the combination. They were investigated with immunoblots, *in vitro,* and *in vivo* growth assays. We identified two patients with BRAF L597S MM who were treated with dMAPKi. **Results:** NonV600 BRAF mutants comprise 10-35% of all BRAF mts in MM. NonV600 BRAF mts are frequently co-expressed with NRAS mts and associated with poor survival compared to BRAF V600E/K MM (HR 1.49, 95% CI 1.09-2.06). BRAFi impaired Erk phosphorylation and cell growth in class I and IIa BRAF mt cells. dMAPKi was more effective than either single MAPKi at inhibiting cell growth in all class IIa and IIb cell lines tested. PDXs retained high genomic fidelity to the primary tumors from which they were derived. In two independent BRAF L597S (class IIa) PDX models, single MAPKi only slowed the progression of tumor growth whereas dMAPKi resulted in significant tumor shrinkage. Two patients with BRAF L597S mt melanoma obtained objective clinical responses to dual MAPKi. **Conclusions:** NonV600 BRAF mt MM are associated with poor prognosis. Class II BRAF mt MM are growth inhibited by dMAPKi. Responses to dMAPKi have been observed in two patients with class II BRAF mt MM. Our data provide rationale for clinical investigation of dual MAPKi in patients with class II BRAF mt MM.

12094 Poster Session (Board #207), Mon, 1:15 PM-4:45 PM

Large-scale analyses of tumor mutation burdens (TMBs) across various advanced gastrointestinal (GI) malignancies in the nationwide cancer genome screening project, SCRUM-Japan GI-SCREEN. *First Author: Yoshiaki Nakamura, Department of Gastroenterology and Gastrointestinal Oncology, National Cancer Center Hospital East, Kashiwa, Japan*

Background: Tumor mutation burdens (TMBs) in advanced gastrointestinal (GI) malignancies have not been well-characterized. We analyzed TMB in tissue samples from advanced GI malignancies using the Oncomine Cancer Research Panel (OCP), a targeted next-generation sequencing panel, as part of the Nationwide Cancer Genome Screening Project (SCRUM-Japan GI-SCREEN). **Methods:** The performance of the OCP panel for TMB analysis was assessed using whole-exome sequencing (WES) data from 10,183 samples in the Cancer Genome Atlas (TCGA). Then, TMBs were calculated based on somatic non-synonymous mutations in the following 1,759 GI tumors: colorectal cancer (CRC, n = 751), gastric cancer (GC, n = 509), esophageal cancer (EC, n = 143), pancreatic cancer (PC, n = 136), biliary tract cancer (BTC, n = 92), small intestinal cancer (SIC, n = 30), gastrointestinal stromal tumor (GIST, n = 29), hepatocellular carcinoma (HCC, n = 27), neuroendocrine tumor/cancer (NET/NEC, n = 27), appendiceal cancer (AC, n = 12), and anal canal cancer (ACC, n = 3). High TMB was defined as more than 20 mutations per megabase (mt/Mb). CRC microsatellite instability (MSI) status was assessed using a PCR-based method. **Results:** TMBs estimated from the OCP-targeted region based on TCGA data were strongly correlated with those from TCGA whole-exome sequencing data (R^2 = 0.720). TMBs in the GI-SCREEN ranged from 0 to 103.6 mt/Mb across various tumor subtypes. In CRC, 75% of MSI-high (MSI-H) and 17% of non-MSI-H tumors had high TMB. In non-CRC, high TMB was identified in 13% of GC, 17% of EC, 28% of PC, 26% of BTC, 30% of SIC, 7% of GIST, 7% of HCC, 15% of NET/NEC, 25% of AC, and 33% of ACC tissues. TMB was not associated with sex, age, histology (adenocarcinoma vs. squamous cell carcinoma), prior chemotherapy, or radiotherapy. Tumors with mutations in DNA damage response (DDR) genes (*ATM*, *BRCA1*, *BRCA2*, *MLH1,* and *MSH2*) had higher TMB than those with wild-type DDR genes ($p < 0.001$). **Conclusions:** TMB varied widely across various advanced GI malignancies. TMB analysis may be used as an agnostic histologic indicator to identify patients with GI malignancies who can benefit from immunotherapy. Clinical trial information: UMIN000016343.

12095 Poster Session (Board #208), Mon, 1:15 PM-4:45 PM

Preselection of lung cancer cases using FGFR1 mRNA and gene copy number for treatment with ponatinib. *First Author: Terry L. Ng, University of Colorado Cancer Center, Aurora, CO*

Background: NSCLC and SCLC cell line data suggested high FGFR1 mRNA levels and FGFR1 amplification (FGFR1-AMP) could predict sensitivity to FGFR TKIs. Overlap with KRAS mutations did not preclude TKI sensitivity. Ponatinib is a multi-kinase inhibitor of ABL, RET and FGFR1-4. **Methods:** Metastatic EGFR- and ALK-negative lung cancers were pre-screened for FGFR1-mRNA by in-situ hybridization (ISH) and FGFR1-AMP by silver in-situ hybridization (SISH). Initial positivity cutpoints were based on cell line sensitivity at predicted ponatinib exposure. ISH and SISH positive cases were offered treatment with ponatinib at 45 mg QD. Differences in overall survival (OS) between cohorts were assessed using log-rank test. Association of FGFR1 positivity with clinicopathologic features were assessed using Fisher's exact test and Kruskal-Wallis rank sum test. **Results:** From 2013-2017, 171 cases were prescreened (123 SISH and 126 ISH samples reported): 9/123 (7.3%) were SISH+; 53/126 (42.1%) were ISH+; 6 were concordantly positive for SISH and ISH. At the initial cutpoint, no specific correlations with age, sex, smoking status, or response to platinum therapy were identified. However, SISH+ cases had fewer coincident KRAS mutations (p = 0.03) than SISH- cases, and ISH+ cases had worse OS (p = 0.020) than ISH- cases. Exploring data for natural higher cutpoints did not alter SISH positivity but did suggest a higher cutpoint for FGFR1 ISH (≥ 20% dot cluster [23% [29/126] cases]), associated with SCLC histology (p = 0.022), soft tissue metastases (p = 0.050) and shorter OS (p = 0.031). Four patients received ponatinib: All were FGFR1 ISH+ by the initial cutpoint (≥ 1% dot cluster), 2/4 were ISH ≥ 20% dot cluster, and 1/4 was SISH+. Tolerability was poor. The best response for the two ISH ≥ 20% cases was SD and for the two ISH ≥ 1% cases, it was PD (ORR 0%, DCR 50%). **Conclusions:** High FGFR1-mRNA is more common than FGFR1-AMP and was associated with worse OS. Higher levels of FGFR1 mRNA may be associated with a specific phenotype and is worthy of further exploration. Ponatinib's poor tolerance suggests further FGFR exploration in ISH+ cases should utilize more selective FGFR1 inhibitors. Clinical trial information: NCT01935336.

12096 Poster Session (Board #209), Mon, 1:15 PM-4:45 PM

***RAS* alterations: Next-generation sequencing of 1,526 patients with diverse malignancies reveals prognostic and therapeutic correlates.** *First Author: Shumei Kato, University of California, San Diego, La Jolla, CA*

Background: To date, there is no successful strategy to target *RAS* alterations. To better understand the clinical impact of different *RAS* abnormalities, we interrogated the genomics of diverse metastatic/recurrent solid cancers. **Methods:** We evaluated the molecular profiles of 1,526 patients with diverse malignancies for *RAS* aberrations as well as co-altered genes using clinical grade next-generation sequencing (NGS) (Foundation Medicine) (182 - 406 gene panels). Therapy and clinical outcomes were assessed (NCT02478931). **Results:** Overall, 23.5% (358/1,526) harbored *RAS* alterations (*KRAS*: 19.3%, *NRAS*: 3.2%, *HRAS*: 1.1% [N = 1 with both *K*- and *NRAS* alterations]). Patients with *RAS* alterations had shorter overall survival (OS) than *RAS* wild-type patients: OS (hazard ratio [HR]: 1.24, 95% confidence interval [CI]: 1.03-1.48, P = 0.02) (multivariate analysis). Amongst *RAS* mutations, *KRAS G12V, KRAS G13D*, and *KRAS* amplification had the shortest OS (multivariate analysis, P = 0.004, 0.004, and 0.02). Co-alterations were seen in 96.4% (345/358) of *RAS*-mutated patients; patients with PI3K signaling pathway or cell cycle-associated co-altered genes had significantly worse OS when compared to patients without such alterations (HR: 1.52, 95% CI: 1.15-2.01, P = 0.004 and HR: 1.99, 95% CI: 1.49-2.67, P < 0.0001 respectively) (multivariate analysis). 293/358 *RAS*-mutated recurrent/metastatic solid tumors were evaluable for progression-free survival (PFS). Patients treated with matched therapy targeting non-MAPK co-altered signals (N = 124) had a trend towards longer PFS (HR: 0.79, 95% CI: 0.61-1.03, P = 0.07) but OS was not impacted (HR: 0.98; P = 0.92) when compared to patients who received unmatched therapies (N = 143). **Conclusions:** Across cancers, *RAS* alterations were independently associated with poor OS, with *KRAS G12V, KRAS G13D*, and *KRAS* amplification having the shortest survival. Most *RAS*-mutated tumors harbored co-altered genes. Therapy that included drugs matched to co-altered genes did not impact survival, suggesting that MAPK is an important resistance pathway even in the presence of other tractable genomic alterations. Clinical trial information: NCT02478931.

