POSTMASTER: Send address changes to American Society of Clinical Oncology, 2318 Mill Road, Suite 800, Alexandria, VA 22314. ASCO members should send changes of address to American Society of Clinical Oncology, 2318 Mill Road, Suite 800, Alexandria, VA 22314. Nonmembers should send changes of address to *Journal of Clinical Oncology* Customer Service, 2318 Mill Road, Suite 800, Alexandria, VA 22314.

2018 annual subscription rates, effective September 1, 2017: United States and possessions: individual, $625 one year, $1,188 two years; single issue, $40. International: individual, $867 one year, $1,647 two years; single issue, $50. Institutions: bundled (print + online): Tier 1: $1,078 US, $1,495 Int'l; Tier2: $1,243 US, $1,650 Int'l; Tier 3: $1,795 US, $2,185 Int'l; Tier 4: contact *JCO* for quote. Institutions: online only, worldwide: Tier 1: $909; Tier 2: $1,040; Tier 3: $1,500; Tier 4: contact *JCO* for quote. See ascopubs.org/jco/site/misc/librarians.xhtml for descriptions of each tier. Individuals in training and advanced practice providers: United States and possessions: $303; all other countries, $421. Current prices are in effect for back volumes and back issues. Back issues sold in conjunction with a subscription rate are on a prorated basis. Subscriptions are accepted on a 12-month basis. Prices are subject to change without notice. Single issues, both current and back, exist in limited quantities and are offered for sale subject to availability. *JCO* Legacy Archive (electronic back issues from January 1983 through December 1998) is also available; please inquire.

American Society of Clinical Oncology
54th Annual Meeting

2018 Abstracts

Descriptions of Scientific Sessions

Plenary Session
The Plenary Session includes abstracts selected by the Scientific Program Committee as having practice-changing findings of the highest scientific merit.

Highlights of the Day Sessions
Highlights of the Day Sessions invite expert discussants to provide an overview of the previous day's Oral Abstract presentations, focusing on key findings and putting abstracts into clinical context.

Oral Abstract Sessions
Oral Abstract Sessions include didactic presentations of abstracts of the highest scientific merit, as determined by the Scientific Program Committee. Experts in the field serve as discussants and provide comprehensive themed discussions of the findings from the abstracts.

Clinical Science Symposia
Clinical Science Symposia provide a forum for science in oncology, combining didactic lectures on a specific topic with abstract presentations. Experts in the field serve as discussants, placing studies in the appropriate context and critically discussing the applicability of the conclusions in clinical practice. Three special Clinical Science Symposia will be designated around specific topics that cut across cancer types.

Poster Discussion Sessions
Select posters from the Poster Sessions will be discussed by expert discussants, with the abstract authors participating in a question and answer period as panel members. These sessions will be followed by networking with the discussants and authors.

Poster Sessions
Poster Sessions include selected abstracts of clinical research in poster format. Trials in Progress (TPS) abstracts are presented within a track's Poster Session.

Publication-Only Abstracts
Publication-only abstracts were selected to be published online in conjunction with the Annual Meeting, but will not be presented at the Meeting.

All presented and publication-only abstracts are citable to this Journal of Clinical Oncology *supplement. For citation examples, please see the Letter from the Editor.*

This publication contains abstracts selected by the ASCO Scientific Program Committee for presentation at the 2018 Annual Meeting. Abstracts selected for electronic publication only are available in full-text versions online through ASCO.org and JCO.org. The type of session, the day, and the session start/end times are located to the right of the abstract number for scheduled presentations. To determine the location of the abstract session, refer to the Annual Meeting Program or the iPlanner, the online version of the Annual Meeting Program, available at am.asco.org.

Dates and times are subject to change.
All modifications will be posted on am.asco.org.

Letter From the Editor

The *2018 ASCO Annual Meeting Proceedings* (a supplement to *Journal of Clinical Oncology*) is an enduring record of the more than 2,400 abstracts selected by the ASCO Scientific Program Committee for presentation at the 54th ASCO Annual Meeting. Accepted abstracts not presented at the meeting are included in the online supplement to the May 20 issue of *Journal of Clinical Oncology* at JCO.org.

The majority of abstracts selected for presentation are included here in full and are categorized by scientific track. Abstracts can be also accessed online through ASCO abstracts website (abstracts.asco.org) or Meeting Library (meetinglibrary.asco.org). Online abstracts include the full list of abstract authors and their disclosure information.

Late-Breaking Abstracts are represented here by abstract title and first author only. The full-text versions of these abstracts will be publicly released during the Annual Meeting. Print versions of these abstracts will be available onsite at the Annual Meeting in the *ASCO Daily News*.

All abstracts carry *Journal of Clinical Oncology* citations. The following are citation examples for print and electronic abstracts:

J Clin Oncol 36:5s, 2018 (suppl; abstr LBA1)

J Clin Oncol 36, 2018 (suppl; abstr e12000)

Should you have any questions or comments about this publication, we encourage you to provide feedback by contacting us at abstracts@asco.org.

Important Tiers and Pricing Notes

Additional rates along with tier descriptions are available online at ascopubs.org/pb-assets/pdfs/2018-ASCO-Institutional-Products-Catalog.pdf

1. Prices are in effect from September 1, 2017, through August 31, 2018. Prices are subject to change.
2. Print-only subscriptions or additional print subscriptions are available for $886 in the US and $1,281 outside the US.
3. For multisite licenses, please contact the appropriate agent for a quote.
4. Subscribers outside the US, add $150 per print subscription for expedited delivery.
5. Single-issue price: $40 US, $50 international.
6. Prices quoted are in US dollars, and payments must be made in US dollars.
7. Except on consortia orders, the publisher allows for a 5% discount on Tiers 1-3 to recognized subscription agents.

Prices are subject to change without notice. Current prices are in effect for back volumes and back issues. Single issues, both current and back, exist in limited quantities and are offered for sale subject to availability. Back issues sold in conjunction with a subscription are on a prorated basis.

Free Public Access

Journal of Clinical Oncology (*JCO*) provides free online access to original research articles older than one year at jco.org. In addition, all ASCO Special Articles, Rapid Communications, Editorials, Comments and Controversies articles, the Art of Oncology series, and Correspondence articles are free immediately upon publication.

Disclaimer

The ideas and opinions expressed in *JCO* do not necessarily reflect those of the American Society of Clinical Oncology (ASCO). The mention of any product, service, or therapy in this publication or in any advertisement in this publication should not be construed as an endorsement of the products mentioned. It is the responsibility of the treating physician or other health care provider, relying on independent experience and knowledge of the patient, to determine drug dosages and the best treatment for the patient. Readers are advised to check the appropriate medical literature and the product information currently provided by the manufacturer of each drug to be administered to verify approved uses, the dosage, method, and duration of administration, or contraindications. Readers are also encouraged to contact the manufacturer with questions about the features or limitations of any products. ASCO assumes no responsibility for any injury or damage to persons or property arising out of or related to any use of the material contained in this publication or to any errors or omissions.

ASCO Abstracts Policy

Public Release of Abstracts

The abstracts published in the *2018 ASCO Annual Meeting Proceedings,* including those abstracts published but not presented at the Meeting, were publicly released by ASCO at 5:00 PM (EDT) on Wednesday, May 16, 2018. These abstracts are publicly available online through ASCO.org, the official website of the Society. Late-Breaking Abstracts, which include all Plenary Abstracts, will be publicly released according to the following schedule:

- Late-Breaking Abstracts presented in a press briefing or scientific presentation (whichever comes first) on Friday, June 1, will be publicly released Friday, June 1, through ASCO.org at 2:00 PM (EDT).
- Late-Breaking Abstracts presented in a press briefing or scientific presentation (whichever comes first) on Saturday, June 2, will be publicly released Saturday, June 2, through ASCO.org at 7:30 AM (EDT).
- Late-Breaking Abstracts presented in a press briefing or scientific presentation (whichever comes first) on Sunday, June 3, will be publicly released Sunday, June 3, through ASCO.org at 7:30 AM (EDT).
- Late-Breaking Abstracts presented in a press briefing or scientific presentation (whichever comes first) on Monday, June 4, or Tuesday, June 5, will be publicly released Monday, June 4, through ASCO.org at 7:30 AM (EDT).

Late-Breaking Abstracts will be available in Section D of *ASCO Daily News* on the day of their scientific presentation, with the exception of abstracts presented on Friday (these will appear in the Saturday issue) and those presented on Tuesday (these will appear in the Monday issue).

In the unlikely event that ASCO publicly releases an abstract in advance of the scheduled time, the release will be publicly announced on ASCO.org.

Conflict of Interest Disclosure

As the CE provider for the Symposium, ASCO is committed to balance, objectivity, and scientific rigor in the management of financial interactions with for-profit health care companies that could create real or perceived conflicts of interest. Participants in the Symposium have disclosed their financial relationships in accordance with ASCO's Policy for Relationships with Companies; review the policy at asco.org/rwc.

ASCO offers a comprehensive disclosure management system, using one disclosure for all ASCO activities. Members and participants in activities use coi.asco.org to disclose all interactions with companies. Their disclosure is kept on file and can be confirmed or updated with each new activity.

Please email coi@asco.org with specific questions or concerns.

ABSTRACTS
American Society of Clinical Oncology
54th Annual Meeting
June 1-5, 2018
McCormick Place
Chicago, IL

SPECIAL AWARD LECTURE ABSTRACTS

David A. Karnofsky Memorial Award and Lecture
Saturday, June 2, 9:30 AM

Oligometastasis from conception to treatment.
Ralph R. Weichselbaum, MD; The University of Chicago Medical Center, Chicago, IL

Metastases account for 80-90% of cancer deaths. Despite recent advances in systemic therapies, almost all patients who develop metastases from adult solid tumors are not cured. We proposed that a subset of patients develop few metastatic lesions within limited destination organs, termed oligometastasis. These patients may be amenable to cure by ablative therapies including radiotherapy and surgery. We also proposed that patients who respond well to systemic therapies, but later re-present with a limited number of persistent or oligo-progressive tumors, may be cured when ablative therapies are combined with systemic therapies. I will review laboratory data that provides clues regarding the biological basis of oligometastases, and discuss retrospective data and early level 1 evidence to demonstrate improved PFS and OS in patients with oligometastatic disease. Looking forward, I will discuss a rationale for designing clinical trials that integrate ablative therapies combined with systemic approaches including hormonal manipulation, targeted cytotoxic drugs, and immunotherapy in order to optimize cure in various stages of metastatic disease.

Science of Oncology Award and Lecture
Sunday, June 3, 1:00 PM

Preventing HPV-associated cancers by vaccination.
Douglas R. Lowy, MD; Deputy Director, National Cancer Institute, Bethesda, MD

The laboratory developed the virus-like particle technology that underlies the three FDA-approved HPV vaccines, which have the potential to prevent the majority of the HPV infections that lead to ~30,000 anogenital and oropharyngeal cancers annually in U.S. men and women, and to ~8% of all female cancers worldwide. They are the first vaccines that successfully target an infectious agent that mainly induces local sexually transmitted disease. The vaccines, which are given systemically, confer more than 90% protection against new mucosal and cutaneous infections.

We have studied the mechanisms that underlie the efficacy of the vaccine, using an HPV mouse genital tract challenge model after validating that it recapitulates vaccine responses that are similar to those observed in women. Passive transfer studies indicate that neutralizing antibodies induced by the vaccine account for its high protective efficacy, although the vaccine also induces cell-mediated responses. Factors that contribute to vaccine efficacy include: intrinsically high immunogenicity of the virus-like particle (VLP) structure of the vaccine immunogen, high in vivo sensitivity of HPV to neutralizing antibodies, and high antibody levels at potential sites of infection.

The HPV vaccines are already having an impact on HPV-induced early disease markers in vaccinated populations, including evidence of herd immunity. The high immunogenicity of the vaccines has led us to hypothesize that, in contrast to most other protein-based subunit vaccines, it may be possible to safely reduce the number of recommended vaccine doses from the current two or three to a single dose in young adolescents, who represent the main target group for the vaccine. A randomized clinical trial has been started to test this hypothesis.

Disclosure: I am an inventor of the virus-like particle technology that underlies the technology for the HPV vaccines. The technology has been licensed by the NIH to Merck and GlaxoSmithKline, the manufacturers of the FDA-approved vaccines.

ASCO–American Cancer Society Award and Lecture
Monday, June 4, 9:45 AM

Hereditary cancer genetic testing and risk reduction: Evolving strategies.
Karen H. Lu, MD; The University of Texas MD Anderson Cancer Center, Houston, TX

As a gynecologic oncologist, I have had an ongoing interest in the intersection of cancer treatment and cancer prevention. With the approval of parp inhibitors for BRCA-associated ovarian cancer and immune checkpoint blockade for MSI-H endometrial cancers, there has been increasing emphasis on universal genetic screening for women who have these cancers. However, the real impact on decreasing mortality will be in the "cascade testing" of family members, who can then undergo risk reduction strategies. Traditional models of delivering cancer genetics services and cascading the information to family members need to be re-examined. Strategies for genetic testing must focus on increasing access and using technology to provide genetic counseling. We are currently studying this paradigm in a national study called Making Genetic Testing More Accessible (MAGENTA). Described as "Genetic Testing from your Living room," the study aims to examine novel delivery models of genetic counseling and testing. Two other strategies need to be employed if we are to realize the full potential of cancer risk reduction through genetic risk assessment and testing. First, partnership with advocates at the time of research planning is essential, as the development of prevention strategies must consider patient preferences beyond efficacy. A national study of immediate salpingectomy and delayed oophorectomy in women at increased risk of ovarian cancer was based on scientific evidence that BRCA-associated ovarian cancer begins in the fimbriae of the fallopian tube, and was strongly driven by the advocacy community as an option to delay the effects of surgical menopause. Second, those of us in the cancer prevention community need to embrace a more patient-centered, multidisciplinary approach for care of these genetically high risk patients who are at risk for multiple cancers. As the number of "previvors" increases, we will need to continually innovate to develop novel approaches for multi-organ chemoprevention or coordinated screening.

B. J. Kennedy Award and Lecture for Scientific Excellence in Geriatric Oncology
Monday, June 4, 3:00 PM

Honoring the preferences of older patients with cancer and caregivers through improved communication.
Supriya Gupta Mohile, MD, MS; University of Rochester Medical Center, Rochester, NY

Geriatric oncology has undergone a transformation over the last 15 years. Following advocacy from key leaders in research such as BJ Kennedy, Lodovido Balducci, and John Bennett, ASCO partnered with the John Hartford Foundation to invest in geriatric oncology fellowship training programs that spawned 28 fellows. These fellows, working with senior mentors in the field such as Harvey Cohen, Hyman Muss, Stuart Lichtman, and Martine Extermann, developed a cohesive voice dedicated to improving care delivery for older patients with cancer. To translate this voice and passion into action, geriatric oncology investigators, spearheaded by Arti Hurria, formed the Cancer and Aging Research Group. Three investigators (Hurria, Dale, and Mohile) organized 3 conferences through a U13 partnership with the NIH to develop the research priorities in aging and cancer. By partnering with ASCO, the Society of International Geriatric Oncology, the Alliance, and the NCI Community Oncology Research Program, geriatric oncology investigators are now taking action to improve policy, foster educational efforts in geriatric oncology, and conduct high quality, high impact research. Better care for older adults with cancer requires geriatric assessment and management; a new ASCO guideline highlights the high quality evidence developed by geriatric oncology investigators from around the world, which demonstrates that geriatric assessment measures can identify older patients at highest risk for adverse outcomes. Geriatric oncology research will now need to undergo another transformational shift and should focus on how best to improve communication around decisions for treatment for "real world" older patients. Geriatric assessment can enhance communication about risks and benefits and thus allow us as clinicians to elicit, respect, and honor what older patients with cancer and caregivers want and need. The transformational shift in geriatric oncology research will require strong partnerships with stakeholders, including older patients and caregivers, and will be enhanced by innovative research methods such as mixed methods, social network analyses, and machine learning.

Pediatric Oncology Award and Lecture
Monday, June 4, 1:15 PM

Facilitating precision oncology for children: Implementing new legislative provisions for the therapeutic orphans.
Gregory H. Reaman, MD, FASCO; U.S. Food and Drug Administration, Silver Spring, MD

Although the cure rates for childhood cancer have improved dramatically over the past several decades resulting in extended disease-free survival for >80% of those afflicted, cancer remains the leading cause of death from disease in children. This is a direct result of suboptimal treatment results for some specific cancers particularly when metastatic at diagnosis and when recurrent due to resistance to therapy. The dismal outcomes for some rare

pediatric cancers have not improved. In addition, the short and long term toxicities related to current therapies negatively impact quality of life and survivorship. The unmet clinical need for new drugs for children with cancer and cannot be overstated.

Molecularly targeted drugs developed for cancers which occur predominantly in adults have advanced the concept of precision medicine in oncology, which is transforming cancer care for adults. Similar treatment advances are yet to be realized in children. Although large scale efforts at genomic interrogation of various pediatric cancers have provided evidence that the genetic and epigenetic repertoire of driver gene aberrations differ between the cancers of adults compared to those which predominate in children, recent evidence reveals that many of the same genetic and other molecular biological vulnerabilities evident in many adult cancers may present opportunities for the use of certain targeted agents in up to 50% of children with tumors which are histologically and biologically different. Pediatric cancer drug development has historically leveraged adult drug discovery and development. Laws envisioned to assure equitable access to new therapies for both children and adults by requiring or incentivizing sponsors to conduct studies to evaluate efficacy and safety in children have greatly improved therapeutic options in many clinical areas except cancer. Recent amendments to Section 505B of the Food, Drug, and Cosmetic Act promise to change the landscape of pediatric cancer drug development. Responsible implementation of these new provisions to expedite evaluation of novel agents promises a change for children as therapeutic orphans.

Gianni Bonadonna Breast Cancer Award and Lecture
Monday, June 4, 4:45 PM

Mentoring, empowering, opening doors.

Gabriel N. Hortobagyi, MD, MACP, FASCO; The University of Texas MD Anderson Cancer Center, Houston, TX

Gianni Bonadonna was an outstanding oncologist, clinical investigator, academic leader, educator, role model, writer, philosopher and most importantly, a dear friend. Our 40-year friendship started in 1975 and continued through collaborations in clinical research, publishing, international speaking, mentoring and sharing the finer aspects of life. At the top of his career, a sudden illness transformed his life; he then became an example to all of us about how to overcome adversity with dignity, persistence and grace. His continued productivity during the last decade of life is a testimony to his willpower, creativity, intelligence and dedication to oncology and medicine.

My own career focused on clinical and translational research in breast cancer and the training and mentoring of a number of young oncologists from around the world. My initial focus was the development and implementation of neoadjuvant chemotherapy, first, in the management of locally advanced and inflammatory breast cancer, later, in the curative therapy of earlier stages of operable breast cancer. I was fortunate to work with outstanding colleagues in surgical, radiation and medical oncology, as well as imagers and pathologists at one of the premier cancer centers in the world. Our multidisciplinary approach to the management of malignant disease was the cornerstone of our practice since the early 1970s. Since then, it has been adopted by many other institutions around the world as a superior method to manage all solid tumors. Other major research interests resulted in the development and implementation of clinical trials that demonstrated the role of multiple new drugs (anthracyclines, taxanes, bisphosphonates, everolimus and ribociclib) in the management of advanced and early breast cancer, the development of gene expression profiling for prognostication, classification and prediction of benefit from treatment, and the initial steps in gene therapy for solid tumors. However, the most satisfying aspect of my career has been the opportunity to interact with, mentor and empower my younger colleagues (residents, fellows, junior faculty) and open doors for successful career development. Many of them occupy today leadership positions in oncology all around the world. They will carry the torch and will train the next generation of oncologists to move the field forward.

Allen S. Lichter Visionary Leader Award and Lecture
Saturday, June 2, 3:00 PM

Serendipity and purpose.

Nancy E. Davidson, MD, FASCO; Fred Hutchinson Cancer Research Center, Seattle, WA

Reducing the burden of cancer is a daunting task and requires vision, collaboration, and hard work from all. During my career as a physician-scientist working in the biology and treatment of breast cancer and inspired by our patients, I worked in the nascent fields of apoptosis and epigenetics of breast cancer, moving lab discoveries from bench to bedside. Our teams at Johns Hopkins, University of Pittsburgh, and Fred Hutchinson Cancer Research Center/Seattle Cancer Care Alliance enabled this work. The imperative to work nationally and internationally led us to found the Translational Breast Cancer Research Consortium and initiate the AURORA project in metastatic breast cancer to accelerate our goals to bring scientific discovery to patient care. My service as director of an NCI Cancer Center and advisor to many others crystallized the need for and importance of collaborative and visionary

leadership. The unusual honor of serving as president of both the American Society of Clinical Oncology and the American Association for Cancer Research provided an extraordinary platform to champion the vital roles of the entire community of cancer practitioners, researchers, and advocates to catalyze progress and change.

LBA1 **Plenary Session, Sun, 1:00 PM-4:00 PM**

TAILORx: Phase III trial of chemoendocrine therapy versus endocrine therapy alone in hormone receptor-positive, HER2-negative, node-negative breast cancer and an intermediate prognosis 21-gene recurrence score. *First Author: Joseph A. Sparano, Montefiore Medical Center, Bronx, NY*

The full, final text of this abstract will be available at abstracts.asco.org at 7:30 a.m. ET on Sunday, June 3, 2018, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2018, issue of the *Journal of Clinical Oncology*. On-site at the Meeting, this abstract will be printed in the Sunday edition of *ASCO Daily News*.

LBA2 **Plenary Session, Sun, 1:00 PM-4:00 PM**

Maintenance low-dose chemotherapy in patients with high-risk (HR) rhabdomyosarcoma (RMS): A report from the European Paediatric Soft Tissue Sarcoma Study Group (EpSSG). *First Author: Gianni Bisogno, Department of Women and Children Health, University Hospital of Padova, Padova, Italy*

The full, final text of this abstract will be available at abstracts.asco.org at 7:30 a.m. ET on Sunday, June 3, 2018, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2018, issue of the *Journal of Clinical Oncology*. On-site at the Meeting, this abstract will be printed in the Sunday edition of *ASCO Daily News*.

LBA3 **Plenary Session, Sun, 1:00 PM-4:00 PM**

CARMENA: Cytoreductive nephrectomy followed by sunitinib versus sunitinib alone in metastatic renal cell carcinoma—Results of a phase III noninferiority trial. *First Author: Arnaud Mejean, Department of Urology, Hôpital Européen Georges-Pompidou - Paris Descartes University, Paris, France*

The full, final text of this abstract will be available at abstracts.asco.org at 7:30 a.m. ET on Sunday, June 3, 2018, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2018, issue of the *Journal of Clinical Oncology*. On-site at the Meeting, this abstract will be printed in the Sunday edition of *ASCO Daily News*.

100 Clinical Science Symposium, Sat, 8:00 AM-9:30 AM

Ado-trastuzumab emtansine (T-DM1) in patients (pts) with HER2 amplified (amp) tumors excluding breast and gastric/gastro-esophageal junction (GEJ) adenocarcinomas: Results from the National Cancer Institute (NCI) Molecular Analysis for Therapy Choice (MATCH) trial. *First Author: Komal L. Jhaveri, New York University Cancer Institute, New York, NY*

Background: The NCI-MATCH is the largest national signal-finding trial incorporating centralized genomic testing to direct pts to molecularly targeted phase 2 treatment arms. HER2 gene amp is observed in many different tumor types. **Methods:** HER2 amp was defined as copy number (CN) ≥7 based on tumor sequencing on an adapted Oncomine AmpliSeq™ panel under FDA investigational device exemption. Pts with prior trastuzumab, pertuzumab or T-DM1 treatment were excluded. Pts received T-DM1 at 3.6 mg/kg IV Q3 weeks until toxicity or disease progression. Tumor assessments occurred Q3 cycles for 33 cycles and Q4 cycles thereafter. Primary endpoint was objective response. Correlative studies included correlating HER2 CN, HER2 protein levels by IHC, HER2:CEP17 ratio (by FISH), PTEN loss, MYC amplification and PIK3CA mutation status with response. **Results:** 37 eligible pts were treated between 11/15-3/17. Median age was 65 (range 39-80). 33% had received > 3 lines of prior therapy. Median HER2 CN was 17 (7-139). Various histologies were treated: colon carcinoma (ca) (n = 7), ovarian ca (n = 6), rare tumors such as cholangioca (n = 1), carcinosarcoma of the uterus (n = 1), salivary gland ca (n = 3), among others. 3/37 (8.1%, 90% CI 2.2%-19.6%) had a confirmed partial response including 1 patient each with salivary duct ca of parotid gland, squamous cell ca of parotid gland and extramammary Paget's disease of the scrotum. Additionally, 43% had stable disease (SD) including 3/3 evaluable ovarian and uterine ca respectively. Median duration of SD was 4.6 months. The 6-month PFS rate was 24.8% (90% CI 15.0%-41.1%). Common toxicities included fatigue, anemia, fever and thrombocytopenia with no new safety signals. Median treatment duration was 4 cycles (range 1- 23). Data from correlative analysis will be presented at the meeting. **Conclusions:** T-DM1 was well tolerated. Clinical activity was observed in HER2 amp non breast and gastric/GEJ adenoca pts warranting further study either alone or in combinations particularly in some histologies such as salivary gland tumors. Clinical trial information: NCT02465060.

101 Clinical Science Symposium, Sat, 8:00 AM-9:30 AM

Results from molecular analysis for therapy choice (MATCH) arm I: Taselisib for PIK3CA-mutated tumors. *First Author: Ian E. Krop, Dana-Farber Cancer Institute, Boston, MA*

Background: MATCH is a trial that assigns patients (pts) with solid tumors, lymphomas, or multiple myeloma to specific targeted therapies based on genetic alterations identified in fresh tumor biopsies. Arm I evaluated the PI3-kinase inhibitor taselisib in pts with activating mutations in PIK3CA, the catalytic subunit of PI3-kinase. **Methods:** Pts with KRAS mutations or PTEN mutation or loss were excluded, as were pts with breast or squamous lung cancer. Pts received taselisib 4 mg po daily on 28 d cycles until progression or intolerable toxicity. Staging was every 2 cycles. The primary endpoint was objective response (OR); secondary endpoints were PFS, 6-month PFS, and predictive biomarkers. **Results:** 65 pts (enrolled 3/2016-4/2017) received ≥1 dose of study therapy; 45 tumor types were represented; 38% of pts had > 3 prior lines of therapy. There were no ORs, but prolonged stable disease was observed (estimated PFS6 rate 27%, 90% CI 19%-39%), and 2 pts remain on study > 1 yr. The most common toxicities were fatigue (38%), diarrhea (38%) and nausea (34%), all predominately grade 1-2, with 2% of pts requiring dose reductions, and 11% discontinuing taselisib because of toxicity. No hyperglycemia or rash were observed. PIK3CA mutations occurred in the helical domain (HD, 69%), kinase domain (KD, 17%), or other domains (14%). There was an observed trend (non-significant) toward longer PFS in tumors with KD mutations compared to HD or other mutations (median PFS 4.6 mo vs 3.5 mo vs 1.8 mo, respectively). Co-occurring mutations were detected in 67% of tumors. In exploratory analyses, TP53/MDM2 alterations (n = 24) were associated with PFS < 6 mo, and enrichment for PFS ≥ 6 mo was observed in pancreatic-biliary tumors/cholangiocarcinoma (3/6) and adenoid cystic carcinoma (3/4). Only 1 of 9 pts with BRAF, NRAS, HRAS, MAP2K1, MAPK1, or NF1 mutations achieved PFS ≥ 6 mo. **Conclusions:** In a mixed histology cohort selected for activating PIK3CA mutations, taselisib did not achieve any ORs, although 27% of pts had PFS ≥ 6 mo. PIK3CA mutation independent of histology is an insufficient predictor of taselisib activity. Associations of individual histologies and PIK3CA mutation subtypes with PFS may be worthy of further study. Clinical trial information: NCT02465060.

102 Clinical Science Symposium, Sat, 8:00 AM-9:30 AM

A phase 1 study of LOXO-292, a potent and highly selective RET inhibitor, in patients with *RET*-altered cancers. *First Author: Alexander E. Drilon, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Multikinase inhibitors (MKIs) have limited activity in *RET* fusion-positive (+) and *RET*-mutant cancers, questioning the therapeutic potential of these targets. LOXO-292 selectively targets RET and has preclinical activity against activating *RET* fusions/mutations, potential resistance mutations, and brain metastases. **Methods:** This global phase 1 study for patients (pts) w/ advanced solid tumors included *RET* fusion+ NSCLC and papillary thyroid cancer (PTC), *RET*-mutant medullary thyroid cancer (MTC), and any other cancer w/ these alterations. Pts were dosed orally in 28-day cycles. Dose escalation followed a 3+3 design. The primary endpoint was MTD determination. Secondary endpoints included safety, overall response rate (ORR, RECIST 1.1) and duration of response (DoR). **Results:** As of 05-Jan-18, 57 pts were treated at 7 doses (20 mg QD→160 mg BID), including 35 *RET* fusion+ tumors (27 NSCLC, 7 PTC, 1 pancreatic) and 20 *RET*-mutant MTCs. 67% were MKI pre-treated (median 1, range 1-4; included pts w/ acquired MKI resistance). No DLTs were observed. The MTD was not reached. AEs (≥10% of pts) were fatigue (16%), diarrhea (16%) and dyspnea (12%); most were grade 1-2. No AEs ≥ grade 3 were attributed to LOXO-292. The ORR in evaluable *RET* fusion+ pts was 69% (95% CI 50%-84%, n = 22/32, 11 pending confirmation, 9/13 MKI-naïve,13/19 MKI pretreated): 65% (n = 17/26) in NSCLC and 83% (n = 5/6) in PTC. 84% (27/32) had radiographic tumor reduction (range -19% to -67%). NSCLC responses occurred independent of upstream partner when known (9/13 *KIF5B* vs 7/9 non-*KIF5B*) and included 3 pts w/ baseline brain metastases. Tumor reduction was achieved in 79% of MTC pts (n = 11/14 evaluable, range -9% to -45%), including 2 PRs, 1 in a patient w/ a hereditary *RET* V804M gatekeeper mutation treated w/ 3 prior MKIs. 79% (n = 11/14) of MTCs had a ≥50% decrease in serum calcitonin (for ≥4 weeks). Most pts (n = 52/57) remained on treatment. The median DoR was not reached (all responses ongoing, longest > 6 months). **Conclusions:** LOXO-292 was well-tolerated and had marked antitumor activity in pts w/ *RET*-altered cancers, including those w/ resistance to prior MKIs and brain metastases. Rapid development w/ registrational intent is planned. Clinical trial information: NCT03157128.

103 Clinical Science Symposium, Sat, 8:00 AM-9:30 AM

Impact of next-generation sequencing (NGS) on treatment selection in acute myeloid leukemia (AML). *First Author: Rita Elias Assi, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Until recently, therapy options for AML patients (pts) were limited. The advent of NGS and novel targeted agents raise the question of how broader use of testing will impact treatment and outcomes. **Methods:** From October 2012 to June 2016, we included 1470 AML pts with available NGS-based detection of somatic mutations. 17 genes (*ALK, CSF1R, FGFR1/2/3, FLT3, IDH1/2, JAK2, KDR, KRAS/NRAS, NPM1, PDGFRA, PTPN11, RET and TP53)* were considered potentially actionable due to the possibility to be directly or indirectly targeted with standard or investigational agents. **Results:** of the 1271 treated pts, 982 (77%) had a median of 2 actionable mutations (AMs) (1-5): *TP53* (n = 241; 16%), *IDH2* (n = 240; 16%), *IDH1* (n = 238; 16%), *FLT3* (200; 14%), *NPM1* (n = 195; 13%), *NRAS* (n = 175; 12%), *JAK2* (103; 7%), *KRAS* (n = 82; 6%). 41% (271/518) of pts started new therapy after NGS results availability. NGS guided targeted therapy in 36% of pts: 53% of these enrolled on clinical trials (CT) and 6% received off-label agents. Considering AMs only, relapsed/refractory (R/R) pts were more likely to receive targeted therapy than newly diagnosed (51% vs 23%, p < 0.0001). At different timepoints, the probability of receiving targeted agent for pts with AMs was 9% (13/140) for the period 2012-Sept 2013, 21% (143/685) for Oct 2013-2014 and 23% (147/645) in 2015-June 2016 (p = 0.001). Pts who received targeted therapy had higher response rate compared to those who did not whether newly diagnosed (72% vs 60%;p = 0.04) or R/R (31% vs 21%; p = 0.001). **Conclusions:** NGS can impact therapy decision in more than 30% of AML pts when performed in a timely manner. R/R pts were more likely to receive targeted agents than newly diagnosed. Possible reasons are delays in NGS results, urgency to start therapy and presumption that standard therapy may be better than investigational targeted agents. The results of current CT may change the way we treat AML pts.

Treated pts		**1271/1470 (86%)**	
Median age		63 yrs (17-92)	
Male		782 (62%)	
Median time to inform results		9 days (3-90)	
		Newly diagnosed (N = 519)	**R/R (N = 463)**
Actionable mutation(s)		390 (75%)	338 (73%)
Subsequent targeted therapy	p < 0.0001	91/390 (23%)	173/338 (51%)
On CT		75 (19%)	149 (44%)
Off-label		16 (4%)	24 (7%)
Alive at last follow-up		55%	76%

104 Clinical Science Symposium, Sun, 9:45 AM-11:15 AM

Randomized phase II neoadjuvant study (GeparNuevo) to investigate the addition of durvalumab to a taxane-anthracycline containing chemotherapy in triple negative breast cancer (TNBC). *First Author: Sibylle Loibl, German Breast Group (GBG), Neu-Isenburg, Germany*

Background: Combining immune-checkpoint inhibitors with chemotherapy yielded high response rates in patients (pts) with metastatic TNBC. Therefore, we evaluated the addition of durvalumab, an anti-PD-L1 checkpoint inhibitor, to standard neoadjuvant chemotherapy in pts with primary TNBC. **Methods:** GeparNuevo randomized pts to durvalumab (D) 1.5 g i.v. or placebo every 4 weeks (wks). D/placebo monotherapy (0.75 g i.v.) was given for the first 2 wks (window phase), followed by a biopsy and D/placebo plus nab-paclitaxel (nP) 125 mg/m^2 weekly for 12 wks, followed by D/placebo plus epirubicin/cyclophosphamide (EC) q2 wks for 4 cycles. Randomization was stratified by stromal tumor infiltrating lymphocyte (sTILs) (low (≤10%), intermediate (11-59%), high (≥60%)). Pts with primary cT1b-cT4a-d disease, centrally confirmed TNBC and sTILs status were included. Primary objective compares pCR (ypT0 ypN0) rates. Secondary objectives are pCR rates in stratified subpopulations and according to other pCR definitions; response rates; breast conservation rate; toxicity; compliance and survival. Sample size was planned assuming a pCR rate of 48% for placebo based on the GeparSepto results and 66% for D (as clinically meaningful benefit), requiring 158 pts to show superiority of D (2-sided α=0.2, 80% power). Assuming a 10% drop-out rate, randomization of 174 pts was planned. **Results:** A total of 174 pts were enrolled between June 2016 and September 2017 and all pts had completed treatment. Median age was 49.5 years [range 23.0-76.0]; 44.5% of pts had cT1, 49.7% cT2, 3.5% cT3, 2.3% cT4; 83.3% G3 and 31.4% cN-positive tumors assessed by sonography; sTILs categories were 37.9% low, 47.7% intermediate, and 14.4% high; median Ki67 was 49.0% [range 3.0%-96.0%]. A total of 86 SAEs and 65 immune related AEs of special interest (irAESI) were reported; 34.5% of pts had at least one SAE and 27.6% had at least one irAESI. Overall, 84 of 174 pts (48.3% 95%CI [40.7-56.0]) had a pCR. **Conclusions:** Combination of chemotherapy with durvalumab/placebo yielded a high pCR rate in TNBC. Treatment was feasible. Unblinded results will be presented at the meeting. Funding and drug was provided by AstraZeneca and Celgene. Clinical trial information: NCT02685059.

105 Clinical Science Symposium, Sun, 9:45 AM-11:15 AM

Phase 3 study of carboplatin-paclitaxel/nab-paclitaxel (Chemo) with or without pembrolizumab (Pembro) for patients (Pts) with metastatic squamous (Sq) non-small cell lung cancer (NSCLC). *First Author: Luis G. Paz-Ares, University Hospital 12 de October, Madrid, Spain*

Background: Pembro plus pemetrexed and carboplatin resulted in superior objective response rate (ORR), progression-free survival (PFS) and overall survival (OS) for untreated pts with non-sq NSCLC. Pembro is active in sq NSCLC, so combining with chemo is a rational next step. **Methods:** KEYNOTE-407 (NCT02775435) is a randomized, placebo-controlled, global study of 560 untreated pts with metastatic sq NSCLC with ECOG 0-1. Pts were stratified by type of taxane, PD-L1 (TPS <1% vs ≥1%), and site (East Asia vs other). Investigators chose taxane. Pts were randomized 1:1 to receive carboplatin 6 mg/mL/min and paclitaxel 200 mg/m^2 every 3 weeks or nab-paclitaxel 100 mg/m^2 weekly plus pembro or saline placebo for 4 cycles followed by pembro/placebo for a total of 35 treatments. Imaging is sent for blinded independent central review (BICR) per RECIST 1.1. The primary endpoints are PFS by BICR and OS in the intent-to-treat population. Alpha is strictly controlled at 0.025 one-sided; PFS and OS each have 0.01. A key secondary endpoint is ORR by BICR in about the first 200 pts randomized with 0.005 alpha. A second interim analysis will be performed on PFS and OS when approximately 332 PFS events will have occurred. The hazard ratio (target 0.7) will be estimated using a stratified Cox regression model. The arms will be compared with a stratified log-rank test. Enrollment completed at the end of 2017. **Results:** In the first interim analysis, the initial 204 pts were randomized 101 to pembro + chemo and 103 to chemo with median follow-up of 7.7 m (range 0.4, 13.9). Pts were 78% male, 48% < 65 y, and 28% ECOG PS 0. PD-L1 status was 35% TPS<1%. 32% used nab-paclitaxel. Per BICR pembro + chemo had an ORR of 58.4% compared to 35.0%, p-value 0.0004. Duration of response ≥6m was 65.8% for pembro + chemo and 45.6% for chemo by Kaplan-Meier estimates. Incidence grade ≥3 AEs was 64.4% for pembro + chemo and 74.5% for chemo. No new safety concerns were observed. **Conclusions:** Adding pembro almost doubled the ORR of chemo for pts with untreated metastatic sq NSCLC. Pembro + chemo has a tolerable safety profile. Results from a second interim analysis may be available prior to the meeting. Clinical trial information: NCT02775435.

106 Clinical Science Symposium, Sun, 9:45 AM-11:15 AM

TOPACIO/Keynote-162 (NCT02657889): A phase 1/2 study of niraparib + pembrolizumab in patients (pts) with advanced triple-negative breast cancer or recurrent ovarian cancer (ROC)—Results from ROC cohort. *First Author: Panagiotis A. Konstantinopoulos, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA*

Background: Platinum-resistant OC (PROC) has few treatment options. Niraparib is an oral PARP inhibitor (PARPi) approved for maintenance treatment of ROC. Anti–programmed death (PD)–1 monotherapies (eg, pembrolizumab) have shown low level activity in ROC, and beyond *BRCA*-mut, PARPi have shown minimal activity in PROC. Preclinical data demonstrate synergy with PARPi + anti-PD-1 combinations. **Methods:** Eligible pts must have experienced a response lasting ≥6 months to first-line platinum therapy and were considered to have PROC per investigator's assessment (eg, pts not eligible for further platinum) and no more than 5 prior treatment lines. While primary platinum-refractory (PRef) disease was excluded, secondary PRef disease was not. A phase 1 study previously established RP2D of niraparib 200 mg orally once daily + pembrolizumab 200 mg IV every 21 days. Primary and secondary endpoints included objective response rate (ORR = CR+PR) and disease control rate (DCR = CR+PR+SD). Genetic biomarkers were assessed by Stand Up To Cancer (SU2C) Ovarian Cancer Dream Team. **Results:** As of Jan 2018, 60/62 pts were evaluable for response assessment (≥1 on-study scan). Median age was 60 years. Median prior lines of chemotherapy was 2 (range: 1-5). Based upon platinum-free interval (PFI) to last platinum treatment, 64% of pts had PROC (PFI < 6 months), 19% had PRef disease (PFI < 30 days), and 17% had platinum-sensitive (PSens; PFI ≥6 months) disease. Twenty pts remain on treatment and 11 have received treatment for ≥6 months. Among the 60 evaluable pts, ORR/DCR were 25%/68%; among the 11 tumor *BRCA* (t*BRCA*) mut evaluable pts, ORR/DCR were 45%/73%. Responses were observed in 11/38 PROC pts, 2/11 PRef pts, and 1/10 PSens pts (platinum status unknown in 1 responder). Durability of response data will be presented. Follow-up is ongoing. The most common grade ≥3 TEAEs were anemia (19%) and thrombocytopenia (9%). **Conclusions:** With ORR of 25% in all PROC and ORR of 45% in t*BRCA*mut pts, niraparib + pembrolizumab appears promising. Additional evaluation of this combination in ROC is warranted. No new safety signals were identified with the combination. Clinical trial information: NCT02657889.

108 Clinical Science Symposium, Sun, 9:45 AM-11:15 AM

Epacadostat (E) plus pembrolizumab (P) versus pembrolizumab alone in patients (pts) with unresectable or metastatic melanoma: Results of the phase 3 ECHO-301/KEYNOTE-252 study. *First Author: Georgina V. Long, Department of Medical Oncology and Translational Research, Melanoma Institute Australia, The University of Sydney, Mater Hospital and Royal North Shore Hospital, Sydney, Australia*

Background: In a phase 1/2 study, the combination of E, a selective oral inhibitor of the IDO1 enzyme, plus P, a PD-1 inhibitor, suggested promising antitumor activity with minimal additive toxicity. ECHO-301/KEYNOTE-252 (NCT02752074) is a phase 3, randomized, double-blind study evaluating the efficacy and safety of E + P vs placebo + P in pts with untreated unresectable or metastatic melanoma. **Methods:** Pts had histologically confirmed unresectable stage III or IV melanoma and were treatment naive for advanced or metastatic disease, except for pts with the *BRAF* V600 mutation who could have received prior BRAF/MEK therapy. Pts were stratified by PD-L1 expression and *BRAF* mutation status (*BRAF* mutant with prior BRAF-directed therapy, *BRAF* mutant without prior BRAF-directed therapy, and *BRAF* wild type) and randomized 1:1 to E 100 mg BID + P 200 mg Q3W or matched E placebo + P 200 mg Q3W. Response was assessed per RECIST v1.1 and irRECIST (both by central review). The primary endpoints were PFS per RECIST v1.1 and OS. Secondary endpoints were ORR per RECIST v1.1, duration of response, and safety. This is the final analysis for PFS and interim analysis for OS. **Results:** A total of 706 pts were randomized (354 to E + P and 352 to placebo + P); 72.5% of tumors were PD-L1 positive, 44.5% *BRAF* mutant (12.2% received prior BRAF/MEK therapy). Median follow-up was ~14 mo. E + P did not result in a significantly longer PFS vs placebo + P (median 4.7 vs 4.9 mo; HR=1.00; CI, 0.83-1.21; P=0.517). PFS rate at 12 mo was 37% in both groups. Findings were consistent across PD-L1 and *BRAF* subgroups. OS was not expected to reach statistical significance based on the results of this interim analysis (HR=1.13; CI, 0.86-1.49; P=0.807). The OS rate at 12 mo was 74% in both groups. ORR was 34.2% and 31.5% in the E + P and placebo + P groups, respectively. Grade ≥3 treatment-related AEs occurred in 21.8% of patients receiving E + P and 17.0% receiving placebo + P. **Conclusions:** The addition of E to P did not result in greater clinical benefit over P alone in pts with unresectable or metastatic melanoma. The safety profile was consistent with that observed in previously reported studies of this combination. Clinical trial information: NCT02752074.

109 Clinical Science Symposium, Mon, 9:45 AM-11:15 AM

A comparative clinical study of PF-06439535, a candidate bevacizumab biosimilar, and reference bevacizumab, in patients with advanced non-squamous non-small cell lung cancer. *First Author: Mark A. Socinski, Florida Hospital Cancer Institute, Orlando, FL*

Background: This ongoing, double-blind, randomized, global clinical trial (NCT02364999) evaluated the efficacy, safety, and immunogenicity of PF-06439535 vs. reference bevacizumab sourced from the EU (bevacizumab-EU), in combination with paclitaxel (P) and carboplatin (C), as first-line therapy in patients with advanced non-squamous non-small cell lung cancer (NSCLC). **Methods:** Eligible pts were randomized 1:1 to PF-06439535 or bevacizumab-EU plus P/C on Day 1 of every 3-week (wk) cycle followed by PF-06439535 or bevacizumab-EU blinded monotherapy until disease progression or unacceptable toxicity. The primary objective was to compare objective response rate (ORR) by Wk 19 between treatment arms. Secondary objectives included safety, 1 year (yr) PFS, 1 yr survival rate and immunogenicity. **Results:** 719 pts were randomized: PF-06439535 (n = 358) and bevacizumab-EU (n = 361). The majority of patients were male (65%) with a median age of 61y and newly diagnosed Stage IV NSCLC (76%). For the primary endpoint, relative risk of ORR was 1.015. The 90% confidence interval (CI), 0.886-1.163, was contained within the FDA pre-specified therapeutic equivalence margin of 0.73–1.37. Secondary endpoints further support similarity between the 2 treatment arms (Table). Incidence of treatment-emergent adverse events (AEs) (all-causality) was similar (PF-06439535: 96.6%) and (bevacizumab-EU: 96.1%). AE results indicate no clinically meaningful differences between the two arms for arterial thromboembolic event (TE)/venous TE events, bleeding events, hypertension, GI perforation, and proteinuria. **Conclusions:** In patients with advanced non-squamous NSCLC, PF-06439535 and bevacizumab-EU showed similar ORR (primary endpoint) PFS, OS, safety and immunogenicity. Clinical trial information: NCT02364999.

Efficacy endpoints.

	PF-06439535	Bevacizumab-EU
ORR	45.3% (95%: 40.01%, 50.57%)	44.6% (95%: 39.40%, 49.89%)
1 yr PFS rate	29.4% (95% CI: 23.2%, 35.9%)	29.3% (95% CI: 23.5%, 35.3%)
1 yr survival rate	65.2% (95% CI: 59.0%, 70.7%)	66.4% (95% CI: 59.9%, 72.0%)

110 Clinical Science Symposium, Mon, 9:45 AM-11:15 AM

Biosimilar trastuzumab-dkst monotherapy versus trastuzumab monotherapy after combination therapy: Toxicity, efficacy, and immunogenicity from the phase 3 Heritage trial. *First Author: Aleksei Manikhas, City Clinical Oncology Dispensary, St. Petersburg, Russian Federation*

Background: The Heritage trial is a multicenter, double-blind, randomized, parallel-group, phase 3 study (NCT02472964) evaluating efficacy and safety of trastuzumab-dkst (Ogivri), a trastuzumab biosimilar, vs trastuzumab, in combination with taxane as first-line therapy for patients with HER2+ metastatic breast cancer. The primary endpoint, overall response rate on combination therapy at week 24, was previously reported (Rugo et al, *JAMA* 2017). **Methods:** Eligible patients were randomized 1:1 to trastuzumab-dkst or trastuzumab, combined with taxane. After 24 weeks, patients with responding or stable disease received monotherapy as per randomization. Here, we describe secondary endpoints of safety and immunogenicity during monotherapy and cumulative through 48 weeks; progression-free survival (PFS) and event-based overall survival (OS) will be presented in the future. **Results:** 500 patients were randomized, 342 continued treatment after 24 weeks, and 214 continued through 48 weeks. Treatment-emergent adverse event (TEAE) rates during monotherapy were similar (trastuzumab-dkst, 54.7%; trastuzumab, 60.1%); most were low grade. Grade ≥3 TEAEs were more frequent with trastuzumab (11.7%) vs trastuzumab-dkst (6.7%); serious TEAE rates were similar (trastuzumab-dkst, 2.8%; trastuzumab, 2.5%). When assessed over 48 weeks of combination and monotherapy, cumulative rates of TEAEs of special interest were similar for pulmonary events, significant cardiac disorders, and infusion-related events (trastuzumab-dkst, 13.0%, 4.9%, and 9.3%; trastuzumab, 12.2%, 4.1%, and 8.1%, respectively). Immunogenicity and incidence of left ventricular ejection fraction < 50% ≥1 time postbaseline and ≥10% reduction at week 48 were similar between groups (trastuzumab-dkst, 3.9% and 3.6%; trastuzumab, 4.4% and 2.8%, respectively). No new safety signals were detected. At week 48, median PFS was 11.1 months in both groups and OS curves were similar. **Conclusions:** Maintenance monotherapy with FDA-approved trastuzumab-dkst after combination with taxane was well tolerated, with safety and efficacy profiles similar to originator trastuzumab. Clinical trial information: NCT02472964.

111 Clinical Science Symposium, Mon, 9:45 AM-11:15 AM

Comparison of efficacy and safety of biosimilar filgrastim in a RCT (PIONEER) and real-world practice (MONITOR-GCSF). *First Author: Nadia Harbeck, Brustzentrum der Universität München (LMU), Munich, Germany*

Background: Sandoz biosimilar filgrastim has been approved in the US since 2015 for several indications including prevention of chemotherapy-induced neutropenia. US approval was based on results from PIONEER, a phase III confirmatory trial in breast cancer (BC) patients receiving chemotherapy randomized to either Sandoz biosimilar or reference filgrastim (Blackwell et al. Ann Oncol 2015;26:1948-53). BC is considered a sensitive indication to demonstrate filgrastim biosimilarity. Post-approval, safety of Sandoz biosimilar filgrastim has been monitored in MONITOR-GSCF, an observational study in patients with solid or hematological malignancies undergoing chemotherapy (Gascon et al. Support Care Cancer 2016;24:911-25). The results from PIONEER were compared to the MONITOR-GCSF BC cohort to evaluate Sandoz biosimilar filgrastim in a RCT and a real-world practice setting in BC. **Methods:** Results were compared for corresponding endpoints. Patient- and cycle-level comparisons were made between patients in PIONEER, and all BC patients receiving biosimilar filgrastim in MONITOR-GCSF. **Results:** There were 217 evaluable patients in PIONEER and 466 in MONITOR-GCSF. Patients were generally younger in PIONEER (mean age, years ± SD: 48.9 ± 11.3 vs 56.2 ± 11.7). Patient level results are reported. Febrile neutropenia (FN) was reported in 5.1% (PIONEER) vs 6.2% (MONITOR-GCSF). All grade adverse events (AEs) were generally reported at a higher level in PIONEER than MONITOR-GCSF, including musculoskeletal/connective tissue disorders (PIONEER: 261, MONITOR-GCSF: 20 [absolute numbers]); infections/infestations (PIONEER: 31, MONITOR-GCSF: 3); skin/subcutaneous tissue disorders (PIONEER: 258, MONITOR-GCSF: 5) and general disorders/administration site conditions (PIONEER: 673, MONITOR-GCSF: 7). Cycle level results were generally similar between studies. **Conclusions:** Sandoz biosimilar filgrastim prevented FN in a RCT and in real-world practice in BC patients receiving (neo-)adjuvant chemotherapy. In real-world practice, experiencing AEs may be perceived as unavoidable in order to achieve clinical efficacy. Thus Phase III RCTs remain an effective tool to assess and monitor AEs.