12097 Poster Session (Board #210), Mon, 1:15 PM-4:45 PM

Landscape of *BRCA1* and *BRCA2* germline, somatic, and reversion alterations detectable by cell-free DNA testing among patients with metastatic breast, ovarian, pancreatic, or prostate cancer. *First Author: Aditya Bardia, Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA*

Background: PARP inhibitors (PARPi) have shown efficacy in breast (BC), ovarian (OC), pancreatic (PaC), and prostate (PrC) cancers harboring deleterious germline or somatic alterations (alts) in *BRCA1* or *BRCA2 (gBRCA, sBRCA).* Additional acquired reversion alts (*rBRCA)* which restore the open reading frame (ORF) have been reported in the setting of resistance to PARPi or platinum-based chemotherapy. Next-generation sequencing (NGS) of cell-free DNA (cfDNA) provides a platform to evaluate the relative frequency of all three of these types of *BRCA* alts in pts with advanced cancers. **Methods:** *BRCA* alts were identified among 1,122 samples from 828 pts with metastatic BC, OC, PaC, or PrC with tumor DNA detected on a clinical 73-gene cfDNA NGS assay (tests run between 11/2016-10/2017, Guardant360). This assay evaluates single nucleotide variants and indels in *BRCA1/2* and tracks individual DNA molecules allowing for phasing. *BRCA* alts were classified as *gBRCA, sBRCA,* or *rBRCA* based the variant allele fraction (VAF), AFs of neighboring germline SNPs, and relative positions of all alts in a sample. Treatment history was obtained from test request forms. **Results:** At least one deleterious *BRCA* alt was detected in 67 pts (8.1%), including 35/472 pts with BC, 6/47 OC, 5/85 PaC, and 21/223 PrC. 36 of these patients had putative *gBRCA* alts, 8 of whom had additional alts consistent with *rBRCA* (5 had BC, 3 had PrC). The remaining 31 *BRCA+* pts had only *sBRCA,* 1 of whom had BC and multiple somatic alts consistent with *rBRCA.* Treatment history was available for 29/67 *BRCA+* pts. Among the 7 who were indicated as having exposure to a PARPi, 2 had a *rBRCA.* **Conclusions:** Rates of cfDNA-detected g*BRCA* and *sBRCA* alts in pts with advanced BC, OC, or PaC are comparable to that reported by TCGA, and higher among men with PrC. Approximately half of the *BRCA+* pts had *gBRCA* and half only had *sBRCA*, highlighting the value of cfDNA NGS testing to identify both types of targetable *BRCA* alts. Moreover, *rBRCA* were identified in a significant percentage (13%) of *BRCA*+ pts without foreknowledge of germline- or tissue-based testing, and may identify pts unlikely to respond to PARPi.

12098 Poster Session (Board #211), Mon, 1:15 PM-4:45 PM

Genetic variants within the glucocorticoids related genes to predict outcome in patients with metastatic colorectal cancer (mCRC). *First Author: Alberto Puccini, Division of Medical Oncology, USC Norris Comprehensive Cancer Center, Keck School of Medicine, Los Angeles, CA*

Background: Glucocorticoids (GC) have important anti-inflammatory and pro-apoptotic activities. CRC cells produce immunoregulatory GC, a process regulated by nuclear receptor liver receptor homolog-1 (LRH-1). Additionally, LRH-1 plays a critical role in the control of cell cycle and tumorigenesis. Therefore, CRC cells have a strong steroidogenic potential and tumor-derived GC may contribute to tumor immune evasion. Thus, we aim to evaluate whether variations in *LRH1* and GC receptor (*NR3C1*) genes may predict outcome in mCRC patients treated with first-line FOLFIRI and bevacizumab (bev). **Methods:** Genomic DNA from whole blood samples was obtained from 378 mCRC patients who were treated with FOLFIRI/bev in the TRIBE (discovery cohort; N = 215, female/male 83/132; median age 60; median follow-up 48.9 months) and MAVERICC (validation cohort; N = 163, female/male 60/103; median age 62; median follow-up 23.3 months) trials, and subsequently genotyped through the OncoArray, a custom array manufactured by Illumina including approximately 530K SNP markers. The impact on outcome of six selected SNPs in *LRH1* and *NR3C1* genes were analyzed. **Results:** In the discovery cohort, patients carrying *NR3C1 rs10041520* any C showed a longer OS compared to T/T variant in the univariate analysis (28.9 months vs 20.5 months, HR = 0.69, 95%CI = 0.50-0.97, P = 0.029). *LRH1 rs2737656* any T variant showed longer PFS compared to C/C genotype in multivariate analysis (10.3 months vs 9.4 months, HR = 0.62, 95%CI = 0.41-0.93, P = 0.020). Patients carrying any G in *LRH1 rs2690034* showed shorter OS compared to those carrying C/C variant in multivariate analysis (25.0 months vs 29.8 months, HR = 1.46, 95%CI = 1.02-2.10, P = 0.040). The *NR3C1 rs10041520* findings were validated in the MAVERICC FOLFIRI/bev arm. Here, patients carrying any C variants had a longer OS compared to T/T genotype in multivariate analysis (27.9 months vs 26.5 months, HR = 0.42, 95% CI = 0.19-0.92, P = 0.030). **Conclusions:** Our results provide the first evidence that the genetic variants within *NR3C1* and *LRH*-1 genes might serve as a prognostic/predictive markers in patients with mCRC treated with first-line FOLFIRI and bevacizumab.

12099 Poster Session (Board #212), Mon, 1:15 PM-4:45 PM

Phosphorylation of AKT kinase substrates to predict response to the AKT inhibitor MK2206 in the I-SPY 2 trial in both HER2- and HER2+ patients. *First Author: Julia Dianne Wulfkuhle, George Mason Univ, Columbia, MD*

Background: In the I-SPY 2 TRIAL, the allosteric AKT inhibitor MK2206 was available to all HR/HER2 subtypes and graduated in the HR-/HER2+ signature. Qualifying biomarker analysis was performed on 26 proteins/phosphoproteins in the HER-AKT-mTOR pathway to identify candidate proteins correlated with pCR in the HER2+ and HER2- populations treated with MK2206. We postulated that response to MK2206 could be predicted by the relative level of phosphorylation of AKT kinase substrates. **Methods:** Of 151 patients in the MK2206 and control arms, 138 patients (MK2206: 87, controls: 51) had RPPA and pCR data. Data for 26 (phospho-) proteins involved in HER-AKT-mTOR signaling were assessed for association between biomarker and response in the MK2206 and control arms alone (likelihood ratio test), and relative performance between arms (biomarker x treatment interaction) using a logistic model. Analysis was also performed adjusting for HR/HER2 status. Markers were analyzed individually; p-values are descriptive and were not corrected for multiple comparisons. **Results:** In the HER2+ cohort, phosphorylation of the AKT kinase substrates mTOR S2448 (p = 0.004), GSK3 S21/9 (p = 0.009), FOXO1 S256 (p = 0.007), FOXO1 T24/FOXO3a T32 (p = 0.026), S6RP S240/S244 (p = 0.036), Tuberin/TSC1 Y1571 (p = 0.043) and eIF4G S1108 (p = 0.047) were associated with response. FOXO1 S256 also had a significant interaction with treatment in logistic model testing. In the HER2- population, AKT S473 (p = 0.012), AKT T308 (p = 0.011), Estrogen Receptor alpha (p = 0.013), mTOR (p = 0.04), NFkB S536 (p = 0.017) and Tuberin/TSC2 Y1571 (p = 0.03) were negatively associated with MK2206 response. FOXO S253 (p = 0.031) and ERBB2 Y877 (p = 0.02) were both positively associated with response and had a significant interaction with treatment in this cohort. **Conclusions:** While our sample size is too small to draw definitive conclusions, our results suggest that the measurement of AKT kinase substrate phosphoproteins could be predictive of MK2206 clinical activity in both HER2+ and HER2- tumors regardless of HR status. These results will need to be validated in independent study sets in order to judge the significance of these initial findings. Clinical trial information: NCT01042379.

12100 Poster Session (Board #213), Mon, 1:15 PM-4:45 PM

Non-V600 BRAF mutations in advanced malignancies: Prevalence and survival impact. *First Author: Ed Kheder, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: *BRAF* mutations that occur outside of codon 600, non-V600 BRAF ($^{non\text{-}V600}$*BRAF*), have been detected in various types of tumors. Prevalence, and prognostic impact remain underestimated **Methods:** We conducted a retrospective study to characterize prevalence, and potential survival impact of $^{non\text{-}V600}$*BRAF* in advanced malignancies. We pooled patients who had *BRAF* mutant malignancies at MD Anderson Cancer Center. We used Kaplan-Meier to estimate survival outcomes and log rank test to compare OS between groups. We used chi-squared tests to compare mutation prevalence between cancer types. We computed survival from *BRAF* positive biopsy date. **Results:** Between September/2006 and July/2017, 3337 patients were found with *BRAF* mutant tumors. $^{non\text{-}V600}$*BRAF* mutations were detected in 596 (18%) patients. [238 (40%) female, 358 (60%) male; median age: 63 years, range (4, 90), 345 (58%) > 60 years; median OS, 25.0 months]. Most common cancers (%): melanoma 179 (30%); non-small cell lung (NSCLC) 83 (14%); colorectal 76 (13%), leukemia 52 (9%); myeloma 19 (3%); prostate 15 (3%); sarcoma 14 (2%); bladder, brain 11 (2%) each. Most common mutations (%): [G469A 64 (11%); D594G 58 (10%); K601E 46 (8%); D594N 37 (6%); G466E 23 (4%); G466V 22 (4%); G469V 19 (3%); E26D, G469E, G469R 18 (3%) each; S467L 15(3%); L597R, N581I, N581S 11 (2%) each]. Common mutations against common cancers are summarized in table-1. Three-year survival rate significantly changed with tumor type (P: < 0.0001): Melanoma 65%; Leukemia 62%; NSCLC 40%; other 30%; Colorectal 24%, but not with sex, age (P = 0.22); or $^{non\text{-}V600}$*BRAF* subtypes (P = 0.4). **Conclusions:** Non-V600 BRAF mutations occur in 18% of advanced malignancies. Their survival impact and prevalence significantly vary among tumor types. Future studies are warranted with MAPK or ERK kinase inhibitors.

Cross-tabulation of common mutations against common cancers.