112 Clinical Science Symposium, Mon, 9:45 AM-11:15 AM

Treatment approach for non-Hodgkin lymphoma patients since first biosimilars of rituximab approved in EU5. *First Author: Alessandra Franceschetti, Ipsos Healthcare, London, United Kingdom*

Background: Non-Hodgkin Lymphoma (NHL) is the tenth most common cancer in Europe. In 2017, the first biosimilars of rituximab were approved in Europe to treat NHL. Using real world data from Ipsos' Global Oncology Monitor, this study explores prescription patterns of rituximab biosimilars in EU5 to determine if biosimilars are favoured over branded versions for certain patient types. **Methods:** An online multi-country, multi-centre medical chart review study of NHL patients; 97 physicians provided de-identified data on 640 patients treated with anti-cancer drugs in France (117), Germany (73), Italy (117), Spain (136) and UK (197) between July and September 2017. Physicians were geographically representative and screened for treatment involvement levels and number of patients managed per month. Reporting on patients seen in consultation, they provided date of diagnosis, current and historic treatment, and reasons for prescribing/discontinuing anti-cancer drug treatment. Data on patients treated with and without a rituximab biosimilar were compared using descriptive statistics. **Results:** Of the 640 NHL patients studied, 77% were treated with a regimen that included branded rituximab. Prescribing of rituximab biosimilars was highest in Germany and UK (14% and 13%, respectively). For recently-initiated patients in Germany and UK, prescription of biosimilars increased towards 2nd and 3rd lines of treatment (1L: 11%; 2L:18%; 3L:30%). A profile comparison of German and UK patients treated with a rituximab biosimilar (27) vs. branded rituximab (179) shows that the former is more likely to have: ECOG 0-1 (93% vs. 82%); no comorbidities affecting cancer drug treatment (52% vs. 31%); indolent vs. aggressive status (70% vs. 52%); and Follicular Lymphoma as sub-type of cancer (56% vs. 35%). **Conclusions:** Physicians responsible for the drug treatment of NHL patients in EU5 have begun prescribing rituximab biosimilars. This seems to be more frequent after first line treatment, in fitter patients, and for those with indolent disease and Follicular Lymphoma.

	Total EU5	France	Germany	Italy	Spain	UK
	640	**117**	**73**	**117**	**136**	**197**
Rituximab (branded version)	**70%**	68%	66%	75%	76%	66%
Rituximab (biosimilar version)	**7%**	0%	14%	3%	5%	13%

500 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Adjuvant denosumab in early breast cancer: Disease-free survival analysis of 3,425 postmenopausal patients in the ABCSG-18 trial. *First Author: Michael Gnant, Comprehensive Cancer Center, Medical University of Vienna and Austrian Breast and Colorectal Cancer Study Group, Vienna, Austria*

Background: Adjuvant aromatase inhibitors (AI) are standard of care for postmenopausal women with hormone receptor positive (HR+) early stage breast cancer but cause osteoporosis and fractures. ABCSG-18 showed previously that adjuvant denosumab significantly reduces clinical fractures (primary endpoint, HR = 0.5, $p < 0.0001$, Lancet 2015). Here, we present the impact of adjuvant denosumab on disease-free survival. Patients and **Methods:** 3,425 postmenopausal patients with early HR+ BC receiving adjuvant AI were recruited in 58 trial centers into this prospective, double-blind, placebo-controlled, phase-III trial. Patients were randomized 1:1 to receive either denosumab 60mg s.c. (N = 1712) or placebo (N = 1713) q6 months during AI therapy. We here present results of ABCSG-18's secondary endpoint disease-free survival (DFS), including relevant subgroup and sensitivity analyses (accounting for cross-over either by censoring or by using a rank preserving structural failure time model). **Results:** After a median follow-up (FU) of 72 months, 287 events occurred in the placebo group, and 240 in the denosumab group. DFS was significantly improved in the denosumab arm (HR = 0.823, 95% CI 0.69-0.98, Cox p = 0.026*). In the denosumab group, DFS was 89.2% (95% CI 87.6-90.7) at 5 years and 80.6% (78.1-83.1) at 8 years of FU, compared to 87.3%, (85.7-89.0) at 5 years and 77.5% (74.8-80.2) at 8 years for patients who received placebo. Similar results were obtained from sensitivity analyses. No case of osteonecrosis of the jaw (ONJ) was recorded so far, despite proactive adjudication of potential cases by an independent expert panel. One potential atypical femur fracture was seen in the denosumab arm. **Conclusion:** Adjuvant denosumab improves disease-free survival of HR+ postmenopausal breast cancer patients receiving AI. Based on these results and the previously reported dramatic reduction of fractures, adjuvant denosumab 60mg s.c. q6 months should be offered to postmenopausal HR+ breast cancer patients receiving AI. ** descriptive, without controlling for multiplicity.* Clinical trial information: EudraCT #: 2005-005275-15.

501 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Adjuvant denosumab in early breast cancer: First results from the international multicenter randomized phase III placebo controlled D-CARE study. *First Author: Robert E. Coleman, University of Sheffield, Weston Park Hospital, Sheffield, United Kingdom*

Background: Denosumab (Dmab) is a potent RANK ligand inhibitor approved for the management of treatment induced bone loss in early breast (EBC) and prevention of skeletal morbidity associated with metastatic bone disease. Preclinical data suggested that Dmab could prevent development of bone metastases. This trial evaluated the addition of Dmab to standard (neo) adjuvant therapy for high-risk EBC patients (pts). **Methods:** 4509 pts with EBC (93.5% node+) from 407 centers were randomized to standard loco-regional and (neo)adjuvant therapy plus either Dmab 120mg sc or matching placebo (P) monthly x 6 then 3 monthly for up to 5 years. In addition to routine clinical follow-up, pts underwent annual CT and bone scan imaging to screen for recurrence. Primary endpoint was bone metastasis free survival (BMFS) defined as first bone metastatic event confirmed by central imaging review or death from any cause. Secondary endpoints included disease free survival (DFS), DFS in the postmenopausal (PM) subgroup, overall survival (OS) and safety. **Results:** Patient groups were balanced for baseline characteristics with median age 51y, 77% ER+, 20% Her2+ and use of anthracycline and/or taxane chemotherapy in 95.9%. No benefits for the addition of Dmab were seen at a time-driven analysis performed after a median follow-up of 67 months that allowed for the full 5 years of treatment in all pts. Hazard ratio (HR) for BMFS (597 events) was 0.97, 95%CI 0.82-1.14, p = 0.70 and 1.04, 95%CI 0.91-1.19, p = 0.57 for DFS (875 events). OS (412 events) was similar in both groups (HR = 1.03, 95%CI 0.85-1.25). Dmab did not improve BMFS, DFS or OS in the PM subset (n = 2149). Exploratory analysis of time to bone metastases as first recurrence suggested benefit for Dmab (HR = 0.76, 95%CI 0.59-0.97) for this endpoint. Time to on-study fracture prior to bone recurrence was reduced with Dmab (HR = 0.76, 95%CI 0.63-0.92). 122 (5.4%) pts on Dmab and 4 (0.2%) on P developed osteonecrosis of the jaw. 9 (0.4%) pts on Dmab experienced an atypical femoral fracture. **Conclusions:** Adjuvant Dmab does not reduce breast cancer recurrences or deaths in EBC pts receiving optimal loco-regional and standard of care systemic adjuvant therapy. Clinical trial information: NCT01077154.

502 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Role of adding ovarian function suppression to tamoxifen in young women with hormone-sensitive breast cancer who remain premenopausal or resume menstruation after chemotherapy: The ASTRRA study. *First Author: Woo Chul Noh, KIRAMS, Seoul, Republic of Korea*

Background: The role of adding ovarian function suppression (OFS) to tamoxifen (T) for premenopausal patients with breast cancer after completing (neo) adjuvant chemotherapy is uncertain. The prospective randomized phase III trial was conducted to evaluate the efficacy of adding OFS to T in patients with hormone receptor-positive breast cancer who remain in premenopausal status or resume ovarian function after chemotherapy (NCT00912548). The primary and key secondary endpoints were to compare the 5-year disease-free survival and overall survival, respectively, between patients who received T and those who received T and OFS. **Methods:** We enrolled 1483 premenopausal women (aged ¡Â45 years) with estrogen receptor-positive breast cancer who were treated with definitive surgery after completing neoadjuvant or adjuvant chemotherapy. Ovarian function was assessed every 6 months for 2 years since enrollment based on follicular-stimulating hormone levels and menstruation history. If ovarian function was confirmed to be premenopausal at each visit, the patient was randomized to receive 5 years of T (T-only group) or 5 years of T plus 2 years of OFS by monthly goserelin (T + OFS group). A total of 1282 patients was randomly assigned. Disease-free survival was defined as the time from enrollment to the detection of recurrence of breast cancer, contralateral breast cancer, secondary malignancy, or death by any cause. **Results:** After a median follow-up of 63 months, the estimated disease-free survival rate at 5 years was 91.1% in the T + OFS group and 87.5% in the T-only group (hazard ratio 0.686; 95% confidence interval [CI], 0.483 to 0.972; P = 0.033). The estimated overall survival rate after 5 years was 99.4% in the T + OFS group and 97.8% in the T-only group (hazard ratio 0.310; 95% CI, 0.102 to 0.941; P = 0.029). **Conclusions:** Ovarian function needs to be monitored for at least 24 months after completing chemotherapy to establish eligibility for OFS. Adding 2 years of OFS to T significantly improved disease-free survival as compared to T alone in those who remained premenopausal or resumed ovarian function after chemotherapy. Clinical trial information: NCT00912548.

503 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Absolute improvements in freedom from distant recurrence with adjuvant endocrine therapies for premenopausal women with hormone receptor-positive (HR+) HER2-negative breast cancer (BC): Results from TEXT and SOFT. *First Author: Meredith M. Regan, Dana-Farber Cancer Institute, Boston, MA*

Background: The TEXT and SOFT trials randomly assigned premenopausal women with HR+ BC to exemestane plus ovarian function suppression (E+OFS), tamoxifen+OFS (T+OFS) and T alone. We previously examined absolute treatment effects on any BC recurrence across a continuum of recurrence risk to individualize endocrine therapy decision making. After 8.5 yrs median follow-up we now consider effects on freedom from distant recurrence. **Methods:** The TEXT and SOFT HR+/HER2- analysis population included 4891 pts and was stratified by chemotherapy use. The endpoint was distant recurrence-free interval (DRFI; time from randomization to first appearance of DR). For each pt, a previously defined continuous, composite recurrence risk index (CRI) was calculated from a Cox model incorporating age, nodal status, tumor size and grade, and ER, PgR and Ki-67 expression levels. Subpopulation Treatment Effect Pattern Plot (STEPP) methodology estimated 8yr absolute treatment effects for subpopulations defined by CRI values. **Results:** Overall 8yr DRFI was 91% (433 DRs) and ranged from ~100% to 63% across lowest CRI of 0.2 to highest CRI of 3.4. TEXT pts (n = 2267) had median [IQR] CRI of 1.7 [1.2-2.3]. Overall 8yr DRFI was 92% (194 DRs) and absolute benefit of E+OFS vs T+OFS was 3%; benefit ranged from 0% at lowest CRI (both therapies having 100% 8yr DRFI) to 15% at highest CRI. SOFT pts who remained premenopausal after chemo (n = 1271) had median CRI of 2.1 [1.5-2.7]. Overall 8yr DRFI was 82% (216 DRs) and absolute benefit of E+OFS vs T was 5%; benefit ranged from 2% to 10% across CRI. For T+OFS vs T the absolute benefit ranged 0% to 5%. The SOFT no-chemo cohort (n = 1353) had median CRI of 1.1 [0.3-1.4]. Overall 8yr DRFI was 99% (23 DRs), and across CRI exceeded 97% with all three endocrine therapies. **Conclusions:** Premenopausal pts with HR+/HER2- BC and high recurrence risk, as defined by clinicopathological characteristics, may experience 10-15% absolute improvement in 8yr DRFI with E+OFS vs T+OFS or T alone. Potential benefit of escalating endocrine therapy vs T alone is minimal for those at low risk, and may be 4-5% for pts at intermediate risk. Clinical trial information: NCT00066690, NCT00066703.

504 **Oral Abstract Session, Mon, 8:00 AM-11:00 AM**

Fifteen-year results of the randomised EORTC trial 22922/10925 investigating internal mammary and medial supraclavicular (IM-MS) lymph node irradiation in stage I-III breast cancer. *First Author: Philip Poortmans, Institut Curie, Paris, France*

Background: EORTC trial 22922-10925 investigates whether internal mammary and medial supraclavicular (IM-MS) lymph nodes (LN) irradiation improves outcome for stage I-III breast cancer patients (Clinicaltrials.gov NCT00002851). The 10 years analysis showed an improvement of 3.0% in metastases free survival (p = 0.02) and of 1.6% in overall survival (p = 0.056). Toxicity was limited and no increased lethal side effects were seen. This is the second of 3 scheduled analyses, at 15-year follow-up. **Methods:** Eligible patients had involved axillary nodes and/or a medially located primary tumour. Randomisation was to irradiate or not the IM-MS. The final trial design aimed at detecting a 4% increase in 10-year overall survival (OS) (from 75 to 79%, HR = 0.82) with 2-sided unadjusted Log-rank test at the 5% significance level. Secondary endpoints are disease-free survival (DFS), metastases-free survival (MFS) and cause of death. Two long-term analyses were planned, at respectively 15 and 20 years of follow-up. **Results:** Between 1996 and 2004, 4004 patients were randomized in 43 centres. Median age was 54 years; 59.0% were postmenopausal; 55.6% had involved axillary LN; 33.8%, 52.0% and 14.2% had stage I, II and III, respectively. Nearly all LN-positive (99.0%) and 66.3% of LN-negative patients received adjuvant systemic treatment. At a median follow-up of 15.7 years, 1117 patients died. At 15 years, overall survival was 73.2% in the nodal-irradiation group and 70.8% in the control group (HR IM-MS RT vs. control = 0.95; 95%CI, 0.84-1.06;P = 0.358).). Regional recurrences in IM-MS LN occurred in 1.8% vs. 3.1% of patients. Distant disease-free survival rate was 70.1% vs. 68.1% (HR = 0.92; 95%CI, 0.83-1.04; P = 0.178), breast-cancer mortality was 15.8% vs. 19.7% (HR = 0.81; 95%CI, 0.69-0.94; P = 0.005). Probability of breast cancer recurrence was 24.5% vs. 27.1% (HR = 0.87; 95%CI, 0.77-0.98; P = 0.024. No difference was observed in the incidence of second malignancies, contralateral breast cancer or cardiovascular deaths. **Conclusions:** The 15-years results show a significant reduction of breast cancer mortality and breast cancer recurrence by internal mammary and medial supraclavicular lymph node irradiation in stage I-III breast cancer. However, this is not converted in improved overall survival without a clear explanation for this. Subgroup analyses and continued follow-up will be performed to better define patients that may benefit from this treatment and define the causes of death. Clinical trial information: NCT00002851.

505 **Oral Abstract Session, Mon, 8:00 AM-11:00 AM**

A gene expression assay for prediction of radiotherapy benefit in breast cancer. *First Author: Laura A Knight, Almac Diagnostics, Craigavon, United Kingdom*

Background: We have previously developed and clinically validated a 44-gene DNA damage response deficiency (DDRD) assay in breast cancer for predicting response to adjuvant anthracycline based chemotherapy. The assay defines a molecular group of patients with loss of the DNA damage response FA/BRCA pathway. We investigate a further utility of the assay as a predictor of response to radiotherapy in the Molecular Taxonomy of Breast Cancer International Consortium (METABRIC) cohort. **Methods:** The DDRD assay was applied to RNA-seq data for 1904 patients from the METABRIC study. Of these patients, 1137 (59.7%) had received adjuvant radiotherapy. Chi-squared tests were applied to test the association between DDRD and clinical factors (ER, PR, HER2, Grade, and tumour stage). 396 patients that received chemotherapy were excluded, and a multivariable Cox model was performed to test the effect of radiotherapy on overall survival (OS) within DDRD positive and DDRD negative groups respectively. **Results:** 635 patients were classified as DDRD positive and 1269 as DDRD negative. A statistically significant association was observed between DDRD groups and ER ($p < 0.0001$), HER2 ($p < 0.0001$), PR ($p < 0.0001$), grade ($p < 0.0001$) and tumour stage ($p < 0.0001$). The effect of radiotherapy was evaluated in a multivariable analysis for DDRD positive and DDRD negative respectively, whereby clinical factors known to be associated to DDRD status were adjusted for. In the DDRD positive group, a significant improvement in overall survival was observed in patients treated with adjuvant radiotherapy (adjusted HR = 0.65 [0.49-0.87], p = 0.0043). In the DDRD negative group, no significant effect on survival was observed with radiotherapy treatment (adjusted HR = 0.95 [0.78-1.16], p = 0.6203). **Conclusions:** The DDRD assay detects a molecular subgroup of patients with DNA repair defects through loss of the FA/BRCA pathway. Previous studies have demonstrated that the assay is predictive in the context of DNA damaging chemotherapy, such as anthracycline. Here we show that the DDRD assay has further utility for predicting patients that are most likely to derive benefit from adjuvant radiotherapy in breast cancer.

506 **Oral Abstract Session, Mon, 8:00 AM-11:00 AM**

PERSEPHONE: 6 versus 12 months (m) of adjuvant trastuzumab in patients (pts) with HER2 positive (+) early breast cancer (EBC): Randomised phase 3 non-inferiority trial with definitive 4-year (yr) disease-free survival (DFS) results. *First Author: Helena Margaret Earl, University of Cambridge, Department of Oncology & NIHR Cambridge Biomedical Research Centre & Cambridge University Hospitals NHS Foundation Trust, Cambridge Breast Cancer Research Unit, Cambridge, United Kingdom*

Background: Adjuvant trastuzumab has significantly improved outcomes for HER2+ EBC pts, using the 12m duration empirically adopted from the pivotal registration trials. A shorter duration could reduce toxicities and cost whilst providing similar efficacy. No reduced-duration trial to date has demonstrated non-inferiority. **Methods:** PERSEPHONE is a randomised phase 3 non-inferiority trial comparing 6 to 12m trastuzumab, the largest reduced-duration non-inferiority trial internationally. Mapping onto standard UK practice, all HER2+ EBC pts were eligible. Stratification is by ER status, chemotherapy (CT) type, and CT and trastuzumab timing. The primary endpoint is DFS from diagnosis (first relapse or death from any cause). Randomising 4000 pts (1:1) enabled the trial to assess the non-inferiority of 6m (5% 1-sided significance, 85% power), defining non-inferiority as 'no worse than 3%' below the 12m arm's assumed 80% 4-yr DFS. The pre-planned definitive DFS analysis required 500 events. **Results:** 4089 pts were randomised from 152 UK sites (Oct'07 – Jul'15). ER+ 69%; CT - 41% anthracycline (A)-based / 49% A and taxane (T)-based / 10% T-based; adjuvant CT 85%; sequential trastuzumab 54%. At 4.9 yrs median follow-up, there were 319 (8%) deaths and 500 (12%) DFS events. With a 4-yr DFS rate of 89% (95%CI 88 – 91) in both arms, the hazard ratio (HR) non-inferiority limit was set at 1.29. The calculated HR was 1.05 (95%CI 0.88 – 1.25, 95th percentile = 1.22) demonstrating non-inferiority (HR < 1.29) of 6m trastuzumab (1-sided p = 0.01). Congruent results were found for overall survival (OS) and for the pre-planned DFS and OS landmark analyses (after 6m of trastuzumab). Heterogeneity was observed in some stratification variables. Cardiac events were reduced in 6m pts (4% v 8% of 12m pts stopping treatment due to cardiotoxicity ($p < 0.0001$)). **Conclusions:** PERSEPHONE has demonstrated 6m of trastuzumab as non-inferior to 12m (3% non-inferiority margin). Given cardiac and other toxicities during months 7-12 of treatment, our results would support a reduction of standard trastuzumab duration to 6 months. Clinical trial information: 52968807.

507 **Oral Abstract Session, Mon, 8:00 AM-11:00 AM**

De-escalated treatment with trastuzumab-pertuzumab-letrozole in patients with HR+/HER2+ operable breast cancer with Ki67 response after 2 weeks letrozole: Final results of the PerELISA neoadjuvant study. *First Author: Valentina Guarneri, Department of Surgery, Oncology and Gastroenterology, University of Padua, Medical Oncology 2, Instituto Oncologico Veneto IRCCS, Padova, Italy*

Background: Neoadjuvant trials with chemotherapy plus anti-HER2 agents consistently showed a lower rate of pathologic complete response (pCR) in HER2+/HR+ vs HER2+/HR-tumors. Here we report the final results of the PerELISA study, aimed to evaluate the efficacy of a de-escalated, chemotherapy-free neoadjuvant regimen in HER2+/HR+ patients (pts) selected on the basis of Ki67 response after a short course letrozole (L). **Methods:** PerELISA is a phase II, multicentric, non-profit study for postmenopausal, operable HER2+/HR+ BC pts. Eligible pts received 2 wks window therapy with L, then underwent re-biopsy for Ki67 evaluation. Pts classified as Ki67 responders (relative Ki67 reduction ≥20% from baseline) continued L and started trastuzumab (T) and pertuzumab (P) q21 days for 5 cycles. Pts without Ki67 response discontinued L and started wkly paclitaxel for 13 wks combined with P and T. Primary aim was breast and axillary pCR. At least 8 pCR in 43 Ki67 responders were required to satisfy the study hypothesis in a two-step Simon's design. Correlative analyses included: PAM50, TILs, PIK3CA. **Results:** 64 pts from 8 centers were enrolled: median age 63 yrs (49-83 yrs); stage IIA 67%, IIB 23%; IIIA 9%. Median (range) ER, PgR and ki67 expression: 90% (10-100), 14% (0-100); 30% (7-90). Median TILs level 10% (Q1 2%-Q3 15%). PIK3CA mutation was reported in 25% of the cases. 44 pts (69%) achieved a Ki67 response after 2 wks L and underwent surgery after L+T+P (breast conserving 66%; mastectomy 34%). A pCR was observed in 9 cases (20.5%). pCR rate was significantly higher in HER2-E vs other subtypes (45.5% vs 13.8%, p = 0.042). Intrinsic subtype was significantly associated with ki-67 response ($p < 0.001$).The proportion of pts with a Ki67 response in Luminal vs non Luminal subtypes was 92.6% and 44% respectively. **Conclusions:** The PerElisa study met its primary aim: a chemotherapy-free regimen for patients with Ki67 response after short term L warrants further investigation. Among Ki67 responders, the HER2-E subtype can identify pts most likely to benefit from de-escalated therapy. Clinical trial information: NCT02411344.

508 Oral Abstract Session, Mon, 8:00 AM-11:00 AM

Neoadjuvant talazoparib (TALA) for operable breast cancer patients with a BRCA mutation (BRCA+). *First Author: Jennifer Keating Litton, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: TALA has demonstrated efficacy in patients (pts) with BRCA+ metastatic breast cancer. We previously reported a window trial with median 88% tumor volume reduction after 2 months for early stage breast cancer. This study expanded to evaluate the pathologic response of TALA alone x 6 months in BRCA+ pts and operable breast cancer. **Methods:** The study was approved by the Institutional Review Board. Eligibility included ≥ 1 cm tumor and BRCA+. HER2+ tumors were excluded. Twenty pts underwent a pre-treatment biopsy, 6 months of once daily oral TALA (1 mg), followed by definitive surgery. Pts received adjuvant therapy at physician's discretion. Endpoint was residual cancer burden (RCB). With 20 patients, the RCB0 + RCB1 response rate can be estimated with a 95% confidence interval with half width < 20%. **Results:** All 20 planned pts have enrolled from 08/2016-09/2017: median age = 38 (range 23-58); BRCA1+ = 16 and BRCA2+ = 4; 17 patients had triple negative breast cancer (TNBC, ER/PR < 10%) and 3 had hormone+ disease; Clinical stage I = 5, stage II = 12, Stage III = 3 including 1 patient with inflammatory breast carcinoma (IBC) and 1 with metaplastic chondrosarcomatous carcinoma (MpBC). One pt chose to receive chemotherapy prior to surgery so no RCB obtained. To date 18 pts have completed TALA and 17 surgery. This report will be updated with the final 2 patients scheduled for surgery in 03/2018. RCB0 = 9 (including the 1 pt with IBC and 1 pt with MpBC, 8 pts had TNBC and 1 with ER+ invasive lobular). RCBI = 1; RCB II = 5, RCBIII = 2. RCB0/1 rate = 10/17 = 59%, 95% CI = (36%, 78%). There was 1 grade 4 toxicity of thrombocytopenia. Grade 3 toxicities included: anemia = 8; neutropenia = 3, UTI = 1. Most common grade 1/2 toxicities included: nausea, fatigue, neutropenia, alopecia, dizziness and dyspnea. Toxicities were managed by dose reduction and transfusions. Nine pts required dose reduction. **Conclusions:** Single agent oral TALA once daily given preoperatively without chemotherapy produced significant pathologic complete responses with manageable toxicity. This pilot trial exceeded our expectations and is novel to demonstrate RCB0 in TNBC by a single targeted therapy. These results warrants a larger study for this pt population. Clinical trial information: NCT02282345.

HER2-enriched subtype and ERBB2 mRNA as predictors of pathological complete response following trastuzumab and lapatinib without chemotherapy in early-stage HER2-positive breast cancer: A combined analysis of TBCRC006/023 and PAMELA trials. *First Author: Aleix Prat, Department of Medical Oncology, Hospital Clinic, Barcelona, Spain*

Background: HER2-Enriched (HER2-E) intrinsic subtype within HER2-positive breast cancer is characterized by high expression of ERBB2 and related genes. Here we retrospectively evaluated the value of the HER2-E subtype and ERBB2 mRNA expression alone to predict pathological complete response (pCR) in tumor samples from PAMELA and TBCRC 006/023 trials. **Methods:** All patients had HER2-positive early breast cancer and were treated with neoadjuvant lapatinib and trastuzumab. Patients with hormone receptor-positive tumors were also treated with letrozole or tamoxifen. In PAMELA (NCT01973660), 151 patients were treated for 18 weeks. TBCRC 006 (NCT00548184) treated 66 patients for 12 weeks and TBCRC 023 (NCT00999804) randomized 97 patients to 12 vs. 24 weeks of treatment. pCR was defined as no residual invasive carcinoma in the breast. Baseline intrinsic subtypes and ERBB2 mRNA expression were determined using the nCounter-based PAM50 predictor. ERBB2 expression was dichotomized as low (lowest 1/3) vs high (highest 1/3) as used in PAMELA. **Results:** Two-hundred and sixty-five tumors (84.4%) were profiled; 65.7% were classified as HER2-E. pCR was more likely to occur if HER2-E (35.1% vs. 9.9%; odds ratio [OR] = 4.92; 95% CI 2.31-10.50; P < 0.001) or ERBB2-high (36.1% vs. 8.2%; OR = 6.51; 95% CI 2.96-14.31; P < 0.001). HER2-E subtype represented 84.0% and 46.0% of ERBB2-high and ERBB2-low groups, respectively. Rates of pCR in HER2-E/ERBB2-high, nonHER2-E/ERBB2-high, HER2-E/ERBB2-low, and nonHER2-E/ERBB2-low groups were 45.0%, 16.1%, 10.8%, and 6.7%, respectively. Finally, the HER2-E/ERBB2-high group independently predicted pCR (adjusted OR = 6.0; 95% CI [3.1-11.8]; *P*< 0.001). **Conclusions:** Combining HER2-E subtype and ERBB2 mRNA levels better identifies anti-HER2 sensitivity than each variable alone in HER2-positive breast cancer. The combined biomarker identified nearly 50% of patients with pCR to an all-biologic regimen, and if validated may provide a means for rational therapeutic de-escalation.

Evaluation of trastuzumab without chemotherapy as a postoperative adjuvant therapy in HER2-positive elderly breast cancer patients: Randomized controlled trial (RESPECT). *First Author: Masataka Sawaki, Aichi Cancer Center Hospital, Nagoya, Japan*

Background: The relative value of trastuzumab (H) monotherapy as an adjuvant treatment compared to the standard combination treatment with chemotherapy (CT) is not clear for elderly breast cancer (BC) patients (pts). **Methods:** We randomly assigned pts over 70 years (yrs) old with HER2-positive invasive BC who received curative surgery into either H (H group) or H plus CT (H+CT group) selected from pre-specified regimens (PTX/DTX/TC/AC/EC/FEC/CMF/TCb [CBDCA]). The primary endpoint was disease-free survival (DFS), and the total required numbers of events and pts were set to 120 and 260, respectively, for assuring a statistical power of 80% for a 95% confidence interval (CI) with a hazard ratio (HR) of H to H+CT not to exceed 1.69. Restricted mean survival time (RMST) was calculated as a supplementary endpoint for interpreting the relative benefit of H because the blinded interim analysis showed the number of events was much fewer than expected, and the statistical power of the non-inferiority test based on HR is not assured. **Results:** A total of 275 pts were randomized from 2009 to 2014. The median age was 73.5 (70-80) yrs and the median follow up time was 3.52 yrs. Stage I (pT > 0.5cm) 43.6%, IIA 41.7%, IIB 13.5%, IIIA 1.1%. The planned analysis showed that DFS at 3 yrs was 94.8% in H+CT (n = 131, 12 events) vs 89.2% in H (n = 135, 18 events) (HR = 1.42; 95% CI, 0.68 to 2.95, P = 0.35). The difference in RMST between arms at 3 yrs was 0.45 months (mo). Relapse-free survival at 3 yrs was 95.6% (9 events with 4 deaths) in H+CT vs 91.7% (13 events with 5 deaths) in H. Common adverse events (AE) in H+CT vs H were anorexia (44.3% vs 7.4%, P < 0.0001), alopecia (71.8% vs 2.2%, P < 0.0001) and grade 3/4 non-hematological AE were 29.8% vs 11.9% (P = 0.0003). The total score of FACT-G improved more in H at 12 mo (H: 42.9% vs H+CT: 25.3%, P = 0.021). **Conclusion:** Small number of events precluded the evaluation of H monotherapy based on HR of DFS, and comparison of RMSTs revealed the lost survival due to omitting CT was less than 1 mo at 3 yrs. In light of less toxicity and a better QOL profile, H monotherapy can be an option as an adjuvant therapy for elderly HER2-positive BC pts. Clinical trial information: NCT01104935.

TBCRC026: Phase II clinical trial assessing the correlation of standardized uptake value (SUV) on positron emission tomography (PET) with pathological complete response (pCR) to pertuzumab and trastuzumab in patients with primary operable HER2-positive breast cancer. *First Author: Roisin M. Connolly, Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins School of Medicine, Baltimore, MD*

Background: Predictive biomarkers to identify patients with HER2-positive breast cancer (BC) that may be treated with targeted therapy alone are of great interest. We hypothesized that early changes in tumor standardized uptake values corrected for lean body mass (SULmax) on FDG-PET/CT would predict pathologic complete response (pCR) to pertuzumab and trastuzumab (PT) in early stage BC. **Methods:** The multicenter phase II TBCRC026 trial administered 4 cycles of neoadjuvant PT in women with stage II/III, ER-negative, HER2-positive BC (NCT01937117). FDG-PET/CT were performed at baseline and C1D15. Primary Objective: Correlate baseline and change in SULmax on PET with pCR (no invasive cancer breast/axilla). We correlated baseline, D15 and % reduction in SULmax with pCR using logistic regression and compared median values between those with pCR vs no pCR using Wilcoxon rank-sum tests. We evaluated odds ratio (OR), positive (PPV) and negative predictive value (NPV) with selected cutoffs for response assessment. Fisher's exact tests evaluated null hypothesis that OR = 1. **Results:** Between 01/2014-08/2017, 88 enrolled (83 evaluable) with median age 58 (range 29-82), median tumor size 3.9cm (range 2-15). 85% (75/88) completed all 4 cycles PT. pCR after PT alone was 34% (28/83). In an intent to treat analysis (n = 83 evaluable), baseline SULmax did not predict pCR. We observed a significant difference in median % reduction in SULmax between pCR vs no pCR (63.8 % vs 33.5%, p < 0.001), and higher proportion of SULmax reduction ≥40% in pCR vs no pCR (86% vs 54%, p < 0.001, OR 7.2, PPV 49%, NPV 88%). We observed a significant difference in median D15 SULmax between pCR vs no pCR (1.6 vs 3.9, p < 0.001), and a higher proportion of D15 SULmax ≤ 3 in pCR vs no pCR (93% vs 62%, p < 0.001, OR 21, PPV 55%, NPV 94%). **Conclusions:** Percent reduction and D15 SULmax significantly differ between those with pCR versus not, after 4 cycles PT, in ER-negative/HER2-positive BC. This strategy, once optimized, may facilitate escalation and de-escalation of therapy in this setting. Clinical trial information: NCT01937117.

Factors associated with lymphedema in patients/women with node positive breast cancer treated with neoadjuvant chemotherapy and axillary dissection on a prospective clinical trial. *First Author: Judy Caroline Boughey, Mayo Clinic, Rochester, MN*

Background: Lymphedema (LE) is a known complication of breast cancer treatment. Herein we report the factors associated with LE after neoadjuvant chemotherapy (NAC) and axillary dissection (ALND) in the ACOSOG Z1071 (Alliance for Clinical Trials in Oncology) trial of patients with node-positive breast cancer. **Methods:** Patients who consented to the LE substudy underwent prospective arm measurements and symptom assessment after completion of NAC and at 6, 12, 18, 24, and 36 months after surgery. All patients had node-positive disease and underwent ALND after NAC. LE was defined based on symptoms of arm heaviness or swelling (LE-symptoms) or by arm volume increase of $>$ 10% (LE-V10); severe LE was defined as volume increase $>$ 20%. Kaplan-Meier methods were used to determine cumulative incidence. **Results:** 488 of 701 eligible patients consented to the LE substudy. Cumulative incidence of LE at 3 years was 37.8% (33.0-43.1%) by LE-symptoms; 58.6% (53.4-64.4%) by LE-V10; 37.2% (32.2-42.9%) for severe LE. In a univariable analysis, patient age, type of chemotherapy regimen used, breast surgical procedure, number of positive lymph nodes, and use of adjuvant radiation were not associated with risk of LE. Incidence of LE-symptoms was higher in obese patients (BMI $>$ 30, p = 0.02) and in patients with NAC duration $>$ 144 days (p = 0.029). Severe LE incidence was also higher with longer duration of NAC (p = 0.01). LE-V10 incidence was highest in patients with 30+ lymph nodes removed and lower when fewer lymph nodes were removed (p = 0.009). On multivariable analysis, obesity and length of NAC remained significant for LE-symptoms. **Conclusions:** In patients treated with NAC and ALND for node-positive breast cancer, risk of LE-symptoms increases with longer duration of neoadjuvant chemotherapy and obesity. Patients in these groups may benefit from closer surveillance for LE to allow early intervention. Support: U10CA180821, U10CA180882, UG1CA189823; Clinical trial information: NCT00881361.

Phase II national clinical trial of prophylactic irradiation to the contralateral breast for BRCA mutation carriers treated for early breast cancer (EBC). *First Author: Ella Evron, Assaf Harofeh Medical institution, Zerifin, Israel*

Background: Women who carry germ line mutations in BRCA1/2 face a very high risk of breast and ovarian cancer. Recommendations for BRCA mutation carriers advocate intensified screening and BSO. Risk-reducing bilateral mastectomy is considered by healthy BRCA mutation carriers and by carrier patients who already developed breast cancer. Yet, the procedure is disfiguring. Women fear its effects on body image, sexuality and sensation and seek alternative preventive measures. Most studies found that breast conserving therapy was associated with similar risk of ipsilateral cancer recurrence in BRCA carriers compared to non-carriers. However, the risk of subsequent contralateral (CLT) breast cancer in carriers was markedly increased. In Israel, BRCA associated breast cancer is relatively common. Accordingly, a national protocol was devised for this enriched population. **Methods:** In this IRB-approved trial, the choice of prophylactic irradiation to the CLT breast, in addition to radiation of the involved side, was offered to BRCA carrier patients treated for EBC who declined CLT mastectomy. Radiation to both sides was delivered by the same schedule and dose. The primary end point was CLT breast cancer. **Results:** Between May 2007 and October 2017, 162 patients were enrolled. 81 opted for standard treatment including surgery and radiation to the involved side only (control group) and 81 chose additional radiation to the CLT breast (intervention group). At a median follow up of 60 months, 9 patients developed CLT breast cancer in the control group within a median of 24 months, as compared to 2 patients in the intervention group who developed CLT breast cancer 80, 109 months after bilateral breast irradiation (log-rank P = 0.027). One patient developed sarcoma in the muscle behind a CLT breast, 5 years after bilateral irradiation. There was no increase in other early or late radiation toxicities among the intervention group. **Conclusions:** Among BRCA carrier patients treated for EBC, the addition of CLT breast irradiation significantly reduces the risk of subsequent CLT breast cancer and constitutes a viable option for high-risk women declining mastectomy. Clinical trial information: NCT00496288.

Persistence of circulating tumor cells in high risk early breast cancer patients five years after adjuvant chemotherapy and late recurrence: Results from the adjuvant SUCCESS A trial. *First Author: Wolfgang Janni, University of Ulm, Ulm, Germany*

Background: Recent data suggest that circulating tumor cells (CTCs) are of prognostic relevance in early as well as metastatic breast cancer. However, there is a lack of data on the prognostic impact of CTCs to predict late recurrences during long-term follow-up, especially in patients with hormone receptor positive tumors. **Methods:** The SUCCESS A trial is a randomized Phase III study, in which patients with high-risk early breast cancer were first randomized to 3 cycles of epirubicin-fluorouracil-cyclophosphamide followed by either 3 cycles of docetaxel or 3 cycles of gemcitabine-docetaxel, followed by a second randomization to 2 vs. 5 years of zoledronate treatment. Presence of CTCs 5 years after chemotherapy was assessed using the CellSearch System (Janssen Diagnostics, LLC), and CTC positivity was defined as $\geq$ 1 CTC in 7.5 ml whole blood. Recurrence-free survival (RFS) was analyzed by univariable and multivariable Cox regressions. Survival time was measured as of the date of blood sampling for CTC assessment. **Results:** Follow-up data for patients with known CTC status 5 years after chemotherapy were available for 206 (5.5%) of 3754 randomized patients (median time interval of CTC assessment 62.4 months since randomization). The CTC status was positive in 16 (7.8%) patients (range 1 – 53 CTCs). Median follow-up time after CTC assessment was 360 days (range 1 – 911 days). Overall, 13 late recurrences were observed; 11 in 153 hormone receptor positive patients and 2 in 53 hormone receptor negative patients. In hormone receptor positive patients, CTC status was a significant prognostic factor for RFS in univariable (hazard ratio [HR] 5.14, 95% confidence interval [CI] 1.47 – 18.03, p = 0.011) and in multivariable cox regressions adjusted for age, tumor stage, nodal stage, grade, histological type, and HER2 status (HR 5.95, 95%CI 1.14 – 31.16, p = 0.035). **Conclusions:** The presence of CTCs 5 years after chemotherapy was associated with decreased RFS, suggesting that persisting CTCs during long term follow-up independently predict late recurrences in hormone receptor positive patients. Extended follow-up data will be presented at the meeting. Clinical trial information: NCT02181101.

516 Poster Discussion Session; Displayed in Poster Session (Board #8), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 3:00 PM-4:15 PM

Genomic stratification with BCI of ER+ early breast cancer patients with limited long-term risk of breast cancer death. *First Author: Virginia G. Kaklamani, Northwestern University Division of Hematology/Oncology, Chicago, IL*

Background: An increasing body of evidence from extended endocrine therapy trials underscores the unmet need to manage risk-benefit at the individual patient (pt) level. Breast Cancer Index (BCI) is a multigene assay that identified women with a 4.8%-6.6% low risk of cumulative recurrence (0-10y) and a low risk of late recurrence of 2.5%-3.5% in validation studies. In this post-hoc analysis, an optimized assay threshold to identify patients with favorable long-term breast cancer–specific survival was developed and characterized. **Methods:** An adjusted BCI cut point for indolent disease was trained using a cohort of node-negative, post-menopausal women with HR+ breast cancer from the Stockholm trial treated with surgery alone (UNT, n = 283). Initial performance of the optimized model was evaluated in tamoxifen-treated HR+ patients (TAM, n = 317). Breast cancer–specific survival (BCSS) was the primary analysis using Kaplan-Meier estimates over 0-20y and 5-20y. Subsets based on tumor size and tumor grade were also analyzed for BCSS. Median follow-up was 17 years. **Results:** Long-term survival analysis demonstrated that BCI optimized for minimal risk classified pts into 4 distinct risk groups for years 0-20 ($p < 0.0001$) and 5-20 (p = 0.032), with an 8% risk of breast cancer–specific death for the minimal risk group in the UNT arm. BCI classified 27% of pts treated with adjuvant TAM into a BCI minimal risk group with 98% and 99% BCSS for years 0-20 and 5-20, respectively. Among clinically high-risk grade 2 and 3 tumors (n = 250), BCI classified 20% of pts as BCI minimal risk with 98% BCCS for years 0-20 and 5-20. **Conclusions:** In this analysis, a BCI minimal risk group identified more than 1/4 of pts as having favorable long-term outcome (2% risk of breast cancer death) over 20 years after 2-5 years of tamoxifen therapy. Results suggest that the specific gene characteristics of BCI, which combine measures of cell proliferation and estrogen signaling, are an effective prognostic marker of indolent disease. BCI stratification of a genomic subset with favorable long-term outcome may identify node-negative pts with early-stage breast cancer in which more than 5 years of endocrine therapy is unlikely to be of benefit.

Molecular alterations and late recurrence in postmenopausal women with hormone receptor-positive node-positive breast cancer (BC): Results from the "SOLE" trial. *First Author: Elena Guerini Rocco, Department of Pathology, European Institute of Oncology, Milan, Italy*

Background: Women with hormone receptor-positive BC have an ongoing risk of relapse. We performed molecular analyses of primary BC from postmenopausal patients (pts) enrolled in the extended adjuvant intermittent letrozole vs. continuous letrozole (SOLE) trial to identify prognostic factors and potential targets. **Methods:** From 4884 pts enrolled, 3162 had FFPE tumor samples and were eligible. A case-cohort design selected 599 pts, and 499 DNA samples underwent next-generation sequencing of 35 and 19 actionable genes for mutation (SNV) and copy number gain (CNG) analyses. Correlations of SNV/CNG with clinicopathologic factors were analyzed. Associations with breast cancer free-interval (BCFI) and distant recurrence free-interval (DRFI) were assessed using weighted proportional hazards models to obtain unbiased and consistent estimates representing the overall trial population. With 403 pts there was 90% power to detect a hazard ratio (HR) = 2.0 (SNV/CNG+ vs. -; assuming a 40% mutation prevalence), with 0.05 two-sided significance level and adjusted standard error estimate from the weighed Cox model. **Results:** SNV and CNG data were available for 403 (81%) and 350 (70%) of 499 samples, respectively. 294 samples had ≥1 SNV or CNG; 132 had concurrent alterations. *PIK3CA* was the most frequently mutated gene (42%). Other genes showed < 5% SNV rate. Recurrent CNGs were seen in *CCND1* (15%), *ERBB2* (10%), *FGFR1* (8%) and *MYC* (8%). *PIK3CA* SNVs and *MYC* CNG were associated with low (p = 0.032) and high (p = 0.004) tumor grade. Ki-67 index was high in tumors with CNG of *CCND1*, *ERBB2* and *MYC* (each p < 0.01). No association was seen between *PIK3CA* SNV and recurrence. *FGFR1* CNG was associated with worse outcomes (BCFI: HR = 3.2; 95% CI, 1.5-6.9, p = 0.003; and DRFI: HR = 3.5; 95% CI, 1.6-7.7, p = 0.002). The results were consistent in multivariable models adjusting for clinicopathologic factors. **Conclusions:** We showed that pts with hormone receptor-positive node-positive BC with *FGFR1* CNG had an increased risk of late recurrence despite extended therapy. *FGFR1* analysis may improve the risk stratification in this population and represent a potential therapeutic target. Clinical trial information: NCT00553410.

Precision neoadjuvant therapy (P-NAT): A planned interim analysis of a randomized, TNBC enrolling trial to confirm molecular profiling improves survival (ARTEMIS). *First Author: Stacy L. Moulder, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: ARTEMIS is a double blind, randomized trial to determine if P-NAT impacts rates of excellent pathologic response [Residual Cancer Burden (RCB) 0-I]. P-NAT used a CLIA-certified chemosensitivity mRNA gene signature (GES) and subtyping of triple negative breast cancer (TNBC) by immunohistochemistry (IHC) to select targeted therapy (TT) trials for chemo insensitive tumors. **Methods:** ARTEMIS planned to randomize 360 TNBC patients (pts) 2:1 to 'know' vs. 'not know' P-NAT results using a group sequential design with one-sided O'Brien-Fleming boundaries and two interim tests for futility and superiority; overall α set at .05 with 80% power to detect improved RCB 0-1 rate from 50% to 64%. After biopsy, pts began a planned 4 cycles of Adriamycin-based chemo (AC). Volumetric change by ultrasound (US) upon completion of AC (or at progression) combined with GES results (if known) determined sensitivity using a protocol defined algorithm. Pts with sensitive disease received subsequent taxane-based (T) therapy. Pts with insensitive disease were offered phase II trials (TT; table) using IHC results, if known. To gauge impact of TT independently from GES, pts having < 50% volumetric reduction by US to AC were evaluated (US-resistant cohort). **Results:** The first interim analysis (n = 133 pts with RCB status) revealed a RCB 0-1 rate of 56% (know P-NAT) v 62% (not know P-NAT); p = 1.0; thus, randomization was discontinued for futility. In total 232 pts were enrolled; 168 evaluable for RCB. In the US-resistant cohort (n = 43), RCB 0-I rates were higher in pts treated with TT (n = 30) v AC-T (n = 13); (30% v 8%; odds ratio = 5.1 with 95% CI = (0.6-45.7); Fisher's exact test 1-sided p-value = 0.11). **Conclusions:** GES failed to improve rates of RCB 0-I in TNBC; however, in pts with resistant disease identified by US after AC, RCB 0-I rates were higher in pts treated with targeted therapy compared to chemo alone. Clinical trial information: NCT02276443.

Regimen	Entry criteria (IHC)	# pts treated
Atezolizumab + nab-paclitaxel	None	19
Panitumumab + paclitaxel + carboplatin	None	14
Liposomal doxorubicin + bevacizumab + everolimus	Vimentin > / = 50% or metaplastic	12
Enzalutamide + paclitaxel	Androgen receptor > / = 10%	11
AC-T	None	153

Evaluation of homologous recombination deficiency (HRD) status with pathological response to carboplatin +/- veliparib in BrighTNess, a randomized phase 3 study in early stage TNBC. *First Author: Melinda L. Telli, Stanford University School of Medicine, Stanford, CA*

Background: HRD status is significantly associated with a higher rate of response to neoadjuvant platinum-based therapy and improved PFS following adjuvant doxorubicin and cyclophosphamide (AC) in TNBC. We assessed the prognostic and predictive role of the HRD assay for platinum and PARP inhibitor response in BrighTNess. **Methods:** 634 stage II-III TNBC pts were randomized 2:1:1 to: Arm A: Paclitaxel (T) q wk x 12 + carboplatin (P) (AUC 6) q3 wk x 4 + veliparib (TPV) - > AC q2-3 wk x 4; Arm B: T + P + placebo (TP) - > AC; or Arm C: T + dual placebo (T) - > AC. HRD status was defined as HRD+ (HRD score ≥ 42 or a tumor *BRCA1/2* mutation) or HRD- (HRD score < 42 and no tumor *BRCA1/2* mutation). An exploratory HRD threshold of ≥ 33 vs < 33 was also assessed. **Results:** HRD status was available for 438 pts. HRD data by arm for pCR for the 42 and 33 cut-offs are shown. Within each arm using the 42 and 33 cut-offs, respectively, ORs for pCR by HRD status (HRD +/HRD-) were 2.85 (p = 0.0005) and 3.10 (p = 0.004) for Arm A, 1.55 (p = 0.30) and 2.28 (p = 0.10) for Arm B and 2.13 (p = 0.13) and 1.52 (0.48) for Arm C. Comparing between arms using the 42 threshold, ORs for pCR (Arm A/Arm B, Arm A/Arm C, Arm B/Arm C) in the HRD+ group were 1.04, 3.02 and 2.90 and were not statistically significantly different than in the HRD- group (0.57 [p = 0.23], 2.26 [p = 0.60] and 4.0 [p = 0.61]). Similar results were observed with the 33 cut-off. **Conclusions:** In BrighTNess, higher rates of pCR were observed in HRD+ pts across all treatment arms. However, pts treated with P had higher rates of pCR in both HRD+ and HRD- subsets. The exploratory HRD threshold of 33 appeared to provide greater sensitivity to identify responders with the addition of P + V. Receipt of AC in all pts may have contributed to the lack of interaction observed between HRD status and P +/- V treatment. Clinical trial information: NCT02032277.

Residual cancer burden (RCB) as prognostic in the I-SPY 2 TRIAL. *First Author: William Fraser Symmans, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: I-SPY2 is a multicenter phase 2 trial in high risk stage II/III breast cancer (BC) using adaptive randomization within biomarker subtypes to evaluate novel treatment agents added to standard neoadjuvant chemotherapy (NAC) in different phenotypic subsets of breast cancer. Residual cancer burden (RCB) quantifies the extent of residual disease (RD) for patients who did not achieve pathologic complete response (pCR = RCB-0). **Methods:** Local site pathologists reported RCB in the I-SPY2 trial. We performed a pooled analysis of 678 patients in I-SPY2 with RCB data and known follow-up (median 2.5 years). Cox models for event-free survival (EFS) were evaluated for RCB index (continuous) and RCB classes (hazard ratio; 95% CI) in all patients and in subtypes defined by hormone receptor (HR) and HER2 status. We separately compared experimental and control arms (Wilcoxon rank sum test) in a pooled analysis of RCB index (498 patients in total) from the first six treatment comparisons that "graduated" a therapy based on ≥85% predicted probability of increasing pCR rate over control therapy in a future 300-patient phase 3 trial. **Results:** RCB index was prognostic overall (hazard ratio; 95% CI: 1.86; 1.62-2.14) and in each subtype: TNBC (2.09; 1.70-2.57, N = 224), HR-/HER2+ (2.91; 1.79-4.73, N = 69), HR+/HER2+ (1.41; 1.00-1.99, N = 134), and HR+/HER2- (2.08; 1.54-2.81, N = 251). Overall, estimates of 3-year EFS for RCB classes were: pCR 94%, RCB-I 87%, RCB-II 80%, RCB-III 62%. The distribution of RCB index decreased with graduating treatments, relative to control therapy, in TNBC (p < 0.001) and HER2+ (p = 0.03), but not in HR +/HER2- (p = 0.21). In those with RD (excluding pCR), there was a trend for decreased RCB index with graduating treatments, relative to control therapy, in TNBC (P = 0.08), but not in HER2+ (p = 0.43) or HR+/HER2- cancers (p = 0.94). **Conclusions:** RCB determined by local site pathologists was prognostic in all subtypes of breast cancer. Observed differences in RCB index distribution between randomized treatments suggested different patterns, possibly by class of experimental treatment and phenotype of disease. Clinical trial information: NCT01042379.

521 Poster Session (Board #13), Sat, 8:00 AM-11:30 AM

Patient (pt)-reported function and symptoms in APHINITY: A randomized comparison of chemotherapy (C) + trastuzumab (H) + placebo (Pla) versus C + H + pertuzumab (P) as adjuvant therapy in pts with HER2-positive early breast cancer (EBC). *First Author: Jose Baselga, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: In APHINITY (NCT01358877), adding P to H + C significantly improved invasive disease-free survival in pts with HER2-positive EBC (von Minckwitz, *NEJM* 2017). Pt-reported health-related quality of life (HRQoL; symptoms of therapy, patient functioning, and global health status) was a secondary outcome, assessed by EORTC QLQ-C30, QLQ-BR23, and EQ-5D 3L questionnaires. **Methods:** Pts received 1 year (18 cycles) of P or Pla and H + standard adjuvant C (3–4 cycles of anthracycline-based C followed by 3–4 cycles of taxane, or 6 cycles of docetaxel + carboplatin). Pts completed measures until recurrence or 36 months post-randomization (whichever was first). Assessments were performed at screening, end of anthracycline, taxane, and HER2-targeted therapy, at Week 25, and at 6, 12, and 24 months following the end of HER2-targeted therapy. Mean and mean change from baseline (BL) scores were assessed in each arm and time point; results were defined as clinically meaningful if they differed by ± 10 points (Osoba, *JCO* 1998). **Results:** Questionnaire completion rates were > 85% throughout. Mean physical function scores (SD; 95% CI) decreased from BL to Week 13 (end of taxane): –10.7 (17.2; –11.4, –10.0) with P and –10.6 (17.7; –11.4, –9.9) with Pla during C. Scores returned to BL during HER2-targeted treatment. There was no clinically meaningful decline in role function from BL to Week 13 in either arm: –8.0 (28.6; –9.2, –6.8) with P and –8.5 (29.5; –9.8, –7.3) with Pla during C. Diarrhea symptom score differences from BL were clinically meaningful with P (at Week 13), and scores returned to BL at the end of targeted therapy (P + H). Diarrhea symptom scores were worst at Week 13 in both arms (P +22.3 [29.8; 21.0, 23.6]; Pla +9.2 [23.9; 8.2, 10.2]). **Conclusions:** In one of the largest HRQoL data sets reported to date in HER2-positive EBC, there was no clinically meaningful worsening of role function, indicating that patients' abilities to conduct daily activities did not differ by treatment arm. Patient-reported diarrhea symptoms worsened to a greater extent in the P arm during both C and HER2-targeted treatment. Clinical trial information: NCT01358877.

522 Poster Session (Board #14), Sat, 8:00 AM-11:30 AM

Pooled analysis of two randomized phase III trials (PlanB/SuccessC) comparing six cycles of docetaxel and cyclophosphamide to sequential anthracycline taxane chemotherapy in patients with intermediate and high risk HER2-negative early breast cancer (n=5,923). *First Author: Wolfgang Janni, University of Ulm, Ulm, Germany*

Background: Recent studies draw different conclusions concerning whether omission of anthracyclines (A) in adjuvant chemotherapy for HER2-negative early breast cancer (EBC) may reduce toxicity without compromising efficacy. **Methods:** The prospectively randomized PlanB and Success C trials compared 6 cycles of docetaxel (D) and cyclophosphamide (C) with either 4 cycles of epirubicin (E) and C, followed by 4 cycles of D (EC-D, PlanB) or 3 cycles of 5-FU, E and C, followed by 3 cycles of D (FEC-D, SuccessC). Disease-free survival (DFS) was analyzed using univariable and multivariable Cox models adjusted for hormone receptor status (HRS) and histologic grade (G), age, menopausal status, type of surgery, pT, pN, and histologic type. **Results:** Overall, 5923 patients with follow-up data were available for this pooled analysis, with 2979 and 2944 patients randomized to A-free and A-containing chemotherapy, respectively. After 62 months median follow-up, DFS of patients receiving A-free vs A-containing chemotherapy was quite similar in univariable analysis (hazard ratio, HR = 1.04; 95% confidence interval, CI: 0.88 – 1.22, p = 0.64) and in multivariable analysis (HR = 1.00, 95% CI: 0.85 – 1.19, p = 0.96). Defining biological subtypes "luminal A-like" as HRS positive, G1/2, "luminal B-like" as HRS positive, G3, and TN (triple negative), no significant differences were seen in DFS between A-free and A-containing chemotherapy in luminal A-like (HR = 1.06, 95% CI 0.81 – 1.39, p = 0.66), luminal B-like (HR = 1.07, 95% CI 0.78 – 1.48, p = 0.68), or TN tumors (HR = 0.99, 95% CI 0.76 – 1.30, p = 0.95). However, in high-risk patients with four or more affected lymph nodes (pN2-3), A-containing chemotherapy was associated with significantly better DFS (HR = 0.69, 95%-CI 0.48- 0.98, p = 0.04). **Conclusions:** Our results suggest that 6 cycles of DC provide sufficient efficacy compared to an anthracycline-containing regimen in most patients with HER2-negative EBC. However, subgroup analyses indicate that high-risk patients might benefit from anthracycline-containing chemotherapy.

523 Poster Session (Board #15), Sat, 8:00 AM-11:30 AM

A prospective study on the effect of endoxifen concentration and CYP2D6 phenotypes on clinical outcome in early stage breast cancer patients receiving adjuvant tamoxifen. *First Author: Anabel Beatriz Sanchez-Spitman, Department of Clinical Pharmacy & Toxicology, Leiden University Medical Center, Leiden, Netherlands*

Background: It has been postulated that endoxifen levels are better predictors of tamoxifen efficacy than CYP2D6 phenotype. Although in a retrospective study an endoxifen threshold of 5.9 ng/ml for efficacy was described, confirmation based on prospective studies is lacking. The objective of the prospective CYPTAM study (NTR1509) is to associate endoxifen levels and, CYP2D6 phenotypes with clinical outcome in early stage breast cancer patients receiving tamoxifen. **Methods:** Breast cancer patients who were receiving adjuvant tamoxifen were included. Blood samples were used for CYP2D6 genotyping and endoxifen levels by Amplichip and high-performance liquid chromatography-tandem mass spectrometry assay, respectively. Endoxifen levels and CYP2D6 phenotypes were associated with relapse-free survival (RFS) by using Cox-regression analysis. Patients who changed to an aromatase inhibitor, were censored at the time of switch. **Results:** A total of 667 pre and post-menopausal patients were enrolled. No association was found between endoxifen serum levels used as a continuous variable and RFS (Adjusted Harzard Ratio (HR): 0.991, 95 % CI: 0.946-1.038, p-value: 0.691). Categorizing endoxifen levels in quartiles, or using 5.9 ng/ml as threshold did not alter these results. In addition, no association was observed between CYP2D6 phenotypes and RFS (Adjusted HR: 0.929, 95 % CI 0.525-1.642, p-value 0.799). **Conclusions:** This first prospective clinical study shows no association between endoxifen levels and CYP2D6 phenotypes with RFS in early breast cancer patients using adjuvant tamoxifen. These results do not support the use of therapeutic drug monitoring based on endoxifen levels or CYP2D6 genotyping. Associations between Endoxifen levels and CYP2D6 phenotypes with RFS. Clinical trial information: NTR1509.

524 Poster Session (Board #16), Sat, 8:00 AM-11:30 AM

Duration of extended adjuvant therapy with neratinib in early-stage HER2+ breast cancer after trastuzumab-based therapy: Exploratory analyses from the phase III ExteNET trial. *First Author: Michael Gnant, Comprehensive Cancer Centre, Medical University of Vienna, Vienna, Austria*

Background: The optimal duration of adjuvant therapy with targeted agents remains a question of ongoing relevance in oncology. ExteNET, an international, randomized, placebo-controlled phase III trial, showed that neratinib given for 12 months after trastuzumab-based therapy significantly improved 2- (HR 0.67, p = 0.009) and 5-year (HR 0.73, p = 0.008) invasive disease-free survival (iDFS) in early-stage HER2+ breast cancer [Chan et al. *Lancet Oncol* 2016; Martin et al. *Lancet Oncol* 2017]. We examined the influence of duration of neratinib therapy on efficacy in the ExteNET study. **Methods:** Patients with early-stage HER2+ breast cancer were randomly assigned to oral neratinib 240 mg/day or placebo for 12 months (or until disease recurrence) after standard primary therapy and trastuzumab-based (neo)adjuvant therapy. Patients who received neratinib for ≤3 or ≥11 months (the median duration of neratinib treatment) were each compared with the ITT placebo group. iDFS (primary endpoint) was analyzed using Kaplan-Meier methods and Cox proportional-hazards models adjusted for prognostic factors. Data cut-off: March 1, 2017. Clinicaltrials.gov: NCT00878709. **Results:** ITT population comprised 2840 patients (neratinib, n = 1420; placebo, n = 1420). Median treatment duration (ITT population) was 11.6 and 11.8 months in the neratinib and placebo groups, respectively. 391 patients received neratinib for ≤3 months. 872 patients received neratinib for ≥11 months or stopped treatment prior to 11 months due to recurrence. Results after a median of 5.2 years follow-up are shown below. **Conclusions:** These exploratory data suggest that patients who remained on neratinib for ≥11 months derived clear benefits from therapy, whereas neratinib efficacy was considerably reduced in those who stopped treatment early (≤3 months).Clinical trial information: NCT00878709.

		5-year iDFS rate, %		
Duration of neratinib	**N**	**Neratinib**	**Placebo**	**HR (95% CI)**

525 Poster Session (Board #17), Sat, 8:00 AM-11:30 AM

Predicting expected absolute chemotherapy treatment benefit in women with early-stage breast cancer using a 12-gene expression assay. *First Author: William John Gradishar, Feinberg School of Medicine, Northwestern University, Chicago, IL*

Background: Previous studies have validated the ability of a 12-gene expression assay to predict risk of distant recurrence (DR) in women with estrogen receptor-positive (ER+), human epidermal growth factor receptor 2-negative (HER2-) early stage breast cancer. Here, we employed a mathematical approach to estimate an expected absolute chemotherapy benefit based on the 12-gene expression test results. **Methods:** Data was included for patients who had clinical testing with the 12-gene expression assay in the US (Myriad Genetic Laboratories Inc., Salt Lake City, Utah) or Germany (Myriad GmbH, Munich, Germany). FFPE breast resections of treatment-naïve ER+, HER2- breast tissue were tested to generate a combined molecular and clinical score (EPclin score). For the entire group, the *relative* chemotherapy benefit was assumed to be 30% based on meta-analyses from the Early Breast Cancer Trialists' Collaborative Group. This was used to calculate the expected *absolute* chemotherapy benefit across the EPclin score continuum. This was first done in a conservative scenario where chemotherapy benefit was assumed to be independent of EPclin score (no interaction). The degree of interaction between expected chemotherapy benefit and the EPclin score was then systematically increased until the maximum possible EPclin score was associated with the maximum chemotherapy benefit. The mean *absolute* benefit was calculated for patients at high risk (EPclin $\geq$3.3) or low risk (EPclin $<$ 3.3) of distant recurrence. **Results:** Overall, 2,205 ER+, HER2- breast resections (303 tested in USA, 1902 tested in Germany) were included here [1286 samples (58%) with low EPclin scores; 919 (42%) with high EPclin scores]. The mean absolute benefit ranged from 1.5% to 1.8% (mean 10-year risk of DR 4.6% to 4.3%) for patients with low risk EPclin scores compared to 5.3% to 7.3% (mean 10-year risk of DR 14.7% to 12.8%) for patients with high risk EPclin scores. **Conclusions:** In this analysis, the 12-gene expression assay was able to predict *absolute* benefit from adjuvant chemotherapy in women with ER+, HER2- early stage breast cancer, regardless of which EPclin score cohorts accrued maximal *relative* treatment benefit.

527 Poster Session (Board #19), Sat, 8:00 AM-11:30 AM

Tumor infiltrating lymphocytes to predict DFS from intense dose-dense (idd) EPC regimen: Results from the German Adjuvant Intergroup Node-positive study (GAIN-1). *First Author: Aurelia Noske, Institut für Pathologie, Technische Universität München, München, Germany*

Background: Immunogenic infiltrate in breast cancer (BC) may influence the prognosis and response to systemic therapies. The association and prognostic role of tumor infiltrating lymphocytes (TILs), PD-1 and PD-L1 expression were investigated in high-risk, node positive breast carcinomas. **Methods:** The prospective adjuvant phase III GAIN trial compared two dose-dense regimens, iddEPC (epirubicin (E), paclitaxel (P), cyclophosphamide (C)) vs. EC-PX (capecitabine (X)) and Ibandronate vs. observation in patients with node-positive primary breast cancer. A total of 1318 FFPE tumor samples were available for analysis of TILs by HE morphology, and PD-1, and PD-L1 by immunohistochemistry. The association of immune parameters and their prognostic and potential predictive role were analyzed by Cox regression models. The median FU was 74.3 months (range: 0.1-113.7). **Results:** Increased TILs, PD-1 and PD-L1 positive TILs were significantly associated with higher grade, higher Ki67, ER/PR negative and triple negative BC (each $p < 0.0001$). TILs and PD-L1 positive TILs were slightly more frequent in HER2 positive BC ($p = 0.005$). Spearman analysis revealed positive, moderate to low correlations between TILs, PD1 and PD-L1. At multivariate Cox regression analysis with clinical covariables, TILs had a significant positive impact on DFS in the iddEPC-arm (HR = 0.57 [0.39-0.84], $p = 0.0043$) but not in the EC-PX-arm (HR = 1.26 [0.86-1.87], $p = 0.2384$, interaction $p = 0.0336$). Especially, HR+/HER2- BC with TILs and treated with iddEPC had a better DFS compared to no TILs (HR = 0.59 [0.38-0.93], $p = 0.0227$). PD-1 positive TILs in TNBC were associated with a significant better DFS (HR = 0.50 [0.25-0.99], $p = 0.0457$). PD-L1 expression had no impact on patient outcome. **Conclusions:** TILs and expression of immune checkpoints are common in high-grade, highly proliferative, triple negative and in part in HER2 positive BC. Tumor infiltrating lymphocytes predict the benefit from intense dose-dense EPC whereas the prevalence and prognostic impact of PD-1 /PD-L1 seem to play an inferior role in this node-positive breast cancer cohort with adjuvant chemotherapy.

529 Poster Session (Board #21), Sat, 8:00 AM-11:30 AM

Residual risk assessment with the Breast Cancer Index (BCI) for prediction of late distant recurrence (DR) in patients from the TransATAC study. *First Author: Ivana Sestak, Centre for Cancer Prevention, Wolfson Institute of Preventive Medicine, Queen Mary University of London, London, United Kingdom*

Background: The Breast Cancer Index (BCI) is a gene-expression based signature comprised of two complementary functional domains: the molecular grade index (MGI) for tumor proliferation, and the HoxB13/IL17BR ratio (H/I) for estrogen signalling. BCI provides a quantitative assessment of the likelihood of overall (0-10yr), late (5-10yr) DR and reported to show endocrine benefit in patients with estrogen receptor positive (ER+) breast cancer. The aim of the current study was to further characterize BCI performance to predict late DR for postmenopausal women with N- and N+ disease treated with either anastrozole or tamoxifen. **Methods:** 883 women with ER+, N- or N+ (1 to 3 nodes) breast cancer from TransATAC study who were recurrence free at 5 years were included in this analysis. Time to late DR (5 years after diagnosis) was the primary endpoint. Cox regression models were utilized to determine the prognostic value of the BCI and KM-estimates were used to determine 5-10 year DR. **Results:** 75 late DRs were recorded in all 883 patients who were recurrence free at 5 years. Patients with a high BCI score were associated with a significantly worse outcome compared to those with a low BCI score (HR = 1.88 (1.49-2.39)). This relationship was observed for both N- (HR = 1.96 (1.41-2.72)) and N+ (HR = 1.51 (1.08-2.12)) patients. BCI added significant prognostic information beyond that from CTS in all patients (ΔLR-χ^2= 11.51, P = 0.0007). For women with N- disease, significant differential risk stratification was observed between low and intermediate groups and between low and high groups. For N+ patients a significant difference was observed between low and high risk groups (HR = 3.10 (1.28-7.49)), but not low and intermediate or intermediate and high. For N+ patients, a BCI model integrating tumor size and grade provided significantly more prognostic value than BCI alone (LR-χ^2= 21.34 vs. LR-χ^2= 5.86, respectively). **Conclusions:** In this post-hoc analysis with an expanded group of patients from the TransATAC cohort, BCI was a significant prognostic factor for late DR in both N- and N+ patients, with a combined BCI model providing more prognostic value in N+ patients.

530 Poster Session (Board #22), Sat, 8:00 AM-11:30 AM

Overall survival in female Medicare beneficiaries with early stage breast cancer receiving bisphosphonates or denosumab. *First Author: Raul A Herrera Pena, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Adjuvant bisphosphonates in early breast cancer (BC) have resulted in reduction in bone metastasis and improved overall survival (OS), particularly in post-menopausal women. We aim to evaluate the effect of bone-modifying agents (BMA) on survival in a population based cohort of older BC patients. **Methods:** Patients aged $\geq$ 66 yo diagnosed with stage I-III BC between 2007 and 2013 were identified in SEER-Medicare and TCR-Medicare database. Patients were required to have Medicare Parts A, B and D coverage. Patients receiving at least 6 months of an oral bisphosphonate, two doses of ibandronate or one dose of zoledronate or denosumab at doses equivalent or higher to those approved for osteoporosis, during the first two years of BC diagnosis were identified as having received a BMA. Five year-OS was estimated with Kaplan-Meier with groups compared with the log rank test. Cox proportional hazards models were fitted to determine the association of BMA and OS after propensity score adjustment. Subgroup analysis were stratified by stage. **Results:** The final cohort included 37,604 patients. Median age was 75 years. 32,045 (85.2%) of the patients had hormone receptor-positive tumors. Overall, 8,591 (22.8%) of the patients were treated with BMA. Of these, 7,349 (85.5%) received bisphosphonates only. The unadjusted 5 year OS was 81% and 77 % for those who did and did not receive BMA, respectively ($P < 0.0001$). After multivariate analysis including propensity scores adjustment, treatment with BMA was associated with a statistically significant increased survival (Hazard ratio [HR] 0.91, 95% CI = 0.85-0.96). When stratified by stage, BMA vs no BMA showed an improvement in unadjusted 5 year OS in patients with Stage II (5y OS 79% vs 72%, $P < 0.0001$) and Stage III (64% vs 57%, $P = 0.002$) but not for Stage I (86% vs 85%, $P = 0.88$). After multivariate adjustment, survival remained significant for Stage II (HR 0.81, 95% CI = 0.73-0.90) but not for Stage III (HR 0.91, 95% CI = 0.78-1.07). **Conclusions:** Use of BMA in post-menopausal woman with early stage BC patients was associated with improved 5 year OS. Stage stratified subgroup analysis showed that the difference in survival was significant only for patients with stage II.

531 Poster Session (Board #23), Sat, 8:00 AM-11:30 AM

Safety and tolerability of adjuvant enzalutamide for the treatment of early stage androgen receptor positive (AR+) triple negative breast cancer. *First Author: Tomas Lyons, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: A subset of triple negative breast cancer (TNBC) is characterized by androgen receptor (AR) expression and dependence on AR signaling (Doane Oncogene 2006; Gucalp CCR 2013). Enzalutamide (ENZA), an AR-antagonist, has a clinical benefit rate of 33% in evaluable patients(pts) with metastatic AR+ TNBC (Traina et al, JCO 2018). This study tests the feasibility of 1 year (y) of adjuvant ENZA for the treatment (tx) of early stage, AR+ TNBC (NCT02750358). We now report safety data observed in our phase II trial. **Methods:** Eligible pts have centrally confirmed, Stage I-III, ER/PR $<$ 1%, HER2(-) AR $\geq$1% BC and completed all planned tx (surgery, (neo)adjuvant chemotherapy and radiation) within 6 months of study start. Tx consists of ENZA 160mg orally daily for 1y with option for 2y at pt discretion. Toxicity assessment per NCI CTCAEv4 every 4 weeks for 12 weeks, then every 3 months. Primary endpoint: feasibility of 1y ENZA, measured as the tx discontinuation rate due to toxicity, withdrawal of consent or tolerability. 46 evaluable pts are required to discriminate between feasibility of 50% and 70%, with type I error 5% and 88% power. Secondary endpoints: feasibility rate at 1y in adherent pts, safety of extended duration ENZA and 3y DFS and OS. Exploratory endpoints: pt reported outcomes and biomarker development. **Results:** Between 5/2016-1/2018, 38 pts on tx, with complete accrual planned by 6/2018. Pt characteristics: median age 53y(32-80), Stage I/II 81%, III 19%, Grade 2 21%, Grade 3 79%. 35(92%) received chemo: Neo 49%, Adj 51%; Anthracycline/Taxane-based 29 (83%), Platinum 2 (6%), Other 6 (17%). 5(14%) received adjuvant capecitabine for lack of pCR. 79% received XRT. AR $>$ 10% in 24 pts(63.2%) and AR $\leq$10% in 14(36.8%). Any grade (gr) AE possibly attributed to ENZA: fatigue (31.5%), hot flashes (21%), reduced white blood cells (7.9%), nausea (5.3%) and increased alkaline phosphatase (5.3%). The only ENZA-related gr $\geq$3 AE was fatigue (1pt, 3%). No seizures were observed. 3 pts had dose reduction due to AE. **Conclusions:** ENZA administered in the adjuvant setting is well tolerated following definitive locoregional tx and standard of care chemotherapy. No new safety signals were observed. Clinical trial information: NCT02750358.

532 Poster Session (Board #24), Sat, 8:00 AM-11:30 AM

Adherence to hormonal therapy among commercially insured breast cancer patients. *First Author: Hui Zhao, Health Services Research Department, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Tamoxifen and aromatase inhibitors (AI) are adjuvant hormone therapy (HT) routinely used for the treatment of early-stage estrogen-positive breast cancer, their use reduces the risk of breast cancer recurrence by about 30%. Despite the survival benefit, the side effects of HT and other factors may affect patients' adherence. No large observational study has assessed the 5 year HT adherence for breast cancer. We evaluated HT adherence over a five-year course using the commercial health claims data provided by Truven Health Analytics. **Methods:** Breast cancer patients who received mastectomy or lumpectomy aged 18 years and older between 1999 to 2014 and initiated HT within 1 year since surgery were selected. The outcome variable was HT adherence rate from years 1 to 5. HT adherence was defined as proportion of days covered (PDC) $\geq$ 80% during a treatment year. HT adherence rate was computed as adherence patients in a given year divided by all HT users who had insurance coverage in that year. Covariates included patient's age, geographic region, type of health insurance plan, year at cancer surgery, comorbidity, type of HT drugs, and primary cancer treatment such as surgery, chemotherapy, and radiation treatment. Logistic regression was used to evaluate factors associated with HT adherence. **Results:** 27,790 patients initiated HT within 1 year of breast cancer surgery. The median age was 55 years old and the median time from breast cancer surgery to HT initiation was 114 days. 29.2% of patients used tamoxifen, 28.2% used anastrozole, 8.9% used letrozole, 1.4% used exemestane, and 32.3% used more than one type of HT drugs. Each year, about 60 to 70% patients were adherent to the treatment. The five year adherence rate decreased from 81.4% in the first year to 21.1% in the 5th year. Patients who were $\geq$ 50 years old, lived not in the South, with insurance other than HMO, received lumpectomy or mastectomy combined with chemotherapy and radiation therapy, with no comorbidity, used AI, and received surgery in 2003 were more likely to be adherent to HT. **Conclusions:** The five year HT adherence rates were low among breast cancer patients. Health care providers need to identify ways to improve HT adherence to prevent breast cancer recurrence. [1996 characters]

Selection for Oncotype Dx testing among young women with early-stage ER+/HER2- breast cancer. *First Author: Philip Daniel Poorvu, Dana-Farber Cancer Institute, Boston, MA*

Background: The Oncotype Dx Recurrence Score (RS) predicts distant recurrence risk and benefit from chemotherapy for women with early-stage estrogen receptor (ER) positive (+)/human epidermal growth factor receptor 2 (HER2) negative (-) breast cancer (BC). Due to the independent risk of young age and small proportion of young women in the validation studies, providers may be hesitant to rely on the RS among young women. **Methods:** Using a multi-center, prospective cohort study of women newly diagnosed with BC at age $\leq$40 years enrolled from 2006-2016, we identified participants with stage I-III, ER+/HER2- BC. Clinical data were obtained through patient surveys and medical record review. Factors associated with RS testing by univariable analyses ($p < 0.20$) were used to generate a multivariable logistic regression model. **Results:** 182 (32%) of 575 eligible women had a RS performed (Table 1). Younger women ($OR_{age \leq 30 \text{ vs } 36\text{-}40} = 0.49$, $p = 0.03$) and those with larger ($OR_{> 2cm \text{ vs } \leq 2cm} = 0.54$, $p = 0.007$), node positive ($OR_{pos \text{ vs } neg} = 0.14$, $p < 0.0001$) or high grade tumors ($OR_{high \text{ vs low/intermediate}} = 0.37$, $p < 0.0001$) were less likely to have a RS performed. Of women who had a RS performed, chemotherapy usage was 21/88 (24%), 44/77 (57%), and 17/17 (100%) among those with low, intermediate, and high RS, respectively. Most women with low risk RS who received chemotherapy had other low risk features: 67% T1, 67% N0, and 86% low/intermediate grade. **Conclusions:** Despite the development of multigene testing to assess the benefit of chemotherapy, many young women with node-negative ER+/HER2- BC are not tested, and when tested, a substantial percentage receive chemotherapy despite a low RS. This highlights an opportunity to improve individualized care for young women with BC.

Recurrence score testing.

	RS/N (%)	OR (95% CI)	p-value
Age ≤30	18/75 (24)	0.49 (0.26,0.93)	0.03

Assessment and management of bone health in women treated with adjuvant anastrozole in the DATA study. *First Author: Irene Van Hellemond, Maastricht University Medical Centre, Maastricht, Netherlands*

Background: The phase III DATA study (NCT00301457) investigates the efficacy of 6 versus 3 years of adjuvant anastrozole (AI) after an initial 2-3 year treatment with tamoxifen in postmenopausal women with breast cancer. In a planned side study, we assessed patterns of care in detection and treatment of osteopenia/osteoporosis and linear trends over time in bone mineral density (BMD). **Methods:** BMD measurements and bisphosphonate use in the DATA study were left to the treating physician. We registered all BMD measurements and start of bisphosphonate-use. BMD was measured by a dual-energy x-ray absorptiometry (DEXA) scan of the lumbar spine and/or the hip and transformed to a T-score. Time to osteopenia or osteoporosis was analysed by reverse Kaplan Meier methodology. For the linear trend in BMD T-score, linear mixed models with random effects for patient were used. **Results:** Of the 1860 eligible patients in the DATA study, 910 (48.9%) had a BMD measurement at the start of anastrozole (baseline). In 417 (45.8%) patients the baseline measurement indicated a normal BMD, in 408 (44.8%) osteopenia, and in 85 (9.3%) osteoporosis. In patients with a normal baseline BMD, osteopenia was observed in 53.5% of patients in the 6-year group, and 55.4 % in the 3-year group ($p = 0.18$), while none developed osteoporosis within 6 years after randomization. Of the patients with osteopenia at baseline, 24.4 % developed osteoporosis in the 6-year group and 20.4% in the 3-year group ($p = 0.89$). The yearly BMD change in the lumbar spine showed a decline of the mean T score of 0.075. When bisphosphonates were added the decline became 0.047 per year ($p < 0.001$), and when the AI was stopped and bisphosphonates continued the BMD increased yearly with 0.047. **Conclusions:** In postmenopausal women who had been treated with 2-3 years of adjuvant tamoxifen, BMD measurement showed osteopenia in 44.8% of women and osteoporosis in 9.3%. Although subsequent AI-use was associated with a further decrease of BMD, none of the patients with a normal BMD at baseline developed osteoporosis regardless of treatment arm. Clinical trial information: NCT00301457.

Comprehensive transcriptomic profiling to identify breast cancer patients that may be spared adjuvant systemic therapy. *First Author: Martin Sjostrom, Lund University, Department of Oncology and Pathology, Lund, Sweden*

Background: Some women with early stage breast cancer (BC) may not require additional systemic therapy after breast-conserving surgery (BCS). While this subgroup of ultra low-risk women has been difficult to identify with conventional clinical metrics, transcriptomic profiling may offer improved risk stratification. Previously described genomic signatures perform well on the group level, but reports indicate that there may be substantial disagreement between signatures for an individual patient. **Methods:** We analyzed tumors from 765 patients in the SweBCG91-RT trial, which randomized node-negative BC patients to +/- radiation following BCS, with minimal use of adjuvant systemic treatment (9%). Median follow-up was 18.6 years for breast cancer-specific survival (BCSS). The original study demonstrated a benefit from radiation on locoregional events, but not BCSS. Tumors were profiled with the Affymetrix Human Exon 1.0 ST microarray and 14 genomic signatures from literature (including Mammaprint-like, OncotypeDX-like and PAM50-like signatures) were calculated. The average of all signatures was used as an average genomic risk (AGR), which was further used to derive a novel 141-gene signature, with independent features from the previous signatures. **Results:** Most previously described signatures performed well in our data and were highly prognostic for BCSS. The performance of AGR was in line with the best individual genomic signatures, and among the systemically untreated, ER+, HER2- and postmenopausal patients (N = 454, 59% of the entire study population), the BCSS at 15 years for the 50% of patients with lowest AGR was 93% (95%CI 90-97%). The 141-gene signature had a similar performance with 92% (95%CI 88-96) BCSS for the 50% of patients with lowest risk at 15 years. **Conclusions:** AGR, based on 14 previously published signatures, is highly prognostic for BCSS and identifies a large proportion of patients with an excellent outcome. An associated novel 141-gene signature performs similarly and identifies patients that may be spared adjuvant systemic treatment. Based on several individual signatures, AGR and the novel 141-gene signature may be more robust on an individual patient level.

536 Poster Session (Board #28), Sat, 8:00 AM-11:30 AM

Breast cancer cell-free DNA (cfDNA) profiles reflect underlying tumor biology: The Circulating Cell-Free Genome Atlas (CCGA) study. *First Author: Minetta C. Liu, Mayo Clinic, Rochester, MN*

Background: New breast cancer screening approaches are needed to detect clinically aggressive subtypes that may not be detected by mammography or are detected late in unscreened populations. CCGA (NCT02889978) is a prospective multi-center observational study for the development of a noninvasive assay for cancer detection. A preplanned substudy of a Women-Only Cohort is reported. **Methods:** Blood was prospectively collected (N = 1627) from 878 participants (pts) with newly diagnosed untreated cancer (20 tumor types, all stages) and 749 pts with no cancer diagnosis (controls, C) for plasma cfDNA extraction. This substudy included 358 pts with invasive breast cancer (IBC) and 452 C. Three prototype sequencing assays were performed: paired cfDNA and white blood cell (WBC) targeted sequencing (507 genes, 60,000X) for single nucleotide variants/indels, paired cfDNA and WBC whole genome sequencing (WGS, 30X) for copy number variation, and cfDNA whole genome bisulfite sequencing (WGBS, 30X) for methylation; WBC sequencing identified the contribution of clonal hematopoiesis (CH). For each assay, a classification model using 10-fold cross-validation was developed to discriminate IBC from C using a subset of women; sensitivity was estimated at 95% specificity. **Results:** IBC pts and C had similar age (mean yrs±SD: 58±13 IBC, 59±12 C). 46% of IBC pts were symptomatic (a subset were documented interval cancers), 82% were stage I/II. The subtype breakdown of HR+/HER2+/triple-negative breast cancer (TNBC) was 65%/17%/15%. WGBS returned the highest sensitivity of the 3 assays and is reported here; results were consistent across all assays. Sensitivity (95% CI) was higher for TNBC vs HER2+ vs HR+/HER2- (58% [43-72] vs 40% [28-54] vs 15% [10-20]), and higher for symptomatic vs screen-detected breast cancer (44% [36-52] vs 10% [6-16]). Comparison to tumor WGS and multi-assay classification will be reported. **Conclusions:** Breast cancers with detectable cfDNA signals at time of diagnosis included clinically aggressive subtypes and symptomatic presentation. Further assay and clinical development in the intended use population is ongoing (NCT03085888). Clinical trial information: NCT02889978.

538 Poster Session (Board #30), Sat, 8:00 AM-11:30 AM

Dose tailoring of breast cancer adjuvant chemotherapy aiming at avoiding both over and undertreatment: Results from the prospective PANTHER study. *First Author: Alexios Matikas, Department of Oncology, Karolinska Institutet and University Hospital, Stockholm, Sweden*

Background: Adjuvant breast cancer chemotherapy (ACT) improves relapse free (BCRFS) and overall survival (OS). Differences in terms of efficacy and toxicity could partly be explained by the significant interpatient variability in pharmacokinetics which cannot be captured by dosing according to body surface area. Consequently, tailored dosing was prospectively evaluated in the phase III PANTHER trial with 2017 patients. **Methods:** PANTHER is a multicenter, open-label, randomized phase III trial which compared tailored, dose dense epirubicin/cyclophosphamide (EC) and docetaxel (D) (group A) with standard interval 5-fluorouracil/E/C and D (group B), with identical duration of therapy in both arms. The primary endpoint was BCRFS. The primary efficacy analysis revealed an improved event free survival and favorable trends for BCRFS, OS and distant disease free survival compared with standard ACT. In this secondary analysis, we aimed to explore the concept of dose tailoring. Our two hypotheses regarding patients treated at group A were that BCRFS would not differ according to the cumulative administered dose; and that dose tailoring would lead to appropriate dosing and improved outcomes for obese patients. **Results:** Patients randomized in group A had similar BCRFS regardless of the cumulative epirubicin (p = 0.495) or docetaxel dose (p = 0.575). There were consistent, non-statistically significant trends in favor of patients receiving < 360 mg/m^2 epirubicin compared to 360-420 and > 420 mg/m^2. In addition, there were no differences in outcomes between patients receiving tailored ACT with a body mass index (BMI) of < 24 (n = 307), 24-28 (n = 296) and 28-40 (n = 312) (p = 0.384). Patients with a BMI of 28-40 had a non-significant trend for improved BCRFS, using BMI < 24 as reference (HR = 0.73, 95% CI 0.45-1.18) **Conclusions:** Dose tailoring could spare patients from unnecessary overdosing without compromising outcomes and may overcome the negative impact on prognosis conferred by obesity. Although exploratory, these results highlight the feasibility of tailored ACT, and underscore the need for further studies. An in-depth discussion will be presented at the ASCO meeting. Clinical trial information: NCT00798070.

539 Poster Session (Board #31), Sat, 8:00 AM-11:30 AM

In silico evaluation of the 12-gene molecular score (EndoPredict) and the recurrence score (Oncotype DX) as predictors of response to neo-adjuvant chemotherapy in estrogen receptor positive (ER+), HER2 negative (HER2-) breast cancer. *First Author: Hatem Hussein Soliman, Moffitt Cancer Center, Tampa, FL*

Background: Neo-adjuvant chemotherapy (NaCT) facilitates complete surgical resection in locally advanced, ER+, HER2- breast cancer. Due to its association with improved outcome, pathologic complete response (pCR) to NaCT treatment has been accepted as a surrogate for long-term outcome in clinical trials of patients with HER2+, triple-negative, or luminal B breast cancer. However, only 7-10% of patients with ER+, HER2- disease who receive NaCT achieve pCR. Biomarkers predictive of NaCT response would facilitate patient stratification and enable individualized therapeutic strategies. Here we evaluated the ability of two prognostic biomarker assays to predict NaCT response in ER+, HER2- breast cancer by means of a microarray-based in silico analysis. **Methods:** Expression and corresponding clinical data associated with pre-treatment biopsies obtained from patients with breast cancer who subsequently received NaCT were obtained from public datasets (GSE entries 16716, 20271, 25066, 32646, 41656, 41998). ER+, HER2- samples were selected based on available immunohistochemistry (IHC) data. The 12-gene molecular score (12-MS) and 21-gene recurrence score (21-RS) were approximated in silico according to published algorithms using expression means of array probes corresponding to the respective genes. Association with pCR was tested by logistic regression with adjustment for cohort. **Results:** A total of 764 patients with ER+, HER2- disease had available IHC data; 59 experienced pCR (response rate 8%). 12-MS and 21-RS were moderately well correlated (0.71). Both scores were predictive of pCR (12-MS p = 6.9×10^{-5}; 21-RS p = 0.0023). In bivariate analysis the 12-MS remained a significant predictor of response (p = 0.01) while the 21-RS did not (p = 0.73). **Conclusions:** In this microarray-based in silico analysis, 12-MS was highly predictive of ER+, HER2- response to NaCT. Optimal stratification of patients with ER+, HER2- breast cancer for NaCT offers the opportunity to individualize care, improve response rates, and possibly avoid ineffective treatment.

540 Poster Session (Board #32), Sat, 8:00 AM-11:30 AM

Image-based risk score to predict recurrence of ER+ breast cancer in ECOG-ACRIN Cancer Research Group E2197. *First Author: Nishant Verma, Inspirata, Tampa, FL, US*

Background: Tumor grade is a predictor of breast cancer recurrence, independent of gene expression assays such as Oncotype Dx (ODx). However, grade suffers from significant intra- and inter-observer variability, limiting its clinical utility. Advances in whole slide imaging facilitate computerized analysis of H&E slides. We have developed a prognostic assay called Image-based Risk Score (IbRiS) which extracts and leverages morphometric signatures from H&E slides to classify patients into low- vs. high-risk groups for recurrence. **Methods:** IbRiS was evaluated on 378 ER+ patients treated with chemo-hormonal therapy obtained from ECOG-ACRIN study E2197; patients had 0-3 positive axillary nodes and H&E slides of acceptable quality; 60 patients suffered recurrence. A subset of 124 patients (27 recurrences) were HER2-. Another (enriched) subset (116 patients with 27 recurrences) had accompanying ODx scores. To establish IbRiS low- and high-risk groups, we determined (over the 378 patients) a cutoff such that the low-risk group had a 10-year recurrence rate of ~10%. We evaluated IbRiS risk groups using Cox proportional hazard analysis, controlling for node status, age, and tumor size. We also compared the recurrence rates in the IbRiS risk groups to those of ODx and a combined assay (IbRiS + ODx). **Results:** IbRiS risk groups predicted recurrence with a hazard ratio of 2.41 (n = 378, 95% CI = 1.21-4.79, $p = 0.01$) and 2.52 (n = 124, 95% CI = 0.85-7.46, $p = 0.09$) for the HER2- subset. Over the 378 patients, IbRiS classified as low-risk 35.3% of the patients who did not suffer recurrence. Table 1 compares the low-/high- risk stratifications of IbRiS, ODx, and the combined assay. **Conclusions:** IbRiS assay is a significant predictor of breast cancer recurrence and contributes prognostic information independent of ODx. The combined genomic and morphometric assay outperforms either individual assay. Also, while ODx was reported to lose prognostic ability when restricted to HER2- patients in E2197, IbRiS remains a predictor of recurrence.

Performance of assays (N = 116).

	% of patients without recurrence classified as low-risk	10-year recurrence rate in low-risk group
IbRiS	37.5%	17.2%
ODx	56.3%	19.6%
IbRiS + ODx	75.0%	20.0%

541 Poster Session (Board #33), Sat, 8:00 AM-11:30 AM

Long-term benefit from tamoxifen therapy for patients with Luminal A and Luminal B breast cancer: Retrospective analysis of the STO-3 trial. *First Author: Linda Lindström, Karolinska Institutet, Stockholm, Sweden*

Background: Breast cancer patients with estrogen receptor (ER)-positive disease have a continuous long-term risk for fatal breast cancer spanning more than 20 years, but the biological factors influencing this risk are unknown. Here we aimed to investigate the long-term survival and benefit from tamoxifen therapy for patients with Luminal A and Luminal B subtype tumors. **Methods:** The Stockholm Tamoxifen (STO-3) trial enrolled 1780 postmenopausal patients from 1976 until 1990 with lymph node-negative breast cancers and tumors less than or equal to 30 mm in diameter, randomly assigned to at least two years of adjuvant tamoxifen (40 mg daily) vs no adjuvant treatment. All patients had a complete long-term follow-up until December 31, 2012, and detailed patient and clinical information. Gene expression data was generated using custom designed Agilent arrays from FFPE breast cancer tumor tissue and was used to define Luminal A and Luminal B subtype tumors. ER, PR, HER2 and Ki-67 were also reassessed in 2014. Long-term breast cancer-specific survival was performed using Kaplan-Meier analysis and flexible parametric survival models were used to estimate the time-varying hazard ratios (HRs) adjusting for patient and tumor characteristics. **Results:** A statistically significant difference in long-term survival (25 years) by Luminal subtype and trial arm was seen (Log Rank, $P < 0.0001$). For Luminal A and Luminal B patients, the 25 year survival was 88% versus 69% for treated patients and 73% versus 58% for untreated patients. Luminal A patients in the tamoxifen treated arm had a significantly reduced long-term risk of fatal breast cancer up to 20 years after breast cancer diagnosis (HR at 15-years: 0.59; 95% CI, 0.35-0.98; and HR at 20-years: 0.65; 95% CI, 0.32-1.30) as compared to the untreated arm. However for patients with Luminal B tumors, a significantly reduced long-term risk was only seen up to 10 years after diagnosis (HR at 5-years: 0.37; 95% CI, 0.18-0.73; and HR at 10-years: 0.68; 95% CI, 0.31-1.47). **Conclusions:** Patients with Luminal A subtype tumors have a long-term benefit from tamoxifen therapy, whereas the benefit for patients with Luminal B tumors is up to ten years after diagnosis. Clinical trial information: STO-3 trial from 1976 no registration# at the time.

542 Poster Session (Board #34), Sat, 8:00 AM-11:30 AM

Next-generation targeted sequencing (NGTS) investigating *CDK4* as a prognostic driver in pure invasive lobular breast carcinoma (ILC): Preliminary results in early-stage patients (pts) stratified according to a validated clinico-pathological model. *First Author: Luisa Carbognin, University of Verona, Verona, Italy*

Background: The aim of this analysis was to investigate the distribution of molecular abnormalities and their potential role as therapeutic targets (with particular regard to CDK4/6 alterations) in resected ILC pts, grouped according to prognosis. **Methods:** Clinico-pathological multi-center data of early-stage pure ILC pts were correlated to disease-free survival (DFS). A continuous score was derived according to multivariate Hazard Ratios, to develop a 3-class model. The model was validated in an external pts' cohort. Mutational and Copy Number Variation (CNV) analyses by NGTS, including 26 genes, were performed for pts at Poor and Good Prognosis (PP/GP). Quantitative-PCR analysis was applied for CNV validation; IHC for CDK6 was accomplished. Fisher's exact test and *Peto* Odds Ratio (OR) were adopted for comparison. **Results:** Data from 773 pts (Training/Validation Set [TS/VS]: 491/282) were gathered. At multivariate analysis, T-size and N-status were independent predictors for DFS. A significant difference between pts at low/intermediate/high risk was found (10-yrs DFS: 76.3%/67.6%/39.8%, respectively, $p < 0.0001$) in the TS. The model discriminated DFS in the VS ($p < 0.0001$). According to the developed model, 20 PP and 14 GP pts underwent molecular analysis. In PP group, *CDH1* was the most mutated gene (50.0%) followed by *PIK3CA* (35.0%). *MAP3K1* (10.0%), *ERBB2* and *PTEN* were mutated with low frequency (6.1%), only in the PP group. With regard to CNV, *CDH1* loss (55.0%) were the most frequent event, followed by gain in *ESR1*, *FGFR1* and *CDK4* (35.0%), which was present exclusively in PP group ($p = 0.03$) and validated by quantitative-PCR. Moreover, *CDK4* gain reported a significant higher chance to be associated with PP (OR = 7.98, 95%CI 1.51-42.1, $p = 0.014$). CDK6 overexpression showed a trend toward an association with PP (OR = 3.29, 95%CI 0.56-19.25, $p = 0.18$). **Conclusions:** These preliminary data first suggest that *CDK4* gain is potentially associated with PP. The potential *druggable* of this alteration deserves further clinical investigations in the context of ILC.

543 Poster Session (Board #35), Sat, 8:00 AM-11:30 AM

Association of a low-expression SLCO1B1 polymorphism with estrogen concentrations before and during aromatase inhibitor treatment for breast cancer. *First Author: Jacqueline M Dempsey, University of Michigan College of Pharmacy, Ann Arbor, MI*

Background: Three aromatase inhibitors (AI), the steroid exemestane, and the azoles anastrozole and letrozole, are effective in the treatment of estrogen receptor positive (ER+) breast cancer by preventing biosynthesis of estrogens including estradiol (E2), estrone (E1), and estrone-sulfate (E1S) in postmenopausal women. OATP1B1, encoded by *SLCO1B1*, transports E1S into the liver for desulfation to active E1. Women carrying the low-expression *SLCO1B1* rs4149056 single nucleotide polymorphism (SNP) have higher E1-conjugate levels (Dudenkov Breast Cancer Res Treat 2017). We hypothesized that patients carrying this SNP would have increased E1S at baseline, and this E1S reserve could resupply E1 and E2 resulting in detectable estrogen levels during AI treatment. **Methods:** Five hundred postmenopausal women with ER+ breast cancer were randomized 1:1 to either exemestane 25 mg/day or letrozole 2.5 mg/day. Plasma estrogen concentrations were measured prior to and after 3 months of AI treatment using LC/MS/MS (LLOQ for E2 = 0.625 pg/mL, E1 = 1.56 pg/mL, E1S = 3.13 pg/mL). The additive genetic associations between rs4149056 and 1) log-transformed concentrations of E2, E1, and E1S at baseline and 2) detectable (> LLOQ) concentrations of E2, E1, and E1S after 3 months of AI treatment, were tested using linear and logistic regression, respectively. **Results:** Patients carrying the low-expression rs4149056 (minor allele frequency = 0.18) SNP had 51% (per allele) higher baseline E1S concentrations (n = 438, 95% CI (29%-76%), $p < 0.0001$). After 3 months of AI treatment, 15% (58/378) of patients had detectable E1; carrying rs4149056 increased risk of maintaining detectable E1 by 84% (per allele) (odds ratio = 1.84, 95% CI (1.08-3.14), p = 0.025). **Conclusions:** Patients carrying a low-expression OATP1B1/*SLCO1B1* SNP have higher pre-treatment E1S and greater risk of maintaining detectable E1 during AI treatment, possibly due to replenishment from E1S reserves. Further studies are needed to assess whether this common SNP is associated with increased risk of AI treatment failure.

544 Poster Session (Board #36), Sat, 8:00 AM-11:30 AM

Patient(Pt)-reported toxicities by chemotherapy regimen for early breast cancer (BC) (LCCC1334/1440). *First Author: Kirsten A. Nyrop, UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC*

Background: Pt-reported outcomes reflect toxicity of anticancer drugs, and can be measured using "moderate, severe or very severe" ratings (MSVS) that mirror physician-assessed CTCAE grades 2-4. **Methods:** We prospectively collected pt-reported MSVS in pts with stage I-III BC at each cycle of conventional (neo)adjuvant chemotherapy. **Results:** In 135 patients, mean age was 52, 26% non-white, 32% ≤high school education. Fatigue, arthralgia, constipation, diarrhea, nausea, myalgia, and peripheral neuropathy toxicities varied significantly by chemotherapy regimen ($p < 0.05$). Pts who received anthracycline-based chemotherapy reported significantly more MSVS toxicities compared those who did not (mean 5.3 vs 3.5, $p < 0.001$). **Conclusions:** Modern (neo)adjuvant chemotherapy has substantial toxicity that varies by regimen; anthracycline-based regimens appear particularly difficult. These findings support efforts to tailor therapy and minimize overtreatment. Clinical trial information: NCT02328313.

Patient-reported MSVS toxicities, by chemotherapy regimen.

Impact of high deductible insurance on out-of-pocket cost burden in breast cancer. *First Author: Christine Lu, Department of Population Medicine, Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, MA*

Background: High-deductible health plans (HDHP) requiring out-of-pocket (OOP) costs for most services may place heavy economic burden on patients. This study examined the impact of modern HDHPs on OOP costs among women with early-stage breast cancer. **Methods:** We included 886 women with incident early-stage breast cancer, age 25 to 64 years, who were insured by employers that mandated a transition from low-deductible (< = $500/year) to high deductible (> = $1000/year) coverage, and 3099 exact matched contemporaneous patients whose employers offered only low-deductible plans. Measures were pharmacy and medical OOP costs per person-year. Medical services were categorized as inpatient, emergency room (ER), primary care visits, and outpatient care which included specialist visits, radiology, lab tests, and chemotherapy. We calculated OOP costs as the sum of deductibles, copays, and coinsurance. Effect estimates of changes between study groups were established using difference-in-differences analyses. **Results:** HDHP members faced an absolute baseline-to-follow-up increase in total OOP costs of $1067 per person-year compared to controls ($p = < 0.001$). The absolute change in medical OOP costs per person-year among HDHP members compared to controls from baseline to follow-up was significant ($1004, 95% CI: [$580, $1429]) and the relative change was also significant (41.2%, 95% CI: [17.8%, 64.5%]). The increase in medical OOP costs was driven by increases in outpatient care OOP costs. The absolute change in outpatient care OOP costs per person-year among HDHP members compared to controls from baseline to follow-up was $919 (95% CI: [$506, $1332]; relative change: 43.7%, 95% CI: [17.0%, 70.5%]). Changes in OOP costs for pharmacy, inpatient, ER, and primary care visits were not significant. **Conclusions:** In this rigorous, natural experimental study, women with incident breast cancer experienced increases in total OOP costs after employer-mandated HDHP switches, a change driven by a 44% increase in outpatient care OOP costs. Further research should examine which outpatient services contributed to this substantial economic burden, when the differences occur and the proportion of women reaching their annual deductible.

546 Poster Session (Board #38), Sat, 8:00 AM-11:30 AM

Patient(Pt)-reported toxicities during breast cancer (BC) chemotherapy (CRx): Associations with pre-treatment (Tx) measures of quality of life (QOL) and Tx discontinuation. *First Author: Kirsten A. Nyrop, UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC*

Background: CRx completion is essential to Tx effectiveness and may depend on pt-reported toxicities rated "moderate, severe or very severe" (MSVS) that mirror physician-assessed CTCAE grades 2-4. Methods: We prospectively collected pt-reported MSVS in pts with stage I-III BC at each cycle of conventional (neo) adjuvant CRx. Pts also completed a pre-Tx measure of QOL (Functional Assessment of Cancer Therapy-General). Results: 158 pts were mean age 54, 28% non-white, 37% ≤high school (HS), 56% married. 44% received anthracycline-based CRx. Pt-rated maximum toxicity level was 12% mild, 37% moderate, 33% severe, and 18% very severe. Mean number of toxicities rated MSVS was 4.5 (range 0-12), with 51% rating ≥4 toxicities as MSVS. In multivariable analysis (R^2= 45%), un-married ($p = .04$), ≤HS ($p = .03$), lower pre-Tx QOL ($p < .0001$), and anthracycline-based CRx ($p = .001$) were associated with increased number of MSVS toxicities. 28 pts (18%) discontinued CRx. Mean number of MSVS toxicities was 5.5 (range 1-7) in pts who discontinued CRx compared to 4.3 (range 0-11) in pts who completed CRx ($p = .08$). Mean number of severe/very severe toxicities was 2.0 (range 1-7) in pts who discontinued CRx compared to 1.3 (range 0-9) in pts who completed CRx ($p = .01$). Conclusions: Pt characteristics and pre-Tx QOL are associated with pt reports of Tx toxicities. Cumulative number of higher severity toxicities is associated with CRx discontinuation. Patients whose chemotherapy treatment was discontinued, by patient-reported symptom severity Clinical trial information: NCT02328313.