Tumor	Number	D594G (%)	D594N (%)	G469A (%)	K601E (%)
Colorectal	76	22 (29%)	4 (5%)	8 (11%)	4 (5%)
Leukemia	52	3 (6%)	2 (4%)	5 (10%)	9 (17%)
Lung	83	7 (8%)	4 (5%)	16 (19%)	4 (5%)
Melanoma	179	8 (4%)	13 (7%)	11 (6%)	17 (9%)
Other	206	24 (12%)	35 (17%)	6 (3%)	3 (1%)
P-value		*< 0.0001*	*0.85*	*0.033*	*0.038*

12101 Poster Session (Board #214), Mon, 1:15 PM-4:45 PM

Exploring the association between somatic molecular features and tumor mutation burden in 513 non–small-cell lung cancer. *First Author: Chenchen Zhu, Geneplus-Beijing Institute, Changping District, Beijing, China*

Background: Tumor mutation burden (TMB) is new clinical marker that predicts responses to immunotherapy, but the molecular basis of TMB is unknown. Understand the association between genomic landscape and TMB may help to a better guidance of immunotherapy. **Methods:** We performed a retrospective review of 513 non–small-cell lung cancers (NSCLC) patients. Tumor tissues were acquired from initial diagnosis before any drug treatment and sequenced by Next Generation Sequencing (NGS) of 1021 genes. TMB (mutations/Mb) was analyzed as the number of somatic non-synonymous base substitution and indel per Mb in coding region. The top quartile was classified as TMB high. **Results:** A total of 513 patients had an average TMB of 7.5 mut/Mb. The median TMB was 5.8 mut/Mb (range, 1 to 67.68 mut/Mb). 128 patients were assessed as TMB high (TMB-H) and 385 patients were TMB low (TMB-L). The median TMB was 14 and 4.32 mut/Mb for patients with TMB-H and TMB-L respectively. *EGFR* mutations were detected in 28 patients with TMB-H (21.9%) compared with 228 with TMB-L (59.2%; $P < 0.01$). And other known drivers were significantly more common in patients with TMB-L than with TMB-H, which included *ALK* fusion, *ROS1* fusion, *MET* splice and *BRAF* V600E ($P < 0.01$). *KRAS* and *TP53* mutations were more common in patients with TMB-H than with TMB-L, but no significant difference of *KRAS* mutations were found between TMB-H and TMB-L (12.5% *vs* 7.8%; $P = 0.15$). Significant differences of *TP53* mutations were found between TMB-H and TMB-L (81.3% *vs* 54.8%; $P < 0.01$). In addition, alterations of homologous recombination repair and mismatch repair gene were more likely to be the high TMB, e.g. alterations in *BRCA1, BRCA2, ATM, ATR, PMS2* and *MSH2* were significantly enriched in patients with TMB-H. **Conclusions:** TMB-H is associated with lack of current druggable oncogenic drivers, such as *EGFR* mutations/ ALK or *ROS1* fusion. TMB detection provides a clinically useful predictor of response to immunotherapy. *TP53* and *KRAS* mutations specifically enriched in patients with TMB-H, may be served as potential predictive factors in guiding immunotherapy. Lastly, DNA damage repair mutations strongly correlated with high TMB, and may be a primary molecular mechanism for TMB.

12102 Poster Session (Board #215), Mon, 1:15 PM-4:45 PM

Impact of tumor-infiltrating lymphocytes on response to neoadjuvant chemotherapy in triple-negative early breast cancer: Translational subproject of the WSG-ADAPT TN trial. *First Author: Cornelia Liedtke, Charité - Universitätsmedizin Berlin, Berlin, Germany*

Background: In triple-negative breast cancer (TNBC), pathological complete response (pCR, ypT0/is/ypN0) is associated with improved prognosis. The randomized prospective WSG-ADAPT TN phase II trial showed higher pCR with Nab-paclitaxel / Carboplatin (NP/C) compared to paclitaxel / gemcitabine (NP/G) as 12-week neoadjuvant therapy. Presence of tumor-infiltrating lymphocytes (TILs) is associated with increased pCR rates after neoadjuvant chemotherapy, but the role of TIL dynamics during (specific) chemotherapy regimens is still unknown. **Methods:** This pre-planned translational analysis focuses on semi-quantitative TIL measurements in ADAPT-TN among tumor samples at baseline (TIL-0) and after 3 weeks of chemotherapy (TIL-3). Associations of continuous TIL-0 and TIL-3 levels with pCR, with chemotherapy arm and with other clinical / pathological measurements were analyzed using logistic regression, rank correlations, t and chi-square statistics. **Results:** 336 patients were enrolled. TIL-0 and TIL-3 were available among 311 (92.6%) and 223 (66.4%) patients, respectively. "Low cellularity" in 3-week biopsies (tumor necrosis, lack of invasive tumor cells) was recorded in 82 patients. TIL-0 and TIL-3 were strongly correlated (0.64, $p < .001$); average relative increase was about 30%. TIL-0 was significantly associated with baseline tumor grade, clinical tumor size, and nodal status. TIL-3 was significantly associated with nodal status and grade in both biopsies. In all patients, higher levels of both TIL-0 ($p < .001$) and TIL-3 ($p = .002$) were associated with pCR. Higher TIL-0 was also significantly associated with pCR in both arms separately. "Low cellularity" was also associated with pCR in all patients (OR = 3.9, 95%-CI: 2.3-6.8) and in both arms separately (NP/G: OR = 3.6, 95%-CI: 1.7 to 7.9; NP/C: OR = 4.2, 95%-CI: 1.9-9.3). **Conclusions:** In TNBC patients, higher levels of tumor-infiltrating lymphocytes were associated with pCR, both at baseline and after 3 weeks of neoadjuvant chemotherapy. "Low-cellularity" at week 3, which indicates extensive response to chemotherapy, was itself strongly associated with response to therapy.

12103 Poster Session (Board #216), Mon, 1:15 PM-4:45 PM

Association of activation levels of TIE2 with response to the angiogenesis inhibitor trebananib in HER2+ patients in the I-SPY 2 trial. *First Author: Rosa Isela Gallagher, George Mason University, Manassas, VA*

Background: Trebananib (T), an angiopoietin 1/2 neutralizing peptibody that inhibits interaction with TIE2 receptors, was available to all HR/HER2 subtypes in the I-SPY2 TRIAL. The agent did not achieve the prescribed graduation threshold for any eligible signatures prior to accrual of maximum sample size. We postulated that response to a drug that blocks TIE2 receptor-ligand interaction could be predicted by the measurement of basal TIE2 phosphorylation and downstream signaling in the pre-treatment biopsies. **Methods:** Of 267 patients in the T and control arms, 203 patients (T: 128, controls: 73) had reverse phase protein microarray (RPPA) and pCR data available. RPPA data for 33 (phospho- and total) proteins involved in TIE2 signaling were evaluated for association between biomarker and response in the T and control arms alone (likelihood ratio test), and relative performance between arms (biomarker x treatment interaction) using a logistic model (LM). Analysis was also performed adjusting for HR/HER2 status. Markers were analyzed individually; p-values are descriptive and were not corrected for multiple comparisons. **Results:** In the TN subpopulation, TIE2 receptor levels ($p = 0.037$), ERBB3 ($p = 0.048$), total ERα ($p = 0.05$) and ERα S118 ($p = 0.016$) were negatively associated with response to T. In HER2+ patients, phospho-TIE2 Y1119 ($p = 0.001$) and Y992 ($p = 0.0007$) were positively associated with T response, as were downstream AKT-mTOR signaling activation proteins such as eIF4G S1108 ($p = 0.005$), p70S6K T389 ($p = 0.011$) and T412 ($p = 0.038$) and FOXO3a S253 ($p = 0.041$). ERBB2 Y877 ($p = 0.028$) was negatively associated with response in these patients. TIE2 Y1119, TIE2 Y992, eIF4G S1108, ERBB2 Y877, and FOXO3a S253 all demonstrated a significant treatment interaction by LM. **Conclusions:** While small sample sizes preclude drawing definitive conclusions, our results suggest that activation levels of the TIE2 receptor may be predictive of T efficacy in HER2+ patients and signaling activation downstream of TIE2 such as AKT-mTOR signaling may correlate with response in the HER2+ and TN populations. These results need to be independently validated to determine the significance of these findings. Clinical trial information: NCT01042379.

12104 Poster Session (Board #217), Mon, 1:15 PM-4:45 PM

Single-cell profiling of NSCLC tumor treated with Durvalumab and in combination with Tremelimumab. *First Author: Yashaswi Shrestha, MedImmune, Gaithersburg, MD*

Background: Combination of anti-PD1/L1 and anti-CTLA4 is under investigation for treatment of multiple tumors. However, how this combination modifies the immune micro-environment of tumors is not well understood. Using single cell RNA sequencing (scRNAseq), we are systematically characterizing the ex vivo cellular and molecular effects of Durvalumab (D) and Tremelimumab (T) treatment on NSCLC tumors. **Methods:** Commercially available dissociated NSCLC tumor was treated with low dose interleukin-2 (IL-2) plus D, D+T or isotype control (IsoCtrl) at 20ug/ml each. For scRNAseq, T cells were isolated using αCD4 and αCD8 beads. Over 20,000 immune cells were profiled on D7 after treatment using 10X genomics. Exhausted T cells were defined based on the signature by Singer et al. (2016). Cell clustering and differential expression analyses were conducted using R package Seurat. Functional enrichment analyses, including KEGG and GO were performed by ClusterProfiler. **Results:** At D7 of D or D+T treatment, intracellular IFNG expression increased 60 and 80%, respectively. scRNAseq results were consistent with this functional data, showing 6% and 12% more IFNG expression in CD4+/CD8+ T cells following D and D+T, respectively. Checkpoint inhibitor expression (*PDCD1, CTLA4, TIGIT, LAG3, HAVCR2*) increased 4-9% and 7-15% upon D or D+T treatment, respectively. D and D+T treatment increased fraction of total CD4+ cells from 21% to 27% and 28%, respectively; however, there was a reduction in the specific CD4 subfraction of T regs (*CD4+FOXP3+*) in both treatments compared to IsoCtrl. D+T treatment shifted the molecular phenotype of exhausted T cells toward a more activated state by inducing a significant upregulation of *PTPRCAP, ITGB1*, and *KLF2*, genes important for T cell activation and/or reduced T reg function. **Conclusions:** Single-cell profiling of NSCLC tumor suggest that D+T treatment alters the molecular profile of exhausted T cells and T regs to generate a more active phenotype, which may contribute to clinical benefit for patients treated with this combination.