547 Poster Session (Board #39), Sat, 8:00 AM-11:30 AM

Treatment and outcomes in older women with DCIS: SEER-Medicare 2007-2013. *First Author: Mary Chen Schroeder, University of Iowa, Iowa City, IA*

Background: Ductal carcinoma in situ (DCIS) is a low-risk precursor lesion for which hormonal therapy (HT) has been shown in clinical trials to lower risk of subsequent (subs) breast cancer (bc) but not improve overall survival (OS). We report population-based uptake of HT and outcomes by type of local therapy. **Methods:** SEER-Medicare data identified women (wm) with no comorbidity, ages 66+ and diagnosed 2007-2013 with DCIS as first cancer. Wm were required to have Medicare Parts A, B & D at diagnosis. Treatments were identified with Medicare claims (2007-2014): surgery within 6 months and HT within one year of diagnosis. Outcome and survival analyses included 2007-2009 diagnoses, for adequate follow up. Subs breast events were identified: any bc and ipsilateral invasive bc (ips ibc). Local therapy included NONE, lumpectomy (BCS), BCS with radiation (w/XRT), and mastectomy (MAST). **Results:** 4,098 wm with DCIS were studied. 40.7% of wm received HT: 26.7% Tamoxifen, 14.0% an aromatase inhibitor. HT use varied by local therapy [BCS (32.8%), BCS w/XRT (52.0%), MAST (28.0%), NONE (19.6%), $p < 0.01$] but not race [white (40.4%), black (46.3%), other (38.7%), $p = 0.13$]. More wm ages 66-74 received HT than wm aged 75+ (45.9% v 32.7%, $p < 0.01$). Outcomes for the full cohort are shown (Table). For wm ages 66-74 outcomes did not differ between those having NONE v any local therapy [5yr OS (95.7% v 96.9%, $p = 0.71$), subs bc (0% v 4.2%, $p = 0.31$), subs ips ibc (0% v 1.0%, $p = 0.64$)]. On multivariate Cox model of wm 66-74, HT was associated with better OS (HR = 0.60, CI: 0.40-0.9992, $p = 0.0497$) but not marital status or age (66-69 v 70-74, HR = 1.56, $p = 0.10$); blacks had worse OS than whites (HR = 2.45, $p = 0.01$). **Conclusions:** In this large population-based cohort of older wm with DCIS, about half received HT. Wm who received HT had fewer subs bc and superior survival. OS for wm who elected NONE was inferior to those undergoing local therapy, though this was not significant for wm ages 66-74. These findings suggest opportunities remain to improve outcomes for wm with DCIS.

Urgent hypertension as a biomarker for bevacizumab in the curative setting. *First Author: Nawal Kassem, Indiana University School of Medicine, Indianapolis, IN*

Background: Bevacizumab is FDA approved across many tumors including lung, colon, and glioblastoma. It is unclear which patients are destined to respond and/or experience the most toxicity. We previously demonstrated that bevacizumab-induced hypertension (HTN) in the metastatic breast cancer setting (E2100) was correlated with an improved overall survival (OS). In this study we evaluated the impact of bevacizumab-induced urgent HTN on outcome in the curative setting in E5103 and BEATRICE. We further evaluated for germline biomarkers to predict patients destined to experience HTN using whole exome sequencing (WES). **Methods:** Cases were defined as those who experienced urgent HTN (systolic blood pressure (SBP) $>$ 180 mmHg) and controls included those with SBP $<$ 160 mmHg. Log rank test was used to compare DFS and OS between cases and controls. WES was performed using germline DNA from patients in E5103 and BEATRICE. Exomes were enriched via Ion AmpliSeq Exome RDY kits. Templates were prepared on Ion Chef Systems and sequenced on Ion Proton Sequencers. Rare variants with a minor allele frequency $<$ 3% and those which were predicted to be deleterious by standard protein prediction programs were retained. A gene-based, case-control analysis using SKAT was performed to generate level of significance. **Results:** There were 93 cases of urgent HTN and 3000 matched controls. Patients with urgent HTN had a markedly superior DFS (p-value = 0.01) and superior OS (p-value = 0.02). There was no effect seen in the control arm. We also identified rare variants in SLC7A7 as predictors of urgent hypertension. **Conclusions:** Urgent HTN is associated with improved outcomes in the curative setting. We have also identified rare variants associated with severe HTN through WES. Exploring the biology of those who experience bevacizumab-induced HTN may help explain the heterogeneity of outcomes and elucidate secondary drug targets.

549 Poster Session (Board #41), Sat, 8:00 AM-11:30 AM

Timing of initiation of neratinib after trastuzumab-based adjuvant therapy in early-stage HER2+ hormone receptor (HR)-negative breast cancer: Exploratory analyses from the phase III ExteNET trial. *First Author: Bent Ejlertsen, Department of Oncology, Rigshospitalet, Copenhagen, Denmark*

Background: ExteNET, an international, randomized, placebo-controlled phase III trial, showed that neratinib given for 1 year after trastuzumab-based adjuvant therapy significantly improved 2- (HR 0.67, p = 0.009) and 5-year (HR 0.73, p = 0.008) invasive disease-free survival (iDFS) in early-stage HER2+ breast cancer [Chan et al. 2016; Martin et al. 2017]. Pre-specified subgroup analyses showed greater benefit with neratinib in HR+ than HR tumors, and in patients who initiated neratinib ≤12 months of completing trastuzumab. To better understand the effects of neratinib in patients with HR disease, we examined the impact on efficacy of the interval from prior trastuzumab to start of neratinib in the HR subpopulation. **Methods:** Patients with early-stage HER2+ breast cancer received oral neratinib 240 mg/day or placebo for 1 year after standard trastuzumab-based (neo)adjuvant therapy. iDFS, the primary study endpoint, was examined in subgroups categorized according to the interval between completing trastuzumab and randomization (i.e. 06, 612 and $>$ 12 months). Data cut-off: March 1, 2017. Clinicaltrials.gov: NCT00878709. **Results:** The ITT population comprised 2840 patients; 1209 (43%) had HR disease (neratinib, n = 604; placebo, n = 605). Results after a median of 5.2 years in the HR subgroup are shown below. **Conclusions:** Patients with HER2+ HR tumors tend to recur early. The risk of recurrence is higher in patients who have recently completed trastuzumab-based therapy (reflected in the iDFS rates of the placebo group). Consistent with these observations, our analyses suggest that the benefits of neratinib in HR disease are greater when treatment is started closer to completion of trastuzumab (i.e. ≤6 months). Clinical trial information: NCT00878709.

Interval between prior trastuzumab and randomization, months	n	5-year iDFS rate, %		Hazard ratio (95% CI)[a]
		Neratinib	Placebo	
06	695	88.9	86.1	0.73 (0.471.14)
612	268	86.1	91.7	1.61 (0.733.70)
> 12	246	91.3	93.7	1.39 (0.523.90)

550 Poster Session (Board #42), Sat, 8:00 AM-11:30 AM

Adjuvant tamoxifen adherence in men with early stage breast cancer. *First Author: Oluchi Oke, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Most male breast cancers (MBC) are hormone-receptor positive, part of the standard treatment of these patients includes adjuvant tamoxifen. Prior small, single-institution studies have suggested that men may have high rates of discontinuing adjuvant endocrine treatment. We examined rates of tamoxifen discontinuation and medication adherence in a large population-based cohort of MBC patients. **Methods:** In the SEER-Medicare database male patients with non-metastatic MBC, diagnosed between 2007-2013, age 65 and older, with Part D coverage, and with tamoxifen prescriptions within one year of diagnosis were identified. The cumulative incidence of drug discontinuation was calculated for each year after diagnosis. Adherence was defined as a medication possession ratio (MPR) of $>$ -80% among those patients who were filling tamoxifen prescriptions. A logistic regression model was used to assess predictors of tamoxifen adherence. **Results:** We identified 451 patients who met eligibility criteria. Median age at diagnosis was 75 years. Median follow-up was 32.5months. 34% of patients had Stage I breast cancer, 48% Stage II, and 18% Stage III. Among those with known hormone receptor status, 99% had hormone receptor positive cancer. Rates of tamoxifen discontinuation were 19.8%, 30.7%, 39.6%, 46.8% and 61.4% at 1, 2, 3, 4, and 5 years after diagnosis, respectively. Among the men who were still taking tamoxifen, the corresponding adherence rates were 77.4%, 75.2%, 71.4%, 67.9%, and 63.5%. In the adjusted model, significant predictors of lower adherence included residing in a high poverty area (OR 0.26, 95% CI 0.08-0.86) and Charlson comorbidity score of ≥2 (OR 0.46, CI 0.21-1.00). **Conclusions:** Older men with breast cancer have high rates of tamoxifen discontinuation, with 61% of patients discontinuing tamoxifen before the end of year 5. In addition, even among those patients continuing tamoxifen, a substantial number of patients are non-adherent. Further research should evaluate potentially modifiable reasons for treatment discontinuation and lack of adherence to tamoxifen.

551 Poster Session (Board #43), Sat, 8:00 AM-11:30 AM

Predicting Oncotype DX scores using clinicopathologic features: A report from the National Cancer Database. *First Author: Catherine Pesce, Department of Surgery, NorthShore University Health System, Evanston, IL*

Background: The Oncotype DX recurrence score is used to predict the benefits of chemotherapy added to adjuvant hormone therapy in ER positive early-stage breast cancer. While its use has been validated and cost effectiveness has been established, its expense remains a concern in some health care systems and communities. Using clinical and pathologic features and the National Cancer Data Base (NCDB) we aim to predict patients with low or high Oncotype DX scores. **Methods:** From 2010-2014, 78,663 breast cancer patients with Oncotype DX scores were selected from the NCDB. Seven clinical and pathologic variables including age, ER, PR, histologic subtype, lymphovascular invasion (LVI), grade, and tumor size were used to predict high-risk ($>$30) or low-risk ($<$18) Oncotype DX scores using logistic regression. Data were split into training (70%) and testing (30%) sets for external validation. The predictive accuracy of the regression model was assessed using a Receiver Operator Characteristic (ROC) analysis. Model fit was analyzed by plotting the predicted probabilities against the actual probabilities. Nomograms were created for visualization of the high-risk and low-risk models using bootstrap estimation method of the model coefficients. **Results:** Estrogen receptor status, progesterone receptor status, and grade were the strongest predictors of both low-risk and high-risk Oncotype DX scores, followed by age, histology, tumor size, and LVI, yielding AUC of 0.70 for the low-risk model and 0.86 for the high-risk model. **Conclusions:** We have developed a model that can predict high-risk Oncotype DX scores with very good reliability. Such a tool may be useful in health care systems with limited resources. Model Coefficients of Strongest Predictors of High-Risk Oncotype DX Score

Factors		Coefficients
ER	negative	2.977
PR	negative	2.095
Grade	well differentiated	0.000
	moderately differentiated	1.356
	poorly differentiated	3.374
Tumor size	$<$ 10mm	0.000
	10-20mm	0.264
	20-30mm	0.584
	30mm+	0.78

552 Poster Session (Board #44), Sat, 8:00 AM-11:30 AM

Estimation of historical control rate for a single arm de-escalation study: Application to the POSITIVE trial. *First Author: Zhuoxin Sun, IBCSG Statistical Center, Boston, MA*

Background: A randomized, controlled clinical trial is the optimal method to evaluate the effect of an experimental therapy. However a single arm trial can be used when randomization is infeasible or unethical. POSITIVE is a prospective, single arm, international study aimed at young (age 18-42) women with endocrine responsive (ER+) breast cancer (BC) who desire pregnancy. It will assess whether temporary interruption of adjuvant endocrine therapy (for up to 2 yrs) after 18-30 months of use is safe in terms of risk of recurrence. We describe methods to estimate a historical control rate for POSITIVE using data from the SOFT/TEXT Phase 3 trials. **Methods:** The primary endpoint of POSITIVE is breast cancer recurrence (BCR) at 3 yrs. In this analysis, we first identified a cohort of SOFT/TEXT pts meeting POSITIVE eligibility criteria. Method I uses the SOFT/TEXT cohort to calculate 3 yr annualized hazard rates by a piecewise exponential model and 3 yr BCR rate by Kaplan-Meier (KM) estimate. Method II uses the SOFT/TEXT cohort to group-match SOFT/TEXT pts to POSITIVE pts; sample sets of SOFT/TEXT pts were randomly drawn with replacement 5000 times to obtain sets having baseline characteristics well-balanced with POSITIVE pts. The mean 3 yr annualized hazard rates and 3 yr KM BCR rates, and their 2.5th and 97.5th percentiles, were estimates (95% CI) for the control group. **Results:** 149 POSITIVE pts were included; 1499 SOFT/TEXT pts met the eligibility criteria. POSITIVE pts were younger, had fewer positive nodes, and fewer received chemotherapy. Method II refines Method I to adjust for the imbalanced characteristics and provides more precise estimates of the annualized BCR hazard rates and 3 yr BCR rates (Table). Clinical trial information: NCT02308085. **Conclusions:** The methods used only baseline characteristics of the POSITIVE study and in addition to final analysis interpretation, have a potential role for trial monitoring. The methods should, and will, be applied using data from other sources (e.g. ABCSG-12, ASCO CancerLinQ) to assure a consistent, robust estimate of an historical control rate across different cohorts.

	Annualized BCR hazard rate	95% CI	3 yr BCR rate	95% CI
Method I	3.4%	2.8%, 4.0%	9.5%	7.9%, 11.1%
Method II	3.1%	2.6%, 3.7%	8.7%	7.2%, 10.3%

553 Poster Session (Board #45), Sat, 8:00 AM-11:30 AM

Evaluation of the OncoMasTR prognostic signature in postmenopausal women with primary ER-positive breast cancer. *First Author: Ivana Sestak, Centre for Cancer Prevention, Wolfson Institute of Preventive Medicine, Queen Mary University of London, London, United Kingdom*

Background: The assessment of distant recurrence (DR) risk in patients with early estrogen receptor (ER) positive breast cancer receiving adjuvant endocrine therapy is essential in making decisions on additional treatment. OncoMasTR (OM) is a continuous risk prediction model that provides a quantitative assessment of the likelihood of DR in patients with ER-positive breast cancer. The aim of this study was to assess the prognostic performance of OM in predicting DR for postmenopausal patients treated with anastrozole or tamoxifen. **Methods:** OM incorporates three genes and was developed in an endocrine treated population. OMclinical incorporates clinical parameters into the molecular OM. OM was evaluated for 648 ER-positive, HER2-negative patients with 0 to 3 involved lymph nodes in the TransATAC cohort. DR was the primary endpoint. Cox regression models were used to assess the prognostic performance. OM was evaluated for the overall time period and secondarily for late DR (years 5-10), and in node-negative and node-positive patients separately. **Results:** OM and OMclinical were highly prognostic for the prediction of DR in years 0-10 among all patients ($LR\chi^2$= 25.43 and $LR\chi^2$= 48.73, respectively, $P < 0.001$). OM/OMclinical provided significant additional prognostic value beyond standard clinicopathological variables. In women with node-negative disease, OM identified 37.8% of women as low risk with a 10-year DR risk of 3.5% (1.6-7.7), which was significantly lower compared to those categorised as high risk (10-year DR risk: 16.4% (12.4-21.5); HR = 4.8 (2.0-11.2)). Similar risk stratification and 10-year DR risks were observed for OMclinical in women with node-negative disease (HR = 6.5 (2.6-16.3)). Little prognostic information was provided for node-positive patients. OM and OMclinical were also highly prognostic for the prediction of late DR ($LR\chi^2$= 12.84 and $LR\chi^2$= 25.61, respectively, $P < 0.001$). **Conclusions:** OM and OMclinical were highly prognostic for early and late DR in women with early-stage (particularly node-negative) ER-positive breast cancer receiving 5 years of endocrine therapy and merit further evaluation as risk stratifiers to identify women who can safely forego chemotherapy.

554 Poster Session (Board #46), Sat, 8:00 AM-11:30 AM

Balancing the risks versus benefits of trastuzumab: A call to action for oncologists, cardiologists, and cardio-oncologists. *First Author: Moira Katherine Rushton, University of Ottawa - Post Graduate Medical Education, Ottawa, ON, Canada*

Background: One year of adjuvant trastuzumab (T) is standard for early stage (I-III) HER2 + breast cancer (BC) patients (pts). Cardiac imaging is recommended every 3 months during treatment to monitor for cardiotoxicity (CTx) without evidence this practice improves pt care. Up to 30% of pts will experience transient, asymptomatic, drops in left ventricular ejection fraction (LVEF) on T, which may lead to early termination of T. Our objective was to evaluate the impact of routine CI on disease free (DFS) and overall survival (OS) in early stage HER2+ BC. **Methods:** Retrospective population-based cohort study of early stage BC pts treated with adjuvant T in Ontario, Canada, 2007–2016. Patient-level data was sourced through the Institute for Clinical Evaluative Sciences, which captures all patients in Ontario. The cohort was divided into three arms; A: 17-18 cycles T, no CTx; B: no CTx, ≤16 cycles T, stopped within 30 days of last cardiac imaging; C: developed CTx. CTx was defined as new diagnosis heart failure (HF), cardiomyopathy (CM) or pulmonary edema within 90 days of last cycle of T. Primary outcome: DFS; secondary outcomes: OS, cancer-specific, and cardiovascular mortality. Survival analysis was performed using Cox and subdistribution hazard models. **Results:** 4820 pts met inclusion criteria; 4018, 442 and 360 in arms A, B, and C respectively. Median cycles of T were 18, 13 and 14 in arm A, B and C. 5-year DFS was significantly worse in arms B (70.3%; 95% CI 63.5-74.7) and C (74.9%; 69.5-79.5) vs. 93.2% (92.3-94.0) arm A; HR for DFS were 2.96 (2.35-3.72) and 2.41 (1.87–3.12) respectively. 5-year OS was significantly worse in arms B (75.4%) and C (80.1%) vs. arm A (95.2%); HR for OS 3.99 (3.10–5.14) and 2.98 (2.24–3.95) respectively. All p-values were < 0.05. **Conclusions:** BC pts in Ontario who did not complete adjuvant T had significantly worse DFS and OS. A significant population stopped T shortly after cardiac imaging, without developing CTx, likely due to detection of asymptomatic drops in LVEF. These findings support the need to consider strategies to continue cancer therapy in pts with abnormal cardiac imaging, including concurrent optimization of cardiac function and cardiac risk factors.

555 Poster Session (Board #47), Sat, 8:00 AM-11:30 AM

Comparison of outcomes for AJCC 8th Anatomic and Prognostic staging in contemporary triple negative breast cancer (TNBC) multisite registry. *First Author: Rajvi H. Shah, University of Kansas Medical Center, Westwood, KS*

Background: Eighth edition of the AJCC TNM staging system incorporates biological prognostic factors along with the traditional anatomical factors and currently Prognostic (P) stage must be used for reporting of all cancer patients in the US. Comparison of patient distribution between P and Anatomic staging and outcomes associated with the P stages in a contemporary TNBC population are not known. **Methods:** 574 patients with stage I-III TNBC were enrolled in an IRB approved multisite prospective registry between 2011 and 2017. Patients were followed for recurrence and survival. AJCC 8th edition Anatomic (A) Stage and clinical Prognostic (P) stage groups were applied to all patients. Recurrence free survival (RFS) (STEEP criterion) was estimated according to the Kaplan-Meier method and compared among groups by log-rank test. **Results:** Median age was 53 years (23-85). 96% of patients received neo/adjuvant chemotherapy. 82% (468/574) of patients were upstaged on P compared to A staging. Significantly lower numbers of patients were categorized within P stage II (36%) compared to A stage II (51%) (p = 0.001). Conversely, higher number of patients were categorized within P stage III (29%) compared to A stage III (14%) (p = 0.0001), with largest relative increase in stage IIIC (3% to 13%). Table 1 provides 5 years RFS for all A and P stages. Compared to A stage IIIAB, P stage IIIAB was associated with better RFS (HR = 0.42 [0.21-0.86]; p = 0.013), whereas P and A stages IIIC had similar RFS. This suggests appropriate upstaging of TNBC patients to IIIC on P staging. **Conclusions:** 82% of TNBC patients are upstaged on P staging compared to A staging. Knowledge of outcomes associated with various P stages can guide prognostic counselling for TNBC patients who plan to undergo standard local and systemic treatment.

	Stage			5 year RFS (Est)	
N = 574	**Anatomic**	**Prognostic**	**P value**	**Anatomic**	**Prognostic**

Role of cardiac reserve as a tool to unmask cardiotoxicity following anthracycline therapy and whether exercise training can attenuate cardiotoxicity. *First Author: Steve Fraser, Deakin University, Burwood, Australia*

Background: Anthracycline-based chemotherapy (AC) is associated with an increased risk of cardiac damage and long-term heart failure. However, diagnosis of cardiac damage is infrequent, while long-term heart failure risk is substantial. Thus, we sought to evaluate whether exercise cardiac reserve may be a more sensitive marker of cardiac toxicity than standard measures of cardiac function and if exercise training maintained cardiac function and exercise capacity during AC. **Methods:** 28 BC patients undergoing AC were recruited into a non-randomised trial and allocated to exercise training (ET) (46.7±9.0 yrs, n = 14) or usual care (UC; 53.2±8.9 years, n = 14), respectively. Tests including echocardiography (left ventricular ejection fraction [LVEF] and global longitudinal strain [GLS]), cardiopulmonary exercise test (peak oxygen uptake, VO_2peak), and exercise cardiac magnetic resonance imaging (exCMR, cardiac reserve) were performed prior to and after completion of AC. The ET group completed a twice weekly supervised aerobic and resistance exercise program at a moderate-vigorous intensity. **Results:** There was a small statistically significant reduction resting in LVEF in both UC and ET, whereas GLS was unchanged (Table 1). VO_2peak fell by 15% in the UC, while ET significantly attenuated the decline in fitness (~4%). Cardiac reserve was reduced following AC (Visit×Exercise P= 0.05), which was not attenuated by exercise training (Visit×Exercise×Group P= 0.06). Exercise training had no effect on resting measures of LV function (Table 1). Clinical trial information: ACTRN12616001602415. **Conclusions:** AC treatment caused profound reductions in peak oxygen uptake and impaired cardiac reserve. Resting measures of cardiac function did not account for the large reduction in VO_2peak which was attenuated by exercise training.

Effect of AC and ET on resting measures of cardiac function, biomarkers and peak oxygen uptake.

557 Poster Session (Board #49), Sat, 8:00 AM-11:30 AM

CA15-3/MUC1 in CCTG MA-32 (NCT01101438): A phase III RCT of the effect of metformin vs. placebo on invasive disease free and overall survival in early stage breast cancer (BC). *First Author: Ryan JO Dowling, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: The diabetes drug metformin may improve BC outcomes through enhanced obesity-related physiology or direct anti-tumor effects. We studied the effect of metformin on CA15-3 (the soluble moiety of the MUC1 protein), a marker associated with BC prognosis that also has mitogenic and metabolic effects that favor tumorigenesis. **Methods:** 3,256 women with T1-3, N0-3, M0 BC who had completed standard therapy (ongoing hormone therapy permitted) provided fasting blood (stored at -80C) at baseline and 6 months. CA15-3 and insulin were measured by Roche ECLIA; leptin, and hs-CRP by Luminex Milliplex MAP and Roche ITA. Spearman coefficients were calculated and comparisons analyzed using Wilcoxon signed rank test and multivariable linear regression models. Tests were two-sided. **Results:** Mean age was 52.3 and BMI 28.6 kg/m^2. Tumor and treatment characteristics were balanced between arms (overall: T2/3 in 59.8%, N +ve in 52.9%, grade 1/2/3 in 9.1%/35.3%/54.4%, ER+ in 69.6%, HER2+ in 17.1%; 50.4% underwent mastectomy, 74.0% received radiation, 89.2% chemotherapy, 17% trastuzumab, and 64.4% hormones). Baseline values and 6 month changes are shown below. In multi-variable analyses (including age, BMI, tumor characteristics, treatment), metformin (vs placebo) led to a greater relative reduction in CA15-3 (-5.81%; 95% CI: -3.94% to -7.64%, p < 0.0001). CA15-3 change at 6 months significantly correlated with change in BMI (r=0.10, p<0.0001), glucose (r=0.05, p=0.011) and hsCRP (r=0.05, p=0.022). **Conclusions:** Metformin significantly lowered CA15-3; change in CA15-3 was associated with improved obesity-associated physiology and BMI, consistent with hypothesized beneficial actions of metformin. Clinical trial information: NCT01101438.

Association of clinical/pathological parameters with axillary involvement in early breast cancer in patients with limited sentinel node involvement (< 3 LK) after neoadjuvant chemotherapy (NACT). *First Author: Hans-Christian Kolberg, Marienhospital Bottrop, Klinik für Gynäkologie und Geburtshilfe, Bottrop, Germany*

Background: The association between pathological complete remission (pCR) in the breast and clinical/pathological parameters is well established, whereas the association of clinical/pathological parameters and residual axillary involvement after NACT is still not sufficiently defined. We used data from the SENTINA trial to analyze this association in a patient population with limited sentinel lymph node (SLN) involvement. **Methods:** Patients were included if before NACT they presented with a clinically negative axilla but showed involvement of SLNs prior to NACT (Arm B). Analysis was restricted to patients with < 3 involved SLNs before NACT. All patients received SLNB and axillary dissection after NACT. Univariate and multivariate analyses were carried out to evaluate the association between clinical/pathological parameters and axillary involvement after NACT. **Results:** Arm B of the SENTINA study contained 360 patients, 265 of which were evaluable with respect to the above parameters. After NACT 66/265 (24.9%) patients had involved SLNs or non-SLNs after NACT; 71/265 (26.8%) achieved a pCR in the breast. We observed a significant association between pCR in the breast and ER negativity (p < 0.0001), PR negativity (p < 0.0001) and triple negative (TN) status (p = 0.001). However, no statistically significant association between residual axillary involvement after NACT and clinical/pathological parameters ER (p = 0.381), PR (p = 0.52), HER2 (p = 0.771), TN status (p = 0.937), grade (G) 1 (p = 0.081), G 2 (p = 0.335), G 3 (p = 0.747), age (p = 0.789), tumor size before NACT (p = 0.761) and pCR in the breast (p = 0.136) could be demonstrated. **Conclusions:** Our analysis demonstrates that patients enrolled in the SENTINA trial with clinically negative axilla but limited SLN involvement show positive axillary nodes in 24.9% of cases after NACT. We found no association between residual axillary involvement after NACT and clinical/pathological parameters. We could not identify a subset of patients in this cohort for whom axillary surgery after NACT could be safely omitted.

560 Poster Session (Board #52), Sat, 8:00 AM-11:30 AM

Hypofractionated whole breast IMRT and brachytherapy boost after conservative surgery for breast cancer: Early results of a prospective non-randomised trial. *First Author: Ines Guix, IMOR Foundation, Medical Institute for Radiotherapy and Oncology, Barcelona, Spain*

Background: To report the early results obtained in a prospective group of patients (pts) treated with whole breast IMRT radiotherapy plus brachy. boost to tumor bed after conservative surgery (CS), given either with hypofractionated or normofractionated radiotherapy. **Methods:** Between 10/2008 and 06/2016, 1,277 pts with < 4cm, N0-2 breast cancers treated with CS entered the study. Pts were offered to be treated either with IMRT hypofr. whole breast and lymph areas (if needed) radiotherapy 42.6 Gy (266cGyx16) plus a 7 Gy brachy. boost, (hypofractionated group) or IMRT normofr. 50 Gy (200cGyx25) to the whole breast and lymph areas (if needed) plus 16 Gy brachy. boost (200cGyx8) (normofractionated group). Treatment assignation was done according to the pts preference or, if none, were randomly assigned to have both groups uniformly balanced. Systemic therapy was given as needed. During treatment and follow-up special attention was taken to early and late side-effects, breast fibrosis, arm lymphedema, skin reaction, patient satisfaction and local, regional and distant disease control. **Results:** A total of 638 pts were included in the hypofractionated group and 639 in the normofractionated group. All pts completed treatment. Pts were evaluated in a weekly basis during treatment and every 3 months for the first 2 years of follow-up and in a yearly basis after. Photographs were taken at each visit. SOMA-LENT scales were used in every visit. For quality of life EORTC QLQ-C30 plus the BR-15 module were used. No patient had adverse side-effect that required treatment ending in any group. In the hypofract. group, there were 10 local recurrence, 11 distant metastases and 6 death due to the disease. In the normofract. group there were 12 local recurrences, 9 distant metastases and 7 patients died due to the disease. **Conclusions:** Hypofractionated IMRT to the whole breast followed by a 1 fraction HDR breast implant was a safe and effective method of treatment for early breast cancer treated with conservative surgery, even in those patients N+ in which the supraclavicular fossa was included in the treatment fields. Patient satisfaction was greater in the hypofractionated group.

561 Poster Session (Board #53), Sat, 8:00 AM-11:30 AM

Results from a pilot of an innovative 4R Cancer Care Delivery Model in early breast cancer: Impact on timing and sequencing of guideline recommended care. *First Author: Christine B. Weldon, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: Under the "NCI ASCO Teams" Project, we proposed a 4R Model of teamwork and patient self-management (Trosman JOP '16). 4R = Right Info / Care / Patient / Time. It enables patient and care team to manage timing / sequencing of interdependent care with an innovative multimodality personalized 4R Care Project Plan. We piloted 4R at 3 centers (academic, community, safety net) and assessed impact on timing / sequencing of guideline based care. **Methods:** 4R Plans were administered to breast cancer patients stage 0-III Sept '17 – Aug '17. Clinical data for 185 patients who received 4R (4R cohort) were compared with a historical control cohort of comparable patients who received care pre-4R, Jun '16 – May '17. We used simple frequencies and Fisher's exact test in analyses. **Results:** We improved timing / sequencing of 7 guideline recommended metrics (Table). Significant improvements were shown for care lacking in the control cohort. 4R improved rate of patients receiving genetic test results and fertility in a timely manner. Neoadjuvant therapy rate doubled, but low sample size precluded statistical conclusions. However, timing / sequencing of care needed prior to neoadjuvant therapy (eg fertility, flu shot) were significantly improved. **Conclusions:** The 4R model significantly improved timing / sequencing of guideline recommended care in early breast cancer. An ongoing 4R pilot at 12 additional cancer centers across the U.S. is continuing to accrue patients and focusing on other guideline-recommended metrics.

Prospective phase II multicenter trial of ablation after breast lumpectomy added to treat (ABLATE) breast cancer without radiation. *First Author: V. Suzanne Klimberg, University of Arkansas for Medical Sciences, Little Rock, AR*

Background: Background:A plethora of studies have failed to define a group of patients that can forgo radiation to complete BCS without a significant increase in recurrence rate. This has resulted in overtreatment with radiation of an estimated 85% of patients with favorable breast cancers. RFA added to standard BCS (eRFA) may not only reduce the need for re-excision for close or focally positive margins but may obviate the need for whole breast irradiation in favorable breast cancer patients. **Methods:** In an IRB-approved risk-adjusted protocol, 267 T0-2, No breast cancer patients from 7 different sites were screened for a Phase II multicenter protocol of BCS followed by cavitary RFA (eRFA) without adjuvant radiation and followed for margins, recurrence, breast pain, cosmesis and QOL. **Results:** 242 patients were accrued to the study with a median follow-up of 36 months. Re-excision for positive margins was $< 5\%$. The in breast recurrence rate was 2.5%. In this risk adjusted model XRT was added when SLNB was positive. 20% of cohort received XRT. Breast pain @ 6 months was 19% with RFA+XRT Versus 1.7% with RFA alone($p < 0.05$). Cosmesis was good or excellent in $> 90\%$ of patients. QOL did not change after eRFA. **Conclusions:** eRFA may be a new paradigm for treating favorable patients that desire lumpectomy who either cannot or do not want radiation. A majority of the patients avoided re-excision, WBI and/or mastectomy. Treatment in lieu of XRT is safe and effective and may increase definitive treatment compliance for patients as it is complete at the time of surgery. Clinical trial information: 01153035.

563 Poster Session (Board #55), Sat, 8:00 AM-11:30 AM

At surgery for a core needle biopsy diagnosis of ductal carcinoma in situ with microinvasion: Is sentinel lymph node biopsy required? *First Author: Meghan Rose Flanagan, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Surgical excision upstages approximately 20% of patients with a core needle biopsy (CNB) diagnosis of ductal carcinoma in situ (DCIS) to invasive cancer, a rate insufficient to recommend *routine* sentinel lymph node biopsy (SLNB) at the initial procedure. The rate of upstaging for patients with a CNB diagnosis of DCIS with suspected or definite microinvasion (DCISM) is unknown, as is the role of SLNB. **Methods:** We identified consecutive patients with a CNB diagnosis of DCISM, suspected or definite, who underwent surgical excision between 2007 and 2017. The extent of DCISM was stratified as suspicious focus (n = 106), single focus (n = 187), multiple foci in a single biopsy (n = 69) or multiple foci in multiple biopsies (n = 24) (Table). SLNB was performed in 77%, 94%, 96% and 100%, respectively. CNB strata were correlated with imaging characteristics and final pathology in the breast and SLN. **Results:** Across CNB strata there were no clear differences in imaging characteristics. Although there was a trend toward higher final T and N stage with increasing extent of DCISM, the median extent of invasive cancer on final pathology was 0.2 cm for all strata. Among patients with CNB suspicious for DCISM, 28% were upstaged to T1a or greater but the SLNB was positive in only 1 patient (1%). In the definite DCISM strata, 37-46% were upstaged to T1a or greater, and 1-12% were at least pN1. **Conclusions:** In patients with suspicion of DCISM on CNB, 28% were upstaged to invasive cancer but the frequency of SLN metastasis is low, suggesting that SLNB may be deferred to final pathology in this setting. For patients with definite DCISM on CNB, the frequency of clinically significant lymph node metastasis supports SLNB at initial surgery.

565 Poster Session (Board #57), Sat, 8:00 AM-11:30 AM

Comparison of breast conservative therapy to mastectomy in male breast cancer: A NCDB analysis. *First Author: Sarah Bateni, University of California Davis Medical Center, Sacramento, CA*

Background: Current treatment guidelines for male breast cancer (MBC) are largely based on clinical trials limited to female participants. With limited MBC research, it remains unclear if breast conservative therapy (BCT) is equivalent to mastectomy in MBC. Therefore, the purpose of this study was to compare survival among MBC patients for BCT vs. mastectomy using a large national database. **Methods:** We performed a retrospective analysis of 11,406 MBC patients with stage I-III disease from the National Cancer Database (NCDB) years 2004-2015, excluding Paget's, T4/inflammatory, and multicentric disease. Patients were grouped according to surgical and radiation therapy (i.e. BCT, lumpectomy alone, mastectomy alone, and mastectomy with radiation). After performing standard parametric and nonparametric univariate analyses, cox proportional hazards multivariate regression analysis was performed to compare overall survival by treatment group controlling for demographic and clinicopathologic group differences. **Results:** The majority of MBC patients underwent mastectomy alone (n = 6,326, 55%), with the remaining 19% (n = 2,162) undergoing mastectomy with radiation, 18% (n = 2,085) undergoing BCT, and 7% (n = 833) undergoing lumpectomy alone. Compared with mastectomy alone and mastectomy with radiotherapy, BCT was associated with younger age (62 vs. 66 vs. 63 years old, $p < 0.01$), smaller tumors (median 1.5 cm IQR 0.9-2.0 vs. 2.0 cm IQR 1.4-2.6 vs. 2.5 cm IQR 1.8-3.5, $p < 0.001$), and lower nodal disease rates (21% vs. 31% vs. 81%, $p < 0.001$). In the multivariate model, BCT was associated with greater survival compared to mastectomy alone (HR 1.69, 95%CI 1.44-1.98, $p < 0.001$), mastectomy with radiation (HR 1.52, 95%CI 1.27-1.83, $p < 0.001$), and lumpectomy alone (HR 1.91, 1.56-2.33, $p < 0.001$). Increased age, T stage, N stage, histological grade, and triple negative hormone receptor/HER2 status were associated with poorer survival ($p < 0.05$). **Conclusions:** Although mastectomy is more common among MBC, BCT is associated with greater survival. These findings support the use of BCT as a viable treatment approach in MBC and consideration of greater adoption among surgeons and oncologists.

566 Poster Session (Board #58), Sat, 8:00 AM-11:30 AM

Prediction of pathologic complete response by image-guided biopsy before surgery in breast cancer with complete clinical response to neoadjuvant chemotherapy: A prospective feasibility trial. *First Author: Han-Byoel Lee, Department of Surgery, Seoul National University College of Medicine, Seoul, Korea, Republic of (South)*

Background: Patients who attain a pathologic complete response (pCR) after neoadjuvant chemotherapy (NAC) have a favorable long-term outcome. In patients with pCR, it is suggested that the role of surgical excision may be limited to pathological confirmation, and thus may be omitted when pCR can be correctly predicted. The purpose of this study was to evaluate how accurately pCR can be predicted using MRI and image-guided biopsy. **Methods:** We prospectively enrolled 40 patients (mean age 47.1) between September 2016 and January 2018 who were suggested to have pCR on preoperative MRI. Lesion size ≤0.5cm or lesion-to-background parenchymal signal enhancement (SER) ratio ≤1.6 on MRI was defined as complete clinical response. Multiple core needle biopsy(CNB) (14G) or vacuum-assisted biopsy(VAB) (10G) was alternatively performed for the tumor bed around a clip marker placed during the course of NAC. Standard surgical excision was performed after biopsy. Matched biopsy and surgical specimens were compared for pCR assessment. **Results:** Pathologic complete response was confirmed in 27 (67.5%) surgical specimens, including 14/19 (73.7%) of HR-/HER2- and 6/8 (75%) of HR-/HER2+ patients. Preoperative biopsy had an accuracy of 90% (95% CI: 76-97%), negative predictive value of 87.1% (95% CI: 75-94%), and a false-negative rate of 30.8% (95% CI: 14-70%). Among four patients whose biopsy was not accurate in predicting pCR, two tumors were predicted to be > 0.5cm on MRI and two had less than five cores biopsied. Obtaining at least five cores in patients with ≤0.5cm lesion on MRI resulted in an accuracy of 97.1% (33/34), negative predictive value of 96.2% (25/26), and a false negative rate of 10%. There was no difference in accuracy in between multiple CNB and VAB. Breast pCR did not correlate with nodal status in 11.1% (3/27). **Conclusions:** Image-guided CNB or VAB can accurately identify patients with breast pCR in selected patients using preoperative MRI findings. This information will be used in a prospective clinical trial evaluating clinical safety of omitting breast surgery in patients with a breast pCR as determined by image-guided biopsy. Clinical trial information: NCT03273426.

567 Poster Session (Board #59), Sat, 8:00 AM-11:30 AM

Post neoadjuvant chemotherapy vacuum assisted biopsy in breast cancer: Can it determine pathologic complete response before surgery? *First Author: Marios Konstantinos Tasoulis, The Royal Marsden NHS Foundation Trust, London, United Kingdom*

Background: Neoadjuvant chemotherapy (NAC) is increasingly used in phenotype appropriate early operable breast cancer. Pathologic complete response (pCR) rates of up to 60% have been reported, suggesting that a proportion of patients may require less or even no surgery. In our practice, image-guided vacuum assisted biopsy (VAB) has been used after completion of NAC to assess residual disease and facilitate risk-adaptive surgery. The aim of this analysis was to investigate if post-NAC VAB could reliably identify exceptional responders who may not require surgical intervention. **Methods:** Retrospective cohort study of breast cancer patients treated with NAC, who had partial/complete imaging response and underwent post-NAC VAB to aid surgical planning, between 01/2013 and 01/2018. pCR was defined as no residual disease in the breast (ypT0). Diagnostic accuracy of VAB was calculated using final surgical pathology as the reference standard. Simple descriptive statistics and nonparametric analyses were performed. **Results:** 53 patients underwent post-NAC VAB. The overall pCR rate was 41.5% [53.8% for HER2 positive, 72.7% for triple negative (TN) phenotypes]. The post-NAC VAB false negative rate (FNR) was 19.4% (95% CI: 5.5-34.5) and the negative predictive value (NPV) was 76.9% (95% CI: 60.7-93.1) with an overall accuracy of 84.9% (95% CI: 75.3-94.5). Subgroup analysis showed that post-NAC VAB performed best in the TN group (n = 11) [FNR: 0%, NPV: 100%, overall accuracy: 90.9% (95% CI: 73.9-100)]. No significant associations were identified between tumor and technique characteristics and diagnostic performance of VAB. **Conclusions:** Our data suggest that post-NAC VAB may reliably predict pCR in patients with TN breast cancer. However, its diagnostic accuracy was not maintained across all phenotypes. Refinements and standardization in patient selection and VAB technique and more prospective trials are warranted to further explore the role of post-NAC VAB in supporting minimal or no surgery trials.

568 Poster Session (Board #60), Sat, 8:00 AM-11:30 AM

Neo-/adjuvant phase III trial to compare intense dose-dense (idd) treatment with EnPC to tailored dose-dense (dt) therapy with dtEC-dtD for patients with high-risk early breast cancer: Results on pathological complete response (pCR) for patients treated within the neoadjuvant setting. *First Author: Volker Moebus, Department of Gynecology and Obstetrics, Klinikum Frankfurt Höchst, Academic Hospital of the Goethe University Frankfurt, Frankfurt, Germany*

Background: GAIN-2 compares the effectiveness and safety of a predefined idd regimen (EnPC) vs. a dd regimen with modification of single doses depending on individual hematological and non-hematological toxicities (dtEC-dtD) as neo-/adjuvant treatment for patients with high risk breast cancer (BC) (NCT01690702). **Methods:** Patients with high risk BC (HER2+; triple negative BC (TNBC); luminal B-like: ER and/or PgR+, HER2-, Ki67 > 20%, N+; luminal A-like: ≥4 N+) were randomized to receive either iddEnPC (epirubicin 150mg/m^2 q2w, nab-Paclitaxel 330mg/m^2 q2w, cyclophosphamide 2000mg/m^2 q2w for 3 cycles each) or dtEC-dtD (epirubicin 60-100mg/m^2 and cyclophosphamide 450-1200mg/m^2 q2w for 4 cycles followed by docetaxel 60-100mg/m^2 q2w for 4 cycles). The primary objective of the trial is to compare the invasive disease-free survival (iDFS) between the two arms. pCR rates in the breast per arm (ypT0) in the neoadjuvant cohort will be reported. **Results:** In total the GAIN-2 trial accrued 2887 patients. From 08/2016 to 07/2017 598 patients have been randomized in the neoadjuvant setting (EnPC n = 298; dtEC-dtD n = 300). Median age was 49 [range 20-69] years. Overall, 2.3% had bilateral tumors, 38.0% cT1, 52.7% cT2 and 9.3% cT3/4, 55.4% cN+; 62.9% G3; 88.0% had Ki67 > 20%; 17.6% had hormone-receptor (HR)-positive/HER2-, 1.7% luminal A ≥4 N+, 31.9% HR+/ HER2+, 13.7% HR-/HER2+ and 35.1% TNBC. In the modified intention-to-treat population (EnPC n = 291; dtEC-dtD n = 293) the pCR rates for iddEnPC vs dtEC-dtD were 53.6% vs 45.1% (corrected continuity Chi-Square p = 0.047). Overall, 34.8% of the patients had at least 1 severe adverse event (EnPC 38.3% vs dtEC-dtD 31.3%). **Conclusion:** The GAIN-2 trials shows a statistically significant difference in terms of pCR rates within the breast for patients with high-risk BC receiving iddEnPC compared to dtEC-dtD as neoadjuvant chemotherapy. Further analyses are ongoing. Clinical trial information: NCT01690702.

569 Poster Session (Board #61), Sat, 8:00 AM-11:30 AM

Investigating denosumab as an add-on neoadjuvant treatment for RANK/L-positive or RANK/L-negative primary breast cancer and two different nab-paclitaxel schedules: 2x2 factorial design (GeparX)—An iterim safety analysis. *First Author: Sherko Kummel, Kliniken Essen Mitte, Essen, Germany*

Background: The GeparX study aims to investigate whether denosumab, an antibody targeting RANKL, increases the pCR rate when added to an anthracycline/taxane containing neoadjuvant chemotherapy (NACT) in patients (pts) with primary breast cancer (BC). **Methods:** GeparX enrolles pts with primary BC cT1c-cT4d, after central assessment of HER2, HR, TILs, Ki67. 778 pts will be randomized to NACT+/-denosumab (120mg s.c. q4w for 6 cycles), stratified by lymphocyte predominant BC (LPBC, ≤50% vs > 50%), subtype (HER2-/HR+ vs triple negative (TNBC) vs HER2+), and epirubicin/cyclophosphamide schedule (EC, q2w vs q3w). Secondarily, pts are randomized to different nab-paclitaxel schedules (nP): nP 125mg/m² weekly or nP 125mg/m² day 1,8 q22 followed by EC. Pts with TNBC receive carboplatin (AUC 2) and with HER2+ BC ABP 980 (trastuzumab biosimilar)+ pertuzumab. Co-primary objectives compare the pCR (ypT0 ypN0) rates of NACT+/-denosumab and the pCR rates between nP 125 weekly and nP 125 d1,8 q22. Secondary objectives are toxicity; compliance amongst others. An interim safety analysis is planned after the first 200 pts have completed nP treatment. **Results:** A total of 202 pts randomized to denosumab and the nP treatment (101 pts with weekly and 101 pts with nP d1,8 q22) were included in the interim analysis. Overall, median age was 50 years [range 23-76]; 38.6% of pts were cN+ and 5% had LPBC, 102 pts (50.5%) had HER2-/HR+ BC; 82 (40.6%) had TNBC and 18 pts (8.9%) HER2+ BC. Overall, 13.5% with and 13.1% w/o denosumab discontinued nP. 21.0 % of pts with nP weekly vs 5.3% with nP d1,8 q22 discontinued nP mainly due to AEs (17.0% vs 3.2%). During nP treatment 24 SAEs with nP weekly vs 25 SAEs with nP d1,8 q22 were reported. 17 (16.7%) SAEs were reported in the HER2-/HR+ cohort, 29 (35.4%) for the TNBC (with carboplatin) and 3 (16.7%) in the HER2+ cohort (dual-blockade, no carboplatin). **Conclusions:** The addition of denosumab to NACT does not increase toxicity. Weekly nP resulted in a higher rate of treatment discontinuations mainly due to non-serious AEs. The addition of carboplatin resulted in a higher rate of SAEs. Clinical trial information: NCT02682693.

570 Poster Session (Board #62), Sat, 8:00 AM-11:30 AM

A RB-1 loss of function gene-signature (RBsig) as a tool to predict response to neoadjuvant chemotherapy (CT) plus anti-HER2 agents (H): A substudy of the NeoALTTO trial (BIG 1-06). *First Author: Emanuela Risi, Sandro Pitigliani Medical Oncology Department, Hospital of Prato, Prato, Italy*

Background: CT added to H is the treatment of choice in HER2+ early breast cancer (BC) patients (pts). However HER2+ tumors are clinically and biologically heterogeneous and treatment response varies significantly by hormone receptor (HR) status and molecular subtype. Predictive biomarkers are needed in this context. We have previously shown that RBsig expression correlates with pathological complete response (pCR) rate following CT +/− H in ER+/HER2+ BC pts within a metadataset of 10 neoadjuvant clinical trials. The present study assessed whether RBsig is predictive of response to neoadjuvant CT in combination with H, within the NeoALTTO trial. **Methods:** We collected RNA-sequencing data from pre-treatment biopsies derived from NeoALTTO, a trial randomizing pts with HER2+ early BC to receive lapatinib, trastuzumab or both together with weekly paclitaxel. RBsig expression was computed retrospectively and correlated with pCR using receiving-operating characteristic (ROC) curves.The RBsig was dichotomized as High/Low in correspondence to the 25th percentile. The distribution of RBsig expression was evaluated within PAM50 molecular subtypes. Reported p-values resulted from Fisher exact test. **Results:** Of 455 NeoALTTO pts, 245 had available RNA-sequencing data (HR+ n = 129 HR− n = 116). Overall, pCR rate was significantly higher in pts with RBsig High tumors, than those with RBsig Low (36% vs 18% respectively p = 0.01). The area under the ROC curve (AUC) was 0.60 (95% CI 0.52-0.67). A remarkably low pCR rate of 11% was seen in HR+/ RBsig Low pts vs 28% in HR+/RBsig High. HER2-enriched (HER2e) tumors were the predominant molecular subtype in both HR+ (n = 65) and HR− (n = 89) subsets. RBsig could further stratify HER2e tumors, with RBsig High and Low showing a pCR rate of 44% and 21% respectively (p = 0.02).The pCR rate of HR+/ HER2e/ RBsig High pts was 37% vs 7% for HR+/ HER2e/ RBsig Low (p = 0.04). The ROC curve AUC was 0.65 (95% CI 0.50-0.79). **Conclusions:** RBsig Low expression identifies a subset of HER2+ pts less likely to respond to CT + H. This is particularly notable in HER2e tumors thus indicating RBsig may add significant information to molecular subtypes.

571 Poster Session (Board #63), Sat, 8:00 AM-11:30 AM

Prognostic implications of residual disease (RD) tumor-infiltrating lymphocytes (TIL) in triple negative breast cancer (TNBC) after neo-adjuvant chemotherapy (NAC). *First Author: Stephen James Luen, Peter MacCallum Cancer Centre, Melbourne, Australia*

Background: For primary TNBCs treated with NAC, higher pre-treatment TILs correlate with increased pathological complete response (pCR) rates, better recurrence-free survival (RFS) and overall survival (OS). We evaluated the prognostic value of RD TILs to pathological stage and Residual Cancer Burden (RCB) in predicting survival post NAC. **Methods:** We combined individual patient data from 4 TNBC patient series treated with NAC who did not achieve pCR. TILs were evaluated on the RD using our previously published method on H&E stained slides. TILs were investigated for associations with yp stage, RCB, RFS and OS using Cox models with stromal TILs as a continuous variable, stratified by series. The likelihood ratio (LR) test was used to evaluate added prognostic value of TILs to standard yp stage and RCB class. **Results:** In total 376 RD samples were evaluable for TILs. After 6 years median follow-up we observed 193 RFS events and 165 deaths. The median age was 50 years (range 24-83). 62% received combination anthracycline/taxane chemotherapy, and 27% anthracycline alone. For RD stage, 32% were yp node positive; RCB class I/II/III was 11%/50%/39% respectively. The median RD TIL level was 20% (IQR 10-40). TIL levels were significantly lower with increasing yp stage ($P < 0.01$), but did not differ significantly by RCB class ($P = 0.84$). Higher RD TILs were significantly associated with improved RFS (HR per 10% increment 0.86; 95%CI 0.79-0.92; $P < 0.01$) and OS (HR 0.87; 95%CI 0.80-0.94; $P < 0.01$), but were only significant for RFS in multivariate analysis after adjusting for yp stage ($P = 0.03$). RCB class was significant for RFS and OS (both $P < 0.01$). RD TILs added significant prognostic value to RCB class for both RFS and OS (both LR $P < 0.01$). The positive prognostic effect of RD TILs was of greater magnitude in the lower RCB classes I/II vs. III for both RFS and OS (both interaction $P < 0.01$). **Conclusions:** TIL levels in TNBC RD are significantly associated with improved RFS and OS and add further prognostic information to RCB class. The positive prognostic influence of TILs is significantly greater in patients with less RD burden. This data may help refine NAC clinical trial endpoints.

572 Poster Session (Board #64), Sat, 8:00 AM-11:30 AM

Impact of PIK3CA mutation status on immune marker response and pCR in the WSG-ADAPT HER2+/HR+ phase II trial. *First Author: Nadia Harbeck, Brustzentrum der Universität München (LMU), Munich, Germany*

Background: The ADAPT HER2+/HR+ phase II trial (NCT01745965) compared for the first time 12 wks. neoadjuvant T-DM1 (+/- endocrine therapy (ET)) with trastuzumab (T)+ET; pCR (ypT0/is ypN0) was > 40% in T-DM1 arms and 15% in T+ET. High CD8 at baseline or cycle 2, as well as increased CD8 expression on treatment, were associated with favorable pCR. In HER2+ mBC, T-DM1 was reported effective in both mutated and wildtype (WT) PIK3CA tumors. **Methods:** This pre-planned translational analysis aimed to identify potential early predictors for response to neoadjuvant therapy (containing T-DM1 or T) in HER2+/HR+ EBC. PIK3CA mutations were assessed by high-throughput microfluidics qPCR (MUT-MAP 13-gene panel). Immune markers, focusing here on CD8 in tumor center, were assessed by IHC in core biopsies at baseline and cycle 2. CD8 positivity was coded as percentage of positively stained cells; CD8 change was defined as cycle 2 minus baseline value. Associations between pCR and PIK3CA mutation status (mutated vs. WT) or with other variables were characterized by Fisher's exact test and T-statistics. **Results:** In 190 patients, PIK3CA mutation status was assessed in baseline biopsies (177/190) or surgical samples (or both). Results were identical in all 8 repeated assays (baseline & surgery). Prevalence of PIK3CA mutations was 31/190 (16.3%). pCR was 37.4% in WT vs 16.7% in PIK3CA mutated tumors (p = .035). Distributions of nodal status, grade, and Ki67 were independent of PIK3CA mutation status, but T1 tumors were less prevalent (25.8% vs. 47.2%) for PIK3CA mutations (p = .03); the unfavorable impact of PIK3CA mutations on pCR was strong within the T2+ patient subgroup (9.1% vs 33.8%; p = .017). While CD8 protein expression generally increased following 3 weeks of therapy, and larger positive CD8 responses were themselves associated with pCR (particularly in the T-DM1 containing arms (p = .009)), CD8 changes in PIK3CA mutated tumors were small and lower than in WT (p = .020). **Conclusions:** PIK3CA mutations were associated both directly (lower pCR) and indirectly (stagnation of CD8 change) with poorer response to neoadjuvant therapy in HER2+/HR+ EBC. Poor response in PIK3CA mutated cases occurs despite excellent overall pCR with T-DM1. Clinical trial information: NCT01817452.

573 Poster Session (Board #65), Sat, 8:00 AM-11:30 AM

Impact of 12 weeks nab-paclitaxel + carboplatin or gemcitabine followed by anthracycline administration according to pCR in triple-negative early breast cancer: Survival results of WSG-ADAPT-TN phase II trial. *First Author: Oleg Gluz, Breast Center Niederrhein and University Clinics Cologne, Moenchengladbach, Germany*

Background: Optimal chemotherapy in TNBC EBC is unclear. ADAPT TN demonstrated higher pCR (46% vs. 29%) and better safety for only 12 weeks nab-paclitaxel/carboplatin vs nab-paclitaxel/gemcitabine (JNCI 2017). **Methods:** Patients with centrally confirmed TNBC (ER/PR < 1%, HER2-, cT1c-cT4c, cN0/+) were randomized to neoadjuvant A: 4x nab-paclitaxel 125 mg/m^2/gemcitabine 1000 mg/m^2 d1,8 q3w vs. B: 4x nab-paclitaxel 125 mg/m^2/carboplatin AUC2 day 1/8 3-weekly (q3w). Primary endpoint was pCR (ypT0/is/ypN0) after 12 weeks of therapy. Event-free (EFS) – defined as time from registration to any invasive relapse, secondary malignancy or death of any cause – and overall survival (OS) were secondary endpoints. Adjuvant anthracycline-based chemotherapy (4xEC) was optional in patients with pCR. Here, we report the per-protocol interim survival analysis recommended by the DSMB after a median follow-up of 3 years. **Results:** 336 patients were enrolled (48 centers, arms A/B: n = 182/154). Median age was 50 years. At baseline, about 63% had cT2-4c tumors, 26.2% were clinically node-positive. After 36 months median FU, 68 EFS events (A/B: 37/29) and 37 deaths (A/B: 24/13) were observed. pCR (vs. non-pCR) is highly prognostic for EFS (3y EFS: 92% vs. 71%, p < 0.001) and OS (3y OS: 99.1% vs. 81.6%, p < 0.001). Despite the strong impact of carboplatin on pCR, 3y EFS was similar in (77.6% vs. 80.8%) in both arms; OS was numerically higher in Arm B (84.7% vs. 92.2%, p = 0.09). Final analysis regarding anthracycline use and its survival impact will be presented at the meeting. **Conclusions:** 12w nab-paclitaxel/carboplatin is a tolerable and effective neoadjuvant option in early stage TNBC. In ADAPT TN, the strong impact of carboplatin vs. gemcitabine on pCR seems to be "mitigated" regarding survival by subsequent adjuvant anthracycline/cyclophosphamide therapy. Our findings provide first prospective evidence supporting individualized chemotherapy regimens in early TNBC. Clinical trial information: NCT01815242.

574 Poster Session (Board #66), Sat, 8:00 AM-11:30 AM

Signatures of mutational processes and response to neoadjuvant chemotherapy in breast cancer: A genome-based investigation in the neoadjuvant GeparSepto trial. *First Author: Carsten Denkert, Institute of Pathology, Charité - Universitätsmedizin Berlin, Berlin, Germany*

Background: Different mutational processes act over the evolutionary history of a malignant tumor, driven by e.g. abnormal DNA editing, mutagens or age-related DNA alterations. Many of these processes generate defined combinations of mutation types, which have been described as mutational signatures. The clinical relevance of mutational signatures has not been studied to a great extent. We investigate the hypothesis that the individual patterns of mutational signatures determine the clinical behavior of breast cancer (BC) , in particular response to neoadjuvant chemotherapy. **Methods:** In the GeparSepto study (NCT01583426) women with primary invasive BC were randomized to either nab-paclitaxel or solvent-based paclitaxel followed by EC. Pretherapeutic FFPE core biopsies of HER2-neg BC were used for whole genome/exome sequencing (n = 405). Mutational signatures were identified as described by Alexandrov et al. (Cell Rep. 3, 2013). **Results:** 24 of the the 30 mutational signatures were present in at least 10% of the 405 tumors , the most predominant were Sig1 (age-related, 94.8%), Sig13 (APOBEC-related, 87.7%), Sig6 (MMR-def.-related, 69.9%), Sig3 (BRCA-related, 61.5%), Sig28 (60.7%), and Sig16 (60.2%). The signatures 3, 4, 11, 13, 17, 21, and 24 were increased and signatures 10, 16, 28, and 29 decreased in TNBC compared to luminal BC. A significant correlation with the number of stromal tumor-infiltrating lymphocytes was observed for signatures 3, 4, 13, 23, and 24, an association with increased Ki67 was observed for Sig 3, 4, 6, 11, 12, 13, 16, 23, and 24. Tumors with signatures 3, 11 and 13 had a significantly increased response rate to neoadjuvant chemotherapy, this was also observed in the subgroups of TNBC (sign 11) and luminal BC (sign 3, 9, 13). **Conclusions:** Whole-exome sequencing in breast cancer FFPE core biopsies from clinical cohorts can be used to identify mutational signatures. The pattern of these signatures, in particular the presence of BRCA-related (Sig3) and APOBEC-related (Sig13) reflect the clinical behavior of breast cancer and might be used to identify tumors with an increased response rate to neoadjuvant chemotherapy.

575 Poster Session (Board #67), Sat, 8:00 AM-11:30 AM

Does the sequence of anthracycline and taxane matter? The NeoSAMBA trial. *First Author: Jose Bines, Instituto Nacional de Câncer, Rio De Janeiro, Brazil*

Background: Taxanes usually follow anthracyclines in breast cancer neo/adjuvant treatment, likely due to its later introduction in clinical practice. However, there is no biological rationale that justifies this current standard-of-care. We compared an anthracycline-based regimen followed by a taxane (FAC-T) neoadjuvant chemotherapy with the reverse sequence (T-FAC) (NCT01270373). **Methods:** In this randomized, open-label, single center phase 2 trial, women with locally advanced (LABC) HER2 negative breast cancer, stratified by hormone receptor, were randomized to 3 cycles of fluorouracil, doxorubicin and cyclophosphamide followed by 3 cycles of docetaxel vs. docetaxel followed by fluorouracil, doxorubicin and cyclophosphamide. Surgery, radiotherapy and adjuvant hormonal therapy were given as per local guidelines. The primary endpoint was pathological complete response (pCR) and secondary endpoints included disease-free (DFS) and overall survival (OS). The expected baseline pCR was 15%. With 53 patients per arm, we had a 90% probability of selecting a schedule that had a true benefit of 25%. A 10% drop-out was anticipated. **Results:** Between September 2010 and November 2012, we randomly allocated 118 patients: 60 received FAC-T and 58 T-FAC. The median follow-up was 53.8 months (95% CI 51.9- 55.7). The median age was 50 years. Ninety-four patients (70.7%) had stage III tumors and 31 (26.3%) had triple negative disease. pCR was higher in triple negative patients: 21.4% vs 1.2%. Treatment sequence did not improve pCR of all patients operated (114): 3 (5.2%) and 4 (7.3%) in the FAC-T and T-FAC arms, respectively. Taxane-first when compared to anthracycline-first sequencing showed a 5y DFS of 78% and 45% (HR 0.31, 95% CI 0.16–0.59) and a 5y OS of 88% and 65% (HR 0.28, 95% CI 0.12–0.66), respectively. The relative dose intensity was similar between both arms. No unexpected toxicity was reported. **Conclusions:** We showed for the first time an improvement in DFS and OS with taxane-first when compared to anthracycline-first sequencing chemotherapy in HER2 negative LABC. Tumor and blood samples were collected for translational analyses at three time points. Clinical trial information: NCT01270373.

576 Poster Session (Board #68), Sat, 8:00 AM-11:30 AM

Breast Cancer Index (BCI) and prediction of pathological complete response (pCR) to neoadjuvant chemotherapy in estrogen receptor positive (ER+) breast cancer. *First Author: Laura Spring, Brigham and Women's Hospital, Brookline, MA*

Background: Although endocrine therapy is the mainstay of management of ER+ tumors, optimal neoadjuvant strategy for ER+ breast cancer is unclear, and improved selection of patients for neoadjuvant chemotherapy (NACT) vs neoadjuvant endocrine therapy are critical ongoing questions. BCI is a gene expression signature that stratifies patients for risk of overall (0-10y) and late (post-5y) distant recurrence and the likelihood of benefit from extended endocrine therapy. Given BCI's proliferation (MGI) and estrogen-related (HoxB13/IL17BR) activities, this study investigated its ability to predict pCR in ER+ breast cancer patients treated with NACT. **Methods:** BCI analysis was performed on pre-treatment core biopsies from patients with ER+ breast cancer treated with NACT at Massachusetts General Hospital (n = 84) and Institut Gustave Roussy (n = 101). pCR and overall survival were collected from charts by investigators blinded to the BCI results. Multivariate logistic regression and Cox proportional hazards regression were used to evaluate the association of BCI risk categories with pCR and overall survival. **Results:** Patients (N = 185; 100% ER+/HER2-, 56% N+, 65% T2, 49% grade 2) were treated with NACT, mostly anthracycline/taxane-based regimens, and 10 (5.4%) achieved pCR. BCI was significantly associated with pCR, with no pCR observed in the low risk group (P = 0.0003). BCI was the only significant predictor of pCR in multivariate analysis including tumor size, tumor grade, PR status, and nodal status (OR = 14.0 [95% CI 1.19 – 263.5], P = 0.05). BCI was also a significant predictor of overall survival in these patients following NACT (P = 0.008). **Conclusions:** Pre-treatment BCI significantly predicted response to neoadjuvant chemotherapy in ER+ breast cancer patients. Results of this study suggest potential clinical utility of BCI in stratifying ER+ patients with chemo-sensitive disease, while considering alternative treatment strategies such as neoadjuvant endocrine therapy for women who may not respond adequately to NACT and potentially avoid toxicity associated with NACT.

577 Poster Session (Board #69), Sat, 8:00 AM-11:30 AM

Association between adaptive immune signature and outcome in HER2-positive breast cancer treated with trastuzumab and lapatinib in the NCCTG-N9831 (Alliance) and NeoALTTO trials. *First Author: Saranya Chumsri, Mayo Clinic, Jacksonville, FL*

Background: Trastuzumab (H) acts in part through adaptive immune system, whereas lapatinib (L) acts through inhibition of HER2 signaling. Previous studies showed that enrichment of immune-related genes was associated with improved outcome. However, the role of immune system in response to L or LH is not fully understood. **Methods:** NanoString was used to quantify mRNA in 1,378 samples from N9831 trial: Arm A chemotherapy alone, arm B sequential H, and arm C concurrent H. Enrichment analysis was performed on genes with significant HR to generate a signature. RNA-seq data was analyzed from 193 samples from NeoALLTO trial: Arm A L, arm B H, and arm C LH. Cox models for RFS and EFS were analyzed. **Results:** In N9831, enrichment of the 17 gene adaptive immune signature (AIS) was found to be significantly associated with improved RFS in arm C (HR 0.71, 95%CI 0.56-0.90; p = 0.005). Further validation was performed in arm A and B with similar associations observed in arm B (HR 0.76, 95%CI 0.62-0.92; p = 0.006) and arm A (HR 0.84, 95%CI 0.72-0.99; p = 0.04). Enrichment of this signature was significantly associated with higher sTIL ($p < 0.0001$), ER negativity (p = 0.047), and larger tumor size ($p < 0.0001$) but not lymph node status or tumor grade. In NeoALTTO, 134 out of 244 (54.9%) patients were considered deficient AIS (dAIS). NeoALTTO patients with dAIS had significantly lower pathologic complete response (pCR) rate, compared to patients with enriched AIS (eAIS). In arm B, pCR was observed in 43% with eAIS compared to 8% with dAIS (OR = 9.12, 2.25-54.42, p = 0.0004). pCR was observed in 17% with dAIS in arm A and in 52% in arm C . Among dAIS patients, 6 year-EFS was longer in L (68%, 95%CI 0.55-0.85) or combination HL (73%, 95%CI 0.60-0.88), compared to H alone, (63%, 95%CI 0.49-0.80). **Conclusions:** Patients with dAIS had poor outcome despite receiving H likely due to inability to mount proper immune response. However, these patients appear to benefit from L and the combination of LH. Further studies are needed to validate this signature to identify patients who will benefit from dual anti-HER2 therapy. Clinical trial information: NCT00898898 and NCT00553358.

	%pCR		%6-yr EFS	
	dAIS	eAIS	dAIS	eAIS
L	17%	21%	68%	65%
H	8%	43%	63%	74%
LH	52%	44%	73%	85%

578 Poster Session (Board #70), Sat, 8:00 AM-11:30 AM

Immune profiling of pre- and post-treatment breast cancer tissues from the S0800 randomized neoadjuvant trial of weekly nab-paclitaxel with or without bevacizumab and dose dense doxorubicin and cyclophosphamide. *First Author: Xiaotong Li, Yale University, New Haven, CT*

Background: We examined changes in the tumor immune microenvironment during neoadjuvant chemotherapy by comparing immune gene mRNA expression, tumor infiltrating lymphocyte (TIL) count and PD-L1 protein expression in pre- and post-treatment tissues. **Methods:** Paired pre- and post- treatment tumor samples from 60 patients were profiled using the Nanostring Immune Oncology 360 platform to measure the expression of 770 immune-related genes that also allowed us to test 14 immune cell type and 27 previously published prognostic and immuno therapy response predictive gene signatures. All samples were also assessed for TIL counts and PD-L1 protein expression by immunohistochemistry. Gene expression levels were compared by paired t-test with Bonferroni correction. TIL count, PD-L1 protein expression and immune gene signatures were compared using Wilcoxon signed-rank test. Baseline immune markers were correlated with pathologic complete response (pCR) using estrogen receptor (ER) and treatment adjusted logistic regression. **Results:** TIL counts were significantly lower in post- compared to pre-treatment samples (17% vs 7%, p = 0.013) but stromal PD-L1 protein expression was not significantly different. At baseline, higher TIL count and PD-L1 expression were associated with pCR. High expression of a mast cell metagene was associated with residual disease (RD). No individual genes or VEGF gene signature were associated with benefit from bevacizumab. In patients with RD (n = 45), genes involved with tissue repair and inflammation (DUSP1, EGR1, IL6, ATF3, CD36, CXCL2, CD69, NGFR, KLF2, THBD, DAB2) showed significantly higher expression after therapy while most other immune markers decreased. The T effector, T-reg, MHC-I, MHC-II, IFNgamma, STAT-1 and M1 macrophage gene signatures were all significantly lower in post- versus pre-treatment samples and only the IL8/VEGFR and T-helper gene signatures showed higher expression after therapy. **Conclusions:** High mast cell gene expression is associated with lower pCR rate. TIL counts and most immune parameters decrease after neoadjuvant chemotherapy.

579 Poster Session (Board #71), Sat, 8:00 AM-11:30 AM

Integrative cluster classification to predict pathological complete response to neoadjuvant chemotherapy in early breast cancer. *First Author: Emilio Alba, Hospital Clínico Universitario Virgen de la Victoria. GEICAM Spanish Breast Cancer Group., Malaga, Spain*

Background: Integrative Clustering (IntClust) is a breast cancer (BC) classification of 10 different subgroups with distinctive molecular profiles and clinical outcomes (Curtis et al., Nature 2012). We implemented an IntClust classifier based on Copy Number Alterations (CNAs) and explored its prognostic role in a cohort of pre- and post-treatment (ttm) tumors from the neoadjuvant trials GEICAM/2006-03 (NCT00432172) and GEICAM/2006-14 (NCT00841828). **Methods:** GEICAM/2006-03 HER2-negative pts were selectively treated according to clinical subtypes: triple negative (TN) pts with standard taxane/anthracycline-based chemotherapy (TA-CT) +/- carboplatin, and luminal A patients were randomised to TA-CT vs. hormonotherapy; GEICAM/2006-14 HER2+ pts received TA-CT + anti-HER2 therapy. Shallow-whole genome Illumina sequencing DNA data from 204 paraffin-BC (100 pre- and 104 post-ttm tumors) were used to identify CNAs and grouped samples in the 10–IntClust classification. A functional clustering by grouping IntClust 1-2-6-9 as Luminal poor prognosis (LPP), IntClust 3-4-7-8 as Luminal good prognosis (LGP), IntClust 10 (Basal-like) and IntClust 5 (HER2+) were defined. Fisher test was used to analyze IntClust distribution. Logistic regression analyses were performed to explore the association of IntClust groups with outcome (pCR in breast and axila). **Results:** The comparative analysis for IntClust groups in pre- vs post-ttm samples showed significantly different distribution (p = 0.01), with an enrichment of the LGP group (32% vs 55%) in the residual samples after neoadjuvant ttm, due to an increase in IntClusters 3 and 4 (both of them characterized by a low-genomic instability), and a decrease in the rest of the groups. Logistic regression analysis showed that IntClust classification in pre-ttm tumors were significant associated with pCR independently to histological grade, Ki67 and clinical subtype (p = 0.0015) **Conclusions:** Our data suggest an association between IntClust classification and clinical outcome in terms of pCR after neoadjuvant therapy in early BC. In our study, residual tumors after ttm were predominantly Luminal-like phenotypes with low genomic instability Clinical trial information: GEICAM/2006-03 NCT00432172. GEICAM/2006-14 NCT00841828.

580 Poster Session (Board #72), Sat, 8:00 AM-11:30 AM

Intrinsic subtypes of HER2-positive breast cancer and their associations with pathologic complete response (pCR) and outcomes: Findings from NSABP B-41, a randomized neoadjuvant trial. *First Author: Sandra M. Swain, NSABP/NRG Oncology, and Georgetown Lombardi Comprehensive Cancer Center, Georgetown University Medical Center, Washington, DC*

Background: NSABP B-41, randomly assigned 529 patients with HER2 positive breast cancer to receive neoadjuvant trastuzumab, lapatinib, or the combination, with weekly paclitaxel following doxorubicin and cyclophosphamide x 4. No significant difference in pCR was found among three arms (Robidoux 2013), but overall survival was significantly increased for patients who obtained a pCR (Robidoux 2016). This study evaluated outcomes in B-41 based on intrinsic subtype. **Methods:** H&E slides were reviewed by study pathologist for areas of invasive carcinoma having > 10% tumor cells. RNA was isolated and hybridized to the "RUO-PAM50" CodeSet (NanoString Technologies). Intrinsic PAM50 subtype was determined for each sample. Contingence-table analyses were used to compare pCR breast and nodes (ypT0/is ypN0) among intrinsic subtypes and Kaplan-Meier estimates and Cox models were used to compare event-free survival and overall survival among subtypes. **Results:** Core biopsy samples from 276 patients, prior to therapy, were evaluated. Intrinsic subtype was determined in 271: 197 (73%) were HER2 enriched (E) (97 ER negative and 100 ER positive), 26 (10%) basal-like, 23 (8%) luminal A, and 25 (9%) luminal B. pCR was 61% in HER2-E (69% in ER negative and 53% in ER positive) and 26% in others (basal-like, luminal A/B) (p < 0.001). In HER2-E, patients on trastuzumab-based arms had higher pCR than those on the lapatinib arm (67% vs 49%, p = 0.02). Patients with basal-like tumors had higher pCR than those with luminal A/B tumors (38.5% vs 13% & 24%) but their long-term prognosis is poor, compared with other three subtypes: five-year EFS = 0.724 [0.506, 0.858] (p = 0.28) and five-year OS = 0.808 [0.598, 0.915] (p = 0.005). In HER2-E, EFS and OS were no different between the three arms. **Conclusions:** HER2-E subtype is a good marker for predicting benefit from HER2 targeted therapies, particularly if trastuzumab-based. Whether tumors with other subtypes are suitable for HER2 targeted therapies needs further investigation. Survival outcomes are limited by the small number of events and would benefit from meta-analysis with other similar studies. Clinical trial information: NCT00486668.

581 Poster Session (Board #73), Sat, 8:00 AM-11:30 AM

Care 001: Multicenter randomized open label phase II trial of neoadjuvant trastuzumabemtansine (T-DM1) in combination with lapatinib and nab-paclitaxel compared with paclitaxel, trastuzumab and pertuzumab in HER 2 neu over-expressed breast cancer patients (TEAL study). *First Author: Tejal Amar Patel, Methodist Cancer Center, Houston, TX*

Background: Based on data from our phase I study of trastuzumab-emtansine (T-DM1), Lapatinib (L) and Nab Paclitaxel (Nab-P), a multicenter randomized open label phase II neoadjuvant study was conducted comparing this regimen to the standard of care (SOC) Paclitaxel (Pac), Trastuzumab (T), and Pertuzumab (P) in patients with HER2 over-expressed breast cancer. **Methods:** Patients in the experimental arm received T-DM1 3.0 mg/kg Q3W, L 750mg oral daily and Nab-P 80 mg/m^2 weekly (QW) X 12 weeks. Patients in SOC arm received Pac 80mg/m^2 QW, T 2mg/kg QW, and P 420mg Q3W X 12 weeks. The primary objective was to evaluate the proportion of patients with residual cancer burden (RCB) 0 or 1. Key secondary objectives included correlative assessments of PIK3CA mutations, PTEN expression, and HER2 subtypes, all of which are ongoing. **Results:** Thirty of the 33 enrolled patients were evaluable. Patient demographics were.The proportion of patients with RCB 0 & I was significantly higher in the T-DM1, L and Nab-P arm than in the SOC arm (100% vs. 62.5%, p 0.0035). Importantly, the RCB 0 & 1 in the ER positive subset of patients was 100% compared with 25% in SOC (p 0.0035). Common adverse events included elevated liver function tests, fatigue, diarrhea and neuropathy. **Conclusions:** TDM1 plus L and Nab-P therapy was well tolerated with noteworthy responses in all patients, and especially in the ER positive subset, a group which has historically had lower response rates to neoadjuvant anti-HER2-directed therapy. Further evaluation of this regimen is warranted. Clinical trial information: NCT02073487.

Efficacy.

	Experimental	SOC	P-value
RCB 0 - and I	14 (100)	10 (62.5)	0.0035
ER Negative	6 (100)	8 (100)	
ER Positive	8 (100)	2 (25)	
RCB II and III	0	6 (37.50)	

582 Poster Session (Board #74), Sat, 8:00 AM-11:30 AM

Predicting neo-adjuvant chemotherapy response from pre-treatment breast MRI using machine learning and HER2 status. *First Author: Nathaniel Braman, Case Western Reserve University, Cleveland, OH*

Background: Many breast cancer patients receiving neo-adjuvant chemotherapy (NAC) will ultimately fail to achieve pathological complete response (pCR). A pre-treatment clinical marker of pCR could guide NAC without requiring potentially ineffective initial treatment periods. Advances in medical image analysis, such as deep learning (pattern recognition using neural networks) and radiomics (computer-extracted quantitative image features), demonstrate significant potential for non-invasive assessment of NAC outcome. We present a machine learning (ML) approach for pre-NAC response prediction fusing deep learning, radiomics, and clinical variables. **Methods:** 166 patients with pre-treatment contrast-enhanced MRI from the ISPY1-TRIAL and surgically-confirmed NAC response outcome (ypT0N0, 49 pCR, 117 non-pCR) following anthracycline-cyclophosphamide chemotherapy with or without taxane were retrospectively analyzed. Patients were divided randomly into training (n = 133) and testing (n = 33) cohorts, with proportionate distribution of pCR between cohorts. Multinomial logistic regression integrated DL, radiomics, and HER2 status was assessed by area under the receiver operating characteristic curve (AUC), sensitivity, and specificity within the testing set. Deep learning: A six-layer convolutional neural network was trained to predict response using 65 pixel square patches centered within a tumor. Radiomics: From a pool of 215 radiomic intra-tumoral heterogeneity features, the 8 best-performing features were identified algorithmically and used to train a linear discriminant analysis classifier within the training set. **Results:** A ML only approach strongly predicted response (AUC = .84) in the testing set. Integrating clinical HER2 status into the combined imaging model yielded optimal pre-treatment response prediction (AUC = .93), with 75% sensitivity and 92% specificity. **Conclusions:** Further validation of an approach fusing deep learning, radiomic analysis, and clinical information could potentially provide a means of pre-NAC response prediction from MRI.

	AUC	Sensitivity	Specificity
HER2 Status	.69	63%	76%
ML only	.84	63%	84%
ML+HER2 Status	.93	75%	92%

583 Poster Session (Board #75), Sat, 8:00 AM-11:30 AM

Efficacy analyses of central laboratory pCR results from the LILAC study comparing the biosimilar ABP 980 and trastuzumab. *First Author: Hans-Christian Kolberg, Marienhospital Bottrop, Klinik für Gynäkologie und Geburtshilfe, Bottrop, Germany*

Background: The phase 3 LILAC Study compared ABP 980 with trastuzumab (TRAS) on pathologic complete response (pCR) in women with HER2+ early breast cancer. The primary efficacy results, based on local laboratory evaluation of tumor samples, have been reported previously. Here we report the results of pCR analysis based on central laboratory evaluation of tumor samples. **Methods:** After run-in anthracycline-based chemotherapy, patients were randomized 1:1 to ABP 980 or TRAS plus paclitaxel Q3W x 4 or Q1W x 12. The co-primary endpoints were risk difference (RD) and risk ratio (RR) of pCR adjusted for baseline covariates in breast tissue and axillary lymph nodes. Clinical similarity was supported by the central pathology evaluation as the 2-sided 90% CIs were within the equivalence margin for RD (-13% to 13%) and RR (0.759 to 1.318). Representative samples of tumor material were sent to the central laboratory for evaluation. Samples were determined to be adequate for evaluation based on the presence of tumor bed and integrity of nuclear detail. Each sample was evaluated by 2 independent central pathologists, who were blinded to patients' treatment and to each other's assessment. If discordance between the 2 pathologists was found, the case was sent to a third blinded pathologist to determine the outcome. **Results:** 725 patients were randomized; 696 (ABP 980: n = 358; TRAS: n = 338) were included in the pCR evaluable population. pCR was achieved in 48.0% for ABP 980 and 40.5% for TRAS, based on local review. RD of pCR was 7.3% (90% CI: 1.2%, 13.4%); RR was 1.19 (90% CI: 1.033, 1.366). The upper limit of the CIs slightly exceeded the equivalence margin. Based on central review, pCR was achieved in 47.8% for ABP 980 and 41.8% for TRAS. RD was 5.8% (90% CI: -0.5, 12.0%); RR was 1.14 (90% CI: 0.993, 1.312). Both RR and RD were contained within the equivalence margin. **Conclusions:** Results based on central evaluations support clinical equivalence of ABP 980 and TRAS. All sensitivity analyses based on central pathology evaluation were within the prespecified equivalence margins. This study demonstrates the feasibility of including central laboratory review of pCR rates in a large multicenter, multinational study. Clinical trial information: NCT01901146.

584 Poster Session (Board #76), Sat, 8:00 AM-11:30 AM

Impact of residual nodal disease burden on sentinel node mapping and accuracy of intraoperative frozen section in node positive (cN1) breast cancer patients treated with neoadjuvant chemotherapy (NAC). *First Author: Alison Laws, University of Calgary, Calgary, AB, Canada*

Background: Recent trials have demonstrated the feasibility of SLN biopsy in cN1 patients who become cN0 after NAC. We sought to evaluate success of SLN mapping and accuracy of intraop frozen section (FS) by residual nodal disease burden. **Methods:** cT1-3 cN1 patients receiving NAC and surgery (1/2016 to 5/2017) were identified from a prospective database. Pts who converted to cN0 and had SLN biopsy with dual-tracer were included. Adequate mapping (defined as ≥3 SLN) and false negative rate (FNR) of intraop FS were assessed by residual nodal disease burden (ypN0, ypNmi+ITC, ypN1-3). **Results:** Among 137 cT1-3 cN1 pts, 76 met inclusion criteria. Median age 45 yrs [27-82]; median tumor size 4.3cm [0.8-15.0]. 32 (42%) pts were ER+HER2-, 24 (32%) HER2+ and 20 (26%) ER-HER2-. Adequate mapping was achieved in 50 (66%) pts; 14 (18%) failed to map and 12 (16%) had < 3 SLN identified. Adequate mapping was not associated with residual node burden (table, p = 0.21). Among 48 pts with adequate mapping and FS, 16 were ypN+ on FS and 28 were ypN+ on final pathology; FNR of 12/28 (43%). Smaller residual node burden was associated with false negative FS (table, p = 0.005). 28/76 (37%) pts achieved axillary pCR, of whom 20 (71%) had ≥3 negative SLN and were spared ALND. Of 36 pts with successful mapping and positive SLN, 22 (61%) underwent ALND, of whom 8 (36%) had additional nodal disease; the remaining 14 (39%) had axillary radiation. **Conclusions:** Among pre-NAC cN1 pts, SLN biopsy was technically adequate in 66%. Of these, 40% achieved axillary pCR and avoided ALND. The FNR of intraop FS was 43%. Residual nodal disease burden was not associated with adequate mapping; micrometastases and ITCs were associated with higher likelihood of false negative FS. Preoperative counseling for SLN biopsy should include realistic assessment of the limitations of SLN mapping and intraop FS and the potential need for ALND.

	Volume of residual nodal disease in 76 patients with attempted SLN biopsy			
	ypN0 (n = 28, 37%)	ypNmi / ITCs (n = 11, 14%)	ypN1-3 (n = 37, 49%)	p-value
Adequate SLN mapping*	20/28 (71%)	9/11 (82%)	21/37 (57%)	0.21
FNR of FS in pts with ≥3 SLN	–	8/9 (89%)	5/20 (25%)	0.005

*≥3 SLN

585 Poster Session (Board #77), Sat, 8:00 AM-11:30 AM

Immune profiling of BRCA-mutated breast cancers. *First Author: Jeremy Meyer Force, Duke University Medical Center, Durham, NC*

Background: Increased tumor infiltrating lymphocytes (TILs) are predictive and prognostic for improved outcomes in breast cancers. Increased tumor mutational burden can be immune activating. BRCA-mutated (BRCA+) breast cancers may have increased tumor mutational burden compared to BRCA wildtype (BRCA-). Immune system responses to BRCA+ breast cancers have not been well described. The primary aim of our study was to assess tumor infiltrating immune cells in early stage breast cancers with and without germline BRCA mutations. **Methods:** Here we report TILs and genomic profiling from our full study cohort. Assuming the %TILs in the BRCA- group was 20% we determined 124 early stage breast cancers with and without BRCA mutations was needed to detect a 20% difference in TILs between cohorts to attain 80% power with a one-side alpha of 0.05. We identified 124 early stage untreated breast cancers with BRCA mutations (n = 62) and without (n = 62). Our BRCA- control group were matched by hormone receptor (HR) status followed by age then stage. TILs were measured on pretreatment H&E slides. A NanoString BC360 panel was applied to RNA isolated from 80 breast cancers (BRCA+ = 39; BRCA- = 41). **Results:** Compared to BRCA- early stage breast cancers, median TILs were increased in the BRCA+ cohort (median 5 vs 10, p = 0.007). BRCA+/HR- samples did not have more TILs compared to BRCA-/HR- (median 10 vs 15, p = 0.10). BRCA+/HR+ had increased TILs compared to BRCA-/HR+ (median 1 vs 5, p = 0.005). An 18 gene RNA tumor immune score (TIS) moderately correlated with TILs (R^2 = 0.339, p < 0.001), was increased in BRCA+ cancers (p = 0.29), but was primarily elevated in those with a basal-like phenotype (p < 0.001). **Conclusions:** Early stage BRCA+ breast cancers have increased TILs compared to BRCA-. TILs are significantly more abundant in BRCA+/HR+ breast cancers, which might be explained by an increased basal-like phenotype. TIS moderately correlates with TILs. TIS is increased in BRCA+ breast cancers, but reaches significance in the basal-like phenotype. Many BRCA+/HR+ cancers with luminal phenotypes had increased TILs and elevated TIS. To guide development of immunomodulating therapies in BRCA+ cancers, further immune analyses should be investigated in hereditary breast cancers and compared to sporadic cancers.

586 Poster Session (Board #78), Sat, 8:00 AM-11:30 AM

Durvalumab (MEDI4736) concurrent with nab-paclitaxel and dose dense doxorubicin cyclophosphamide (ddAC) as neoadjuvant therapy for triple negative breast cancer (TNBC). *First Author: Lajos Pusztai, Yale Cancer Center, New Haven, CT*

Background: The goal of this Phase I/II trial is to assess the safety and efficacy of concurrent administration of durvalumab with weekly nab-paclitaxel (100 mg/m2) x 12 followed by dd AC x 4 as neoadjuvant therapy for stage I-III TNBC. The primary efficacy endpoint is pathologic complete response (ypT0 ypN0, pCR). **Methods:** The Phase I portion of the trial assessed two dose levels of durvalumab; 3 mg/kg and 10 mg/kg iv every 2 weeks in combination with chemotherapy, dose limiting toxicities (DLT) were evaluated over the entire 20 weeks of therapy. The Phase II portion follows Simon's two step design, with early stopping for futility if < 7 patients achieve pCR among the first 22. **Results:** No DLT were encountered during the Phase I portion of the trial; the 10 mg/kg was recommended as the phase II dose. Thirty-two patients are enrolled in the trial 14 are still receiving therapy, 16 have completed treatment and underwent surgery and 1 patient withdraw consent. Nine patients (56%, 95% CI: 32%-78%) achieved pCR, 2 of the 4 patients at the 3 mg/kg dose level and 7 of the 12 at the 10 mg/kg dose. Eight patients (25%) experienced grade 3 adverse events including 3 patients with neutropenia (1 neutropenic fever), and one patient each with fatigue, dyspnea, line infection, transaminitis, hypertension/skin rash. No perioperative adverse events were seen. **Conclusions:** Concomitant administration of durvalumab with weekly nab-paclitaxel and sequential ddAC neoadjuvant chemotherapy is safe and the pCR rates appear to be higher than what is expected with chemotherapy alone. Clinical trial information: NCT02489448.

587 Poster Session (Board #79), Sat, 8:00 AM-11:30 AM

The impact of chemotherapy sequence on survival in node-positive invasive lobular carcinoma. *First Author: Nina Prabha Tamirisa, Duke University Medical Center, Durham, NC*

Background: Breast cancer patients with invasive lobular carcinoma (ILC) have lower rates of downstaging after neoadjuvant chemotherapy (NACT) than those with invasive ductal carcinoma; however, similar criteria – including lymph node involvement – are used to determine administration of NACT in both subtypes. We sought to determine the impact of chemotherapy sequence on survival among node-positive (cN+) ILC patients receiving systemic therapy. **Methods:** We identified cN1-3 ILC patients in the National Cancer Data Base (2004-2014) who received chemotherapy and divided them into neoadjuvant and adjuvant cohorts. Unadjusted overall survival (OS) was estimated using the Kaplan-Meier method, and differences between groups were tested using the log-rank test. Cox proportional hazards modeling was used to estimate the effect of chemotherapy timing on OS after adjustment for known covariates. **Results:** 75.7% (n = 17,957) of patients with cN+ ILC (n = 23,736) received chemotherapy; 7,609 (42.3%, median age 54, IQR 47-63) received NACT and 10,348 (57.6%, median age 58, IQR 49-66) received adjuvant chemotherapy. In both cohorts, most patients had grade 2 (NACT 50.1% vs adjuvant 54.2%), ER+ (NACT 86.6% vs adjuvant 92.3%), HER2- (NACT 80.6% vs adjuvant 87.6%) disease. NACT patients had higher rates of cT4 disease vs adjuvant patients (17.4% vs 2.3%, $p < 0.001$). Unadjusted 5-year OS was worse for NACT patients vs those receiving adjuvant chemotherapy (73.6% vs 83.1%, log-rank $p < 0.001$). In multivariate analysis, NACT continued to be associated with worse OS (HR 1.33, 95% CI 1.21-1.46). Improved OS was associated with age < 50 (HR 0.82, 95% CI 0.75-0.91), receipt of endocrine therapy (HR 0.60, 95% CI 0.53-0.68), and receipt of radiation therapy (HR 0.81, 95% CI 0.73-0.90). Worse OS was associated with ER- status (HR 1.22, 95% CI 1.03-1.44), PR- status (HR 1.55, 95% CI 1.39-1.72), cT4 stage (HR 2.09, 95% CI 1.76-2.47), and receipt of mastectomy (HR 1.30, 95% CI 1.15-1.45). **Conclusions:** Among node-positive ILC patients, receipt of NACT is associated with worse survival compared with receipt of adjuvant chemotherapy. These findings suggest that use of NACT in node-positive ILC may be of limited benefit and should be used judiciously.

588 Poster Session (Board #80), Sat, 8:00 AM-11:30 AM

Incidence of PI3K pathway aberrations and their impact on response to neoadjuvant chemotherapy (NACT) in triple-negative breast cancer (TNBC) subtypes. *First Author: Reva K Basho, Cedars-Sinai Medical Center, Los Angeles, CA*

Background: TNBC cell lines characterized as mesenchymal (M) and luminal androgen receptor (LAR) commonly have aberrations in the PI3K pathway. However, the incidence in human tumors and impact on response to therapy is less clear. **Methods:** Pre-treatment biopsies were collected from TNBC patients (pts) prior to NACT. Tumors were categorized into 5 groups using the Pietenpol criteria (Lehmann JCI 2011): basal-like (BL) comprised of BL-1 and BL-2, M comprised of M and mesenchymal stem-like, immunomodulatory (IM), LAR, or unspecified (UNS). Using RNAseq data, variants were identified in 16 PI3K pathway genes: *AKT1*, *AKT2*, *AKT3*, *CRKL*, *IRS2*, *MTOR*, *PIK3CA*, *PIK3CG*, *PIK3R1*, *PTEN*, *RICTOR*, *RPTOR*, *RNF43*, *TSC1*, *TSC2*. **Results:** Data was available in 63 pts (N = 4 stage I; N = 41 stage II; N = 18 stage III). There was no significant association between stage and subtype. 67 PI3K pathway variants were identified in 39 (62%) tumors. The incidence of mutated tumors and their differential response to NACT defined by residual cancer burden (RCB) in each subtype is presented in the table. There was no significant association between subtype and incidence of mutated tumors (P = 0.10). However, there were more mutated tumors in the LAR compared to non-LAR subsets (100% vs 57%); the majority of LAR tumors (5/7) had a variant in the *PIK3R1* gene. The incidence of mutated tumors in the M vs non-M subsets was similar (57% vs 63%). Pts with mutated tumors did not have a significantly worse response to NACT overall (46% vs 54%; P = 0.61) or within the M subset (25% vs 50%; P = 0.58). **Conclusions:** In this cohort of TNBC pts, the incidence of PI3K pathway aberrations was higher than previously reported, likely due to the comprehensive genes evaluated. There was no significant difference in incidence of aberrations across subtypes, and PI3K pathway aberration was not associated with altered response to NACT. Larger cohorts are needed to clarify the impact of PI3K pathway aberrations in TNBC subtypes.

Subtype	N	PI3K Mutated Tumors N (%)	RCB 0-I if PI3K Wild Type N (%)	RCB 0-I if PI3K Mutated N (%)

589 Poster Session (Board #81), Sat, 8:00 AM-11:30 AM

Ki67 to predict RCB0/I after neoadjuvant chemotherapy and endocrine therapy in HER2- breast cancer patients from ABCSG 34. *First Author: Christian F. Singer, Department of Gynecology and Obstetrics, Comprehensive Cancer Center, Medical University of Vienna, Vienna, Austria*

Background: Achievement of complete or near complete pCR (RCB0/I) after neoadjuvant systemic therapy is associated with improved DFS. We have evaluated the utility of Ki67 measurements in predicting RCB0/I in women with early breast cancer who were treated with neoadjuvant endocrine (NET) therapy or chemotherapy (NACT). **Methods:** This translational study was carried out within a prospectively randomized phase-II trial in 400 patients with HER2- eBC (ABCSG 34): 89 postmenopausal women with ER+++, or ER++ and Ki67 $< 14\%$, and G1/2/X tumors received 24 weeks of letrozole (NET). 311 postmenopausal patients with ER-, or ER+ and Ki67 $\geq 14\%$, or with G3 tumors, or premenopausal patients, received 8 cycles of anthracycline/taxane-based NACT. Ki67 was measured in the whole specimen area at baseline, after 12 weeks of therapy, and at surgery after 24 weeks, and was correlated with Residual Cancer Burden (RCB) and pCR. **Results:** Median Ki67 profoundly decreased after 12 weeks of NET and NACT, and there was no significant further decrease at 24 weeks. NACT-treated patients with a $\geq 30\%$ decrease at week 12 were more likely to achieve RCB0/I (OR 2.778 [95%CI 1.25-6.19], $p = 0.0124$), while no such effect was found in NET-treated patients. NACT-treated tumors with baseline Ki67$\geq 50\%$ were markedly more likely (OR 3.568 [95%CI 2.08-6.11], $p < 0.0001$) to achieve RCB0/I and pCR (OR 5.797 [2.88-11.66], $p < 0.0001$) when compared to tumors with Ki67 $< 50\%$. Conversely, NET-treated patients with baseline Ki67$\geq 20\%$ were less likely (OR of 0.268 [95%CI 0.08-0.85], $p < 0.0247$) to achieve RCB0/I. 76/153 patients with Ki67$\geq 50\%$ vs 26/120 with Ki67 $< 50\%$ experienced RCB0/I in response to NACT (NPV: 78.3%; PPV: 49.7%). 5/47 patients with Ki67$\geq 20\%$ vs 12/39 with Ki67 $< 20\%$ experienced RCB0/I in response to NET (NPV: 89.4%; PPV: 30.8%). **Conclusions:** Maximal Ki67 suppression was achieved after 12 weeks of neoadjuvant therapy, and a decrease of $\geq 30\%$ under NACT predicted excellent response (RCB 0/1). Baseline Ki67 values were *per se* already highly predictive in a clinically meaningful manner: NACT-treated tumors with a Ki67 of $\geq 50\%$ had a 1:1 chance to achieve RCB0/I, while NET-treated tumors with a Ki67 of $\geq 20\%$ achieved RCB0/I in only 1 out of 9 cases. Clinical trial information: 2011-004822-85.

590 Poster Session (Board #82), Sat, 8:00 AM-11:30 AM

Pathological complete response in basal subtype tumors to predict improved distant metastasis free survival in the NBRST trial. *First Author: Pat W. Whitworth, Nashville Breast Center, Nashville, TN*

Background: In the multi-institutional NBRST study (NCT01479101), conducted from June 2011 to December 2014, 20% of ER+/HER2- patients were classified as Basal subtype by the 80-gene functional subtype signature (80-GS). 3-year event-driven follow-up (FU) is now available. **Methods:** The 70-gene risk of recurrence signature (70-GS) and 80-GS results were combined to classify patients (Pts) into four molecular subtypes: Basal, HER2, Luminal-B (high risk Luminal), and Luminal-A (low risk Luminal). The rate of pathological complete response (pCR) was previously assessed following neoadjuvant therapy. Here we evaluated FU for these Pts to determine if pCR was predictive of positive outcome using distant metastasis free interval (DMFI) as an endpoint. **Results:** Of 706 NBRST Pts currently reporting FU, 35% were Basal, 16% HER2, 34% Luminal-B, and 15% Luminal-A. Overall 26% of Pts had a pCR, with notable differences by subtype: 34% in Basal, 67% in HER2, 9% in Luminal-B, and 5% pCR in Luminal-A patients. FU from diagnosis ranged from 0.3-70.8 months (median 34 months). Sixty-nine percent of Pts received some adjuvant therapy: 51% endocrine therapy (AET), 10% chemotherapy (ACT), and 16% received adjuvant targeted therapy (53% with AET/ACT). There were 94 DMFI events at last FU: 81 in Pts who did not have a pCR, 13 in Pts who did have a pCR. 80-GS basal subtype Pts who achieved a pCR exhibited better 3-yr probability of DMFI, compared to those who did not. **Conclusions:** NBRST's event-driven FU supports the I-SPY2 TRIAL's findings that a pCR predicts better distant metastasis free outcomes. The results in this population further show that 80-GS basal subtype patients with pCR have substantially better outcome at 3 years, compared to those who do not have pCR. 70-GS low risk Luminal Pts showed minimal impact with neoadjuvant chemotherapy. Clinical trial information: NCT01479101.

591 Poster Session (Board #83), Sat, 8:00 AM-11:30 AM

Pharmacokinetics of CT-P6 and reference trastuzumab by clinical factors in patients with HER2 positive early-stage breast cancer (EBC). *First Author: Justin Stebbing, NIHR Research Professor, Imperial College, London, United Kingdom*

Background: CT-P6 is a proposed biosimilar to reference trastuzumab, Herceptin (H) (Genentech, S San Francisco, CA, USA). A randomized phase III trial showed efficacy equivalence and comparable pharmacokinetics (PK) and safety between CT-P6 and H (NCT02162667). Clinical factors have been shown to affect trastuzumab parameters. We compared known factors that may affect the PK of CT-P6 and H in HER2 positive EBC patients. **Methods:** A total of 549 patients were randomized to receive CT-P6 (n = 271) or H (n = 278) with combination chemotherapy in the neoadjuvant setting. CT-P6 or H was administered at 8 mg/kg (Cycle 1 only) followed by 6mg/kg every 3 weeks. The primary endpoint was pathological complete response (pCR). Key PK parameters for CT-P6 and H were assessed during the neoadjuvant period in terms of C_{trough} and C_{max}. C_{trough} at steady state (predose of cycle 8, $C_{troughSS}$) was analyzed by age, race, weight, and pathological response. **Results:** The serum concentration gradually increased and steady state was reached at cycle 7 (predose of cycle 8). There was no statistically significant difference between CT-P6 and H in any of the subgroups analyzed. Clinical trial information: NCT02162667. **Conclusions:** The serum $C_{troughSS}$ level of trastuzumab was comparable between CT-P6 and H groups in all subgroups analyzed. These data support the PK similarity between CT-P6 and H independently of age, race, weight or pCR assessment method.

Statistical analysis of geometric mean $C_{troughSS}$ (μg/ml) for trastuzumab (ANOVA) by subgroup.

592 Poster Session (Board #84), Sat, 8:00 AM-11:30 AM

Dynamic genomic instability modulation by neoadjuvant therapy in early breast cancer (GEICAM/2006-03_2006-14). *First Author: Emilio Alba, Hospital Clínico Universitario Virgen de la Victoria. GEICAM Spanish Breast Cancer Group., Malaga, Spain*

Background: Genomic instability (GI) drives tumor development, generates selective clonal competence and enhances cancer aggressiveness. Copy Number Alterations (CNAs) data from a cohort of pre- and post-treatment (ttm) breast cancer (BC) tumors from patients (pts) in neoadjuvant trials GEICAM/2006-03 (NCT00432172) and GEICAM/2006-14 (NCT00841828) were used to obtain a GI Index for each sample. We analyzed the variation of GI index induced by therapy and their associations with tumor phenotype. **Methods:** GEICAM/2006-03 HER2-negative pts were selectively treated according to clinical subtypes: triple negative (TN) pts were treated with standard taxane/anthracycline-based chemotherapy (TA-CT) +/- carboplatin, while luminal patients were randomized to TA-CT vs. hormonotherapy; GEICAM/2006-14 HER2+ pts received TA-CT plus anti-HER2 therapy. Shallow-whole genome Illumina sequencing DNA data from 204 paraffin-BC (100 pre- and 104 post-ttm tumors) were segmented to obtain CNAs. The area under the segmentation curve (sum of segmented mean normalized by CNAs number) was calculated for each sample as index of GI. Differences between GI indexes in pre- and post-ttm samples were analyzed using Wilcoxon test. **Results:** A significant reduction in GI index was observed after ttm compared to pre-therapy samples (p = 5.1e-07), which was confirmed in a subset of pre/post-therapy paired tumors (N = 39, p = 0.0034). Luminal (61%) tumors revealed a significant decrease in GI index, both in overall population (median GI index: 0.141 pre-ttm vs 0.068 post-ttm, p = 1e-09) and in paired samples (0.126 vs 0.072, p = 0.00013). Similarly, HER2+ (9%) tumors showed a trend towards GI reduction (0.143 vs 0.079, p = 0.085). In contrast, TN (30%) cases presented an increasing trend in GI index in the residual tumor (0.132 pre- vs 0.17 post-ttm, p = 0.68). **Conclusions:** Our data suggest that GI could be a direct target of neoadjuvant therapy in BC. Treatment seems selectively eliminate tumor cells with higher genomic aberrations in luminal and HER2+ BC, resulting in a reduction of GI index in the residuals tumors. In contrast, according to previous publications, we suggest that GI could be a mechanism of adaptative CT resistance in TNBC. Clinical trial information: GEICAM/2006-03 NCT00432172. GEICAM/2006-14 NCT00841828.

593 Poster Session (Board #85), Sat, 8:00 AM-11:30 AM

Impact of metaplastic histology (MpBC) in triple-negative breast cancer (TNBC) patients (pts) receiving neoadjuvant systemic therapy (NAST). *First Author: Clinton Yam, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: MpBCs are aggressive cancers, often TNBC, and considered chemo-resistant, such that some providers avoid NAST. Using data from an IRB approved prospective trial, we compared characteristics and outcomes between MpBC and non-metaplastic (non-MpBC) TNBC pts receiving NAST. **Methods:** Per protocol, pts began a planned 4 cycles of Adriamycin-based chemo (AC). Volumetric change by ultrasound (vUS) was performed after 2 (optional) and 4 cycles of AC and evaluated as a predictor of response in MpBC pts. Pts with chemo-insensitive disease during/after AC were enrolled in targeted therapy trials (TT) as the 2nd phase of NAST. Sensitive disease received taxane-based therapy (T). Residual Cancer Burden (RCB) was assessed after surgery. Differences between MpBC and non-MpBC were analyzed by Fisher's exact, Wilcoxon rank sum and Student's t tests as appropriate. **Results:** 170 pts (21 MpBC, 149 non-MpBC) were evaluable for RCB including 2 pt deaths during AC (counted as RCB II-III). Despite lower rates of nodal positivity, [p = 0.002] and lower grade [p = 0.009], MpBC pts had higher rates of progression (PD) on AC (24 vs 8%; p = 0.041) and RCB II-III status after NAST [67 vs 42%; p = 0.036] (Table). Of the MpBCs with RCB 0-I (n = 7, 33%), 6 received AC-T and 1 had TT. 14 MpBC pts underwent vUS after 2 cycles of AC. Among these 14 pts, 21% had PD on vUS after 2 cycles of AC. Notably, pts with ≥60% volumetric reduction in the primary tumor (n = 4) had significantly higher RCB 0-I rates than those with < 60% (n = 10) [100 vs 10%, p = 0.005]. **Conclusions:** This is the largest prospective series of NAST outcomes in MpBC. A clinically acceptable RCB 0-I rate of 33% and the opportunity to participate in neoadjuvant and adjuvant trials supports the use of NAST in MpBC. MpBC pts should be monitored closely for PD while receiving NAST.