12105 Poster Session (Board #218), Mon, 1:15 PM-4:45 PM

A gene expression signature of *FOXM1-AURKB-CDKN1A* to recapitulate molecular characteristics of standardized uptake value of ^{18}F-FDG-PET in breast cancer. *First Author: Sung Gwe Ahn, Gangnam Severance Hospital, Seoul, Korea, Republic of (South)*

Background: We previously showed that standardized uptake value (SUV), an indicator of the degree of glucose uptake in ^{18}F-FDG-PET, could be used as a prognostic marker in breast cancer and has a correlation with 21-gene recurrence score. We explored genomic features associated with SUV and identified a molecular signature reflecting SUV in breast cancer. **Methods:** Transcriptomic profiling was carried out using gene expression data from 60 breast cancer patients who underwent preoperative FDG-PET to identify a molecular signature associated with SUV. The prognostic value of the signature was verified in other three cohorts (namely YSU, UNC, and TCGA cohorts, n = 301, 500, and 815, respectively). The association between the SUV signature and prognosis of breast cancer patients was assessed. To compare mutation profiles between two patient subgroups divided by SUV signature in the TCGA cohort, we obtained two predefined gene sets involved in oncogenic or metabolic pathways and estimated a difference of their mutation frequencies. **Results:** The determination of gene expression patterns by transcriptome data analysis identified 1,528 genes associated with SUV ($|r| > 0.35$, $p < 0.01$ by Pearson correlation test). The patient subgroups classified by those genes (i.e., SUV-high-cluster and SUV-low-cluster) were significantly similar with patient classification by SUV ($p < 0.001$). When estimating prognostic value of the molecular signature associated with SUV in three cohorts, the signature showed a strong prediction ability in breast cancer prognosis (each $p < 0.05$ by log-rank test). Gene network analyses revealed that a signaling defined by *FOXM1-AURKB-CDKN1A* could be an important pathway reflecting SUV characteristics. Lastly, a mutation profiling in the TCGA cohort showed that *POLD1*, *UGT2A1*, and *UGT1A3* involved in tumor metabolism would be important mediators. **Conclusions:** Our results unveil genomic characteristics of increasing glucose uptake of breast cancer captured by FDG-PET, supporting a poor prognosis in patients with high SUV. Our works shed light on understanding a molecular basis of glucose metabolism in patients with breast cancer.

12106 Poster Session (Board #219), Mon, 1:15 PM-4:45 PM

Circadian clock gene *PER1* mutations in colorectal cancer (CRC). *First Author: Francesca Battaglin, Division of Medical Oncology, USC Norris Comprehensive Cancer Center, Keck School of Medicine, Los Angeles, CA*

Background: *PER1* encodes for one of the main negative regulator of the clock genes pathway, which modulates the circadian expression of key target genes at the cellular level. Downregulation of *PER1* has been observed in CRC and lower expression levels have been associated with poor survival and increased incidence of liver metastases. Few data are available on *PER1* gene mutations (*PER1*mut) in CRC. Therefore, we aimed to explore the clinical and molecular differences between *PER1* mutated versus wild-type (WT) CRCs. **Methods:** 4079 CRCs tested with tumor profiling (Caris Life Sciences, Phoenix, AZ) were included in this analysis. NextGen sequencing (NGS) was performed on genomic DNA isolated from formalin-fixed paraffin-embedded tumor samples using the NextSeq platform (Illumina, Inc., San Diego, CA) on 592 genes. Microsatellite instability high (MSI-H) status was tested by NGS in 3996 tumors. Pathogenicity of PER1mut was estimated using Poly-Phen and SIFT. **Results:** Main characteristics in the global population were as follow: M/F 52.4/47.6%, median age 61 (16-90 yr), primary tumor right-sided 27.4%/left-sided 43.5%/NOS 29.1%, mutational status all WT 38.7%/*RAS*mut 53.4%/*BRAF*mut 7.9%, MSI-H 6.6% (n = 262). Overall, 185 unique *PER1*mut/variants were identified in 304 samples (7.45%); 45 were classified as pathological/possibly pathological (PATHmut) according to predictive scores. *PER1*mut were significantly associated with right-sided tumor location ($p < 0.001$) and MSI-H ($p < 0.001$). Overall incidence of *PER1*mut and PATHmut in the MSI-H group were 24% and 3.4%, respectively. In the multivariate analyses PATHmut were independently associated with mutations in *ARAF*, *BAP1*, *CHEK2*, *NF1*, *PIK3CA* and *POLE*. **Conclusions:** Our results provide the first exploratory data on *PER1*mut association with clinical and molecular features in CRC, in a large population of patients with extensive genetic testing. A deeper understanding of *PER1*mut pathogenicity and functional role is necessary to guide future analyses. Nevertheless, our results suggest a significant association with MSI-H, possibly reflecting an interplay between mismatch repair status and the clock genes pathway in CRC, consistent with previous data and warranting further investigation.

12107 Poster Session (Board #220), Mon, 1:15 PM-4:45 PM

Genetic variations in the β2M/HLA-E immunomodulatory complex to predict outcomes in metastatic colorectal cancer (mCRC) patients (pts) treated with first line FOLFIRI/Cetuximab: Data from the phase III FIRE-3 trial. *First Author: Madiha Naseem, Division of Medical Oncology, USC Norris Comprehensive Cancer Center, Keck School of Medicine, Los Angeles, CA*

Background: Cetuximab(cet) is an anti-EGFR mAb which enhances the antibody-dependent cellular cytotoxicity (ADCC) by Natural Killer (NK) cells in EGFR+ CRCs. Overexpression of MHC class I antigen E (HLAE), and its membrane stabilizer, βeta-2 microglobulin (β2M) inhibit cet-induced ADCC. We hypothesize that single nucleotide polymorphisms (SNPs) in HLAE/β2M will influence cet-dependent NK cell lysis and clinical outcomes. **Methods:** Genome wide association studies were conducted on whole blood from 236 mCRC pts in the randomized phase III FIRE-3 trial treated with FOLFIRI/cet(n = 129) and FOLFIRI/bevacizumab(bev)(n = 107). The OncoArray database provided by Illumina containing 530K SNP markers from these pts was used to extract data on 4 functional SNPs from β2M and HLAE. Log-rank test and Cox proportional hazard regression models evaluated SNP associations with PFS/OS in uni- and multivariable analyses. **Results:** FOLFIRI/cet and FOLFIRI/bev cohort characteristics: median FU (29.1/26.7mo); PFS (12.8/11.5mo); OS (49.8/31.4mo); RAS WT(64%/62%) and RAS mut (15%/16%). Multivariable analysis showed worse PFS in RAS WT pts treated with FOLFIRI/cet with HLAErs1059510 T/T alleles (12.2 vs 13.3 mo; HR = 2.59; 95%CI = 1.05-6.39; p = 0.039) and HLAErs1264457 G/G alleles (12.3 vs 12.9 mo; HR = 2.36; 95%CI = 1.14-4.88; p = 0.021). These effects were not observed in RAS mut pts. β2Mrs1901531 mutant C allele carriers showed improved OS (67.4 vs 40.9 mo) independent of RAS status in FOLFIRI/cet arm in both univariate (HR = 0.27; 95%CI = 0.12-0.59; $p < 0.001$) and multivariable analysis (HR = 0.19; 95%CI = 0.07-0.48; $p < 0.001$). No significance was observed in FOLFIRI/bev overall or FOLFIRI/bev RAS WT pts. **Conclusions:** For the first time, we show that clinical outcomes in mCRC pts treated with FOLFIRI/cet are predicted by genetic variations in HLAE/β2M, which are not observed in FOLFIRI/bev. The predictive utility of HLAE is dependent on RAS status, whereas that of β2M is independent of RAS. The HLAE/β2M complex could be a promising therapeutic target for overcoming cet resistance. Validation in larger cohorts is required.

12108 Poster Session (Board #221), Mon, 1:15 PM-4:45 PM

Landscape of osimertinib resistant mutations between the two common subtypes of EGFR 19del or L858R in NSCLC. *First Author: Yan Zhang, Geneplus-Beijing Institute, Changping District, Beijing, China*

Background: Acquired *EGFR* mutations (C797, L792, G796) co-occurring with T790M were reported to lead the resistance to osimertinib. It was reported that for advanced NSCLC patients, exon 19 deletion (19del) might be associated with longer PFS compared to L858R mutation accepted EGFR-TKIs therapy. In this study, we try to analyze the difference of the resistant mutation spectrum in patients accepted osimertinib treatment carrying these two types of mutations. **Methods:** Using targeted gene capture and next-generation sequencing technologies, we analyzed the somatic mutations in 110 NSCLC patients (pts) that were clinically resistant to osimertinib. **Results:** All of the 110 patients had an *EGFR* activating mutation (19del in 64 pts and L858R in 46 pts) and 104 were *EGFR* T790M positive. *EGFR* mutations which may lead to the acquired resistance of osimertinib were identified in 52.7% (58/110) patients, including C797S (43 pts), C797G (6 pts), L792H (6 pts), L792V (2 pts), G796S (3 pts), G796C (1 pts), L718V (4 pts), L718Q (7 pts), and 18 patients had multi-clonal resistant mutations. In all analyzable patients, at least one resistant mutation was identified *in cis* with T790M, and two of them also carrying an *in trans* mutation who were also co-existent with L858R. No patient had only *in trans* mutation in our study. The resistant mutation were more frequently detected in 19del group than in L858R (62.5% *vs* 39.1%, $p = 0.015$), with 21.9% *vs* 10.9% patients had mult-clones and 15.6% *vs* 8.7% *EGFR* amplification. These may due to the larger drug selection pressure from longer treatment of 19del group. Bypass or downstream co-occurring activating mutations detected were *EML4-ALK* rearrangement (1 pts), *MET* amplification (1 pts), *RET-CCDC6* rearrangement (1 pts), *KRAS* mutations (1 pts), *BRAF* mutations (7 pts), *PIK3CA* mutations (5 pts), and *PTEN* deficiency (3 pts). **Conclusions:** In our study, acquired *EGFR* mutations leading to osimertinib resistance were more likely to be identified with *EGFR* 19del than L858R mutation NSCLC patients. Understanding these resistance mechanisms may be useful to develop more effective therapies for patients resistant to osimertinib.

12109 Poster Session (Board #222), Mon, 1:15 PM-4:45 PM

Comparison of annotation services for the VA Precision Oncology Program. *First Author: Evangelia (Eva) Katsoulakis, SUNY Downstate Medical Center, Bayside, NY*

Background: Multigene NGS testing has become widespread, including through the VA healthcare system through the VA Precision Oncology Program (POP). Algorithms to interpret the pathogenicity of NGS-detected sequence variants and clinical actionability have been implemented as clinical services, but little is known about their relative performance in clinical practice. **Methods:** NGS testing results from patients who had NGS results from VA POP were included. NGS results were generated at Personal Genome Diagnostics and Personalis and annotated by a commercial annotation service (N-of-One) as well as through Watson for Genomics (WfG) and OncoKB. Comparison of annotation results consisted of two parts: determination of pathogenicity and treatment actionability recommendations. Cohen's kappa statistic was calculated for agreement between annotation services. **Results:** Among 1228 NGS results, 1388 unique variants were observed in 117 genes (TP53 270, STK11 92, CDKN2A 81, ATM 67, PTEN 52). Cancer type was lung adenocarcinoma in 440 samples, colon adeno 113, lung squamous 111, unknown primary 88, prostate 62, melanoma 57, H&N 41, NSCLC 40. For pathogenic and likely pathogenic variants, there was 87% agreement between WfG and N-of-One (kappa 0.729), 76% agreement between WfG and OncoKB (kappa 0.227) and 42% agreement between N-of-One and OncoKB (kappa -0.078). For level 1 drug actionability recommendations (not available from N-of-One) there was 91% agreement between WfG and OncoKB (kappa 0.19) with 54 variants identified only by WfG as level 1 and 74 variants identified only by OncoKB as level 1. **Conclusions:** There is substantial variability in assessment of pathogenicity of NGS variants in solid tumors by clinically available annotation services. In addition, there was only slight agreement in level 1 therapeutic actionability recommendations. Improvement of the precision of oncology NGS annotation is needed.