594 **Poster Session (Board #86), Sat, 8:00 AM-11:30 AM**

Neutrophil-to-lymphocyte ratio and platelet-to-lymphocyte ratio as prognostic markers in patients with HER2pos operable breast cancer treated with neo-adjuvant trastuzumab-containing chemotherapy. *First Author: Deirdre Kelly, Department of Medical Oncology, St Vincents University Hospital Dublin Ireland, Cork, Ireland*

Background: Inflammation plays an important role in cancer development and proliferation.Host systemic markers of inflammation including the neutrophil-to-lymphocyte ratio (NLR) have been associated with a poor prognosis in solid tumours. The objectives of our study were to evaluate NLR and platelets-to-lymphocytes ratio (PLR) in patients (pts) with operable HER2pos breast cancer (BrCa) treated with neo-adjuvant trastuzumab (T)-containing chemotherapy (NACT) and to correlate NLR and PLR with Disease Free Survival (DFS) and Overall Survival (OS). **Methods:** This was a retrospective, single-center analysis of a prospectively accrued Institutional database (The One-Thousand HER2pos Patients project) of non-metastatic operable HER2pos BrCa pts who received NACT. Pts with confirmed supraclavicular/internal mammary nodes were excluded. NLR and PLR were calculated at baseline prior to HER2 therapy (Tx) initiation. All patients underwent curative surgery (Sx) following T-containing NACT. **Results:** 156 female patients were included. Pts characteristics: median age 55.6(27-78) yrs, median time from diagnosis to initiation of HER2 Tx 4(1-18)weeks, ER positive 93(60%), cytology-proven positive lymph nodes at diagnosis 41 (26%). NACT was: TCH 116(74%), Docetaxel/Cyclophosphamide/T or single-agent taxane/T 20(13%), AC-TH/FEC-TH 7(4%), other regimens 13 (8%). Median follow up is 4.3(11-1)yrs. Pts with NLR $<$ 2.5 at baseline had significantly better PFS (HR 0.29 p = 0.03)and OS (HR 0.14 p = 0.07) compared to pts with NLR $>$ 2.5. Baseline PLR $<$ 150 was associated with superior OS (HR 0.15 p = 0.08) compared to PLR $>$ 150. No statistically significant association was observed between PLR and PFS. (HR 0.35 p = 0.07) **Conclusions:** This study represents one of the largest real-world datasets looking at NLR and PLR as prognostic markers in NACT for HER2pos BrCa. Baseline NLR $>$ 2.5 and PLR $>$ 150 are inexpensive and readily available prognostic markers of adverse outcome and may play a clinically significant role in refinement of risk estimates within disease stages and subgroups and treatment de-escalation.

595 **Poster Session (Board #87), Sat, 8:00 AM-11:30 AM**

Platinum-based neoadjuvant chemotherapy (NACT) in triple-negative breast cancer (TNBC): A systematic review and meta-analysis of randomized controlled trials (RCTs). *First Author: Francesca Poggio, Department of Medical Oncology, Institut Jules Bordet, L'Université Libre de Bruxelles (U.L.B.), Bruxelles, Belgium*

Background: The role of platinum-based NACT in TNBC is highly controversial and its use is not endorsed by current guidelines in unselected TNBC patients. Our meta-analysis aimed to better evaluate the activity, efficacy and safety of platinum-based NACT in TNBC. **Methods:** A systematic search of MEDLINE, Web of Knowledge and conference proceedings up to October 31th 2017 was performed to identify RCTs evaluating platinum-based vs. platinum-free NACT in TNBC patients. Summary risk estimates (odds ratio [OR] and hazard ratio [HR] with 95% confidence intervals [CI]) were calculated for the effect of platinum-based vs. platinum-free NACT in terms of pathological complete response (pCR: ypT0/is pN0), event-free survival (EFS), overall survival (OS), and grade 3-4 adverse events (AEs: neutropenia, anemia, thrombocytopenia and neuropathy). Pooled analyses were performed using the fixed- and random-effect models. This study is registered in the PROSPERO website (CRD42018080042). **Results:** Nine RCTs (n = 2,107 patients) were included. Overall, platinum-based NACT significantly increased pCR rates from 35.7% to 52.1% (OR 1.99, 95% CI 1.51-2.62). The result did not change and remained significant when considering only the 7 RCTs using anthracycline-and taxane-based NACT in both arms (54.1% vs. 38.7%; OR 1.88, 95% CI 1.34-2.63) or the 3 RCTs using the same standard regimen of weekly paclitaxel ($\pm$ platinum) followed by anthracycline and cyclophosphamide in both arms (54.9% vs. 33.3%; OR 2.53, 95% CI 1.37-4.66). Two RCTs (n = 748) reported on survival outcomes. A non-significant trend for improved EFS favoring platinum-based NACT (HR 0.72, 95% CI 0.49-1.06) was observed, with no difference in OS (HR 0.86, 95% CI 0.46-1.63). Platinum-based NACT was associated with a significantly higher risk of grade 3-4 hematological AEs and no increased risk of grade 3-4 neuropathy. **Conclusions:** Platinum-based NACT significantly improved pCR with a trend towards improved EFS at the cost of higher risk of hematological toxicities in TNBC. Our findings question the current recommendation to limit the use of platinum-based NACT only to *BRCA*-mutated breast cancer patients.

TPS596 **Poster Session (Board #88a), Sat, 8:00 AM-11:30 AM**

POSITIVE (IBCSG 48-14/BIG 8-13/A221405): Evaluating outcomes after interrupting endocrine therapy (ET) for women with endocrine responsive (ER+) early breast cancer (BC) who desire pregnancy. *First Author: Ann H. Partridge, Dana-Farber Cancer Institute, Boston, MA*

Background: Retrospective evidence suggests that pregnancy after BC does not negatively impact disease outcomes in pts with ER+ BC and is safe for the offspring. Young BC pts are often diagnosed before completing family planning, and cannot wait 5-10 yrs to complete ET before attempting pregnancy. Thus, prospectively evaluating the safety of temporary interruption of ET to allow conception is an unmet, patient-oriented, medical need. **Methods:** Young pts with ER+ early BC who desire pregnancy interrupt ET for approximately 2 yrs to attempt pregnancy [treatment wash-out (3 mos), and, ideally, conception (~3-6 mos), delivery (~9 mos), breast feeding if feasible (~6 mos)]. Pts are advised to resume ET as soon as child-bearing is completed to finish 5-10 yrs ET. Major eligibility requirements: pt wishes to become pregnant; histologically-proven stage I-III ER+ BC; age $\geq$ 18 and $\leq$ 42 yrs; prior adjuvant ET for $\geq$18 mos but $\leq$30 mos; premenopausal status at BC diagnosis. With 500 pts enrolled and followed for a median of 3 yrs, the statistical design is based on the 95% CI for the 3 yr BC recurrence rate; interim monitoring assumes a 2% BC recurrence risk/yr with continuous ET and high chance to stop early if the BC risk exceeds 4%/yr with ET interruption. Translational research will evaluate aspects related to fertility, pregnancy and BC biology. The Psycho-oncological Companion Study (POCS) explores psychological distress, fertility concerns and decisional conflicts (mandatory in the US and open to interested centers elsewhere), with a target accrual of 200. More than 170 participating centers in 20 countries: USA/Alliance, Canada/CCTG, Switzerland/SAKK, Italy, Belgium, Spain/SOLTI/GEICAM, Slovenia, Japan/JBCRG, Norway/NBCG, Netherlands/BOOG, Ireland/CTI, Portugal/SOLTI, Australia, Israel, Greece/HORG, Hungary, South Korea, Serbia, Austria/ABCSG and France. Eligible sites can open POSITIVE through NCTN (Alliance) or IBCSG, and referral to participating centers of eligible pts on ET who are interested in having a pregnancy after BC is strongly encouraged. Current Accrual (13 Feb 2018): 205 main study; 114 POCS. Clinical trial information: NCT02308085.

TPS597 **Poster Session (Board #88b), Sat, 8:00 AM-11:30 AM**

ABC trial (A011502): Randomized phase III double blinded placebo controlled trial of aspirin as adjuvant therapy for breast cancer. *First Author: Wendy Y. Chen, Dana-Farber Cancer Institute, Boston, MA*

Background: In-vitro and in-vivo evidence suggest that aspirin may have an anti-tumor effect. Epidemiologic studies have reported improved breast cancer survival among regular aspirin users compared to non-users. Pooled data from randomized trials of aspirin for cardiovascular disease have also reported a decreased risk of metastatic cancer with aspirin use. However, the exact benefits and risks for breast cancer survivors need to be confirmed in a randomized trial. Even if the clinical effect were modest, the global impact would be substantial since aspirin is inexpensive and widely available. **Methods:** Primary objective is to compare the effect of 300 mg daily aspirin vs placebo upon invasive disease-free survival (iDFS) in high risk HER2 negative breast cancer patients. Secondary objectives include effects on overall survival, cardiovascular disease, toxicity, and adherence. A biospecimen repository will be created for correlative analyses including tumor collection at baseline and blood and urine samples and questionnaires assessing lifestyle factors associated with inflammation (pain, sleep, stress, depression) at baseline and 2 years. Study design: Subjects will be randomized 1:1 to aspirin 300 mg vs placebo daily for 5 years in a double-blind fashion. Stratification factors include hormone receptor (HR) status (positive vs negative), body mass index ($<$ or $\geq$ 30 kg/m2), and stage. Subjects will be followed every 6 months while on study drug, then annually for 10 years. Accrual goal is 2936 patients to reach 381 iDFS events with 80% power to detect HR 0.75 assuming 5-year iDFS on placebo of 77%. Eligibility: Patients aged 18-70 diagnosed with a primary invasive HER2 negative breast cancer in the past year. If HR positive, tumors need to be node positive. If HR negative, tumor can be node positive or node negative with tumor size $>$ 2 cm. Patients who currently use any anticoagulant or those with a prior history of GI bleeding, atrial fibrillation, or myocardial infarction will be excluded. Regular aspirin users need to stop 30 days prior to enrollment. Study is actively enrolling. Updated accrual numbers will be given at the time of presentation. Clinical trial information: NCT02927249.

TPS598 Poster Session (Board #89a), Sat, 8:00 AM-11:30 AM

The Breast Cancer Weight Loss (BWEL) trial: Randomized phase III trial evaluating the role of weight loss in adjuvant treatment of overweight and obese women with early-stage breast cancer (Alliance A011401). *First Author: Jennifer A. Ligibel, Dana-Farber Cancer Institute, Boston, MA*

Background: Obesity is a growing health problem in the Unites States and around the world. Excess body weight has been linked to both an increased risk of developing breast cancer and poor prognosis in women diagnosed with early stage disease. A recent meta-analysis of 82 studies demonstrated that risk of breast cancer mortality was increased by 35% in women who were obese at the time of breast cancer diagnosis compared to women who were of normal weight. The Breast cancer Weight Loss (BWEL) study will evaluate the effect of weight loss after breast cancer diagnosis on risk of cancer recurrence. **Methods:** BWEL is a Phase III randomized trial evaluating the impact of a telephone-based weight loss intervention vs control on invasive disease-free survival (iDFS) in 3136 overweight and obese women with Stage II-III breast cancer. Eligibility criteria include diagnosis of hormone receptor positive or triple negative breast cancer within the preceding 12 months, body mass index of $\geq$27kg/m^2, and completion of surgery, chemotherapy, and radiation (if administered). Participants are randomized to a 2-year telephone- and mail-based weight loss intervention, adapted from the Diabetes Prevention Program, plus a health education program or to a health education alone control group. The study has 85% power, using a one-sided Type I error rate of 0.025, to detect a hazard ratio of 0.80 between groups. This equates to a 4.1% absolute reduction in iDFS events in the intervention group vs. controls. Secondary aims will evaluate the impact of the weight loss intervention upon overall survival, weight and body composition, and patient-reported outcomes. Fasting blood is collected serially over time, and tissue samples of malignant and benign breast tissue are collected at baseline to provide insight into the biologic mechanisms linking obesity and breast cancer. BWEL opened in September 2016. To date, 1015 patients have been randomized and more than 1100 sites in the US and Canada have activated the trial. Support: U10CA180821, U10CA180882, U10CA180820, U10CA180868, U10CA077202. Clinical trial information: NCT02750826.

TPS599 Poster Session (Board #89b), Sat, 8:00 AM-11:30 AM

Comparison of operative to monitoring and endocrine therapy for low-risk DCIS (COMET study). *First Author: Thomas Lynch, Duke University, Durham, NC*

Background: Approximately 50,000 women in the U.S. are diagnosed with ductal carcinoma *in situ* (DCIS) each year. Without treatment, it is estimated that only 20-30% of DCIS will lead to invasive breast cancer. However, over 97% of women are currently treated with guideline-concordant care (GCC) including surgery and/or radiation. An alternative to GCC is active surveillance (AS) which focuses on early detection of invasion rather than "treatment" of DCIS. The COMET study will compare risks and benefits of AS versus GCC in the setting of a Phase III pragmatic prospective randomized clinical trial. The study is funded by the Patient-Centered Outcomes Research Institute (PCORI). **Methods:** The primary objective is to assess whether the 2-, 5-, and 7-year ipsilateral invasive breast cancer rate for AS is non-inferior to that for GCC. Secondary objectives include determining whether AS is non-inferior to GCC for 2-year mastectomy rate; breast conservation rate; contralateral breast cancer rate; overall and breast cancer-specific survival. Patient reported outcomes (PROs) will enable comparison of health-related quality of life and psychosocial outcomes between GCC and AS groups at baseline, 6-months and years 1-5. Eligibility criteria include: age $>$ 40 at diagnosis; pathologic confirmation of grade I/II DCIS without invasion by two pathologists; ER and/or PR $\geq$ 10%; HER2-negative (0, 1+, or 2+ if testing performed). Following randomization to either GCC or AS, patients who decline participation will still be eligible to participate in the non-randomized cohort of the study. The planned accrual goal is 1200 randomized patients across 100 Alliance for Clinical Trials in Oncology sites, with a projected drop-out rate of 30%, for a total of approximately 900 patients treated according to randomized arm, analyzed in an intent-to-treat analysis. Sample size of n = 446 per group will have 80% power to detect the specified non-inferiority margin. The COMET trial opened in the U.S. in June 2017. To date, 50 sites have activated the trial. Comparable studies are taking place in UK (LORIS Trial) and Europe (EORTC LORD Trial); data from all three trials will be analyzed in a planned combined analysis. Clinical trial information: NCT02926911.

TPS600 Poster Session (Board #90a), Sat, 8:00 AM-11:30 AM

POSNOC: Positive Sentinel Node—Adjuvant therapy alone versus adjuvant therapy plus clearance or axillary radiotherapy. *First Author: Amit Goyal, Royal Derby Hospital, Derby, United Kingdom*

Background: Role of additional axillary treatment (AxT) (axillary lymph node dissection (ALND) or axillary radiotherapy (ART)) in women with macrometastases and undergoing systemic therapy remains unclear. Z11 included both micro and macrometastases (around 40% micrometastases) and showed that ALND may be omitted in women with $\leq$2 positive nodes undergoing breast conserving surgery (BCS) and receiving whole breast RT. Paradoxically, MA20, demonstrated improved DFS following the addition of regional RT. 51.8% (949/1832) had 1 or 2 positive nodes. 98.9% (1812/1832) had T1/T2 tumors. A post Z11 survey shows that most US oncologists treat the undissected axilla in women with macrometastases with ART rather than omitting AxT. Therefore, a confirmatory study is needed to clarify the role of additional AxT in women with $\leq$2 macrometastases undergoing BCS and other subgroups that were not included in Z11 e.g. mastectomy, extranodal invasion and sentinel node biopsy (SNB) before NACT. **Methods:** Primary objective is to assess whether for women with $\leq$2 macrometastases at SNB, systemic therapy alone is non inferior to systemic therapy plus AxT in terms of axillary recurrence at 5 years. Secondary objectives are arm morbidity assessed by LBCQ and QuickDASH questionnaires; QoL assessed by FACT B+4 questionnaire; anxiety assessed by STAI; locoregional recurrence; distant metastasis; time to axillary recurrence; axillary recurrence free survival; DFS; OS; contralateral breast cancer; non breast malignancy; economic evaluation. Eligibility criteria are: $\geq$18 y, uni or multifocal invasive cancer, T1/T2, 1 or 2 macrometastases, with or without extranodal invasion. Target sample size is 1900 with a projected drop out and non compliance with treatment allocation rate of 10%. Primary analysis will be per protocol. Following pre specified subgroup analyses shall be performed: number of macrometastases, age (50, $\geq$50), type of breast surgery, ER status, tumour grade (1 or 2, 3), SN assessment technique (OSNA, non OSNA), extranodal invasion. POSNOC opened to recruitment in July 2014. To date 960 women have been recruited at 82 sites in the UK and 18 sites in Australia and New Zealand. Clinical trial information: NCT02401685.

TPS601 Poster Session (Board #90b), Sat, 8:00 AM-11:30 AM

NRG Oncology/NSABP B-51/RTOG 1304: Phase III trial to determine if chest wall and regional nodal radiotherapy (CWRNRT) post mastectomy (Mx) or the addition of RNRT to breast RT post breast-conserving surgery (BCS) reduces invasive breast cancer recurrence-free interval (IBCR-FI) in patients (pts) with positive axillary (PAx) nodes who are ypN0 after neoadjuvant chemotherapy (NC). *First Author: Eleftherios P. Mamounas, NSABP/NRG Oncology, and Orlando Health UF Cancer Center, Orlando, FL*

Background: This phase III post-NC trial evaluates if CWRNRT post-Mx or whole breast irradiation (WBI) with RNRT after BCS significantly reduces the IBCR-FI rate in pts with PAx nodes that are negative after NC. Secondary aims are OS, LRR-FI, DR-FI, DFS-DCIS, second primary cancer, and comparison of RT effect on cosmesis in reconstructed Mx pts. Correlative science examines RT effect by tumor subtype, molecular outcome predictors for residual disease pts, and predictors for the degree of reduction in locoregional recurrence. **Methods:** Clinical T1-3, N1 IBC PAx nodes (FNA or core needle biopsy) pts complete $\geq$8 weeks of NC (anthracycline and/or taxane). HER2+ pts receive anti-HER2 therapy. Following NC, BCS or Mx, sentinel node biopsy ($\geq$2 nodes) and/or Ax dissection with histologically negative nodes is performed. ER/PR and HER-2neu status before NC is required. Pts receive appropriate adjuvant systemic therapy. Radiation credentialing with a facility questionnaire/case benchmark is required. Random assignment for Mx pts is to no CWRNRT or CWRNRT and for BCS pts to WBI or WBI+RNRT. Statistics: 1636 pts to be enrolled over 5 yrs (definitive analysis at 7.5 yrs). Study is powered at 80% to test that RT reduces the annual hazard rate of events for IBCR-FI by 35% for an absolute risk reduction of 4.6% (5-yr cumulative rate). Intent-to-treat analysis with 3 interim analyses (43, 86, and 129 events) and a 4th/final analysis at 172 events. Pt-reported outcomes focusing on RT effect will be provided by 736 pts before random assignment and at 3, 6, 12, and 24 mos. Accrual as of 1-23-18 is 848 (51.83%). TPS602 **Poster Session (Board #91a), Sat, 8:00 AM-11:30 AM**

KEYNOTE-522: Phase III study of pembrolizumab (pembro) + chemotherapy (chemo) vs placebo + chemo as neoadjuvant therapy followed by pembro vs placebo as adjuvant therapy for triple-negative breast cancer (TNBC). *First Author: Peter Schmid, Barts Cancer Institute, Centre for Experimental Cancer Medicine, London, United Kingdom*

Background: Recently presented data from the I-SPY 2 trial showed that pembrolizumab, a humanized, anti–PD-1 monoclonal antibody, significantly increased the pathologic complete response (pCR) rate in early-stage TNBC, when combined with neoadjuvant chemotherapy (Nanda et al. ASCO 2017. Abs 506). KEYNOTE-522 (NCT03036488) is a phase III study of pembro+ chemo vs placebo+chemo as neoadjuvant treatment, followed by pembro vs placebo as adjuvant treatment in pts with TNBC. **Methods:** Approximately 855 pts with TNBC, defined as combined primary tumor (T) and regional lymph node (N) staging per AJCC (investigator-assessed: T1c N1-2, T2-4 N0-2), will be randomly assigned to 1 of 2 arms. Stratification will be by tumor nodal status (positive vs negative), size (T1/T2 vs T3/T4), and carboplatin regimen choice (Q3W vs QW). In arm 1, pts will receive 4 cycles of pembro 200 mg Q3W+paclitaxel (80 mg/m^2 QW on d 1, 8, 15)+carboplatin (AUC 5 Q3W on d 1 or AUC 1.5 QW on d 1, 8, 15) and then 4 cycles of pembro+[doxorubicin (60 mg/m^2 Q3W on d 1) or epirubicin (90 mg/m^2 Q3W on d1)]+cyclophosphamide (600 mg/m^2 Q3W on d 1) as neoadjuvant therapy. In arm 2, placebo will replace pembro. Definitive surgery will be 3-6 wk after the last cycle, then pts will receive 9 cycles of pembro (200 mg Q3W) or placebo as adjuvant therapy. All cycles = 21d; treatment is up to 17 cycles or until disease progression/unacceptable toxicity. Primary end points are pCR rate using ypT0/Tis ypN0 and EFS. Secondary end points include safety, OS, and pCR rate by ypT0 ypN0, and ypT0/Tis in all pts; and OS, EFS, and pCR rate by ypT0/Tis ypN0, ypT0 ypN0, and ypT0/Tis in pts with PD-L1+ tumors (combined positive score, CPS$\geq$1). Eligible pts are aged $\geq$18 y with previously untreated, locally advanced, nonmetastatic TNBC. Pts with inflammatory breast cancer or bilateral or multifocal primary tumors are allowed. Adequate organ function and ECOG PS 0-1 are required. Pts with a history of invasive malignancy that was diagnosed and/or treated within the last 5 y are excluded. Clinical trial information: NCT03036488.

TPS603 **Poster Session (Board #91b), Sat, 8:00 AM-11:30 AM**

NSABP B-59/GBG 96-GeparDouze: A randomized double-blind phase III clinical trial of neoadjuvant chemotherapy (NAC) with atezolizumab or placebo in Patients (pts) with triple negative breast cancer (TNBC) followed by adjuvant atezolizumab or placebo. *First Author: Charles E. Geyer, NSABP/ NRG Oncology and Virginia Commonwealth University Massey Cancer Center, Richmond, VA*

Background: TNBC is associated with higher percentages of pathological complete response (pCR) to neoadjuvant chemotherapy (NAC), and women with a pCR have a favorable prognosis. However, Liedtke (2008) and Loibl (2017) found that women with residual disease have a substantially higher risk of recurrence than women with other subtypes of breast cancer. Additionally, Adams (2017) and Schmid (2017) found that therapeutic blockade of PD-L1 binding by atezolizumab has resulted in relevant antitumor efficacy. **Methods:** Design This is a phase III, double blind, placebo-control trial evaluating neoadjuvant atezolizumab with NAC followed by adjuvant atezolizumab in TNBC. Pts are stratified by region (North America; Europe), tumor size (1.1-3.0cm; $>$ 3.0cm), AC/EC schedule (q2w; q3w), and nodal status (positive; negative), then randomized 1:1 to receive atezolizumab/placebo 1200 mg IV every 3 wks concurrently with both sequential regimens of weekly paclitaxel 80 mg/m2 IV for 12 doses with every 3-wk carboplatin AUC of 5 IV for 4 doses followed by AC/EC every 2-3 wks (per investigator discretion) for 4 cycles. Following surgery, pts resume atezolizumab/placebo 1200 mg IV every 3 wks as adjuvant therapy for 6 months. Radiotherapy based on local standards is co-administered with atezolizumab/placebo. Eligibility criteria Centrally-confirmed ER-neg, PR-neg, HER2-neg invasive breast cancer by ASCO/CAP guidelines. Primary tumor must be stage T2 or T3 if cN0 or cN1 with negative biopsy or T1c, T2, or T3 if cN1 with positive biopsy or cN2 or cN3. LVEF $>$ 55% and no significant cardiac history. Statistical methods Co-primary endpoints are event-free survival (EFS) and pCR breast/nodes. Secondary endpoints include pCR breast, overall survival, distant disease-free survival, safety and toxicity. Trial is an academic collaboration between NSABP and GBG with support from Genentech/Roche. NCT03281954 Support: Genentech/Roche Clinical trial information: NCT03281954.

TPS604 **Poster Session (Board #92a), Sat, 8:00 AM-11:30 AM**

NRG Oncology BR005: Phase II trial assessing accuracy of tumor bed biopsies (Bx) in predicting pathologic response in patients (Pts) with clinical/radiological complete response (CR) after neoadjuvant chemotherapy (NCT) in order to explore the feasibility of breast-conserving treatment (BCT) without surgery. *First Author: Mark Basik, NRG Oncology, and The Jewish General Hospital, Montreal, QC, Canada*

Background: The increased use of neoadjuvant chemotherapy (NCT) has enabled higher rates of breast-conserving surgery (BCS) as well as provided prognostic information for women with breast cancer. High pathological complete response (pCR) rates question the requirement for surgery, with its attendant morbidity. In order to avoid surgery, the ability to predict pCR prior to it must be very high. Trimodality imaging alone is inadequate to predict pCR prior to surgery. We hypothesize that performing core needle biopsy (bx) of the tumor bed in addition to trimodality imaging in pts having had a clinical complete response (cCR) will increase the ability to predict pCR. Utilizing predetermined imaging response criteria of complete or near-complete response coupled with a stereotactic core needle bx of the tumor bed, BR-005 aims to determine the predictive value of imaging followed by tumor bed bx for pCR and demonstrate its reproducibility across a multi-institutional setting. **Methods:** 175 pts with operable focal or multifocal (T1-T3), stage II/IIIA invasive ductal carcinoma [all receptor subtypes]) will be entered. Pts must have completed a minimum of 8 wks of standard *neoadjuvant* chemotherapy and achieved a complete or near-complete radiologic tumor response on breast imaging with mammogram, ultrasound, and MRI, and undergo BCS. Following cCR and prior to surgery, pts will undergo a stereotactic-vacuum-assisted breast bx with clip placement. The primary endpoint is the proportion of pts with post-NCT neg image-directed bx who have a pCR. Residual cancer burden (RCB) scores and core bx pathology will be collected along with trimodality imaging data. Evaluation after 135 pts will allow for the possibility of early termination of the study. Results will provide the first step towards a paradigm change in the treatment of breast cancer, enabling a study to assess the criteria for successful avoidance of surgery in pts with high response rates to NCT. Accrual as of 1/19/2018: 13. Support U10CA180868, -180822, UG1CA189867 Clinical trial information: NCT03188393.

TPS605 **Poster Session (Board #92b), Sat, 8:00 AM-11:30 AM**

PARTNER: Randomised, phase II/III trial to evaluate the safety and efficacy of the addition of olaparib to platinum-based neoadjuvant chemotherapy in triple negative and/or germline BRCA mutated breast cancer patients. *First Author: Jean Abraham, University of Cambridge, Department of Oncology & NIHR Cambridge Biomedical Research Centre & Cambridge University Hospitals NHS Foundation Trust, Cambridge Breast Cancer Research Unit, Cambridge, United Kingdom*

Background: No specific targeted therapies are available for triple negative breast cancer (TNBC), an aggressive and diverse subgroup. The basal TNBC subgroup show some phenotypic and molecular similarities with germline BRCA mutated BC (gBRCA). In gBRCA patients, and potentially other homologous recombination deficiencies, these already compromised pathways may allow PARP inhibitors to work more effectively. PARTNER was designed to establish if the addition of olaparib to neoadjuvant platinum-based chemotherapy for basal TNBC and/or gBRCA BC is safe and improves efficacy (pathological complete response (pCR)). **Methods:** Trial design: 3-Stage open label randomised Phase II/III trial of neoadjuvant CP: Carboplatin AUC5 with weekly Paclitaxel 80mg/m2 +/- olaparib 150mgBD for 12 days x 4 cycles, followed by clinicians' choice of anthracycline regimen x 3 cycles. Basal-TNBC and / or gBRCAm patients are eligible for inclusion. Tumour infiltrating lymphocytes and basal profile are assessed at baseline. *Stage 1 and 2:* Patients are randomised (1:1:1) to CP: CP + olaparib from day (D) –2: or CP + olaparib from D 3. *Stage 3:* Patients are randomised (1:1) to either control arm or to the research arm selected in stage 2. Primary endpoints: *Stage 1* – Safety; *Stage 2* - Schedule selection criteria by pCR rate and completion rate of olaparib protocol treatment. 53 patients in each research arm will be evaluated within a "pick the winner" design. Null hypothesis of pCR $\leq$35% versus alternative hypothesis of pCR $\geq$55% will be tested with 90% power and 5% one sided significance level in each of the research arms. *Stage 3* - Efficacy: anticipated pCR ~45-55% for all trial patients and ~50-60% for gBRCA patients. The trial is powered to detect an absolute improvement of 15% (all patients) and 20% (gBRCA patients) by adding olaparib to chemotherapy (enriched design). Enrichment design is applied with overall significance level 0.05(α) = 0.025(αall) + 0.025 (αgBRCA) and 80% power. Current enrolment: 133 of planned 527 patients. *Stage 1* accrual is complete. *Stage 2* began in August 2017. 19 sites open and 12 more in active set-up. Clinical trial information: NCT03150576.

1000 **Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

Ribociclib (RIB) + fulvestrant (FUL) in postmenopausal women with hormone receptor-positive (HR+), HER2-negative (HER2–) advanced breast cancer (ABC): Results from MONALEESA-3. *First Author: Dennis J. Slamon, UCLA Medical Center, Santa Monica, CA*

Background: First-line RIB + letrozole significantly prolonged progression-free survival (PFS) in postmenopausal women with HR+, HER2– ABC. Here we report results from MONALEESA-3 (NCT02422615), a Phase 3 randomized, double-blind, placebo-controlled study of RIB + FUL in pts with HR+, HER2− ABC who received no or up to 1 line of prior endocrine therapy (ET) for ABC. **Methods:** Postmenopausal women with HR+, HER2– ABC were randomized 2:1 (stratified by presence of liver and/or lung metastases and prior ET) to RIB (600 mg/day; 3-weeks-on/1-week-off) + FUL (500 mg) or placebo (PBO) + FUL. Primary objective: investigator-assessed PFS. Secondary objectives included overall survival, overall response rate (ORR), clinical benefit rate (CBR), and safety. **Results:** 726 pts were enrolled. Baseline pt characteristics were balanced between arms. Median duration from randomization to data cut-off: 20.4 months. The primary objective was met: PFS was significantly improved in the RIB arm vs the PBO arm (hazard ratio: 0.593; 95% confidence interval [CI]: 0.480–0.732; $p = 4.10\times10^{-7}$); median PFS: 20.5 months; 95% CI: 18.5–23.5 vs 12.8 months; 95% CI: 10.9–16.3. Blinded independent review committee data supported primary efficacy results. Consistent PFS benefit was observed in pts with no (hazard ratio: 0.577; 95% CI: 0.415–0.802) and up to 1 line of prior ET for ABC (hazard ratio: 0.565; 95% CI: 0.428–0.744). In pts with measurable disease at baseline, ORR was 41% vs 29% (RIB vs PBO arm; p = 0.003); CBR was 69% vs 60% (p = 0.015). Common all-grade (G) adverse events (AEs; ≥30% of pts; RIB vs PBO arm) were neutropenia (70% vs 2%), nausea (45% vs 28%), and fatigue (31% vs 33%). In the RIB vs PBO arms, G3/4 neutropenia occurred in 47%/7% vs 0%/0% of pts, G3/4 increased ALT in 7%/2% vs < 1%/0%, and G3/4 increased AST in 5%/1% vs 1%/0%. Post-baseline QTcF > 480 ms (RIB vs PBO arm) occurred in 6% vs 3% of pts. **Conclusions:** RIB + FUL vs PBO + FUL significantly prolonged PFS and demonstrated a manageable safety profile in postmenopausal pts with HR+, HER2– ABC who received no or up to 1 line of prior ET for advanced disease. RIB + FUL may, therefore, be a treatment option for this pt population. Clinical trial information: NCT02422615.

1001 **Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

Genetic landscape of resistance to CDK4/6 inhibition in circulating tumor DNA (ctDNA) analysis of the PALOMA3 trial of palbociclib and fulvestrant versus placebo and fulvestrant. *First Author: Nicholas C. Turner, Royal Marsden NHS Foundation Trust, London, United Kingdom*

Background: CDK4/6 inhibition combined with endocrine therapy is now a standard of care for advanced estrogen receptor (ER) positive breast cancer. Mechanisms of resistance to CDK4/6 inhibitors have been described in pre-clinical models, although there is limited evidence from clinical samples. We investigated the mechanisms of resistance to CDK4/6 inhibitor in the PALOMA3 trial using ctDNA analysis. **Methods:** The PALOMA3 phase III trial randomized 521 patients with endocrine pre-treated disease to palbociclib and fulvestrant (P+F) versus placebo and fulvestrant (F). Using driver mutation targeted sequencing we conducted a longitudinal ctDNA analysis in 193 pairs of baseline and end of treatment (EOT) plasma samples, supplemented with exome ctDNA sequencing in 16 paired samples of high tumor purity from patients treated with P + F. **Results:** Paired ctDNA analysis was performed on P+F (n = 125) and F alone (n = 68), with the ctDNA cohort representative of the overall study. *RB1* mutations emerged at EOT on P+F in a small minority of patients (6/125, 4.8%, p = 0.041), with no *RB1* mutations emerging at EOT on F alone. New driver mutations emerged in both *PIK3CA* (p = 0.00018) and *ESR1* at EOT, in particular the *ESR1* Y537S mutation (p = 0.006), with no difference in frequency between P+F and F groups. Evolution of driver gene mutations was uncommon in patients progressing early on P+F, but common in patients progressing late on treatment. Paired exome analysis in 16 patients on P+F demonstrated that clonal evolution was frequent during P+F therapy, with copy number profiles remaining consistent before and after treatment. **Conclusions:** Breast cancer driver mutation landscapes are largely similar after treatment with P+F and with F alone, with acquired *PIK3CA* and *ESR1* Y537S mutations that likely contribute to fulvestrant resistance. Acquired *RB1* mutations are selected infrequently by P + F. These findings may inform future treatment strategies to address resistance to palbociclib and fulvestrant.

1002 **Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

Abemaciclib for pre/perimenopausal women with HR+, HER2- advanced breast cancer. *First Author: Patrick Neven, University Hospitals Leuven, Leuven, Belgium*

Background: Abemaciclib is a selective inhibitor of CDK4 & 6 that is dosed on a continuous schedule and is approved for the treatment of HR+, HER2- advanced breast cancer (ABC) as monotherapy and in combination with fulvestrant (F). In the intent-to-treat (ITT) population in the MONARCH 2 study, abemaciclib in combination with F demonstrated improved progression-free survival (PFS) and objective response rate (ORR) compared to placebo (P) + F (16.4 vs 9.3 months; hazard ratio [HR] .553; 95% CI: .449, .681; p < .0000001; ORR in measurable disease 48.1% vs 21.3%; p < .001). Here, we compare the efficacy and safety of abemaciclib + F vs P + F in the pre/peri-menopausal subgroup. **Methods:** MONARCH 2 was a Phase 3 randomized, double-blind, placebo-controlled study of abemaciclib + F vs P + F in pts with HR+, HER2- ABC that progressed on ET. Key eligibility criteria were: pre/peri- and post-menopausal women with HR+, HER2- ABC (pre/peri-menopausal pts received a GnRH agonist); ECOG PS ≤ 1; progression on (neo) adjuvant ET, ≤12 months from end of adjuvant ET, or on first line ET for metastatic disease; ≤1 line of ET; no prior chemotherapy for metastatic disease. Pts received orally administered abemaciclib 150 mg twice daily + 500 mg F (per label) or P + F. Primary objective was investigator-assessed PFS. Secondary objectives included ORR, clinical benefit rate, disease control rate, duration of response, safety and tolerability. **Results:** 114 pre/peri-menopausal pts were randomized 2:1 to abemaciclib + F (N = 72) and P + F (N = 42) arms. 57 PFS events were observed. Median PFS was not reached for the abemaciclib + F arm and was 10.5 months for the P + F arm (HR, .446; 95% CI: .264, .754; p = .002). In pts with measurable disease (n = 79, 69.3%), ORR was significantly higher in the abemaciclib + F arm: 60.8% (3.9% complete response [CR]) vs 28.6% (0% CR; p = .006). The most frequent adverse events (any grade) for abemaciclib + F vs P + F were diarrhea (87.3% vs 23.8%), neutropenia (59.2% vs 7.1%) and leukopenia (43.7% vs 4.8%). **Conclusions:** Abemaciclib + F in combination with a GnRH agonist significantly improved PFS and ORR, and had a generally tolerable safety profile in pre/peri-menopausal women with HR+, HER2- ABC. Clinical trial information: NCT02107703.

1003 **Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

Phase III multicenter, randomized study of utidelone plus capecitabine versus capecitabine alone for heavily pretreated, anthracycline- and taxane-refractory metastatic breast cancer. *First Author: Binghe Xu, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Utidelone, a genetically engineered epothilone analog, showed excellent efficacy in phase II and III trials in terms of PFS as a primary end point and ORR as a secondary end point. In this multi-center phase III trial, we sought to determine whether utidelone plus capecitabine (CAP) could improve overall survival (OS) compared with CAP alone in patients with metastatic breast cancer (MBC) previously treated with anthracycline and taxanes. **Methods:** A total of 405 patients with MBC previously treated with anthracycline and taxanes were randomly assigned with a 2:1 ratio to either utidelone (30mg/m^2/d intravenously on d1-d5) plus CAP (1,000 mg/m^2 orally bid on d1-d14) or CAP alone (1,250 mg/m^2 orally bid on d1-d14) given every three weeks. Kaplan-Meier methods were used to estimate the median OS , 2-year survival rate and corresponding 95% confidence intervals (CI) in the intention-to-treat (ITT) population between the two groups by means of two-sided log-rank tests. Survival HR (two-sided 95% CI) is computed using Cox proportional hazards model for the comparisons. **Results:** By March 9, 2018, 281 patients had died with 180 (66.7%) in the combination group and 101 (74.8%) in the CAP alone. In the ITT population, median OS was 14.75 months (95%CI 13.08-16.69) with combination group and 12.22 months (95%CI 11.14-14.26) with CAP alone. OS was significantly improved for the combination group vs CAP alone (HR 0·63, 95% CI 0·45—0·88 ; p = 0·0047). The 2-year survival rate was 39.0% (95% CI 33.2%, 45.1%) vs 26.6% (19.4%, 35.0%), which was significantly improved by 12.4% (1.9%- 22.4% ; p = 0.015) for utidelone plus CAP. Peripheral neuropathy was the only grade 3 adverse event associated with utidelone that occurred at a prominent rate (25%), but was manageable and reversible, in the combination arm. Notably, utidelone caused very mild myelosuppression and no liver toxicities. This is the first study to show a significant OS benefit of an epothilone, and utidelone is the first microtubule inhibitor to demonstrate non-significant myelosuppression with a superior safety profile compared with ixabepilone. **Conclusions:** Utidelone plus CAP significantly improved OS in this heavily pretreated population with no significant increase in myelosuppression and most other adverse events compared to CAP alone. Clinical trial information: NCT02253459.

1004 **Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

Efficacy of sacituzumab govitecan (anti-Trop-2-SN-38 antibody-drug conjugate) for treatment-refractory hormone-receptor positive (HR+)/HER2- metastatic breast cancer (mBC). *First Author: Aditya Bardia, Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA*

Background: Sacituzumab govitecan is a novel antibody-drug conjugate consisting of SN-38, the active metabolite of irinotecan, conjugated to a humanized mAb targeting Trop-2 (trophoblastic antigen-2), which is highly expressed in many epithelial cancers. A phase I/II basket trial (NCT01631552) investigated its activity in patients (pts) with advanced cancers, and we previously reported on pts with triple-negative mBC. Results in HR+/ HER2 negative (as per ASCO/CAP guidelines) mBC pts who had ≥ 1 prior hormonal therapy are presented here. **Methods:** Pts received sacituzumab govitecan at a dose of 10 mg/kg on days 1 & 8 of a 21-day cycle until progression or unacceptable toxicity. Eligibility included ≥ 1 prior line of standard therapy for metastatic disease, measurable disease by CT or MRI. Efficacy was assessed locally by RECIST 1.1. Adverse events (AE) were evaluated according to CTCAE v4.0, **Results:** Fifty-four pts with HR+/HER2- mBC (all female; median age 54 yrs, range 33-79) were accrued between 2/2015 and 6/2017. For metastatic disease, all pts received at least 2 prior treatments, with a median of 3 prior hormonal agents and 2 prior chemotherapy regimens. Prior treatments in any setting included taxane (93%), anthracycline (69%) and CDK 4/6 inhibitors (69%). 16 pts have died, 27 are in long-term follow-up and 11 still on treatment. The median number of doses was 11 (range 1-74). Treatment was generally well tolerated, with no treatment-related deaths. Based on currently available AE data, grade ≥ 3 toxicity (≥10%) included neutropenia and leukopenia; there was 1 case each of grade ≥ 3 diarrhea and febrile neutropenia. As of 12/31/2017 data cutoff, the overall response rate (ORR) was 31% (17 PRs/54) by local assessment, and the clinical benefit rate (CBR: PR+SD > 6 months) was 48%. For pts who received CDK inhibitors, ORR was 24% (9 PRs/37). Maturing durability of response and progression-free survival to be presented at the meeting. **Conclusions:** Sacituzumab govitecan as a single agent induced objective responses in heavily pre-treated HR+/HER2neg mBC, and was well tolerated with a safety profile consistent with previous reports. Clinical trial information: NCT01631552.

1005 **Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

Everolimus (EVE) + exemestane (EXE) vs EVE alone or capecitabine (CAP) for estrogen receptor-positive (ER+), human epidermal growth factor receptor 2-negative (HER2-) advanced breast cancer (ABC): BOLERO-6, an open-label phase 2 study. *First Author: Guy Heinrich Maria Jerusalem, CHU Sart Tilman Liège and Liège University, Liège, Belgium*

Background: BOLERO-6 (NCT01783444) was designed to estimate the clinical benefit of EVE + EXE vs EVE alone or CAP for ER+ HER2– ABC that progressed on nonsteroidal aromatase inhibitors. **Methods:** Patients were randomized 1:1:1 to EVE 10 mg/day + EXE 25 mg/day, EVE alone or CAP 1250 mg/m^2 twice-daily. The primary objective was to estimate the hazard ratio (HR) of progression-free survival (PFS) for EVE + EXE vs EVE. The key secondary objective was to estimate the HR of PFS for EVE + EXE vs CAP. Other secondary objectives were overall survival (OS) and safety. This was not a confirmatory study and no statistical comparisons were planned **Results:** 309 patients received EVE + EXE (n=104), EVE (n=103) or CAP (n=102). Baseline characteristics were generally consistent; however vs the EVE + EXE arm, patients in the CAP arm were younger (68% vs 63% were aged <65 years), more had bone-only lesions (24% vs 13%), were Caucasian (89% vs 75%) or fully active (56% vs 52%) and fewer had visceral disease (62% vs 66%) or ≥3 metastatic sites (44% vs 50%). Median follow-up from randomization to data cut-off (June 1, 2017) was 37.6 months. The estimated HR of PFS for EVE + EXE vs EVE was 0.74 (90% CI 0.57–0.97). The estimated HR of PFS for EVE + EXE vs CAP was 1.26 (90% CI 0.96–1.66) but a stratified multivariate Cox regression model adjusted on prognostic factors and baseline covariates with imbalances between arms gave a HR closer to 1 (HR 1.15; 90% CI 0.86–1.52). More patients in the CAP arm were censored for initiating new antineoplastic therapies (20% vs 9% with EVE + EXE). Median OS was 23.1 months with EVE + EXE vs 29.3 months with EVE (HR 1.27; 90% CI 0.95–1.70) and 25.6 months with CAP (HR 1.33; 90% CI 0.99–1.79). Grade 3/4 adverse events (AEs) were most common with CAP. Serious AEs were most common with EVE + EXE. **Conclusions:** The estimated HR of PFS for EVE + EXE vs EVE (0.74) is indicative of a treatment benefit. While the estimated HR of PFS for EVE + EXE vs CAP was 1.26, the CAP arm may have been favored by baseline imbalances and potential informative censoring. The safety profile of EVE + EXE was consistent with the known profile of this combination. Clinical trial information: NCT01783444.

LBA1006 **Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

Phase III study of taselisib (GDC-0032) + fulvestrant (FULV) *v* FULV in patients (pts) with estrogen receptor (ER)-positive, *PIK3CA*-mutant (MUT), locally advanced or metastatic breast cancer (MBC): Primary analysis from SANDPIPER. *First Author: Jose Baselga, Memorial Sloan Kettering Cancer Center, New York, NY*

The full, final text of this abstract will be available at abstracts.asco.org at 7:30 a.m. ET on Saturday, June 2, 2018, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2018, issue of the *Journal of Clinical Oncology*. On-site at the Meeting, this abstract will be printed in the Sunday edition of *ASCO Daily News*.

1007 **Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

AZD5363 plus paclitaxel versus placebo plus paclitaxel as first-line therapy for metastatic triple-negative breast cancer (PAKT): A randomised, double-blind, placebo-controlled, phase II trial. *First Author: Peter Schmid, Queen Mary University of London, London, United Kingdom*

Background: The PI3K/AKT signalling pathway is frequently activated in triple-negative breast cancer (TNBC). AZD5363 is a highly-selective, oral, small molecule AKT inhibitor. The PAKT trial investigated the addition of AZD5363 to paclitaxel as 1st-line therapy for TNBC. **Methods:** This investigator-led, double-blind, placebo-controlled, randomised phase II trial, recruited women with previously untreated, metastatic TNBC at 42 sites in 6 countries. Patients were randomly assigned (1:1) to paclitaxel 90mg/m^2 (days 1, 8, & 15) with either AZD5363 (400mg BD) or placebo (days 2-5, 9-12, 16-19) every 28 days until disease progression or unacceptable toxicity. The primary endpoint was progression-free survival (PFS). Secondary endpoints included overall survival (OS), PFS in the subgroup with *PIK3CA/AKT1/PTEN*-alterations, response, and safety. **Results:** Between 05/2014 and 06/2017, 140 patients were randomised to paclitaxel + AZD5363 (n = 70) or paclitaxel + placebo (n = 70). Median duration of follow-up was 18.2 months (95% CI, 13.6 to 24.0). In the ITT analysis, median PFS was 5.9 months (m) for AZD5363 compared to 4.2m for placebo (hazard ratio [HR], 0.75; 95% CI, 0.52 to 1.08; one-sided p = 0.06; two-sided p = 0.11 [predefined significance level of 0.10, one-sided]). Median OS was 19.1m for AZD5363 compared to 12.6m for placebo (HR, 0.64; 95% CI, 0.40 to 1.01; one-sided p = 0.02; two-sided p = 0.04). Results for the subgroup with *PIK3CA/AKT1/PTEN*-altered tumours will be presented. Most common grade 3 or worse adverse events were diarrhoea (12% [8/68] of AZD5363-treated patients *vs* 1% [1/70] of placebo-treated patients), infection (4% *vs* 1%), neutropenia (3% *vs* 3%), rash (4% *vs* 0) and fatigue (4% *vs* 0). **Conclusions:** The trial met its primary endpoint. Addition of AZD5363 to 1st-line paclitaxel therapy for TNBC resulted in significantly longer PFS and OS. AZD5363 warrants further investigation for the treatment of TNBC. Clinical trial information: NCT02423603.

1008 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Overall survival (OS) update of the double-blind placebo (PBO)-controlled randomized phase 2 LOTUS trial of first-line ipatasertib (IPAT) + paclitaxel (PAC) for locally advanced/metastatic triple-negative breast cancer (mTNBC). *First Author: Rebecca Dent, National Cancer Center, Singapore*

Background: In LOTUS (NCT02162719), adding the oral AKT inhibitor IPAT to first-line PAC for mTNBC improved progression-free survival (PFS; primary endpoint) [Kim, Lancet Oncol 2017]. The stratified PFS hazard ratio (HR) in the intent-to-treat (ITT) population (n = 124) was 0.60 (95% CI 0.37–0.98; p = 0.037; median PFS 6.2 vs 4.9 months with IPAT vs PBO, respectively). In prespecified analyses of patients (pts) with *PIK3CA/AKT1/PTEN*-altered tumors, the unstratified PFS HR was 0.44 (95% CI 0.20–0.99; median 9.0 vs 4.9 months). We now report updated OS results in the ITT population after OS events in ~50% of pts. OS results in the *PIK3CA/AKT1/PTEN*-altered subgroup are immature. **Methods:** Eligible pts had measurable inoperable mTNBC previously untreated with systemic therapy. Pts were stratified by prior (neo) adjuvant therapy, chemotherapy-free interval (6–12 months vs > 12 months vs not applicable) and tumor IHC PTEN status, and randomized 1:1 to PAC 80 mg/m^2 (d1, 8, & 15) with either IPAT 400 mg or PBO (d1–21) q28d until progression or unacceptable toxicity. OS was a prespecified secondary endpoint. **Results:** The table shows results after 23 months' follow-up (data cutoff 26 July, 2017). No new safety signals were seen. **Conclusions:** The previously observed PFS improvement with IPAT was followed by a trend toward improved OS (~5-month difference in the medians) at the updated OS analysis. Post-progression therapy was similar. These findings support further evaluation of first-line IPAT + PAC for mTNBC in the ongoing IPATunity130 (NCT03337724) randomized phase 3 trial. Final OS results from LOTUS are expected in 2019. Clinical trial information: NCT02162719.

Parameter	IPAT + PAC (n = 62)	PBO + PAC (n = 62)
OS events, n (%)	33 (53)	35 (56)
Median OS, months (95% CI)	23.1 (18.6–28.1)	18.4 (15.1–29.1)
OS hazard ratio (95% CI)	Stratified: 0.62 (0.37–1.05) Unstratified: 0.77 (0.48–1.25)	
1-year OS rate, % (95% CI)	83 (73–93)	70 (58–81)
Post-progression systemic anti-cancer therapy, n (%)	47 (76)	55 (89)
Immunotherapy	7 (11)	7 (11)
Adverse event leading to treatment discontinuation, n (%)[a]		
IPAT/PBO	4 (7)	1 (2)
PAC	7 (11)	6 (10)

1009 Clinical Science Symposium, Mon, 3:00 PM-4:30 PM

The integrated genomic and immune landscapes of lethal metastatic breast cancer (MBC). *First Author: Leticia De Mattos-Arruda, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain*

Background: The heterogeneous fates of MBC preclude our understanding of both resistance to therapy and escape from cancer immunoediting. Here, we performed a comprehensive molecular analysis of lethal MBC patients (pts), interrogating both the malignant and immune tumor microenvironment (TME) compartments, and T-cell receptor (TCR) repertoires, across multiple metastases (mets). **Methods:** Multi-platform profiling of mets (N = 182 mets to 22 organs, 5-36 mets/pt), primary tumors (pr) (N = 6) and ctDNA from body fluids (4.7/pt) in 10 warm autopsies of MBC pts (5 ER+/HER2-, 3 ER+/HER2+, 1 ER-/HER2+, 1 ER-/HER2-), included exome seq (N = 86), shallow whole genome seq (N = 168), RNA seq (N = 61), ultra-deep targeted seq (TS) (N = 243), TCRseq (N = 70) and IHC (N = 102). State-of-the-art bioinformatics was applied to the data. **Results:** Mutation (mut) burden landscape varied between pts (11,579 mut, median 255.41 mut/pt) and across mets within each pt (median 122 mut/met); was greater than TCGA mut burden (median 63.5 mut/pr, p = 4.927e-14). Landscape of mut and predicted neo-antigen were dominated by stem (present in all mets/pt) or clade (some mets/pt), but not private (one met/pt). TS data confirmed that all pr tumors contained the clonal ancestors of 10 pts, and characterized ctDNA bathing organs. Copy number alteration profiles were remarkably similar across mets in 9 of the 10 pts, except in a ER+/HER2- pt, whose mets shared a common ancestor (1q gain/16q loss), then early sub-clonal evolution occurred. Mets were grouped into phylogenic clades that share common genomic ancestry and accumulated previously unknown mutation signatures. Mets evolved as communities of clones as a fraction of the metastatic stem and clade mutations were sub-clonal. Immune TME was either homogeneous in a particular metastatic clade, or different across mets to a particular organ. Stem and clade clonotypes prevailed across TCR landscape within each pt. TCR repertoires revealed adaptive immune responses to co-evolve with the metastatic genomes. **Conclusions:** The genomic and immune landscapes demonstrate an unprecedented integrated view of the heterogeneous landscape of genomic aberrations, TME features and T-cell adaptive immune responses in lethal MBC.