12110 Poster Session (Board #223), Mon, 1:15 PM-4:45 PM

Identification of actionable genomic alterations utilizing cfDNA. *First Author: Nora Sylvia Sanchez, Sheikh Khalifa Bin Zayed Al Nahyan Institute for Personalized Cancer Therapy/ University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Cell-free DNA (cfDNA) next-generation sequencing has become a more accessible, non-invasive approach for genomic testing. We report alteration identification frequency and clinical actionability in patients with advanced/metastatic cancer. **Methods:** Enrollment criteria for prospectively consented patients: Active metastatic/local inoperable advanced cancer, considering trial enrollment within next 2 lines of therapy, and either exhausted tissue block, archival tissue $>$ 1 year, available tissue block but progressed on compelling intervening therapy. Patients had cfDNA testing on a CLIA-certified panel (Guardant360) for point mutations, indels, amplifications, fusions. Alterations were assessed and ranked for functional impact, therapeutic implications and patient's overall actionability profile was determined. **Results:** 295 patients with $\geq$ 6 months follow-up were evaluated. Major diseases represented ($\geq$ 10 patients): hepatocellular (59), pancreatic (51), bile duct/cholangio(37), appendiceal(24), breast(20), sarcoma(18), lung(15), and colorectal(12). Majority of patients were male(167), Caucasian(222), median age 54.5 years. ECOG performance status (PS) upon enrollment: 0 (72), (185), 2(26), 3(2). 77.9% of patients (230/295) had $\geq$1 alteration detected; 56%(128/230) had an alteration in gene associated with FDA approved drug for specific biomarker/tumor type. Evaluation of variant functional significance in context of patient's disease identified 30.5 % (39/128) of patients as high potential for clinical action. Of these, 18%(7/39) were matched to targeted therapy: clinical trial enrollment(4), off label drug use(1), standard of care (SOC)(2). Amongst unmatched patients, 37.5% (12/32) did not return to institution/lost to follow up, 31.4%(11) had poor PS after return of results, while the rest enrolled on another trial(2), continued existing therapy (2) or other(6). **Conclusions:** cfDNA testing represents a readily accessible method for genomic testing and allows for detection of genomic alterations in most patients with advanced disease. Utility may be higher in patients with interest in genomically selected therapy, adequate PS, and enhanced by earlier testing in treatment course.

12111 Poster Session (Board #224), Mon, 1:15 PM-4:45 PM

Pan-cancer mesenchymal assay to predict response to MEK inhibitors. *First Author: Nuala McCabe, Almac Diagnostics, Craigavon, United Kingdom*

Background: Unsupervised hierarchical clustering of gene expression data from 265 high grade serous ovarian cancer (HGSOC) patients identified 3 major molecular subgroups. One subgroup is driven by activation of the MAPK-pathway and is associated with a mesenchymal phenotype, poor prognosis and resistance to platinum.The MAPK pathway is currently being targeted by novel therapeutics and hence an assay to detect activation of the pathway across cancers would be highly valuable as a clinical trial enrichment tool. **Methods:** Using TCGA data we show the existence of the mesenchymal subgroup across a range of solid tumours including stomach, bladder colon, lung, melanoma and prostate cancer. Further to this, a common gene list was generated to include only transcripts with high variability and expression across diseases, and used as a starting list for the development of a 15 transcript assay which can be used to prospectively identify the mesenchymal subgroup from archived tissue. The 15 gene expression assay was tested in preclinical model systems to assess its utility at predicting response to MEK inhibitors. **Results:** The 15 gene expression mesenchymal assay was a poor prognostic marker in 13 different solid tumours: overall HR = 1.78 [95% CI:1.65-1.92]) $p < 0.0001$. Additionally the assay was associated with a mesenchymal phenotype (migration, invasion) and activated MAPK (phospho-MAPK) signalling in preclinical cell line models. The assay also predicted phospho-MEK expression in clinical samples ($p < 0.05$). The assay score was reduced by MEK inhibition ($p < 0.05$) and elevated by KRAS, NRAS and MEK1 overexpression ($p < 0.05$). The assay predicted response to the MEK inhibitors Trametinib and Selumetinib across cell line models from multiple diseases ($p < 0.001$) and to Trametinib in mouse xenograft studies of lung cancer cell lines. **Conclusions:** A 15 gene expression assay has been developed from FFPE samples across multiple diseases to detect a mesenchymal molecular subgroup associated with MAPK signalling. The assay predicted sensitivity to MEK inhibitors in pre-clinical cell line and mouse model systems. Further work aims to validate the assay as a predictive biomarker in clinical samples from patients treated with MEK targeted therapies.

12112 Poster Session (Board #225), Mon, 1:15 PM-4:45 PM

Association of mucosal Fusobacterium with clinical stage and immune gene signatures of rectal adenocarcinoma. *First Author: Michael Sangmin Lee, UNC Lineberger Comprehensive Cancer Center, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Alterations in gut microbial composition are associated with development and progression of colorectal cancer (CRC), and may contribute to interpatient biologic and clinical heterogeneity. Fusobacterium is enriched in CRC and is associated with a proinflammatory microenvironment. We hypothesized that Fusobacterium was associated with distinct clinicopathologic characteristics and inflammatory gene signatures among patients with locally advanced rectal cancer. **Methods:** Patients with T3-4 or N+ rectal adenocarcinoma planned to receive neoadjuvant chemoradiation were prospectively consented to undergo pretreatment endoscopic tumor biopsy. The V1-V2 region of the 16S bacterial ribosomal RNA gene was sequenced to identify tumor mucosal microbiota taxonomy. Tumor mRNA sequencing (RNASeq) was also completed and gene set enrichment analysis (GSEA) with curated immunologic signatures in MSigDB was performed. Multivariate analyses were conducted using PRIMER VII and SPSS v24 software. P-values were determined using Mann-Whitney tests, and Benjamini-Hochberg procedure was used and only results with false discovery rate $<$ 0.25 are presented. **Results:** Of 43 total samples, 37 had adequate bacterial 16S rRNA gene sequencing, and 31 also had adequate RNA quality for RNASeq analysis. Among the 37 patients, mean age at diagnosis was 54 (range 30-77) and pre-treatment clinical stage was II (30%) vs. III-IV (70%). Higher clinical stage (stage III-IV vs II) was associated with enrichment of Fusobacterium (16.2% vs 5.6%, p = 0.019) and Parvimonas (4.6% vs 1.4%, p = 0.033) genera. In the 9 subjects with $>$ 20% relative abundance of Fusobacterium, 179/4872 Immunologic gene sets, were enriched with p-value $<$ 0.01 and FDR $<$ 0.20. Significant gene sets included increased myeloid cell signatures, like monocytes/macrophages and neutrophils, and decreased effective cytotoxic T cell signatures. **Conclusions:** Fusobacterium was more abundant in the mucosal microbiome of rectal cancer with higher clinical stage and was associated with different immune gene signatures. Further investigation into the impact of Fusobacterium on immune cell infiltration and function in colorectal cancers is warranted.

12113 Poster Session (Board #226), Mon, 1:15 PM-4:45 PM

Co-expression patterns of immune checkpoint molecules in relation to *PD-L1* expression. *First Author: Sumanta K. Pal, City of Hope, Duarte, CA*

Background: Targeting immune checkpoints has led to clinical benefit across a variety of tumor types, and employing combinations has enhanced response rates even further. We hypothesize that profiling the tumor and associated microenvironment can help tailor rational combinations of immunotherapeutic strategies. **Methods:** Whole transcriptomic sequencing (RNA-Seq; ~$200x10^6$ reads per tumor) of 1,880 unselected clinical cases was performed (NantHealth; Culver City, CA). Cases reflected 38 distinct histologies including but not limited to breast (17.8%), colon (9.5%), lung (7.9%), pancreatic (6.5%), ovarian (5.4%), brain (4.9%) and prostate cancer (2.7%). Cases were categorized as *PD-L1*-low, *PD-L1*-normal and *PD-L1*-high by cutoffs defined in TCGA expression profiles. Expression and co-expression of 6 checkpoint markers (*PD-L1*, *PD-L2*, *CTLA4*, *IDO1*, *LAG3* and *TIM3*) were analyzed for tissue-specific enrichment and within *PD-L1*-defined categories. Immune-cell infiltration was estimated using RNA deconvolution based on known immune cell marker genes (Bindea *et al* 2013). **Results:** Checkpoint expression did not cluster in a tissue-dependent manner. *PD-L1* shows no significant co-expression pattern with any of the analyzed checkpoint markers aside from its ortholog *PD-L2* ($R = 0.77$; $P = 1.9x10^{-285}$). Within the *PD-L1*-low category, *IDO1* and *TIM3* had relatively high expression and were highly correlated with each other ($R = 0.81$; $P = 4.6x10^{-17}$). The *PD-L1*-low category was especially deprived of memory T cells and eosinophils. Within the *PD-L1*-high category, overall expression of all checkpoint markers was higher. Amongst *PD-L1* high patients, *CTLA4* expression was highly variable (mean 2.5 ± 1.1; $\log_2$[TPM+1]) and lacked correlation with *PD-L1* ($R = -0.09$). In contrast, while *LAG3* also had variable expression in the *PD-L1*-high setting, it was strongly correlated with *CTLA4* ($R = 0.79$, $P = 7.4x10^{-14}$). The *PD-L1*-high category was especially enriched for Th1, NK $CD56_{dim}$, and CD8 T-cells. **Conclusions:** High and low *PD-L1* expression in the tumor and adjacent microenvironment are associated with variations in key checkpoint molecules. Low expression of *PD-L1* may be an ideal setting for use of IDO- or TIM3-directed therapies.

12114 Poster Session (Board #227), Mon, 1:15 PM-4:45 PM

Genomic landscape of diverse rare tumors: Next-generation sequencing of paired DNA and RNA analysis. *First Author: Ryosuke Okamura, Moores UCSD Cancer Center, La Jolla, CA*

Background: Patients (pts) with rare tumors (defined as incidence of < 15/100,000 per year) and ultra-rare tumors (prevalence < 2,000 in the U.S.) may lack standard or investigational therapeutic options. We have recently shown that matched targeted therapy approach based on the molecular profiling may result in responses in these cancers. Herein, we interrogated paired DNA/RNA among rare tumors using next-generation sequencing (NGS). **Methods:** A total of 286 pts with a rare tumor diagnoses were available for this analysis from NantHealth database. Somatic-specific variants were identified using paired tumor/normal comprehensive NGS. Analysis was focused on the 200 most frequently mutated genes in this cohort. Deep whole transcriptomic sequencing (RNA-Seq) (~200x106 reads per tumor) was used to determine expression of observed somatic variants. **Results:** Median age was 57.8 (range 0.60 – 87.7 yo), 48.6% (139/286) were women. The most common diagnoses were bone and soft tissue sarcomas (39.5%, N = 113) followed by oral and throat cancers (9.4%, N = 27) and cholangiocarcinoma (7.3%, N = 21). Ultra-rare tumors such as carcinoma of thymus (N = 10), adrenal (N = 5) and ampulla of Vater (N = 1) were included. All 286 pts had at least one alteration (including characterized alterations and variant of unknown significance). 79.0% (226/286) had ≥ 1 characterized alteration, with median number of alteration = 1 (range: 0-42). Among pts with characterized alterations, 74.3% (168/226) had ≥ 1 potentially actionable target (median: 1, range: 0-12) (with FDA-approved [on- or off-label] or investigational drug). Paired DNA/RNA sequencing revealed 44.1% (126/286) of pts had ≥1 DNA alteration that was not seen at the RNA level. **Conclusions:** Most pts with rare and ultra-rare cancers had theoretically tractable alteration. Interestingly, not all the DNA alterations were seen in RNA level, indicating potential silencing at the RNA level.

12115 Poster Session (Board #228), Mon, 1:15 PM-4:45 PM

Computer-extracted features relating to spatial arrangement of tumor infiltrating lymphocytes to predict response to nivolumab in non-small cell lung cancer (NSCLC). *First Author: Cristian Barrera, Case Western Reserve University, Cleveland, OH*

Background: Immune checkpoint inhibitors are now approved for use as therapy in advanced stage NSCLC. These drugs can decrease risk of progression by up to 60% when compared to standard chemotherapeutic regimens, but only about 20% of treated patients show significant benefit. The current gold standard for predicting response is increased tissue expression of PD-L1, but recent studies have shown this measure to be inadequate. TILs are correlated with PD-L1 levels and with antigen-induced anti-tumor immune pressure, with increased TILs associated with treatment response and longer survival. Recent work suggests that the spatial arrangement of TILs may be prognostic of outcome in several different cancer types. Here we evaluate whether computer-extracted features relating to spatial arrangement of TILs on digitized H&E images could predict response to Nivolumab in NSCLC. **Methods:** The study included fifty-six NSCLC patients with diagnostic tumor biopsies who were treated with Nivolumab. Responders and non-responders were classified according to clinical improvement and radiologic assessment by RECIST criteria on the first post-treatment CT scan. Two expert pathologists manually delineated tumor regions on digitized H&E images of the biopsies. Computerized algorithms automatically identified TILs within these regions, defined TIL clusters based on TIL proximity, and utilized network graph concepts to capture measurements relating to arrangement of these TIL clusters. **Results:** The top five features determined by a statistical feature selection method reflected the area and density of TIL clusters and the spatial proximity of the TILs to each other and to tumor cells. A machine learning classifier trained on these top 5 features had an AUC of 0.76 on the training set (n = 32) and an AUC of 0.64 on an independent validation set from another institution (n = 24). **Conclusions:** Computer extracted features relating to spatial arrangement of TIL clusters on digitized H&E images distinguished between patients who did and did not respond to Nivolumab. These findings need to be validated on in larger, multi-site validation sets.

12116 Poster Session (Board #229), Mon, 1:15 PM-4:45 PM

Detection of germline homologous recombination deficiency (HRD) in patients with metastatic esophagogastric (EG) cancer using clinical next generation sequencing (NGS). *First Author: Yelena Yuriy Janjigian, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Although EG cancer is included in Lynch syndrome (LS) and hereditary diffuse gastric cancer (HDGC), the prevalence of HRD-associated germline mutations in patients with EG cancer remains to be elucidated. To determine the potential therapeutic implications, we assessed the prevalence of clinically actionable germline mutations detected by matched tumor-normal sequencing. **Methods:** The matched tumor-normal DNA were evaluated for somatic (up to 468 genes) and germline (76 genes) alterations under MSK IRB approved protocols. Prevalence of likely pathogenic and pathogenic germline alterations were reported in genes and correlated with clinical and somatic findings. **Results:** Of 400 consecutive pts with metastatic EG adenocarcinoma: 53% had esophagus/GEJ and 47% gastric cancer. 48 (12%) of patients had clinically actionable mutations conferring cancer susceptibility, including 38 moderate- to high- penetrance mutations. 30 of 400 pts (7.5%) pts had deleterious somatic (n = 17) or pathogenic germline (n = 19) mutations in the most commonly observed HRD genes (*ATM, BRCA1, BRCA2*). The prevalence of clinically actionable germline mutations among gastric versus esophagus/GEJ tumors was 15.5% and 8.9%, respectively (p = 0.043). Interestingly, one individual harbored both a *BRCA1* and an *ATM* mutation. Germline DNA mismatch repair mutations, diagnostic of LS, were present in only two pts, both with gastric cancer, *MSH2* mutations, with both tumors exhibiting a mismatch repair deficient signature. Other germline mutations of interest include: 6 *CDH1*, 1 *TP53*, 1 *BRIP1*, 1 *STK11* pts as well as 1 biallelic *MUTYH* carrier diagnostic of *MUTYH*-associated polyposis. When available, correlative tumor data, including somatic mutations and loss of heterozygosity in the gene(s) corresponding to the germline mutation will be presented. **Conclusions:** Clinical NGS in paired germline-tumor DNA samples increases detection of individuals with potential clinically significant germline/somatic mutations. Analysis of therapeutic implications of these HRD mutations is ongoing and updated data will be presented.

12117 Poster Session (Board #230), Mon, 1:15 PM-4:45 PM

Three-fold overestimation of tumor mutation burden using 248 gene panel versus whole exome. *First Author: Andrew Nguyen, NantOmics, LLC, Santa Cruz, CA*

Background: Next generation sequencing (NGS) Gene panel testing is used to imputed tumor mutational burden (iTMB) and has shown rough correlation with TMB derived from whole exome sequencing (WES). TMB is used to estimate immune checkpoint inhibitor (ICT) response based on potential neoantigen load. We hypothesized that actual TMB (aTMB), consisting of mutations across the exome, and expressed TMB (eTMB), consisting of expressed genes, would differ substantially from iTMB. **Methods:** Retrospective analysis of a database from a commercial DNA tumor:normal and RNAseq platform was carried out. We analyzed 890 clinical samples composing of both primary and metastatic disease by whole genome sequencing (WGS) or WES and RNA sequencing (RNA-Seq), and compared true tumor mutational burden to a predicted tumor mutational burden from a list of 248 genes thought to drive cancer. (COSMICv76) **Results:** Estimated tumor mutational burden based only on the list of 248 genes had an average of 15.79 mutations per megabase (14.16–17.43, 95% CI) whereas WGS/WES derived TMB had an average of 5.09 mutations per megabase of coding DNA (4.22–5.96). The relationship between gene panel size, aTMB and eTMB will be presented. **Conclusions:** In this retrospective analysis using a 248 gene list as a panel to impute TMB, we observed a roughly 3-fold over-estimate of TMB. This may impact ICT prescription and expectation of clinical benefit.

12118 Poster Session (Board #231), Mon, 1:15 PM-4:45 PM

Seventeen percent of NGS 50 gene panel variants are not expressed in RNAseq. *First Author: Razelle Kurzrock, Moores Cancer Center, La Jolla, CA*

Background: Next Generation Sequencing (NGS) has gained widespread clinical adoption for the determination of molecular targets for therapy in oncology. Standard NGS panels evaluate DNA only. RNAseq has shown that molecular targets identified by NGS panels are not universally expressed. We hypothesized that heterogeneous epigenomic factors may lead to low or absent RNA expression. We sought to determine the frequency of non-expressed variants that would be tested by a standard NGS panel. **Methods:** Retrospective analysis of a database from a commercial DNA tumor:normal and RNAseq platform was carried out. 992 samples were identified with paired DNA(WGS or WES)/RNAseq NGS. An analysis of expressed variant status for SNVs of the following type: synonymous, silent, missense, nonsense. Expressed variants are based on whether at least 2 alternate reads in the RNA are present at that variant site. A 50 gene panel (AmpliSeq HotSpot V2) was used as the reference comparison: ABL1, EGFR, GNAS, KRAS, PTPN11, AKT1, ERBB2, GNAQ, MET, RB1, ALK, ERBB4, HNF1A, MLH1, RET, APC, EZH2, HRAS, MPL, SMAD4, ATM, FBXW7, IDH1, NOTCH1, SMARCB1, BRAF, FGFR1, JAK2, NPM1, SMO, CDH1, FGFR2, JAK3, NRAS, SRC, CDKN2A, FGFR3, IDH2, PDGFRA, STK11, CSF1R, FLT3, KDR, PIK3CA, TP53, CTNNB1, GNA11, KIT, PTEN, VHL **Results:** A total of 225,727 SNVs were detected in the 992 samples. 669 samples had at least 1 SNV in the 50 gene panel set for a total of 1661 SNVs, of which 1375 SNVs were expressed in the RNAseq (82.8%). Across 37 tumor types the range of expression was 57% (melanoma)-100% (uterine). **Conclusions:** In this retrospective analysis using a 50 gene commonly used hotspot panel as a hypothetical reference comparison, 17% of detected variants were not expressed in the RNAseq. The lack of RNA expression may contribute to less than expected clinical benefit with molecularly targeted therapies. Since the distribution is non-uniform, identification of these genes can yield improved testing algorithms and treatment strategies.