1010 Clinical Science Symposium, Mon, 3:00 PM-4:30 PM

Determinants of high tumor mutational burden (TMB) and mutational signatures in breast cancer. *First Author: Romualdo Barroso-Sousa, Dana-Farber Cancer Institute, Boston, MA*

Background: High TMB correlates with high neoantigen burden, and this is thought to be predictive of response to immunotherapy. The aim of this work is to evaluate frequency, mutational patterns, and genomic profile of hypermutated breast cancer. **Methods:** We used sequencing data from publically available on cbioportal.org, including TCGA, France 2016, MSK-IMPACT, MBCProject, AACR-GENIE, and ongoing studies at our institute (The Center for Cancer Precision Medicine Metastatic Breast Cancer Study; The Young Women's Breast Cancer Study) to evaluate mutational load across breast cancers. Samples were classified as having high TMB if they had > 10 mutations (mut) per megabase (MB). **Results:** We included 3689 samples for the analysis. The median TMB was 1.55 mut/MB. TMB significantly varied according to histology (ductal > lobular, $p = 4.6 \times 10^{-13}$), tumor subtype (HR-/ HER2+ > TNBC > HR+/HER2+ > HR+/HER2-, $p < 0.05$), staging (metastatic > primary, $p = 2.2 \times 10^{-16}$) and site of metastasis (higher soft tissue, and lowest lung, $p < 0.05$). We found a total of 70 (~2%) hypermutated tumors (62.8% metastatic vs 37.2% primary samples). Mutational signature analysis of the hypermutated samples showed the presence of dominant APOBEC (77.1%), homologous recombination (HR; 2.9%), defective DNA mismatch repair (MMR; 18.6%), and POLE hypermutation (1.4%) signatures. Median TMB was higher for samples with POLE and HR signature, followed by those with MMR and APOBEC (93.1, 38.7, 14.6 and 12.4 mut/MB, respectively). Among hypermutated tumors, 8 samples had somatic mutation in the *POLE* gene, but only the case with POLE signature high had a characterized *POLE* driver mutation. In addition, 80% of hypermutated tumors with APOBEC signature had *PIK3CA* mutations *versus* 31% of hypermutated tumors with other signatures (p = 0.0005). **Conclusions:** TMB is correlated with clinical parameters including histology, receptor subtype and site of metastasis. Different mutational signatures are present in this population, including POLE, defective DNA MMR, HR and APOBEC. The potential role of these different signatures in predicting benefit to immunotherapy in hypermutated breast cancers is unclear, and warrants further investigation.

1011 Clinical Science Symposium, Mon, 3:00 PM-4:30 PM

TOPACIO/Keynote-162: Niraparib + pembrolizumab in patients (pts) with metastatic triple-negative breast cancer (TNBC), a phase 2 trial. *First Author: Shaveta Vinayak, Case Comprehensive Cancer Center, Case Western Reserve University School of Medicine, Cleveland, OH*

Background: Chemotherapy is a standard of care for TNBC despite its suboptimal efficacy. ≈15–20% of TNBC have *BRCA1/2* mutations (mut); ≈75% of *BRCA1* mut BCs are TN. Single agent poly(ADP-ribose) polymerase (PARP) inhibitors have clinical activity in pts with *BRCA1/2* mutations (*BRCA*mut) BC and provide median PFS of 6 mos in pts with *BRCA*mut TNBC vs 3.5 mos for chemotherapy. Single-agent pembrolizumab (pembro), a programmed death 1 (PD–1) inhibitor, has shown objective response rates (ORR) of 5–18% in previously treated TNBC. TOPACIO (NCT02657889) is a fully enrolled study evaluating the safety and efficacy of combination treatment with selective PARP1/2 inhibitor niraparib + pembro in pts with met TNBC. **Methods:** Pts received niraparib 200 mg orally once daily + pembro 200 mg IV on day 1 of each 21-day cycle. Primary efficacy endpoint was ORR and secondary endpoints included disease control rate (DCR = CR+PR+SD [stable disease]). **Results:** As of Jan 2018, 12 of 54 enrolled TNBC pts (22%) had deleterious *BRCA*mut; 9 (17%) not tested/indeterminate results. Median age was 54 yrs, with median of 1 prior line of therapy in the met setting (range 0–3); 22 (41%) had received prior platinum in the met setting; 39 (72%) had received prior (neo)adjuvant therapy. Forty-five pts were evaluable, with ≥1 on-study scan. To date, ORR is 29% and DCR is 49%, including 3 CR (7%), 10 PR (22%), 9 SD (20%), and 23 progressive disease (PD) (51%). Ten of 13 responders have ongoing responses; 13 pts have received > 6 mos of treatment (6 *BRCA*mut, 5 *BRCA*wt, 2 *BRCA*unk); 11 pts remain on treatment. The 12 *BRCA*mut pts were 1 CR, 7 PR, 1 SD and 3 PD. Median PFS in *BRCA*mut group is 8.1 mos (95% CI 0.2–NE). ORR (any *BRCA* status) was 33% in PD-L1-pos (combined proportion score ≥1%) vs 15% in PD-L1-neg pts. Treatment-related grade ≥3 AEs occurred in 27 pts (50%); most common were thrombocytopenia (13%) & anemia (11%). Follow-up is ongoing. **Conclusions:** Preliminary activity is encouraging with durable responses observed irrespective of *BRCA*1/2 or PD-L1 status or prior platinum exposure with the highest ORR in *BRCA*mut pts. No new safety signals were identified with the combination. Clinical trial information: NCT02657889.

	ORR	DCR
TNBC overall, n = 45	29%	49%
TNBC *BRCA*mut, n = 12	67%	75%

1012 Clinical Science Symposium, Mon, 3:00 PM-4:30 PM

Adaptive phase II randomized trial of nivolumab after induction treatment in triple negative breast cancer (TONIC trial): Final response data stage I and first translational data. *First Author: Marleen Kok, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Anti-PD(L)1 can result in durable responses in patients with metastatic triple negative breast cancer (TNBC). However, only a subgroup of TNBC patients benefits from anti-PD(L)1 with response rates of 5-10% in unselected cohorts. Strategies to render the tumor micro-environment (TME) more susceptible to anti-PD(L)1 might include stimulation of anti-cancer immune responses by induction treatment with irradiation or low dose chemotherapy. **Methods:** In stage I (non-comparative Simon's two stage design) patients with metastatic TNBC who received $\leq$ 3 lines of palliative chemotherapy were randomly allocated to one of five 2-week induction treatments consisting of 1) 3x8 Gy irradiation of one metastatic lesion 2) 2x doxorubicin 15mg weekly flat dose3) cyclophosphamide 50mg daily orally 4) 2x cisplatin 40mg/m^2 weekly 5) no induction treatment. After this induction period, all patients received nivolumab until iRECIST progression. After at least 5x10 evaluable patients with paired biopsies (stage I) arms will be closed according to a 'pick the winner' concept taking into account safety, clinical responses and immunological correlates. **Results:** Stage I has been closed with 66 patients available for response evaluation. Previous treatments for metastatic disease were 0, 1 or 2+ lines in 23%, 45% and 32%, respectively. For the total group the ORR is 20% with 2 CRs and 11 PRs. In addition, two patients had SD for $>$ 24 weeks (3%), resulting in a clinical benefit rate of 23%. ORR on nivolumab after induction with irradiation, doxorubicin, cyclophosphamide and cisplatin were 8% (1/12), 35% (6/17), 8% (1/12) and 23% (3/13), respectively. In the nivolumab-only cohort the ORR was 17% (2/12). Analyses of changes in the TME, gene expression and TCR sequencing induced by irradiation, low dose chemotherapy and nivolumab will be presented at the meeting as well as the design of stage II according to the 'pick the winner' strategy. **Conclusions:** This basket trial shows that short term induction with irradiation or low dose chemotherapy before nivolumab is feasible. Final clinical and translational results of stage I will be presented at ASCO 2018. Clinical trial information: NCT02499367.

1013 Poster Discussion Session; Displayed in Poster Session (Board #94), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

Final overall survival (OS) analysis of PHEREXA: A randomized phase III trial of trastuzumab (H) + capecitabine (X) ± pertuzumab (P) in patients with HER2-positive metastatic breast cancer (MBC) who experienced disease progression during or after H-based therapy. *First Author: Ander Urruticoechea, Onkologikoa Foundation, San Sebastían and Catalan Institute of Oncology-IDIBELL, L'Hospitalet de Llobregat, Barcelona, Spain*

Background: In PHEREXA (NCT01026142), adding P to H + X did not significantly improve independent review facility-assessed progression-free survival (IRF-PFS; primary endpoint) in patients with HER2-positive MBC who received a prior taxane and progressed during or after H-based therapy (hazard ratio [HR] 0.82; 95% confidence interval [CI] 0.65–1.02; p= .0731). An 8-month increase in median OS to 36.1 months was observed with P, but due to hierarchical testing of IRF-PFS, and subsequently of OS, statistical significance could not be claimed. No new safety signals were identified. We now report the final prespecified analysis. **Methods:** Randomization arms were A: intravenous H 8 mg/kg→6 mg/kg every 3 weeks (q3w) + oral X 1250 mg/m^2 twice daily (2 weeks on, 1 week off q3w) and B: intravenous P 840 mg→420 mg q3w + intravenous H per Arm A + oral X 1000 mg/m^2 (same schedule as Arm A). Treatment was given until disease progression, unmanageable toxicity, or patient request for discontinuation. OS and investigator-assessed PFS (INV-PFS) were assessed in the intent-to-treat population (all randomly assigned patients); adverse events (AEs), in the safety population (patients who received $\geq$1 dose of study drug). Results are descriptive. **Results:** At clinical cutoff (20-Sep-17), median time on study, including follow-up, was 23 months in Arm A and 33 months in Arm B. Efficacy is shown in the table. There was a small increase in AE incidence with longer follow-up, and no new symptomatic left ventricular systemic dysfunction (0 patients in Arm A and 5 [2.2%] in Arm B). **Conclusions:** While final OS results of PHEREXA are descriptive, median OS of 37.3 months in Arm B, with a 9.1-month increase versus Arm A, shows that clinical efficacy of H + P is maintained with longer follow-up. There were no new safety signals and no evidence of late cardiac toxicity. Clinical trial information: NCT01026142.

A phase I expansion cohorts study of SYD985 in heavily pretreated patients with HER2-positive or HER2-low metastatic breast cancer. *First Author: Cristina Saura, Medical Oncology Department, Breast Cancer Group, Vall d'Hebron University Hospital, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain*

Background: SYD985, (vic-)trastuzumab duocarmazine, is a HER2-targeting antibody-drug conjugate with a cleavable linker-duocarmycin payload that causes irreversible alkylation of the DNA in tumor cells. The dose-escalation part of a Phase I study was completed previously; we herein present preliminary efficacy data of the breast cancer expansion cohorts and safety data of all expansion cohorts (breast, gastric, urothelial and endometrial cancer). **Methods:** HER2 tumor expression was determined by a central lab and had to be immunohistochemistry (IHC) 1+ or higher; HER2-positive was defined as IHC 2+/3+/ISH+ and HER2-low as IHC 1+/2+/ISH-. Patients were treated with 1.2 mg/kg SYD985 IV every 3 weeks until disease progression or unacceptable toxicity. Tumor evaluation scans were done every 6 weeks. **Results:** Ninety-nine (99) breast cancer patients were enrolled. Of the 50 patients with HER2-positive breast cancer, the majority received 3 or more prior HER2-targeting regimens in the locally advanced or metastatic setting, including (ado-)trastuzumab emtansine in 80% of the patients. Preliminary results showed that SYD985 demonstrated an overall response rate (ORR) of 33% and a median PFS of 9.4 months. At the time of data cut-off, 8 patients (16%) received SYD985 for over one year and 5 patients (10%) continued to receive treatment. Efficacy has also been demonstrated in heavily pretreated patients with HER2-low metastatic breast cancer, including hormone-receptor positive (N = 32) and triple-negative breast cancer (N = 17). The ORRs were 27% and 40%, respectively, with several patients ongoing on SYD985. The safety profile was manageable and mainly characterized by grade 1 and 2 events. The most common adverse drug reactions were fatigue, dry eyes, conjunctivitis and increased lacrimation. Grade 3/4 adverse drug reactions most commonly reported included neutropenia (6%) and conjunctivitis (4%). **Conclusions:** SYD985 shows promising efficacy in heavily pretreated patients with breast cancer, in both HER2-positive and HER2-low tumors with or without hormone receptor expression. A Phase III study (TULIP) is currently ongoing in HER2-positive breast cancer patients. Clinical trial information: NCT02277717.

Clinical benefit of tucatinib after isolated brain progression: A retrospective pooled analysis of tucatinib phase 1b studies in HER2+ breast cancer. *First Author: Rashmi Krishna Murthy, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: For MBC patients with isolated brain progression, current guidelines recommend treatment with CNS-directed therapy and continuation of current systemic therapy, although there are limited data evaluating this strategy. Two Phase 1b trials of tucatinib permitted patients with HER2+ MBC to continue study treatment following CNS-directed therapy in instances of isolated brain metastases (BM) progression. **Methods:** 2 Phase 1b studies of tucatinib were pooled to identify patients with isolated brain progression (defined as new or progressive BM with stable or responding systemic disease) while on study. In patients treated for isolated brain progression, the median time to any subsequent progression or death was determined. **Results:** 117 patients were analyzed, 57 in the 004 (tucatinib + T-DM1) and 60 in the 005 (tucatinib +/- trastuzumab +/- capecitabine) trials. 25 patients (21%) with isolated BM were identified and comprised 2 groups: 14 who discontinued study and 11 who continued study treatment following CNS-directed therapy. Median time to isolated brain progression differed between these groups (12.3 months in post-progression treated vs. 6.3 months). The median time to any second event was 8.3 months in the post-progression CNS-treated patients. Patients selected for post-progression treatment had less exposure to pertuzumab, were more frequently treated with the triplet combination, had a longer time from pre-study CNS-directed therapy, had better preserved performance status, and were less likely to have new neurologic adverse events compared to patients not treated post-progression. **Conclusions:** Patients with isolated BM progression treated post-progression with CNS-directed therapy and continuation of study therapy had a median of 8.3 months to any second event, suggesting a substantial benefit for this treatment strategy. The selection of patients with post-progression treatment appears to be a composite of characteristics both at baseline and at time of brain progression. These results support the further evaluation of this approach to patients with isolated brain progression in the ongoing randomized HER2CLIMB trial. Clinical trial information: NCT01983501 and NCT02025192.

A phase II, single arm study assessing the efficacy of pembrolizumab (Pembro) plus radiotherapy (RT) in metastatic triple negative breast cancer (mTNBC). *First Author: Heather L. McArthur, Cedars-Sinai Medical Center, Los Angeles, CA*

Background: Overall response rates of 5-7% have been reported with checkpoint inhibitor monotherapy in PD-L1-unselected mTNBC as second line or subsequent therapy. RT is frequently used to enhance local control in mTNBC and has been reported to induce distant (abscopal) tumor responses when combined with immunotherapy. In this study, we evaluate the safety and efficacy of RT combined with pembro, a programmed death 1 (PD-1) inhibitor, in a phase II, single-arm, Simon two-stage, study in mTNBC. **Methods:** Eligible women had biopsy-proven mTNBC and ≥2 measurable sites of metastatic disease with at least one site requiring RT. PD-L1 expression was not required for study entry. A total RT dose of 3000 cGy was delivered in 5 daily fractions. Pembro was given intravenously at 200 mg within 3 days of the first RT fraction, then every 3 weeks +/-3 days until disease progression. The primary endpoint was overall response rate at week 13 in the non-irradiated lesions by RECIST v1.1. Secondary endpoints included safety and overall survival. Tumor biopsies were obtained at baseline and at week 7. **Results:** Of the 17 women enrolled, the median age was 52 y (range 37-73y), and the median number of prior cytotoxic therapies for metastatic disease was 3 (range 0 to 8). Of the 8 women not evaluable at 13 weeks: 5 died secondary to disease-related complications (at weeks 2, 6, 7, 8, and 9) and 3 progressed prior to week 13. Of the 9 women evaluable at week 13, 3 (33%) had a partial response, 1 (11%) had stable disease and 5 (56%) had disease progression. The stable disease response was durable for 22 weeks. The 3 partial responses represented 60%, 54%, and 34% decreases in tumor burden by RECIST v1.1 and were durable for 31, 21, and 40 weeks, respectively. Common toxicities were mild and included fatigue, myalgia and nausea. **Conclusions:** The combination of pembro and RT was well-tolerated with durable responses outside the RT field in 3/9 (33%) evaluable patients unselected for PD-L1 expression. Thus, the addition of RT to PD-1 blockade represents a promising strategy for improving response rates in pre-treated mTNBC. Clinical trial information: NCT02730130.

1018 Poster Discussion Session; Displayed in Poster Session (Board #99), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

Clinical and biomarker results from phase I/II study of PI3K inhibitor BYL 719 (alpelisib) plus nab-paclitaxel in HER2-negative metastatic breast cancer. *First Author: Priyanka Sharma, University of Kansas Medical Center, Kansas City, KS*

Background: Activation of Phosphatidylinositol-3-kinase (PI3K) pathway may confer resistance to taxanes and in preclinical models concomitant inhibition of the PI3K pathway enhances efficacy of taxanes. Alpelisib is a potent oral, class I inhibitor of PI3K alpha isoforms with antitumor activity in tumors that harbor PI3KCA mutations. **Methods:** Eligible patients had HER-2 negative MBC with any number of prior chemotherapy. Phase I was 3+3 dose-escalation design with three dose levels of alpelisib (250mg, 300mg, 350mg) PO daily (D1-28) and nab-Paclitaxel (nP) 100 mg/m^2 D 1, 8, 15 every 28 days. Phase II was designed according to Simon's Minimax design. Aims were to determine 1) Recommended Phase II Dose (RPTD), 2) Objective Response Rate (ORR), 3) Progression-free survival (PFS). PIK3CA activating mutations in tumor and circulating tumor DNA (ctDNA) were assessed using next-generation sequencing. **Results:** There were no DLTs in the three dose levels of phase I (n = 10). 33 patients were treated in phase II on the RPTD (Alpelisib 350mg PO daily plus nP 100mg/m2 D1,8,15 every 28 days). Median age was 55 years; 30% had TNBC. 84% had visceral disease, 74% had received prior chemotherapy for MBC, 84% had received prior taxane. Hyperglycemia (G3:29%,G4:0%), neutropenia (G3:24%,G4: 7%), anemia (G3:12%, G4:0%), diarrhea (G3:7%, G4:0%) were the most common grade 3/4 adverse events. In 42 patients evaluable for response, ORR was 57% (24/42) (CR = 2, PR = 22) and an additional 21% demonstrated SD ≥16wks. ORR for patients treated at RPTD was 55% (18/33). Median PFS is 9 months (95% CI: 6-12). Mean duration of treatment is 8 months(2-26 months). 40%(17/42) demonstrated tissue and/or ctDNA PIK3CA mutation (ctDNA/tissue concordance = 70%). Compared to patients without PIK3CA mutation, those with PIK3CA mutation demonstrated significantly better PFS (7 vs 13 months HR = 0.39, p = 0.03). **Conclusions:** Alpelisib and nP combination shows encouraging efficacy with manageable toxicity in HER2 negative MBC. Efficacy was especially robust in patients with PIK3CA mutation (ORR = 65%, PFS = 13months). Randomized trial of this combination in PIK3CA mutation selected patients is warranted. Clinical trial information: NCT02379247.

1019 Poster Discussion Session; Displayed in Poster Session (Board #100), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

The impact of circulating tumor cells (CTCs) detection in metastatic breast cancer (MBC): Implications of "*indolent*" stage IV disease (Stage IV$_{indolent}$). *First Author: Andrew A. Davis, Robert H. Lurie Comprehensive Cancer Center, Feinberg School of Medicine, Northwestern University, Chicago, IL*

Background: CTCs count has been validated as a prognostic biomarker in MBC. In primary breast cancer, diagnostic tools exist to select less aggressive treatments in patients with indolent disease. In the largest CTC analysis to date, we define an indolent subset of patients in MBC, Stage IV $_{indolent}$, identified using CTC counts. **Methods:** We performed a combined pooled analysis of individual patient data in two large cohorts: the European Pooled Analysis Investigators (EPAC) cohort (N = 1,944) and the MD Anderson Cancer Center (MDACC) cohort (N = 492). For all patients (N = 2,436), CTC enumeration was performed using the FDA-approved CellSearch™ (Menarini Silicon Biosystems, LLC) with baseline samples collected before starting a new treatment. Overall survival (OS) data were collected from both cohorts. Patients were stratified based on 5 CTCs/7.5 mL blood (N = 1,336 with < 5 CTC or Stage IV $_{indolent;}$ ≥5 CTC, Stage IV $_{aggressive}$). Proportional hazards regression model and stratified log rank tests were performed. **Results:** For all patients, CTC ≥5 identified patients with a worse outcome (HR 2.43, 95% CI 2.17-2.73, P < 0.0001), while the indolent CTC group had a median OS of 36.3 months (mts). Moreover, for patients with *de novo* MBC prior to treatment (N = 244), the indolent cohort demonstrated an OS greater than 5.5 years. The Stage IV $_{indolent}$ disease showed significantly longer OS across all disease subtypes compared to the aggressive cohort, HR+ (44 mts vs. 17.3 mts, P < 0.0001), TNBC (23.8 mts vs. 9.0 mts, P < 0.0001), and HER2+ (36.7 mts vs. 20.4 mts, P < 0.0001). Furthermore, Stage IV $_{indolent}$ consistently discriminated a less aggressive cohort among subtypes even in the refractory setting. **Conclusions:** CTC < 5 identifies an indolent subset of MBC, Stage IV $_{indolent}$, independent of line of treatment and molecular subtype. A CTCs-based classification of MBC has tremendous implications and practical applications including, considerations for cost-effective single-agent therapy, particularly in the first-line setting, and the availability of a validated stratification tool in prospective efficacy clinical trials.

Comparison of tissue genotyping (TG) vs circulating tumor DNA (ctDNA) for selection of matched therapy and impact on clinical outcomes among patients with metastatic breast cancer (MBC). *First Author: Neelima Vidula, UC San Francisco, San Francisco, CA*

Background: Oncogenic mutations are attractive targets for targeted therapies, but the clinical impact is unclear. We evaluated the impact of TG or ctDNA on the selection of matched therapy and clinical outcomes in MBC patients. **Methods:** MBC patients with TG (Next Generation Sequencing/NGS, institutional platform) or ctDNA (NGS, Guardant360) at Massachusetts General Hospital between 1/2016-12/2017 were identified. A review of records to identify tumor subtype, demographics, treatment, outcomes, and TG or ctDNA results was performed. Associations between genomic results and the selection of matched therapy targeted to an actionable mutation, progression free survival, and overall survival (OS) were determined. **Results:** Among 252 patients with ctDNA testing, 232 (92%) had detectable mutations. Of those 232 cases, 196 (84%) had actionable mutations and 86 patients with actionable mutations received matched therapy with agents including CDK 4/6, mTOR, PI3K, AKT, PARP, androgen receptor, and FGFR inhibitors, SERDs, HER2 directed therapy, and DNA damaging chemotherapy. Among 118 patients with TG, 90 (76%) had detectable mutations. Of those 90 cases, 59 (66%) were actionable and 13 patients with actionable mutations received matched therapy with agents including mTOR, PI3K, or AKT inhibitors, or SERDs. There were significantly more actionable mutations detectable by ctDNA vs TG (84.5% vs 65.6%, $p < 0.0005$) and a significantly higher proportion of patients with ctDNA vs TG received matched therapy (46.7% vs 27.7%, $p = 0.018$). On multivariate Cox regression analysis adjusted for tumor subtype in ctDNA patients, OS was significantly better for patients with matched therapy vs those with unmatched therapy (HR 0.45, 95% CI 0.25-0.80, $p = 0.007$). Additional survival analyses will be presented at the meeting. **Conclusions:** ctDNA testing resulted in higher detection and greater application of matched therapy as compared with TG. Patients who had matched therapy based on ctDNA results had better OS compared to those with unmatched therapy post-ctDNA testing. These novel findings require confirmation in additional studies.

Molecular alterations in the Ras-Raf-Erk (MAPK) pathway in metastatic hormone receptor positive (HR+)/HER2- breast cancer: Incidence and impact on clinical outcomes. *First Author: Arielle Medford, Massachusetts General Hospital, Boston, MA*

Background: While molecular alterations in PI3K pathway, including *PIK3CA* mutations, are common in HR+ breast cancer, molecular alterations in MAPK pathway, including *KRAS* and *BRAF* mutations, are considered rare in HR+ breast cancer. However, tumors can acquire new molecular alterations over time, and blood-based genotyping via circulating tumor DNA (ctDNA) could provide a more accurate molecular snapshot. **Methods:** This study analyzed data collected from metastatic breast cancer (MBC) patients who had genotyping (2016-2017) via a next generation sequencing-based (NGS) assay that detects ctDNA mutations (Guardant 360 panel), including alterations in MAPK pathway. Mutation profiles were also analyzed in tissue biopsies via SNaPshot-NGS, an institutional genotyping assay. Multivariate analysis was performed to evaluate the hazard ratio (HR) for the association between these mutations and time to progression (TTP), adjusting for key prognostic variables. **Results:** Among the HR+ MBC patients (N = 174), 25% (N = 44) were found to have molecular alterations in MAPK pathway in ctDNA, including mutations in *BRAF* (7.5%), *KRAS* (5.7%), *NRAS* (0.57%), *MAP2K1* (1.1%) and *NF-1* (14.4%); 14.5% had a concurrent *PIK3CA* mutation, 9.2% had a concurrent *TP53* mutation, and multiple alterations were acquired. Among patients with MAPK molecular alterations versus not, there was no significant difference in baseline characteristics, including age at metastatic diagnosis (57 vs 55; $p = 0.78$) and visceral metastases (74% vs 81%; $p = 0.87$). In multivariate analysis, patients with MBC harboring MAPK molecular alterations had worse TTP (HR: 2.08; $p = 0.02$) compared to controls. However, there was no difference among those with *PIK3CA* mutant tumors versus not (HR: 1.09; $p = 0.74$). **Conclusions:** Molecular alterations in MAPK pathway, hitherto considered rare in primary HR+ breast cancer, are not uncommon in metastatic HR+ breast cancer and are associated with worse outcomes. The study highlights the value of blood-based assays for identification of novel targets and their potential clinical utility in development of genotype driven trials for patients with MBC.

First-line ribociclib (RIB) + letrozole (LET) in hormone receptor-positive (HR+), HER2-negative (HER2–) advanced breast cancer (ABC): MONALEESA-2 biomarker analyses. *First Author: Gabriel N. Hortobagyi, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: In MONALEESA-2, first-line RIB + LET improved investigator-assessed progression-free survival (PFS; primary endpoint) vs placebo (PBO) + LET in postmenopausal pts with HR+, HER2– ABC. Previous MONALEESA-2 biomarker analyses, involving immunohistochemistry, gene expression, and NGS of ctDNA, showed consistent RIB benefit. Here, we present additional MONALEESA-2 gene expression data. **Methods:** Tumor samples (n/N, 391/668) were evaluated for gene expression using the NanoString 230-gene nCounter® GX Human Cancer Reference panel. To assess correlations between gene expression level and PFS, pts were classified into low (L) and high (H) messenger RNA expression subgroups using a 10% cut-off for *RB1* and median expression as the cut-off for other genes. Cox proportional hazards models were used to estimate hazard ratios and 95% confidence intervals (CI). **Results:** RIB + LET improved PFS in all pt subgroups (Table). Kaplan–Meier curves will be presented. Clinical trial information: NCT01958021. **Conclusions:** Benefit of RIB was consistent across gene expression subgroups; H vs L *ESR1* and L vs H RTK expression trended towards greater RIB benefit. Genes implicated preclinically in mechanisms of resistance to CDK4/6 inhibitors require further investigation based on metastatic/liquid biopsies, and in larger clinical datasets.

Treatment effect of palbociclib (PAL) plus endocrine therapy (ET) by prognostic and intrinsic subtype: A joint analysis of PALOMA2 and PALOMA3. *First Author: Richard S. Finn, David Geffen School of Medicine at University of California, Los Angeles, Santa Monica, CA*

Background: PAL + ET showed significant progression-free survival (PFS) benefit vs ET alone in patients (pts) with HR+/HER2- advanced breast cancer (ABC) in PALOMA2 (PAL2) and PALOMA3 (PAL3). Exploratory analyses were conducted on pts who received neo/adjuvant therapy to evaluate the effect of initial disease-free interval (DFI) in PAL3 or treatment-free interval (TFI) in PAL2 on PFS outcomes. Other analyses assessed luminal (Lum) subtype on PAL efficacy. **Methods:** Pre/postmenopausal pts whose disease has progressed after prior ET (PAL3; N = 521) and postmenopausal pts previously untreated for ABC (PAL2; N = 666) were randomized 2:1 to receive ET (fulvestrant [F] 500 mg or letrozole [L] 2.5mg/d, respectively) + PAL (125 mg/d, 3 wk on/1 wk off) or placebo (PBO). Median follow up was 14 mos (PAL3; 23Oct2015) and 37 mos (PAL2; 31May2017). DFI in PAL3 was calculated as *time between first diagnosis of BC and disease recurrence* and TFI in PAL2 as *time between end of any neo/adjuvant therapy and relapse*. Subpopulation treatment effect pattern plot (STEPP) analysis evaluated the association between DFI/TFI and PFS outcomes of PAL+ET vs PBO+ET for each study. In PAL3 and PAL2, 226 and 364 pts respectively provided FFPE tissue from recurrent or de novo disease where Lum subtype was determined. Gene expression profiling used HTG Molecular's EdgeSeq OBP to assess Lum A/B subtype. **Results:** In PAL3 and PAL2, 355 and 334 pts, respectively, received adjuvant therapy (232/347 PAL + F and 123/174 F + PBO; 219/444 PAL + L and 115/222 L + PBO). Median DFI in PAL3 was 49.2 mo in PAL + F and 52.0 mo in F + PBO; $>$ 80% of pts had DFI $>$ 2 y. Median TFI in PAL2 was 48.9 mo in PAL + L and 44.9 in L + PBO; ~70% of pts had TFI $>$ 2 y. STEPP analyses suggest no impact on PFS outcomes from baseline DFI in PAL3 and TFI in PAL2. Both Lum A and B pts benefited more from PAL +ET than PBO+ET in PAL2 (Lum A HR [95% CI], 0.546 (0.385-0.773); Lum B: 0.508 [0.335-0.768]) and PAL3 (Lum A: 0.408 [0.253-0.659]; Lum B 0.642 [0.379-1.089]). **Conclusions:** Adding PAL to ET showed a significant increase in PFS regardless of the length of initial TFI/DFI and of Lum subtype. Sponsor: Pfizer Clinical trial information: NCT01740427, NCT01942135.

1024 Poster Discussion Session; Displayed in Poster Session (Board #105), Sat, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sat, 1:15 PM-2:30 PM

Benefit of CDK 4/6 inhibition in less common breast cancer subsets: A U.S. Food and Drug Administration pooled analysis. *First Author: Jennifer J Gao, U.S. Food and Drug Administration, Silver Spring, MD*

Background: Cyclin dependent kinase 4/6 inhibitors (CDKIs) are approved for 1st and 2nd line endocrine-based therapy in hormone-receptor positive, HER2-negative advanced breast cancer. There is limited clinical data on the benefit and value of adding CDKIs to endocrine therapy in less common subtypes, such as progesterone receptor negative (PR-), de novo metastatic, and lobular breast cancer, which may have differing degrees of endocrine sensitivity. **Methods:** We pooled data from 5 phase 3 randomized registration trials of CDKI with an aromatase inhibitor (AI) in the 1st or fulvestrant in the 2nd-line setting. Exploratory subset analyses focused on patients with de novo metastatic, PR-, and lobular cancer. Progression free survival (PFS) was examined in the ITT populations using Kaplan Meier plots and hazard ratios (HR) with 95% confidence intervals (CI). **Results:** We estimated median PFS differences between the CDKI and control arms (Table 1). In patients with PR- tumors (n = 490), the estimated median PFS difference with the additional CDKI to endocrine therapy was 9.1 mo (HR 0.50, 95% CI 0.40-0.64). In patients with de novo metastatic disease (n = 877), the estimated median PFS difference was 9.6 mo (HR 0.59, 0.48-0.71). In patients with lobular cancer(n = 264), the estimated median PFS difference was 6.9 mo (HR 0.58, 0.42-0.80). Analyses of studies limited to the 1st line setting with an AI and studies in the 2nd line setting with fulvestrant showed similar results. These results are considered hypothesis generating. **Conclusions:** Addition of CDKIs to endocrine-based therapy appears to confer a similar benefit in the relative risk of disease progression or death for the studied subsets of patients compared to the broad population in the labeled indication. Further research is needed to help clinicians identify which patients benefit most from addition of CDKI to endocrine therapy and which should receive CDKI in the 1st-line, 2nd-line, or both settings.

Results.

Subset	N	Median PFS (mo), CDKI	Median PFS (mo), Placebo	PFS Difference (mo)	HR (95% CI)
PR Negative	490	16.5	7.4	9.1	0.50 (0.40-0.64)
De Novo Metastatic	877	24.3	14.7	9.6	0.59 (0.48-0.71)
Lobular Histology	264	16.1	9.2	6.9	0.58 (0.42-0.80)

1025 Poster Session (Board #106), Sat, 8:00 AM-11:30 AM

PAM50 HER2-enriched/ERBB2-high (HER2-E/ERBB2H) biomarker to predict response and survival following lapatinib (L) alone or in combination with trastuzumab (T) in HER2+ T-refractory metastatic breast cancer (BC): A correlative analysis of the EGF104900 phase III trial. *First Author: Tomás Pascual, Department of Medical Oncology, Hospital Clínic of Barcelona, Barcelona, Spain*

Background: In HER2+ BC, HER2-E subtype with high ERBB2 mRNA expression (HER2-E/ERBB2H) is better associated with response following neoadjuvant L and T without chemotherapy than either variable alone (ASCO2018 submitted). Here, we evaluated the ability of this combined biomarker to predict response and survival following anti-HER2 therapy alone in T-refractory HER2+ BC. **Methods:** EGF104900 randomized 296 women with HER2+ advanced BC who experienced progression on prior T-containing regimens to receive either L alone or L+T. The primary endpoint was progression-free survival (PFS). Secondary endpoints included overall survival (OS), overall response rate (ORR) and clinical benefit rate (CBR). The expression of 50 PAM50 genes was evaluated from FFPE tumors using an nCounter. A pre-defined HER2-E/ERBB2H definition was applied blinded from clinical data. Multivariable analyses were used to test the association of the HER2-E/ERBB2H variable with PFS, OS, ORR and CBR. Interaction tests between the biomarker and treatment were also evaluated. **Results:** 177 tumors (60%) were analyzed. Subtype distribution was 58.2% HER2-E, 15.3% Basal-like, 10.2% Luminal B, 2.3% Luminal A and 14.1% normal-like. The HER2-E/ERBB2H group represented 48% of all samples. The adjusted PFS hazard ratio (HR) of the HER2-E/ERBB2H group vs. others was 0.48 (95% CI 0.34-0.69, $P < 0.001$). Median PFS of the HER2-E/ERBB2H group was 3.5 months (2.6-54) compared to 1.2 months (1-1.7) in others. The ORR and CBR of the HER2-E/ERBB2H group were higher compared to others (ORR 16.25% vs. 3.66%; $p = 0.017$ and CBR 66.25% vs. 26.83%; $P < 0.001$). For OS, the adjusted HR for HER2-E/ERBB2H vs. others was 0.65 (0.44-0.96, $P = 0.034$). Median OS was higher in the HER2-E/ERBB2H group (14.4 months) compared to others (9.1 months). No significant interaction was observed between HER2-E/ERBB2H and treatment. **Conclusions:** HER2-E/ERBB2-high biomarker in HER2+ T-refractory advanced BC can identify patients who might be good candidates to receive anti-HER2 treatment alone without chemotherapy.

1026 Poster Session (Board #107), Sat, 8:00 AM-11:30 AM

A phase II study of cabozantinib (cabo) alone or in combination with trastuzumab (T) in patients (pts) with breast cancer brain metastases (BCBM). *First Author: Jose Pablo Leone, Dana-Farber Cancer Institute, Boston, MA*

Background: BCBM rely on VEGF pathway activation for angiogenesis and dissemination. Activation of MET leads to tumor invasion and resistance to anti-VEGF therapy. The aim of this study was to analyze the efficacy and tolerability of cabo —a small molecule inhibitor of MET and VEGFR2— alone or with T in BCBM pts. **Methods:** This is a single-arm, two-stage phase II study. Eligible pts had new or progressive measurable BCBM. The study included 3 cohorts: Cohort 1 (HER2+), Cohort 2 (HR+ HER2-) and Cohort 3 (triple negative). Pts received cabo 60 mg daily on a 21-day cycle. Cohort 1 also received standard T every 3 weeks. Pts had restaging scans every 6 weeks for 6 cycles, then every 9 weeks; a research brain MRI was performed at baseline and after 1 cycle. Primary objective was CNS objective response rate (ORR) by RECIST 1.1 in Cohort 1. Target sample size for Cohort 1 was 21 pts; if ≥ 3 pts had CNS ORR the null rate (5%) would be rejected in favor of a 30% rate of activity. Secondary objectives were CNS ORR in Cohorts 2 and 3, progression-free survival (PFS), overall survival (OS), toxicity, and changes in *f*MRI vascular parameters and plasma biomarkers. **Results:** 35 pts (Cohort 1 n = 21, Cohort 2 n = 6, Cohort 3 n = 8) were enrolled and this analysis was done with a median follow up of 7.3 months (range 0.8-30.6). Median age was 50 years (range 28-69). Pts had a median of 3 prior lines for metastatic disease (range 1-9). Prior to enrollment, 4 pts underwent craniotomy, 24 pts whole brain radiation and 11 pts stereotactic radiosurgery. Efficacy is shown in the Table. Most common grade 3/4 AE included elevations in lipase (12%), AST (9%), ALT (6%), hyponatremia (9%), thromboembolism (9%), hypertension (6%), fatigue (6%) and vomiting (6%). Ongoing studies are exploring MRI perfusion changes with cabo, and biomarkers of response. **Conclusions:** Cabo was well tolerated but had insufficient activity in heavily pretreated BCBM. Biomarker changes and their association with outcome will be presented at the meeting. Clinical trial information: NCT02260531.

	Cohort 1	Cohort 2	Cohort 3
CNS ORR	5%	17%	0%
Non-CNS ORR	0%	0%	0%
Clinical benefit rate (CR + PR + SD) at 12 weeks	43%	17%	13%
Median time on therapy (months)	4.2	0.8	2.5
Median PFS (months)	4.2	0.8	2.5
Median OS (months)	13.9	2.2	5.2

1027 Poster Session (Board #108), Sat, 8:00 AM-11:30 AM

NSABP FB-10: Phase Ib dose-escalation trial evaluating trastuzumab emtansine (T-DM1) with neratinib (N) in women with metastatic HER2+ breast cancer (MBC). *First Author: Jame Abraham, NSABP Foundation and Cleveland Clinic, Cleveland, OH*

Background: T-DM1 is an antibody-drug conjugate composed of trastuzumab and the maytansinoid antimicrotubule, DM1. T-DM1 was granted FDA approval in 2nd-line MBC after prior trastuzumab (T) and taxane. Current practice in USA is for pts to receive T and pertuzumab (P) as neoadjuvant or as 1st-line therapy. Retrospective analysis of T-DM1 after T-P suggests a lower response rate (17%) than T-DM1 after T and taxane (EMILIA 43%). This study investigates the safety and efficacy of T-DM1 + N. **Methods:** Eligible pts had prior T-P as neoadjuvant therapy or in 1st-line, measurable disease, ECOG PS ≤2, adequate hematologic, renal, and liver function. Pts with stable brain metastases (CNS) were eligible. Treatment was T-DM1 at 3.6 mg/kg iv q 3 wk and N at escalating doses of 120, 160, 200, and 240 mg/d using 3+3 design. HER2 + was required on primary tissue but was not reassessed at entry. Blood samples were required upon entry. Pharmacokinetic (PK) studies were performed on a limited number of pts. Primary diarrhea prophylaxis with intensive loperamide was mandated. **Results:** Twenty-seven T-P resistant pts were enrolled. 26 were evaluable for toxicity, and 20 were evaluable for efficacy. A dose-limiting toxicity occurred in 6 during cycle 1. The RP2D was N 160 mg/d. Treatment-related grade 3 toxicities included diarrhea (5 pts), thrombocytopenia (4), nausea (3), and ALT elevation (1). Of 20 pts evaluable after 2 cycles, 3 had CRs and 9 had PRs (ORR 64%). The duration of response ranged from 42 d to 650+ d. New CNS disease occurred in 1 (8/27 at entry). Nine pts had PK determinations during the first 24h, and 13 had steady-state neratinib level on cycle 2 d1. There was no correlation between N dose and peak or steady-state levels; responses were seen at all doses. Data from blood samples collected on d 1 for HER2 amplification by ctDNA will be presented. **Conclusions:** Full-dose T-DM1 + N at 160 mg/d was well tolerated with notable activity. Responses were seen at all dose-levels of N. Limited PK analysis did not show that peak or steady-state concentration of N was related to response. Baseline peripheral blood samples are being assessed for HER2 amplification. Support: Puma Biotechnology Clinical trial information: NCT02236000.

1028 Poster Session (Board #109), Sat, 8:00 AM-11:30 AM

An open-label, multicenter, phase Ib study to evaluate RC48-ADC in patients with HER2-positive metastatic breast cancer. *First Author: Binghe Xu, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: RC48-ADC is a novel HER2-targeting antibody–drug conjugate (ADC) that selectively delivers anticancer agent MMAE into HER2-overexpressing tumor cells. A Phase I study (NCT02881138) has preliminary demonstrated that RC48-ADC is well tolerated and has clear clinical activity in patients (pts) with metastatic breast cancer (MBC). **Methods:** This was a phase Ib, open-label, multicenter study with 3 dose cohorts (1.5, 2.0 and 2.5mg/kg , Q2W). Eligible pts (18-70 years) were assessed HER2-positive (IHC 2+/FISH +, or IHC 3+) MBC, with relapsed/refractory to prior standard treatment. **Results:** From Dec, 2016 to Jan, 2018, 30 female pts (6 IHC2+/FISH+; 24 IHC 3+) pretreated with trastuzumab/chemotherapy were enrolled for 1.5 and 2.0 mg/kg cohorts. Median age was 53 years (range: 26-62). 19 pts (63.3%) received HER2-targeting agents. 16 pts (53.3%) received three or more previous chemotherapy regimens in metastatic setting. Disease control (CR+PR+SD) was observed in 29 of 30 evaluable pts who received RECIST 1.1 assessment (96.7%), with 11 PR (ORR: 36.7%; 30-76% regression) and 18 SD (60.0%) with tumor regression. CBR (CR + PR + SD ≥6 months) was presented in 14 pts (46.7%). ORR was 26.7% and 46.7% in the 1.5mg/kg and 2.0 mg/kg cohorts, respectively; it was 57.1% in trastuzumab-naive pts and 33.3% in trastuzumab-pretreated pts (12 pts treated with≥3 prior chemotherapy). The common treatment-related adverse events (TRAEs) reported were AST elevation (50.0%), ALT elevation (43.3%), leucopenia (33.3%), neutropenia (33.3%), numbness (23.3%); most were Grade 1-2 in severity. Only 3 pts (10%) reported Grade≤2 thrombocytopenia. Grade 3 TRAEs occurred in 4 pts (13.3%), including neutropenia (10%), leucopenia (6.7%), AST elevation (3.3%), ALT elevation (3.3%). No Grade ≥4 AE was observed. Pharmacokinetic analyses showed dose-dependent exposure with 1-1.5 d half-life. **Conclusions:** RC48-ADC has showed manageable safety and encouraging efficacy profiles in pts with HER2-positive MBC. Investigation of 2.5 mg/kg expansion cohort has not yet been started. Results obtained from Phase I study will determine whether 2.5mg/kg cohort expansion is performed. Clinical trial information: NCT03052634. Clinical trial information: NCT03052634.

1029 Poster Session (Board #110), Sat, 8:00 AM-11:30 AM

A phase I study of a PD-L1 antibody (Durvalumab) in combination with trastuzumab in HER-2 positive metastatic breast cancer (MBC) progressing on prior anti HER-2 therapies (CCTG IND.229)[NCT02649686]. *First Author: Stephen K. L. Chia, British Columbia Cancer Agency, Vancouver, BC, Canada*

Background: Immune checkpoint inhibitors are active in a broad range of advanced cancers. Antibody dependent cell mediated cytotoxicity is a mechanism of action of trastuzumab. The combination of the two may enhance activity and/or overcome acquired resistance. We performed a phase I study of durvalumab and trastuzumab in HER-2 positive MBC previously treated with chemotherapy and anti HER-2 antibodies to assess safety, efficacy and correlative end-points. **Methods:** Patients with HER-2 positive MBC, PS 0-2, and previously treated with taxanes and trastuzumab were enrolled on a standard 3+3 dose escalation schedule. Dose level 1 was standard doses of durvalumab (1125 mg i.v. day 1) and trastuzumab (8 mg/kg i.v. loading then 6 mg/kg day 1) on a q3 weekly cycle. An expansion cohort at the recommended phase II dose (RP2D) performed baseline and post cycle 1 tumor biopsies. The primary endpoint of the study was to establish the RP2D. **Results:** 15 patients were accrued across 3 Canadian centres from April – December 2016, of which 14 were evaluable for response. Median age was 54 years (range 40-86), the majority had visceral disease (87%); ≥3 prior lines of chemotherapy (73%), including trastuzumab (93%), pertuzumab (60%) and TDM1 (93%) for MBC. No dose limiting toxicities were observed at dose level 1 (n = 6) or dose expansion (n = 9) during cycle 1. One patient developed ≥ grade 3 irAE (grade 4 diabetes mellitus). No responses by RECIST were seen, with 4/14 (29%) demonstrating stable disease as best response at week 6 (median duration 2.7 months). All patients had < 1% PD-L1 expression on archival tissue (7/15) or pre-study biopsy (8/15). In the dose expansion cohort, evaluable pre-treatment and on-treatment tumor biopsies (n = 5) showed minimal CD8 cell infiltration. Work on the serial ctDNA collected is ongoing. **Conclusions:** The RP2D of durvalumab and trastuzumab is standard full doses of both agents. No significant clinical activity was observed in heavily pre-treated HER-2 positive MBC patients with evidence of cytotoxic T-cell exhaustion. Clinical trial information: NCT02649686.

1030 Poster Session (Board #111), Sat, 8:00 AM-11:30 AM

An open-label, dose-escalation phase I study to evaluate RC48-ADC, a novel antibody-drug conjugate, in patients with HER2-positive metastatic breast cancer. *First Author: Jiayu Wang, Department of Medical Oncology, National Caner Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: There is still urgent medical needs for new therapeutics in the patients with metastatic breast cancer (MBC) and other solid tumors with HER2 overexpression. RC48-ADC is an antibody-drug conjugate drug with a novel humanized anti-HER2 antibody conjugated to monomethyl auristatin E (MMAE) through a cleavable linker. Preclinical data in various animal models, including breast cancer, gastric cancer and ovarian cancer, suggested excellent antitumor efficacy. **Methods:** It was an open-label, single-center, phase I study. Eligible pts (18-65 years) were confirmed by immunohistochemistry (IHC) and fluorescence in situ hybridization (FISH) as HER2-positive (IHC 2+/FISH+ or IHC 3+) MBC. A 3+3 dose-escalation was conducted with a 28-day window to evaluate dose limiting toxicity (DLT). DLT was mainly defined as Grade 4 neutropenia effectively managed with symptomatic treatment, Grade 3 neutropenia accompanied by infection and Grade 3 non-hematological toxicity. Tumor response was accessed per RECIST 1.1 every 6 weeks. **Results:** As of 29 Jan, 2018, 23 female pts with MBC were treated in 5 dose escalation cohorts (dose levels 0.5, 1.0, 1.5, 2.0, 2.5 mg/kg) once every two weeks (Q2W). Median age was 57 (32-65), and the course of disease was more than 3 years in 15 pts (65.2%). 16 pts (69.7%) were previously treated with trastuzumab. Median prior lines of therapy in metastatic setting was 3 (1-6). 14 pts (60.9%) had≥3 visceral metastatic sites of disease. MTD was not reached at doses up to 2.0 mg/kg Q2W. The most common treatment-related AEs (TRAEs) were leucopenia (43.5% Grade 1-2; 4.3% Grade 3), AST elevation (43.5% Grade 1-2; 4.3% Grade 3), followed by neutropenia (30.4%, Grade 1-2, 13% Grade 3-4), which could be readily managed. 20 pts were evaluable for response. Of 14 pts at doses≥1.5mg/kg , 8 (57.1%) achieved PR and 4 (28.6%) SD. For 11 trastuzumab-pretreated pts, ORR was 72.7%. **Conclusions:** RC48-ADC administrated with Q2W has demonstrated good tolerability and promising antitumor activity in HER2-positive pts with MBC. The MTD has not been determined and 2.5 mg/kg Q2W dose escalation is ongoing. Clinical trial information: NCT02881138. Clinical trial information: NCT02881138.

1031 Poster Session (Board #112), Sat, 8:00 AM-11:30 AM

Serum PD-L1 and outcomes in CCTG MA.31 phase 3 trial of anti-HER2 therapy in first-line HER2+ metastatic breast cancer patients (trastuzumab arm only). *First Author: Kim Leitzel, Penn State Hershey Medical Center, Hershey, PA*

Background: In MA.31 the lapatinib-taxane combination led to shorter PFS than trastuzumab-taxane in HER2+ metastatic breast cancer. We previously reported the positive prognostic utility of pretreatment serum PD-L1 in 63 trastuzumab-treated patients (ASCO 2017, #1024), and here we evaluated it in the trastuzumab arm of MA.31. **Methods:** MA.31 accrued 652 centrally and/or locally-identified HER2-positive patients; in the trastuzumab arm 186 patients had pretreatment serum available.TheELLA immunoassay platform (ProteinSimple, San Jose, CA) was used to quantitate serum PD-L1. Stratified step-wise forward Cox multivariate analysis was used for PFS and OS. **Results:** In univariate analysis for PFS, serum PD-L1 was not a significant biomarker for PFS. In univariate analysis for OS, higher serum PD-L1 was a significant biomarker for shorter OS (continuous PD-L1: HR 3.86, p = 0.044; quartiles of PD-L1: HR 1.55, p = 0.002; median cutpoint PD-L1: HR 2.16, p = 0.014). In multivariate analysis for OS [14 covariates included: age, race, ECOG status, anthracyclines, other chemo, endocrine, radio, other prior adjuvant therapy, disease status, ER status, PR status, Ki67 (log transformed), CK5, EGFR, serum PD-L1], elevated serum PD-L1 was a significant independent covariate [continuous PD-L1: HR 22.7, p = 0.001; median cutpoint PD-L1: HR 2.91, p = 0.0061 (Table)]. **Conclusions:** In the CCTG MA.31 trial, elevated pretreatment serum PD-L1was associated with a shorter OS (but not PFS) with trastuzumab treatment. Immune evasion by the tumor may decrease the effectiveness of trastuzumab therapy. Elevated serum PD-L1 may identify patients who would benefit from addition of an immune checkpoint inhibitor.

Multivariate significant independent covariates for OS (186 patients).

Covariate	p-value	Hazard Ratio	Lower 95% CI	Higher 95% CI
Prior adjuvant/metastatic endocrine therapy (yes vs no)	0.001	4.07	1.75	9.46
Performance status (0 vs 1 or 2)	0.002	0.30	0.14	0.65
Central Review ER status (continuous IHC score)	0.006	0.99	0.98	0.99
Serum PD-L1 (pretreatment) (> median vs < median)	0.006	2.91	1.36	6.25
Prior adjuvant / metastatic radiotherapy (yes vs no)	0.049	0.44	0.19	0.99

1032 Poster Session (Board #113), Sat, 8:00 AM-11:30 AM

Results from a phase I study of andecaliximab in combination with paclitaxel in patients with previously untreated metastatic breast cancer. *First Author: Erika Paige Hamilton, Sarah Cannon Research Institute/Tennessee Oncology, Nashville, TN*

Background: Matrix metalloproteinase-9 (MMP-9) is highly expressed in several advanced cancers, including metastatic breast cancer, and confers an adverse prognosis. In a preclinical breast cancer model, inhibition of MMP-9 was demonstrated with tumor growth inhibition. Andecaliximab (ADX) is a chimeric antibody directed against MMP-9, engineered to remove T cell epitopes and reduce risk of immunogenicity. In this phase I multicohort study, we hypothesized that the combination of ADX with standard of care chemotherapy (paclitaxel) should be safe and tolerable, and demonstrate clinical activity in patients with previously untreated metastatic breast cancer. (Clinicaltrials.gov NCT# 01803282) **Methods:** We enrolled 15 eligible (13 female) patients with radiographically measurable disease and previously untreated metastatic breast cancer. The median age was 59 years (range 23-81). Patients were treated with 800 mg ADX IV every 2 weeks + paclitaxel (80mg/m^2 on days 1, 8, and 15 of a 28-day cycle). The primary endpoints of this study were safety and tolerability. Exploratory endpoints were investigator assessed objective response rate (ORR), progression free survival (PFS), and overall survival (OS). **Results:** As of September 22, 2017, the median ADX treatment duration for this study was 5.3 months. The most common adverse events were alopecia (60%), fatigue (60%), constipation (47%), neutropenia (40%), diarrhea (33%), and nausea (33%). Serious adverse events (SAEs) were reported in 33% of patients. The most common SAEs were acute kidney injury and atrial fibrillation (7% each). The median PFS was 7.4 months (90% CI 5.3-8.6 months) and the overall response rate was 53% (95%CI 30-76%) with 7% complete response rate. The median OS was not reached at the time. Study treatment continues in 27% of patients. **Conclusions:** Combination of ADX with paclitaxel was safe and effective in first-line treatment of patients with metastatic breast cancer. Updated data will be presented at the time of the meeting. Clinical trial information: NCT01803282.

1033 Poster Session (Board #114), Sat, 8:00 AM-11:30 AM

Safety and efficacy of pembrolizumab (pembro) plus capecitabine (cape) in metastatic triple negative breast cancer (mTNBC). *First Author: David B. Page, Earle A. Chiles Research Institute, Portland, OR*

Background: In mTNBC, anti-PD-1/L1 monotherapy was associated with objective response rates (ORR) of 23-26% in the first-line setting, but ORR of 5-6% in later lines. We hypothesize that concurrent pembro plus standard-of-care chemotherapy is safe, and may increase clinical benefit by allowing for earlier treatment with anti-PD-1, when tumor burden and iatrogenic immunosuppression are minimized. This is the first study to explore the combination cape with PD-1/L1 blockade in breast cancer. **Methods:** In a pilot/phase II study, we evaluate the tolerability and preliminary efficacy of concurrent pembro (200mg IV q21 day) plus investigator-selected 1st/2nd line paclitaxel (80mg/m^2 IV weekly) or oral cape (2,000mg BID, weekly 1 on/1 off). The primary endpoint of the pilot phase is tolerability, defined as the proportion of subjects receiving $>$ 6 weeks concurrent therapy without dose discontinuation. Toxicities are reported per CTCAE v4.0. The secondary endpoint is 12-week ORR by RECIST1.1, with potential phase II expansion according to a Simon 2-stage design (if $\geq$4/14 ORR). Exploratory objectives include intratumoral/peripheral immunologic assessments by T-cell receptor sequencing, multispectral immunofluorescence, and real-time multiparametric flow cytometry. Here, we report the results of the pilot phase of the cape cohort (NCT02734290). **Results:** As of 1/1/2018, 100% (9/9) of safety-evaluable subjects tolerated concurrent cape+pembro for at least 6 weeks. Toxicities were generally consistent with monotherapy experience (diarrhea: grade I-II 56%; hand-foot: grade I-II 67%), and improved with dose-reduction. Partial responses have been observed in three subjects, two having metaplastic pathology. A fourth subject experienced durable stable disease, with ongoing response at 48 weeks. **Conclusions:** This study met the primary endpoint of safety for cape plus pembro in mTNBC and the combination will be explored for efficacy in the next stage of this study. These data may also inform the evaluation of concurrent anti-PD-1/L1 plus cape in the adjuvant setting. Clinical trial information: NCT02734290.

1034 Poster Session (Board #115), Sat, 8:00 AM-11:30 AM

Effect of breast tumor subtype and site of distant metastatic disease on prognostic outcome among patients with brain metastases and stage IV denovo breast cancer. *First Author: Shaheenah S. Dawood, Mediclinic City Hospital, Dubai, United Arab Emirates*

Background: The objective of this study was to examine the impact of breast tumor subtype and site of distant metastatic disease on prognostic outcome among patients with stage IV denovo breast cancer who have brain metastases at diagnosis. **Methods:** We searched the SEER registry to identify 1025 patients(pts) with stage IV denovo breast cancer and upfront brain metastases diagnosed between 2010 and 2014. Pts were divided into four groups depending on the breast tumor subtype: a) triple negative (TNBC), b) HER2-ve/HR+ve, c) HER2+/HR-ve, d) HER2+/HR+ve. The presence of distant metastatic disease (DM) other than the brain was defined as disease in the lung, liver or bone. Overall survival (OS) was computed using the Kaplan Meier product limit method. Multivariable cox models were then fit to look at the association of breast tumor subtype and OS adjusted for various pt and tumor characteristics. **Results:** Median age at diagnosis was 60 years and median OS was 9m. 225 (21.5%), 480 (46.8%), 138(13.4%) and 186 (18.15%) pts had TNBC, HER2-ve/HR+ve, HER2+/HR-ve and HER2+/HR+ve disease respectively. Median OS was 5m(TNBC), 13m(HER2-ve/HR+ve), 9m (HER2+/HR-ve), and 21m(HER2+/HR+ve) across the subtypes($p < 0.0001$) respectively. Median OS among those who did and did not have surgery of their primary tumor was 14m and 7m respectively ($p < 0.0001$). Median OS among those with lung , liver , bone only or no distant metastases was 8m, 6m, 15m and 10m respectively ($p < 0.0001$). In the multivariable cox model compared to pts who had TNBC pts who had HER2-ve/HR+ve (HR0.59, CI 0.48-0.73, $p < 0.001$), HER2+/HR-ve (HR0.79, CI 0.60-1.04, $p = 0.09$) and HER2+/HR+ve (HR0.35, CI 0.27-0.47, $p < 0.001$) had a lower risk of death. 250 (24%)pts did not have DM at presentation. Median OS in this cohort was 5m(TNBC), 10m (HER2-ve/HRve+), 14m(HER2+/HR-ve) and 34m (HER2+/HR+ve) across the subtypes respectively($p = 0.0003$). **Conclusions:** Among pts with stage IV denovo breast cancer and brain metastases at diagnosis factors such as bone only or no distant metastatic disease and HER2+v/HR+ve subtype was associated with the best prognostic.

1035 Poster Session (Board #116), Sat, 8:00 AM-11:30 AM

Phase ib study of trastuzumab emtansine (TDM1) in combination with lapatinib and nab-paclitaxel in metastatic HER2-neu overexpressed breast cancer patients: Stela results. *First Author: Tejal Amar Patel, Methodist Cancer Center, Houston, TX*

Background: Based on our preclinical data, we conducted a phase I study oftrastuzumab-emtansine (T-DM1) in combination with Lapatinib and Nab-paclitaxel in patients with HER2 over-expressed stage IV breast cancer. **Methods:** Phase Ib study was conducted using 3+3 dose de-escalation design, with TDM1 with Lapatinib and nab-paclitaxel administered for a total of 4 cycles. Primary purpose was to evaluate the maximum tolerated dose (MTD) of T-DM1 with Lapatinib and Nab-paclitaxel. Safety, tumor response and pharmacokinetics (PK) were also assessed. Dose limiting toxicities (DLTs) were defined as $\geq$ grade 3 non hematological toxicity attributed to the study drugs. Key inclusion criteria were stage IV HER2 positive breast cancer, LVEF $\geq$ 45%, and peripheral neuropathy $<$ grade 2. **Results:** The MTD was T-DM1 3.0 mg/kg every 3 weeks along with Lapatinib 750mg oral daily and Nab-paclitaxel 80mg/m^2 weekly. Twenty four patients, median age 50 (47.9-55.9) years were enrolled. The dose limiting toxicities were diarrhea and elevated liver function tests. At MTD, 42.9% (6/14) experienced grade 3 or higher toxicity. Fourteen patients with median of 1 (range 0-5) prior metastatic treatments were evaluable for response. 12 patients (85.7%) had an objective response including 6 CR and 2 PR. T-DM1 pharmacokinetics was unaffected by Lapatinib. **Conclusions:** T-DM1 with Lapatinib and Nab-paclitaxel therapy was relatively well tolerated with significant anti-tumor activity observed. Clinical trial information: NCT02073916.

1036 Poster Session (Board #117), Sat, 8:00 AM-11:30 AM

A phase Ib trial of copanlisib and tratuzumab in pretreated recurrent or metastatic HER2-positive breast cancer "PantHER". *First Author: Niamh M. Keegan, Beaumont Hospital, RCSI, Dublin, Ireland*

Background: PI3K pathway activation is implicated in resistance to trastuzumab (T) therapy in breast cancer (BC). Copanlisib (C) is a pan-class I PI3K inhibitor with particular activity against PI3Kα, the isoform encoded by the PIK3CA gene. PIK3CA mutation may predict response to PI3K inhibition. **Methods:** The maximum tolerated dose (MTD) and safety of C + T were evaluated in an open label, single arm, adaptive multicenter phase Ib dose escalation clinical trial in patients (pts) with HER-2 positive BC. Eligible pts had disease progression following at least one line of (T) or TDM-1 based therapy in the metastatic setting. Pts were treated with T (4mg/kg loading dose then 2mg/kg weekly) given with C intravenously on Day 1, 8 + 15 of 28 day cycle at one of two dose levels (DL) according to a modified 3+3 (6+6) design. Cycle 1 safety data were used to determine dose limiting toxicities (DLTs). Disease assessments were made every 8 weeks. PIK3CA mutation status was determined in formalin-fixed paraffin-embedded (FFPE) primary tumor blocks by standard sequencing and in serial samples of plasma circulating tumor DNA (ctDNA) during treatment by droplet digital PCR. **Results:** Twelve pts were treated with C + T, 6 on DL1 (45mg) and 6 on DL2 (60mg). Median age was 53yrs. Pts had 15 to 85 months of prior therapy in the metastatic setting with a median of 4 prior lines. There were no DLTs. The MTD and recommended dose for phase II is 60mg. Eleven SAEs were reported. Of these, 36% (n = 4) were infections requiring hospitalization and all resolved with no changes in dose. Grade(G) 3 lung infection and G3 abdominal pain SAEs were reported possibly related to C. All others were considered unlikely or not related to C. G3 liver enzyme rise was reported in 1 pt with a single episode of G4 rise in GGT. G3 hypertension was reported in 33% (n = 4) pts. Best response was stable disease in 9/12 pts and 6 pts continued treatment $\geq$16 weeks. PIK3CA mutation was positive in 6/12 (50%) of tumors. Concordance between PIK3CA mutation in tissue and plasma pre-treatment was 80% with evidence of dynamic change in quantity of mutation during treatment. **Conclusions:** C+T is a safe, well tolerated combination. Efficacy of C+T will be assessed in a phase 2 study at the MTD of 60mg. Clinical trial information: NCT02705859.

1037 Poster Session (Board #118), Sat, 8:00 AM-11:30 AM

Real-world (RW) characteristics, treatment (tx) patterns, and overall survival (OS) in US patients (pts) with metastatic breast cancer (mBC) and CNS metastases (CNS mets). *First Author: Ashwini Shewade, Genentech, Inc., South San Francisco, CA*

Background: About 10–16% of mBC pts are reported to have a CNS mets diagnosis (dx; Lin *JCO* 2004). Data on the management of these pts are limited because they are often excluded from clinical trials due to significant morbidity and mortality. We aim to describe RW characteristics, tx patterns, and OS of mBC pts with CNS mets using an oncology electronic health record database (EHR Db). **Methods:** Flatiron Health's Db is longitudinal, demographically and geographically diverse, and derived from EHR data. Female pts with $\geq$2 clinic visits within the Flatiron network following mBC dx made between Jan '11–Jul '17 were included and followed until Oct '17. CNS mets dx was ascertained based on dx codes and/or unstructured part of EHR. mBC subtype was defined using HER2 and hormone receptor (HR) status. Demographic, clinical, systemic tx, and mortality data were used to characterize mBC pts with CNS mets. **Results:** As of 10/31/'17, the analysis cohort included 10145 mBC pts; 1837 had CNS mets dx during the study period. The table describes incidence of CNS mets by subtype, characteristics at mBC dx for pts with CNS mets, and median OS after CNS mets. Depending on whether CNS mets dx was made at or after mBC dx, among pts with CNS mets and a tx recorded after CNS mets, pts with HER2+ dx commonly (70%/65%, respectively) received tx regimens containing HER2-targeting monoclonal antibodies (MAb), HER2–/HR+ dx commonly (51%/74%) received regimens containing hormonal/other targeted tx or chemotherapy, and triple-negative (TNBC) dx commonly (90%/82%) received chemotherapy. **Conclusions:** CNS mets continues to be an unmet medical need. HER2+/HR– and TNBC have the highest prevalence and/or incidence of CNS mets, whereas HER2–/HR+ has the lowest. HER2+ mBC pts with CNS mets commonly receive subsequent tx including HER2-targeting MAbs and show a trend towards better survival from CNS mets dx than HER2–/HR+ and TNBC.

	All mBC (n = 10145)	HER2+/HR+ (15%)	HER2+/HR– (6%)	HER2–/HR+ (66%)	TNBC (13%)

1038 Poster Session (Board #119), Sat, 8:00 AM-11:30 AM

SAFE-HEaRt: A pilot study assessing the cardiac safety of HER2 targeted therapy in patients with HER2 positive breast cancer and reduced left ventricular function. *First Author: Filipa Lynce, Georgetown Lombardi Comprehensive Cancer Center, Georgetown University Medical Center, Washington, DC*

Background: HER2 targeted therapies have substantially improved the prognosis of patients with BC however they can be associated with cardiac toxicity. SAFE-HEaRt is the first investigator-initiated trial that prospectively tests whether HER2 therapies may be safely administered in patients with reduced LV function in the setting of ongoing cardiac treatment and monitoring. **Methods:** Eligibility criteria: stage I-IV HER2 positive BC candidates for non-lapatinib therapy; LV ejection fraction (LVEF) $\geq$40% and $<$ 50% and no symptoms of heart failure (HF). All patients had cardiology visits and echocardiograms at baseline, during treatment and 6 months after treatment, and received beta blockers (BB) and ACE inhibitors (ACEi) unless contraindicated. Primary endpoint was completion of planned oncologic HER2 therapy without development of a cardiac event (CE), defined as HF symptoms or asymptomatic decline in LVEF $\geq$10% points from baseline and/or to LVEF $\leq$35%. **Results:** Of 31 enrolled patients, 30 were evaluable. Mean age was 54 years, 18 had early stage and 13 metastatic disease. Seventeen patients had prior exposure to anthracyclines and 13 had hypertension. On study 15 patients were treated with trastuzumab, 14 trastuzumab/pertuzumab and 2 ado-trastuzumab emtansine. Mean LVEF was 45% at baseline and 46% at the end of treatment. Twenty-two patients completed HER2 therapy as defined per protocol without development of a CE and 5 are still on study. Three patients met CE criteria: 2 developed symptomatic HF (at 24 and 36 wks) and 1 had protocol defined LVEF decline to 35% at 12 wks, all were taken off study. Two of these 3 patients are alive and in follow up and 1 died of disease progression. Demographics, previous anthracyclines and baseline LVEF did not predict development of CEs. Elevation of highly sensitive troponin preceded 2 of 3 CEs which was significant (p = 0.003). **Conclusions:** Patients with BC and mildly reduced LVEF can safely receive HER2 therapies in the setting of regular cardiac monitoring and treatment with BB and ACEi. Our results provide new safety data in this unique population and have potential to contribute to clinical practice changes. Clinical trial information: NCT01904903.

1039 Poster Session (Board #120), Sat, 8:00 AM-11:30 AM

Impact of HER2 mutation status on personalized molecular targeted therapy in advanced breast cancers. *First Author: Zongbi Yi, Department of Medical Oncology, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College (CAMS & PUMC), Beijing, China*

Background: Previous studies have indicated that the mechanism of HER2 activation include not only HER2 protein overexpression and gene amplification but also HER2 somatic mutations. The impact of HER2 mutations may be different in HER2-positive (amplified) and HER2-negative (non-amplified) breast cancers. **Methods:** We used next generation sequencing to detect HER2 mutations in circulating tumor DNA and analyzed the relationship between these mutations and the efficacy of anti-HER2 therapies. **Results:** Twenty three HER2 somatic point mutations were identified in 16 of the 120 patients (13.3%) studied. HER2 amplified patients with HER2 point mutations have shorter progression-free survival (PFS) compared to non-HER2 mutations, the median PFS was 5.0 months versus 8.4 months. There were three cases identified where HER2 mutation status impacted the selection of personalized anti-HER2 therapies. Case 1 was a HER2 positive patient with an ERBB2 mutation (c.1900T>C/p.C634R) who was resistant to trastuzumab and lapatinib but sensitive to afatinib. Case 2 was a HER2-negative patient with an ERBB2 mutation (p.L755_T759del) was response to afatinib and trastuzumab. Case 3 was a HER2-negative breast cancer patient with two detected mutations in *ERBB2* (p.S310F and p.D769Y mutations) who benefited from lapatinib combined with endocrine therapies. **Conclusions:** Our data suggest that HER2 mutation-positive patients might be resistant to trastuzumab but sensitive to irreversible kinase inhibitors of HER2, whereas HER2-negative patients with HER2 somatic mutations may still be sensitive to anti-HER2 therapies.

1040 Poster Session (Board #121), Sat, 8:00 AM-11:30 AM

Phase Ib study of gedatolisib in combination with palbociclib and endocrine therapy (ET) in women with estrogen receptor (ER) positive (+) metastatic breast cancer (MBC) (B2151009). *First Author: Andres Forero-Torres, University of Alabama at Birmingham, Birmingham, AL*

Background: The majority of women with ER+ MBC develop resistance to ET. ET plus a CDK4/6 inhibitor (CDKi 4/6) demonstrate improved progression-free survival (PFS) in first/later line MBC. Preclinical evidence in PI3K mutant cell-line xenografts (PIK3CA) supported developing a triplet combination of gedatolisib (G), a dual inhibitor of PI3K/mammalian target of rapamycin (mTOR), with CDKi 4/6 palbociclib (P)+letrozole (L) or fulvestrant (F) for patients (pts) with $ER^+/HER2^-$ MBC. **Methods:** This ongoing dose escalation/expansion study in pts with $ER^+/HER2^-$ MBC, in first/later line MBC, evaluates dose-limiting toxicities/recommended phase 2 dose (DLTs/RP2D) for triplet regimens of G+P+L or G+P+F. A 3-arm expansion investigates objective response rate (ORR) compared to historical controls of Arm A) G+P+L in first-line, B) G+P+F in pts with no prior CDKi 4/6 in second-line and C) G+P+F in pts with prior CDKi 4/6. Pts receive G (180 mg IV/week) combined with P+L or P+F at standard of care doses. Secondary endpoints include safety, ORR, PFS, and pharmacokinetics (PK); exploratory endpoints include genomic analysis of PI3K/mTOR pathway. **Results:** 35 pts received G at RP2D of 180 mg with P+L (n = 15) or P+F (n = 20). Median numbers of prior therapies: G+P+L: 2 (range: 1-2); G+P+F: 1 (range 1-3). Most common (≥50%), drug-related adverse events (%): G+P+L: nausea (80), stomatitis (73), fatigue (60), neutropenia (60), dysgeusia (53); G+P+F: stomatitis (70), fatigue (70), neutropenia (60), nausea (60), dysgeusia (55). Cycle 1 DLTs: G+P+L: grade (gr) 3 neutropenia (n = 2), gr 3 stomatitis (n = 1), gr 3 febrile neutropenia (n = 1); G+P+F: gr 3 stomatitis (n = 2), gr 3 mucositis (n = 1), gr 3 abdominal pain (n = 1). Preliminary stable disease/partial response: G+P+L: 53%/33%; G+P+F: 55%/20%. No PK interactions were observed. PIK3CA and ER mutation status from circulating free deoxyribonucleic acid and duration of response will be reported. Genomic analysis of tumor tissue is underway. **Conclusions:** G can be combined with P+L or P+F with manageable toxicity and promising preliminary antitumor activity. Dose escalation is completed and expansion is ongoing. Clinical trial information: NCT02684032.

1041 Poster Session (Board #122), Sat, 8:00 AM-11:30 AM

Maintenance of health-related quality of life in elderly patients treated with ribociclib + letrozole in MONALEESA-2. *First Author: Howard A. Burris, Sarah Cannon Research Institute, Nashville, TN*

Background: First-line ribociclib + letrozole significantly prolongs progression-free survival vs letrozole alone in patients aged ≥65 y with hormone receptor–positive (HR+), HER2− advanced breast cancer (ABC). Despite the efficacy benefits observed with combination therapy, elderly patients may be receiving single-agent therapy because of toxicity and health-related quality of life (HRQoL) concerns. Here we present key HRQoL outcomes in patients aged ≥65 y in MONALEESA-2. **Methods:** Postmenopausal patients with HR+, HER2− ABC (N = 668) were randomized 1:1 to receive either first-line ribociclib 600 mg or placebo once daily (QD) for 3 wk on, 1 wk off, + letrozole 2.5 mg QD. Patient-reported outcomes were the EORTC QLQ-C30 questionnaire for overall HRQoL/symptom scores and the breast cancer–specific QLQ-BR23 questionnaire for breast symptom score; changes from baseline were determined by a linear mixed-effect model, including responses through treatment cycle 28 day 1 and at end of treatment. Time to 10% deterioration in HRQoL was compared between treatment arms via a stratified log-rank test. **Results:** Among 295 patients aged ≥65 y in this analysis (ribociclib group, n = 150; placebo group, n = 145), HRQoL was maintained with ribociclib + letrozole treatment and at the end of treatment with no significant difference between treatment groups (mean difference, −1.88; 95% CI, −4.58–0.82). Median time to 10% deterioration of HRQoL was similar between the ribociclib group (27.7 mo) and placebo group (28.0 mo; HR, 1.03; 95% CI, 0.69–1.55). In an analysis of the EORTC QLQ-C30 symptom scales, a clinically relevant improvement (> 5 points) was observed for mean pain score in the ribociclib group through the first year of treatment, while mild improvement was observed with the placebo group. Results of the QLQ-BR23 questionnaire showed similar breast symptom scores between treatment groups through end of treatment. **Conclusions:** Consistent with the full study population of MONALEESA-2, HRQoL was maintained in patients aged ≥65 y treated with ribociclib + letrozole. Preliminary analysis indicated a clinically meaningful improvement in pain score for patients aged ≥65 y treated with ribociclib + letrozole. Clinical trial information: NCT01958021.

1042 Poster Session (Board #123), Sat, 8:00 AM-11:30 AM

Activity of tesetaxel, an oral taxane, given as a single-agent in patients (Pts) with HER2-, hormone receptor + (HR+) locally advanced or metastatic breast cancer (MBC) in a phase 2 study. *First Author: Andrew David Seidman, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Chemotherapy treatments that offer improved quality of life are needed. Tesetaxel (T) is a novel, oral taxane that has potential advantages over currently available taxanes, including: oral administration with a low pill burden and Q3W dosing; no history of hypersensitivity reactions (HSRs); and improved activity against chemotherapy-resistant tumors (Shionoya 2003; Chan 2006). 555 pts have been treated with T in clinical studies. In MBC, T was shown to have robust single-agent activity in 2 multicenter, Phase 2 studies. In TOB203, 46 pts with HER2- MBC received single-agent T Q3W, including 38 pts with HR+ MBC, the population being enrolled in CONTESSA, an ongoing Phase 3 study. **Methods:** Pts eligible for TOB203 had HER2- MBC, ECOG PS 0-1, measurable disease and adequate organ function. Adjuvant chemotherapy (including taxanes) was allowed. T was administered orally as first-line chemotherapy at 27 mg/m^2 on Day 1 of a 21-day cycle, with escalation to 35 mg/m^2 in subsequent cycles depending on tolerability, without anti-allergy premedication. ORR was the primary endpoint. Final results are provided for all 38 HR+ pts who received T Q3W. **Results:** Median age: 58 (36-80 yrs); 74% received prior endocrine therapy; 68% received prior chemotherapy in the adjuvant setting (53% taxane-containing regimen; 50% anthracycline-containing regimen); median organ systems involved: 2 (1-4); 82% had visceral disease. The confirmed ORR per RECIST 1.1 in all 38 pts was 45% (95% CI: 29% - 62%); median duration of response was 8.7 mo (95% CI: 4.3 – 13.6 mo); median PFS was 5.7 mo (95% CI: 4.1 – 9.8 mo). In the 24 HR+ pts receiving 27 mg/m^2 without escalation, Grade ≥ 3 neutropenia, the most common Grade ≥ 3 AE, occurred in 29% of pts (febrile neutropenia 4%), there were no cases of Grade ≥ 3 peripheral neuropathy, and the incidence of Grade 1/2 alopecia was 29%/21%. There were no HSRs or study drug-related deaths. **Conclusions:** T, as a single agent, was well tolerated with significant activity in pts with HER2-, HR+ MBC. T is currently being investigated in CONTESSA, a multinational, multicenter, randomized, Phase 3 study in pts with HER2-, HR+ MBC (NCT03326674). Clinical trial information: NCT01221870.

1043 Poster Session (Board #124), Sat, 8:00 AM-11:30 AM

Neutropenia and response to single agent palbociclib. *First Author: Nicholas Patrick McAndrew, Basser Research Center for BRCA, Abramson Cancer Center of the University of Pennsylvania, Philadelphia, PA*

Background: CDK 4/6 inhibitors have been practice-changing in the treatment of metastatic breast cancer. Their activity against retinoblastoma protein positive (Rb+) breast cancer cells is mediated through cell-cycle arrest at the G1/S checkpoint. The most frequent dose-limiting toxicity is neutropenia (NTP), which, in preclinical studies, also occurs via reversible cell-cycle inhibition. The goal of this study is to determine whether NTP is associated with disease response to single agent palbociclib (PAL) as a predictive biomarker of efficacy. **Methods:** Blood count and response data were analyzed from two phase II clinical trials at different institutions using single agent PAL in 1) advanced Rb+ solid tumors (the "Penn trial", n = 137) and 2) advanced liposarcoma (the "MSK trial", n = 59). The majority of subjects in the Penn trial had breast cancer (45%). The primary endpoint was progression free survival (PFS). For each patient, NTP was examined as cycle 1 nadir absolute neutrophil count (C1ANC) and occurrence of any NTP ≥ Grade 1 (per CTCAE version 3) at any point on trial. **Results:** Results are shown in the table below. Subjects with C1ANCs in the lower quartile had significant improvement in PFS (compared to those in the upper quartile), as did those with any grade NTP (compared to those without NTP). Results were similar in breast cancer subjects, as well as in multivariate cox regression models. Increasing depth of NTP was also associated with increasing PFS days, and subjects requiring dose modification for NTP also had improved PFS. **Conclusions:** NTP on single agent PAL is significantly and independently associated with improved PFS. This should prompt both physicians and patients to avoid stopping the drug prematurely because of neutropenic concerns. Future studies should address dosing based on target ANC. Clinical trial information: NCT01037790; NCT01209598.

Parameter	Subgroup	Median PFS (Days)	HR (95% CI)
C1ANC	> 1.9 K/μL	47	-
	< 0.9 K/μL	144	0.56 (0.37-0.84)
Max Grade NTP	None	42	-
	1	56	0.65 (0.38-1.09)
	2	109	0.33 (0.21-0.50)
	3	145	0.29 (0.20-0.44)
	4	291	0.15 (0.06-0.39)
	Any Grade	120	0.32 (0.23-0.47)
NTP, Breast Only	None	28	-
	Any	121	0.34 (0.12-0.95)
Dose Modification	No	60	-
	Yes	128	0.08 (0.03-0.18)
C1ANC ≤ 0.9 K/μL (Multivariate Cox)	-	-	0.54 (0.36-0.81)

1044 Poster Session (Board #125), Sat, 8:00 AM-11:30 AM

Exhausted CD8+ cells (Tex) to predict response to PD-1 therapy in estrogen receptor (+) hormone therapy resistant breast cancer predictive of response to immune checkpoint inhibitors after epigenetic priming. *First Author: Pamela N. Munster, University of California, San Francisco, San Francisco, CA*

Background: Immune checkpoint inhibitors have revolutionized cancer therapy, yet have limited efficacy in estrogen receptor $(ER)^+$ breast cancer. Implicated factors include scarcity of tumor infiltrating lymphocytes (TILs), low PD-L1 expression, female gender and liver involvement. *In vitro* and *in vivo* studies suggest that epigenetic modulation with HDAC inhibitors modulate regulatory T cells (Treg) and change TIL composition which is further associated with the presence of a specific immune signature. **Methods:** Patients (pts) with $(ER)^+$ metastatic breast cancer, who progressed on multiple prior therapies, were treated with tamoxifen in combination with vorinostat and pembrolizumab either immediately or after 3 weeks of epigenetic priming in a phase II trial. Comprehensive flow-cytometric immunophenotyping, PD-L1 staining and histone acetylation were evaluated on tumor and blood cells. **Results:** 34 patients (median age 56 years (32-81), heavily pretreated with a median of 5 (2-13) prior regimens received at least one dose of vorinostat and evaluable for response. Grade $^3/_4$ toxicities in 2 pts each (6%) included immune hepatitis, fatigue and thrombocytopenia. Grade 2 toxicities were pneumonitis and colitis in 3%, fatigue in 27% and thrombocytopenia in 12% pts. Six patients did not receive pembrolizumab due to rapid progression or toxicity. Clinical benefits rate defined as CR, PR and stable disease $>$ 6m was seen in 5/28 (18%) pts. Tumor lymphocyte infiltration and PD-L1 expression were low. High expression of PD-1/CTLA-4 dual staining in CD8 cells of $>$ 20% in tumor or blood was seen in 5 pts overall, 4/5 (80%) patients with benefit and in one other patient, who was withdrawn due to immune hepatitis in week 3. Both tumor and peripheral blood CD8 PD-1/CTLA-4 dual expression strongly correlated with time to progression and reduction in $Foxp3^+/CTLA\text{-}4^{high}$ Treg population in tumors by vorinostat. **Conclusions:** Our data highlight the potential for patient selection based on exhausted CD8+ cells in blood or tumor to predict response to immune checkpoint inhibitors in a small subset of $(ER)^+$ breast cancer patients. Clinical trial information: NCT02395627.

1045 Poster Session (Board #126), Sat, 8:00 AM-11:30 AM

EORTC QLQ-C30 (QLQ-C30) symptoms in patients (pts) with HER2-negative metastatic breast cancer (mBC) and a germline *BRCA* mutation (g*BRCA*m) receiving olaparib vs chemotherapy treatment of physician's choice (TPC) in OlympiAD. *First Author: Mark E. Robson, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: In the Phase III OlympiAD study, pts with HER2-negative mBC and a g*BRCAm* who received olaparib vs TPC showed statistically significant and clinically meaningful benefit in progression-free survival (NCT02000622; Robson *et al. NEJM* 2017). Global health status/quality of life also favored olaparib. This analysis reports the impact of treatment on symptoms using the QLQ-C30 questionnaire. **Methods:** Pts were randomized (open label) to olaparib tablet monotherapy or single-agent TPC (capecitabine, vinorelbine or eribulin). QLQ-C30, completed by patients at baseline and every 6 weeks until disease progression, evaluated three multi-item symptom scales and five single items (common cancer symptoms). Symptoms were scored on a 0 to 100 scale (higher scores indicated worse symptoms). Statistical analysis included clinically meaningful improvement (reduction in score of $\geq$10 points) and adjusted mean change from baseline scores. **Results:** Overall questionnaire compliance rates were 93.2% for olaparib and 77.3% for TPC. Improvement (symptom response) was more frequent with olaparib vs TPC for all symptoms (Table). Adjusted mean changes in pain scores (estimated difference [ED] −7.4; 95% CI −12.68, −2.03) and dyspnea scores (ED −5.8; 95% CI −10.84, −0.66) favored olaparib over TPC. An increase was seen in nausea/vomiting scores (ED 3.7; 95% CI 0.63, 6.82), despite a numerically higher proportion of pts in the olaparib arm having improvement in nausea/vomiting. **Conclusions:** Overall, more pts demonstrated a clinically meaningful improvement in symptom scores with olaparib than with TPC. Clinical trial information: NCT02000622.

Pts (%) with clinically meaningful improvement in QLQ-C30 symptoms.

	Olaparib N = 205	TPC N = 97	Odds ratio* (95% CI)
Fatigue†	32.7	18.6	2.16 (1.21, 4.00)
Pain†	34.6	16.5	2.70 (1.50, 5.10)
Nausea/vomiting†	16.6	13.4	1.30 (0.66, 2.68)
Dyspnea‡	18.0	7.2	2.85 (1.29, 7.24)
Insomnia‡	23.9	12.4	2.24 (1.16, 4.63)
Appetite loss‡	19.5	8.2	2.73 (1.28, 6.53)
Constipation‡	16.6	5.2	3.69 (1.51, 11.05)
Diarrhea‡	11.2	7.2	1.63 (0.70, 4.24)

*Odds ratio $>$ 1 favors olaparib; †multi-item; ‡single item

1046 Poster Session (Board #127), Sat, 8:00 AM-11:30 AM

A randomized phase II trial evaluating *CYP2D6* genotype-guided tamoxifen dosing in hormone receptor-positive metastatic breast cancer: TARGET-1. *First Author: Toshimi Takano, Toranomon Hospital, Tokyo, Japan*

Background: Tamoxifen (TAM) is a prodrug that requires metabolic activation by CYP2D6. Genetic polymorphism of *CYP2D6* has been speculated to cause suboptimal efficacy of TAM. **Methods:** In a phase II multicenter open-label randomized controlled study, we enrolled candidates for first-line TAM therapy who had hormone receptor–positive (HR+) metastatic breast cancer. *CYP2D6* genotyping was performed using DNA extracted from whole blood at baseline. Patients with heterozygous (wt/V) or homozygous (V/V) variant alleles of decreased or no function were randomly assigned to TAM at regular dose (20 mg/day, RD arm) or increased dose (40 mg/day, ID arm), and patients with homozygous wild-type alleles (wt/wt) received TAM at 20 mg/day. The primary endpoint was 6-month (6M) progression-free survival (PFS) rate. Secondary endpoints included PFS and plasma levels of TAM and its metabolites. **Results:** From December 2012 to July 2016, 186 Japanese patients were enrolled. Of 184 evaluable patients, 136 carried wt/V or V/V (ID arm, 70; RD arm, 66), and 48 carried wt/wt. Patient characteristics (genotype; proportion of HR+ cells; status by recurrent or stage IV disease, bone metastasis, menopause, concurrent LHRH agonist therapy) did not differ significantly between the ID arm and RD arm. PFS rates at 6M were not significantly different between arms (67.6% ID arm vs. 66.7% RD arm; P = .45). Median PFS was longer in the ID arm than in the RD arm (14.2 M vs. 11.7 M; HR, 0.75; P = .15) with a median follow-up of 22.9 M. The trough levels of key active metabolite endoxifen (END) were significantly higher in the ID arm than in the RD arm (median 89.2 nM vs. 51.1 nM; P $<$ .0001). Compared with the levels of END in patients with wt/wt receiving TAM 20 mg/day (72.0 nM), those in patients in the ID arm were not significantly different (P = .0680), and those in patients in the RD arm were significantly lower (P = .0026). Adverse events did not differ significantly between arms. **Conclusions:** In patients with *CYP2D6* variant alleles, increasing TAM dosing resulted in higher plasma END levels. There was no PFS rate difference at 6M, but there was a trend for longer PFS for TAM at 40 mg/day than at 20 mg/day. Long-term follow-up is needed. Clinical trial information: UMIN000009155.

1047 Poster Session (Board #128), Sat, 8:00 AM-11:30 AM

Ribociclib (RIB) + tamoxifen (TAM) or a non-steroidal aromatase inhibitor (NSAI) in premenopausal women with hormone receptor-positive (HR+), HER2-negative (HER2-) advanced breast cancer (ABC) who received prior chemotherapy (CT): MONALEESA-7 subgroup analysis. *First Author: Sara A. Hurvitz, UCLA Jonsson Comprehensive Cancer Center, Los Angeles, CA*

Background: Although endocrine therapy (ET) and ovarian function suppression is an established first-line treatment for premenopausal patients (pts) with HR+, HER2– ABC, in some cases first-line CT is administered before ET. In the Phase 3 MONALEESA-7 trial (NCT02278120), RIB + TAM/NSAI and goserelin significantly prolonged progression-free survival (PFS) vs placebo (PBO) + TAM/NSAI and goserelin in premenopausal pts with HR+, HER2– ABC. Here, we report results in pts with and without prior CT for ABC. **Methods:** 672 pts with $\leq$1 line of prior CT and no prior ET for ABC were randomized 1:1 to RIB (600 mg/day, 3-weeks-on/1-week-off) or PBO + TAM (20 mg/day) or an NSAI (letrozole [2.5 mg/day] or anastrozole [1 mg/day]) and goserelin (3.6 mg every 28 days). The primary endpoint was PFS. Secondary endpoints included overall response rate (ORR) and safety. Prespecified subgroup analyses were performed in pts with and without prior CT for ABC. **Results:** 47 (14%) pts in each arm had received prior CT for ABC. The most common reason for treatment discontinuation in the RIB vs PBO arm was disease progression (prior CT: 47% vs 55%; no prior CT: 35% vs 51%). Median PFS was increased in the RIB vs PBO arm both in pts with prior CT (16.6 vs 9.0 months; hazard ratio: 0.547; 95% confidence internal [CI]: 0.314–0.954) and without prior CT (24.7 vs 14.5 months; hazard ratio: 0.566; 95% CI: 0.443–0.724). In pts with measurable disease (n = 559), the ORR was 32% vs 27% for those with prior CT (RIB vs PBO arm; P= 0.262) and 54% vs 38% for those with no prior CT (P= 2.90×10^{-4}). Common all-grade adverse events ($\geq$35% of pts in either arm; RIB vs PBO arm) were neutropenia (prior CT: 77% vs 4%; no prior CT: 76% vs 8%), leukopenia (prior CT: 36% vs 4%; no prior CT: 31% vs 6%), and hot flash (prior CT: 23% vs 36%; no prior CT: 36% vs 33%). **Conclusions:** Although pt numbers were small, those with prior CT had a numerically shorter PFS and lower ORR vs pts with no prior CT. However, consistent treatment benefit with RIB + TAM/NSAI vs PBO + TAM/NSAI was observed in premenopausal pts with HR+, HER2– ABC, regardless of prior CT for ABC. Clinical trial information: NCT02278120.

1048 Poster Session (Board #129), Sat, 8:00 AM-11:30 AM

Impact of abemaciclib on the time to subsequent chemotherapy and the time to second disease progression across the MONARCH 2 and 3 studies. *First Author: Sara M. Tolaney, Dana-Farber Cancer Institute, Boston, MA*

Background: Abemaciclib is a selective oral inhibitor of CDK4 & 6 dosed on a twice-daily continuous schedule. Abemaciclib was an effective treatment with a generally tolerable safety profile in combination with fulvestrant (F) (MONARCH 2) and as initial therapy (MONARCH 3) when combined with a nonsteroidal aromatase inhibitor (NSAI) in patients with hormone receptor-positive, human epidermal growth factor receptor 2-negative advanced breast cancer. To evaluate the impact of abemaciclib in subsequent treatment, we analyzed time to subsequent chemotherapy (TCT) and time to second disease progression (PFS2). **Methods:** Enrollment criteria and study designs of MONARCH 2 and 3 were previously reported (Sledge et al., 2017; Goetz et al., 2017). Exploratory analyses were performed to assess TCT and PFS2 using the Kaplan-Meier (KM) method. Hazard ratios (HR) were estimated using a Cox model. TCT was defined as time from randomization (R) to time to first chemotherapy (CT). Since exact progression date on post-therapies was not available, PFS2 was calculated from R to the discontinuation date of next-line (first line of post-discontinuation treatment), or starting date of the second line of post-discontinuation treatment, whichever was earlier. **Results:** Among randomized patients, 51% and 49% of patients in the MONARCH 2 and 3 trials, respectively, received a post-discontinuation systemic therapy (CT [35%, 26%], endocrine [28%, 38%], targeted agent [18%, 15%], or other [6%, 7%]). Initiation of CT was deferred by adding abemaciclib to F (median: abemaciclib arm, not reached; placebo [P] arm, 26.33 months [m]; HR 0.65, 95% CI 0.50-0.85; $p < .01$) or NSAI (median: abemaciclib arm, not reached; P arm, 32.52 m; HR 0.54, 95% CI 0.38-0.76; $p < .001$). KM analyses of PFS2 showed an improvement in the abemaciclib + F vs P + F arms (HR 0.78, 95% CI 0.61-1.00; $p < .05$) and in the abemaciclib + NSAI vs P + NSAI arms (HR 0.74, 95% CI 0.55-0.99; $p < .05$). **Conclusions:** Adding abemaciclib to F or NSAI delayed the start of subsequent chemotherapy, which is a patient-relevant outcome. Overall, the treatment benefit of abemaciclib + F or + NSAI was extended to the next line of the therapy after the initial disease progression. Clinical trial information: NCT02107703, NCT02246621.

1049 Poster Session (Board #130), Sat, 8:00 AM-11:30 AM

Health-related quality of life (HRQoL) in MONARCH 2: Abemaciclib plus fulvestrant in women with HR+, HER2- advanced breast cancer (ABC) who progressed on endocrine therapy. *First Author: Peter A. Kaufman, Norris Cotton Cancer Center, Dartmouth-Hitchcock Medical Center, Lebanon, NH*

Background: Compared to placebo (P) + fulvestrant (F), the MONARCH 2 HR+, HER2- ABC trial showed abemaciclib + F significantly improved PFS and ORR with a generally tolerable safety profile. Here, patient-reported HRQoL, functioning, and symptoms are reported. **Methods:** Study details were previously reported (Sledge et al. 2017). Data from the modified Brief Pain Inventory short form (mBPI-sf), EORTC QLQ-C30 and EORTC BR23 were collected at baseline, cycle 2 (C2), every 2 cycles from C3 - C13, and then every 3 cycles until short term follow up. Time to worsening (TTW) of pain ($\geq$2 point increase of "worst pain" or $\geq$ 1 level increase of WHO analgesic class) were analyzed by Cox model. Change from baseline for EORTC QLQ-C30 and BR23 subscales and mBPI-sf were analyzed by mixed model. Differences of change from baseline (for each and across all visits) between arms were analyzed. **Results:** PRO completion rates were $>$ 85% for baseline and on-treatment visits; duration of treatment was longer for abemaciclib + F patients (median 15 vs 9 cycles). The TTW for pain was similar between abemaciclib + F and P + F arms (HR = 0.900; p = .4005). No clinical and statistical significance was observed in the EORTC QLQ-C30 and BR23 function and symptom scales or the mBPI-sf; exceptions were higher diarrhea, appetite loss (AL) and nausea/vomiting (N/V) in the abemaciclib + F arm, which were consistent with reported adverse events (AE). The by-cycle analysis showed these higher mean symptom scores were transient for AL and NV, which increased in the first few cycles then gradually returned to near-baseline after cycle 7. Mean diarrhea scores returned to near-baseline levels post-therapy. **Conclusions:** In addition to significantly improved PFS and ORR, abemaciclib + F did not show statistically significant and clinically meaningful differences in patient-reported global health, functioning, or most symptoms compared to P + F. Increased GI-related symptoms were transient and consistent with the manageable, reversible AE profile; the highest symptom burden was reported during early visits. Clinical trial information: NCT02107703.

1050 Poster Session (Board #131), Sat, 8:00 AM-11:30 AM

Combination of paclitaxel and a LAG-3 fusion protein (eftilagimod alpha), as a first-line chemoimmunotherapy in patients with metastatic breast carcinoma (MBC): Final results from the run-in phase of a placebo-controlled randomized phase II. *First Author: Francois P. Duhoux, Department of Medical Oncology, King Albert II Cancer Institute, Cliniques universitaires Saint-Luc and Institut de Recherche Expérimentale et Clinique (Pôle MIRO), Université Catholique de Louvain, Brussels, Belgium*

Background: Eftilagimod alpha (efti, previously IMP321) is a recombinant LAG-3Ig fusion protein that binds to MHC class II and mediates antigen-presenting cell (APC) activation followed by CD8 T-cell activation. The activation of the dendritic cell network with efti the day after chemotherapy may lead to stronger anti-tumor CD8 T cell responses. We report final results of the safety run-in of a phase IIb trial (NCT02614833) in patients (pts) with hormone receptor positive MBC receiving weekly paclitaxel as first line chemotherapy. **Methods:** In the safety run-in phase 15 pts with MBC received paclitaxel (80 mg/m^2; D1, D8, D15; IV) in a 4-week cycle in conjunction with either 6 mg (n = 6; cohort 1) or 30 mg (n = 9; cohort 2) efti injections (D2 and D16; SC) for 6 cycles. Pts without progressive disease could continue for a maximum of 12 additional efti injections every 4 weeks. Blood samples for pharmacokinetics and immuno-monitoring were taken in cycle 1, 4 and 6. The primary endpoint was determination of the recommended phase 2 dose of this combination. **Results:** Between Jan and Oct 2016 15 pts (median age 53 years) were enrolled. A majority (67 %) of pts were pre-treated with hormonal therapy. Nine (67 %) pts had a serious adverse event, out of which 1 was related to paclitaxel (dizziness grade 3) and 1 to efti (cytokine release syndrome grade 1). No grade 4 and 4 grade 3 adverse events (AEs) in 4 pts were related to efti. Grade 1 and 2 injection site reactions were the most common efti related AEs and occurred in 14 pts (93 %). Increased number of circulating monocytes, dendritic cells and CD8 T cells as well as increased cellular activation were observed. This sustained ($\geq$ 6 months) activation of the cellular response was associated with increased Th1 markers (IFN-g, CXCL10) levels in the plasma. Seven pts (47 %) had a partial response according to RECIST 1.1 (mean duration of 9 months). The disease control rate was 87 %. **Conclusions:** Thirty mg efti SC is the recommended phase 2 dose and is currently investigated in the ongoing phase II part of the study. Efti leads to a steady and sustainable APC and T cell activation. Clinical trial information: NCT02614833.

1051 Poster Session (Board #132), Sat, 8:00 AM-11:30 AM

RIBECCA: A phase IIIb, multi-center, open label study for women with estrogen receptor positive locally advanced or metastatic breast cancer treated with ribociclib (LEE011) in combination with letrozole—Results of the first interim analysis. *First Author: Peter A. Fasching, University Hospital Erlangen, Erlangen, Germany*

Background: RIBECCA is a national, multi-center, open-label, single-arm phase IIIb trial assessing the efficacy and safety of ribociclib in combination with letrozole in a patient population similar to the populations of MONALEESA-2, -3 and -7. Here we present the results of the first pre-planned interim analysis. **Methods:** Main inclusion criteria allow enrollment of men or women with metastatic or locally advanced breast cancer not amenable to curative treatment by surgery or radiotherapy, and histological or cytological confirmation of ER+, HER2- breast cancer, irrespective of their menopausal status. The primary objective is to assess the clinical benefit rate (CBR) after 6 months, secondary objectives include progression free survival (PFS), overall survival (OS), safety and changes in quality of life. **Results:** The cut-off date for this first interim analysis was 12 months after the enrollment of the first patient (24-Oct-2017). Here we describe the baseline characteristics and safety data of patients (pts) with at least 12 weeks follow up (n = 338). Baseline characteristics: of 338 pts, 336 were female and 2 male. Median age: 64 yrs; 46 pts pre-or perimenopausal, 290 postmenopausal; ECOC 0-1: 97.3%; median time since first recurrence: 2 months; 74.3% pts had bone metastases, 31.4% liver, 26.9% lung and 28.4% other metastases. 79.6% of pts had received at least one prior endocrine therapy or chemotherapy: 39.5% in the (neo-) adjuvant setting, 39.9% in the palliative setting. Median relative dose intensity was 0.944 for ribociclib and 1 for letrozole. The most common treatment emergent AEs (all grades) were neutropenia (42.3%), nausea (36.7%), fatigue (33.4%), alopecia (29%), diarrhea (20.7%), leukopenia (19.5%), constipation (17.8%), ALT increased (17.1%), AST increased (15.7%) headache (15.9%) and neutrophil count decreased (12.7%). **Conclusions:** The results of the first interim analysis in this additional patient population are in line with data published from the pivotal phase III studies MONALEESA-2 and MONALEESA-7. No new safety signals were detected. Clinical trial information: NCT03096847.

1052 Poster Session (Board #133), Sat, 8:00 AM-11:30 AM

Olaparib versus chemotherapy treatment of physician's choice in patients with a germline *BRCA* mutation and HER2-negative metastatic breast cancer (OlympiAD): Efficacy in patients with visceral metastases. *First Author: Nadine M. Tung, Beth Israel Deaconess Medical Center and Dana-Farber Harvard Cancer Center, Boston, MA*

Background: The OlympiAD study showed a significant progression-free survival (PFS) benefit for olaparib over chemotherapy treatment of physician's choice (TPC) in patients with HER2-negative metastatic breast cancer (mBC) and a germline *BRCA* mutation (g*BRCA*m; HR 0.58, 95% CI 0.43–0.80). Objective response rate (ORR) was 59.9% in the olaparib arm and 28.8% in the TPC arm. Prognosis may vary by location of metastases, so we investigated the overall efficacy of olaparib vs TPC in mBC patients with specific sites of visceral metastasis. **Methods:** OlympiAD was a randomized Phase III study in patients with HER2-negative mBC and a g*BRCA*m who had ≤2 chemotherapy lines for mBC (NCT02000622