12119 Poster Session (Board #232), Mon, 1:15 PM-4:45 PM

FDG-uptake and expression levels of TILs and PD-L1 in primary breast cancer. *First Author: Tomoko Hirakata, Department of General Surgical Science, Gunma University, Maebashi, Gunma, Japan*

Background: ^{18}F-Fluorodeoxyglucose-positron emission tomography (FDG-PET) is used to evaluate the glucose metabolic rates of cancers. Several studies have reported that high FDG uptake is predictive of poor prognosis and aggressive features in patients with breast cancer (BC). However, FDG-uptake is influenced by many factors, including inflammation. In this study, we investigated the relationship between FDG uptake and immunological factors, including degrees of Tumor-infiltrating lymphocytes (TILs), CD8 and programmed cell death ligand 1 (PD-L1), which has been suggested as prognostic factor in BC. **Methods:** Invasive carcinoma tissues of 97 BC patients who underwent surgery without preoperative therapy were examined. Grade of stromal-TILs was immunohistochemically (IHC) evaluated using the criteria of the International Working Group for TILs in BC: low (10-20%), intermediate (20-40%) and high (50-90%). CD8 positive and PD-L1 positive were evaluated by IHC. The evaluation of PET was determined using standardized uptake value max (SUVmax): low (< 5) and high ($\geqq 5$). The relationships between SUVmax and expressions of TILs, CD8 and PD-L1 were investigated. **Results:** Among the 97 patients, 22 (22.7%) had high SUVmax in the primary tumor. We divided the cases into two groups based on the value of SUVmax, low and high. The analysis revealed that large tumor size ($p = 0.004$), high nuclear grade ($p = 0.019$), high degree of TILs ($p = 0.004$) and positive expression of PD-L1 ($p = 0.003$) were significantly associated with high SUVmax in the primary tumor. There were associations between SUVmax and degree of TILs, and between SUVmax and the positive expression of PD-L1 ($r = 0.428$, $p < 0.001$ and $r = 0.413$, $p < 0.001$, respectively). All cases with high degree of TILs showed high expression of CD8. **Conclusions:** The present study demonstrated that the finding of preoperative FDG uptake in BC may be reflective of the grades of TILs and expression of PD-L1 in the tumor. High TILs is to be better prognostic factor, however, high expression of PD-L1 is to be a poor prognostic factor. In light of our results, FDG uptake may be predictive of immunological features in addition to aggressive features among patients with BC.

12120 Poster Session (Board #233), Mon, 1:15 PM-4:45 PM

Survival outcome of breast cancer (BC) patients presenting with recurrent and de novo isolated contralateral lymph node metastases (CLNM). *First Author: Aydah Al-Awadhi, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: In the current staging system, BC patients with isolated CLNM are considered to have distant or stage IV disease. The prognosis of these patients has not been described in contemporary series. In this study we compared the outcomes of patients with CLNM and those with stage IV disease with metastases other than CLNM. **Methods:** We identified metastatic BC patients treated at MD Anderson Cancer Center between 2000-2015. 235 patients had isolated recurrent CLNM (supraclavicular, infraclavicular and/or axillary) and 7617 patients had metastases other than CLNM. Among patients diagnosed with stage IV de novo, 37 had isolated CLNM and 1544 had distant metastases other than CLNM. Overall survival (OS) and breast cancer-specific survival (BCSS) were calculated from date of distant metastases for the recurrent cohort and from date of diagnosis for the de novo cohort. Descriptive statistics, Kaplan-Meier method with log-rank test and Cox proportional hazards model were used. **Results:** In the recurrent cohort (median follow-up 20 months) the 3-year OS rate was 43% for CLNM patients and 41% for those with non-CLNM ($p = 0.04$). After multivariable adjustment, patients with recurrent CLNM had decreased risk of death (HR = 0.66; 95%CI 0.56-0.78) compared to patients with metastases other than CLNM. Patients with CLNM had comparable OS to the subgroup of patients with bone-only metastases (HR = 0.97; 95%CI 0.82-1.16). Among stage IV de novo patients (median follow-up 31 months) the 3-year OS was 62% for patients with CLNM and 57% for patients with metastases other than CLNM ($p < 0.001$). In multivariable analyses, CLNM patients had decreased risks of death (HR = 0.63; 95%CI 0.39-1.00) compared to patients with metastases other than CLNM. BCSS analysis was similar. **Conclusions:** Metastatic BC patients with isolated CLNM have better outcomes compared to patients with non-CLNM metastases. The prognosis of patients with isolated CLNM was similar to the prognosis of patients with bone-only metastases. Our data can be helpful in identifying patients with limited regional disease that may potentially benefit from multidisciplinary treatment given improved outcomes.

12121 Poster Session (Board #234), Mon, 1:15 PM-4:45 PM

Early mortality with immune checkpoint inhibitors (IOs) in solid tumors: An inconvenient truth? *First Author: Eric Winquist, Western University and London Health Sciences Centre, London, ON, Canada*

Background: Overall survival (OS) benefit with IOs has been demonstrated in several solid tumor types leading to their rapid adoption and use in practice. We noticed IO randomized controlled trials (RCTs) with early crossover of OS Kaplan-Meier (KM) curves favoring control therapy but with overall benefit favoring IO therapy. This suggests a subpopulation of patients at a higher risk of death on IO therapy compared to control therapy early in treatment. We performed a systematic review to examine the frequency and characteristics of IO RCTs showing this negative discordant crossover (NDC). **Methods:** RCTs studying IOs and non-IOs in solid tumors with published OS KM curves were identified by electronic database search and FDA approvals 2015-17. Early OS divergence was identified by blinded reviewers. NDC of OS KM curves was defined as early divergence discordant with an overall beneficial survival trend. RCT characteristics were compared using Fisher's exact test. **Results:** 29 IO RCTs providing 33 comparisons and 24 non-IO RCTs providing 25 comparisons were identified. Nine IO RCTs (27%) and 1 non-IO RCT (4%) demonstrated NDC ($p = 0.03$). NDC occurred in NSCLC (3/9), urothelial cancer (2/2), melanoma (2/9), SCLC (1/2) and CRPC (1/2) RCTs. RCTs with NDC trended to less often study melanoma (22% v 46%) and squamous cancer (0% v 13%), and less often report OS benefit (22% v 71%). They trended to more often study urothelial cancer (22% v 0%) and 2nd-line treatment (56% v 38%), and more often have active treatment control arms (89% v 75%). **Conclusions:** Early NDC of overall survival curves occurs commonly in IO RCTs. This suggests a subpopulation of patients at higher risk of early death with IO therapy. Causes of this mortality are unclear but could include toxicity of IO therapy, superior antitumor effects of control therapy, and/or tumor growth promoting effects of IO therapy. We are quantitating this risk. Such crossover complicates proportional hazards modeling. Further research to identify the causes of and patients at risk for early mortality with IO therapy should be a priority and patients should be informed of this potential risk.

12122 Poster Session (Board #235), Mon, 1:15 PM-4:45 PM

Acquired *BRAF* fusions as a mechanism of resistance to *EGFR* therapy. *First Author: Morana Vojnic, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: While multiple genetic mechanisms have been identified in *EGFR* mutant lung cancers as mediators of acquired resistance (AR) to EGFR tyrosine kinase inhibitors (TKI), either first generation (EGFR T790M), or third generation (EGFR C797S), or both (gains of MET or ERBB2), many cases lack a known mechanism of AR. **Methods:** To identify novel mechanisms of EGFR TKI, we performed targeted large panel sequencing (MSK-IMPACT assay; PMID: 28336552) on 374 consecutive patients with metastatic *EGFR* mutant lung cancer, including 200 tested prior to EGFR TKI, 136 tested after progression on EGFR TKI, and 38 patients with both types of samples. Genetic alterations hypothesized to confer AR were introduced into drug-sensitive EGFR-mutant lung cancer cell lines (H1975, HCC827, PC9) using CRISPR-Cas9 genome editing. We also generated a cell line from a biopsy of a patient with AR (MSK-LX138cl). A kinase-focused inhibitor library was used to screen for agents that would overcome AR. **Results:** We identified 4 patients with a *BRAF* fusion (3 *AGK/BRAF*, 1 *PJA2/BRAF*) in a sample obtained at AR to EGFR TKI (2 post-erlotinib; 2 post-erlotinib and post-osimertinib). A pre-TKI sample was available in one of these 4 patients and was negative for BRAF fusion. In the 200 patients only studied pre-EGFR TKI, no BRAF fusions were identified, further supporting the acquired nature of the BRAF fusion. Induction of *AGK/BRAF* formation in H1975 (L858R+T790M), PC9 (ex19del) and HCC827 (ex19del) cells by genome editing increased phosphorylation of BRAF, MEK1/2, ERK1/2 and STAT3, and conferred resistance to growth inhibition by osimertinib. A patient-derived cell line, MSK-LX138cl, with ex19del and the *PJA2/BRAF* fusion, was confirmed to be resistant to EGFR TKIs and then used to screen a library of 61 drugs targeting the MAPK pathway in the absence or presence of osimertinib to derive a potential therapeutic strategy. This identified trametinib as an agent that reduced growth of MSK-LX138cl and H1975-AGK/BRAF cells in a synergistic manner with osimertinib. **Conclusions:** Our findings identify acquired BRAF fusion as a recurrent mechanism of AR to EGFR TKIs including osimertinib and suggest combined MEK and EGFR inhibition as a possible therapeutic strategy.

A comprehensive genomic analysis of squamous cell carcinomas of the lung, esophagus, and head and neck. *First Author: Lara Ann Kujtan, University of Missouri at Kansas City, KC, MO*

Background: Squamous cell carcinomas (SCC) of the lung, esophagus and head and neck (H&N) are indistinguishable by histology. Data from large-scale genomic studies have identified significant similarities in the mutational profiles of these tumors. Combined genomic analysis will lead to the discovery of unique molecular similarities and dissimilarities of these tumors. **Methods:** We analyzed whole exome, RNA, miRNA and methylation data of 1221 patients with lung (39.6%), esophagus (26.3%), and HPV-negative H&N SCC (34.1%) from the Cancer Genome Atlas (TCGA) and International Cancer Genome Consortium (ICGC). WTSI Mutational Signature Framework was used to develop mutational signatures (MS). **Results:** Nine novel significantly mutated genes were identified in the combined analysis, including *PYHIN1,* a key mediator in the inflammasome pathway. Mutations in the inflammasome pathway (*PYHIN1*, *MNDA*, *CIITA*, *AIM2*, *IFIT*, *IFNG*), which is key for tumor antigen processing and presentation to T cells, were identified in 136 SCC samples (11.1%). All mutations were mutually exclusive of one another. We also discovered a novel tumor suppressor gene mutation in Asian patients with esophageal SCC, *NEFH* (7%), which was mutually exclusive of the *TP53* mutation. Seven novel gene amplifications and two deletions were detected in the combined population. Two novel MS with high stability (0.83 and 0.85) were recognized in H&N (7% and 13% of all mutations) with maximum cosine similarities of 0.37 and 0.34 respectively. All TCGA samples displayed COSMIC MS 1(age-related), 2 (APOBEC), and 4 (tobacco-related), while the esophageal ICGC sample showed COSMIC MS 13(APOBEC) and 17 (unknown). **Conclusions:** Our analysis identified a novel tumor suppressor mutation in Asians with esophageal SCC. We report possible dysregulation of the tumor antigen-processing pathway in a small but significant proportion of patients. Two novel MS in H&N SCC were identified, and the remaining MS were similar across all three tumor types in the TCGA. Esophageal ICGC tumors had different mutational profiles suggesting a unique mutational process in Asians.

12124 Poster Session (Board #237), Mon, 1:15 PM-4:45 PM

Molecular comparison of interval and screen-detected breast cancers. *First Author: Dane Anthony Cheasley, Peter MacCallum Cancer Centre, North Melbourne, Australia*

Background: Breast cancer diagnosed after a negative mammogram but prior to the next screening episode are termed an "interval breast cancer" (IBC) and account for ~20% of breast cancer diagnoses in women attending population-based screening programs. IBCs are a major issue limiting the effectiveness of mammographic screening particularly as IBCs are generally diagnosed at later stages and have a worse prognosis in compared to screen detected breast cancer (SDC). To understand if IBC are biologically distinct from SDC we assessed the frequency of germline and acquired somatic genomic aberrations in a prospective cohort is 1060 screen detected and interval breast cancers. **Methods:** Using the Lifepool cohort, an Australian prospective population-based cohort of over 54,000 women, 1001 cases of breast carcinoma (811 invasive and 180 in situ) with known screening status at time of diagnosis were identified. Clinicopathological information, mammographic density data, and family history data was recorded. Germline and tumour DNA was also collected where available and sequenced for breast cancer predisposition and driver genes. **Results:** IBCs were significantly associated with more aggressive tumour characteristics including higher grade, more advanced stage and higher proportion hormone receptor negative cancers. Women diagnosed with an IBC also had a higher frequency of actionable germline mutations in HBOC genes (4.4% versus 2.3%). Analysis of the breast cancers did not identify any significant differences in the somatic mutation spectrum or frequency, overall copy number profiles or homologous recombination deficiency scores. **Conclusions:** In the emerging era of clinical sequencing, it is timely to investigate the genomic alterations of IBCs, as they impose a major limitation on effective mammography screening and are associated with a high mortality burden. Within this study, Clinicopathological and molecular differences observed rather form the continuum from less aggressive (SDC) to more aggressive (IBC) cancers. Whilst analysis of an actionable germline mutations revealed subtle risk increases in IBCs (in particular BRCA2), additional cohorts will be required to define

12125 Poster Session (Board #238), Mon, 1:15 PM-4:45 PM

Are racial differences in obesity and insulin resistance related to aggressive breast cancer? *First Author: Emily Gallagher, Division of Endocrinology, Diabetes and Bone Diseases, Department of Medicine, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Black women are more likely to die of breast cancer and develop more aggressive subtypes than white women. Black women are also more likely to be obese and have insulin resistance than white women. Insulin resistance has been associated with faster tumor growth but has not been studied as a potential mediator of racial disparities in women with breast cancer. We hypothesized that black women would present with more aggressive breast cancer and this would be associated with obesity and insulin resistance. **Methods:** We recruited 810 (83% white, 17% black) women with new primary breast cancer, measured fasting blood glucose and insulin, body mass index (BMI), triple negative breast cancer (TNBC) & Nottingham prognostic index (NPI). We classified aggressive breast cancer as NPI $>$ 4.4. We calculated insulin resistance scores (HOMA) and classified insulin resistance as HOMA $>$ 2.8. Patients self-identified race. Immunohistochemistry (IHC) of insulin receptors (IR) was performed on a subset of tumor specimens (N = 181). **Results:** Of 810 women, average age was 58 years (sd = 12.2). 293 (37%) were stage 2+ at time of diagnosis; 18% had an NPI $>$ 4.4. Black women presented with higher stage of cancer than white women (stage 2+: 48% vs 35%; p = 0.004), were more insulin resistant (18% vs 11%, p = 0.03), had higher BMI (31.1kg/m^2 vs 26.7 kg/m^2; p $<$ .0001), and NPI scores (4.0 vs 3.6; p $<$ .05). Black women had more TNBC than white women (17% vs 6%, p = 0.0001). HOMA score was not associated with NPI score (r = 0.06; p = 0.12). IR expression was intermediate or highly expressed in 79% of cancers in black women & 51% in white women (p = 0.004) but was not significantly related to NPI $>$ 4.4 (66% vs 54%; p = 0.2). **Conclusions:** In women with newly diagnosed breast cancer, black women are more likely to be obese, have higher HOMA & NPI scores than white women. While these data are consistent with the hypothesized relationship of hyperinsulinemia promoting more aggressive breast cancer, to date, insulin resistance does not appear to mediate the effect of race and poor prognostic breast cancer.

TPS12126 Poster Session (Board #239a), Mon, 1:15 PM-4:45 PM

A phase 1/2 dose-escalation and expansion study of a conditionally active anti-AXL humanized monoclonal antibody (BA3011) in patients with advanced solid tumors. *First Author: Jordi Rodon Ahnert, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The AXL receptor tyrosine kinase is often highly expressed in certain cancers. AXL appears to sustain resistance to anticancer therapies including chemotherapy, targeted therapy and immune checkpoint inhibitors (1, 2). BA3011 is an anti-AXL humanized monoclonal antibody conjugated to monomethyl auristatin E using a cleavable linker (CAB-AXL-ADC) and specifically binds to AXL under conditions found within the tumor microenvironment. The pharmacokinetic (PK) and toxicity profile of BA3011 has been established in cynomolgus monkeys; anti-tumor activity has been shown in non-small-cell lung cancer (NSCLC), pancreatic, castration-resistant prostate cancer (CRPC) and other tumor models. **Methods:** A multi-center, open-label, Phase 1/2 study will evaluate the safety, tolerability, PK, immunogenicity, and antitumor activity of BA3011 in patients with advanced solid tumors. The study consists of a dose-escalation phase (Phase 1) and a dose-expansion phase (Phase 2). The primary objective of Phase 1 is to define the safety profile (including dose-limiting toxicity [DLT]), maximum tolerated dose, and recommended Phase 2 dose (RP2D). BA3011 will be administered every 3 weeks (q3w) via intravenous infusion, with a starting dose of 0.3 mg/kg, escalating to 2.4 mg/kg using a modified Fibonacci method, until DLT occurs. In Phase 2, patients will receive the RP2D. Treatment will continue q3w until disease progression or unacceptable toxicity; safety and efficacy will be evaluated in specific tumor types (NSCLC, CRPC, and pancreatic ductal adenocarcinoma). Approximately 120 patients will be enrolled (11-30 in Phase 1 and approximately 90 in Phase 2). Patients must have histologically or cytologically confirmed locally advanced, unresectable or metastatic solid tumors and have failed available standard-of-care therapy and for whom no curative therapy is available. Follow-up information will be collected approximately every 3 months after the last dose until disease progression for patients with stable disease or better at the end of treatment. Clinical trial information: NCT 03425279.

TPS12127 Poster Session (Board #239b), Mon, 1:15 PM-4:45 PM

Canadian profiling and targeted agent utilization trial (CAPTUR/PM.1): A phase II basket precision medicine trial. *First Author: Tanya Skamene, McGill University, Montreal, QC, Canada*

Background: Genomic profiling of cancers is increasingly used to refine prognostication and aid in treatment decisions by allowing matching of targeted agents to specific genetic variants. Clinical reports to date suggest that 30-80% of advanced solid tumours harbor potentially actionable genomic variants but difficulties in obtaining matched targeted agents in clinical practice limits the application of precision medicine. CAPTUR is a pan-Canadian trial leveraging existing clinical genomic profiling platforms and the research capabilities of the Canadian Cancer Trials Group (CCTG) to evaluate targeted drug-genetic variant matches in patients with advanced cancers. CAPTUR was developed in collaboration, and plans to share data, with ASCO's TAPUR and the Netherland's DRUP trials. **Methods:** CAPTUR/PM.1 (NCT03297606) is a multi-centre, open-label, phase II basket trial, matching Canadian patients who have undergone genomic profiling with genetic variants to appropriate targeted agents. Drug matches are drawn from a list of 17 commercially available anticancer agents. Patients must have incurable metastatic solid tumours, multiple myeloma, or B cell non-Hodgkin lymphoma, must have no standard treatment options known to prolong life and must have an actionable genomic variant known to be a target of, or predict sensitivity to, the commercially available targeted anticancer drug. Patients who possess an actionable tumour genetic variant and meet non-drug specific study requirements are entered into the study. A drug-variant match is assigned based on protocol specified matching criteria or input of the Molecular Tumour Board. Determination of the best treatment is then made by physician and patient based on drug-specific eligibility requirements. Cohorts are defined by tumour type, genomic alteration and matched drug treatment. The primary endpoint is response rate, as determined by disease-appropriate objective criteria. Maximum sample size per cohort is 24 patients based on a Simon 2-stage admissible design. Maximum planned number of cohorts is 30 (maximum sample size for the trial of 720 patients). CAPTUR was activated November 2017 and is open to enrolment. Clinical trial information: NCT03297606.

Publication-Only Abstracts

Publication-only abstracts, which are selected to be published in conjunction with the 2018 Annual Meeting, but not to be presented at the Meeting, can be found online in full-text, fully searchable versions at abstracts.asco.org and JCO.org.

The publication-only abstracts are not included in the print volume, but are citable to this *Journal of Clinical Oncology* supplement. Please refer to the following example when citing publication-only abstracts:
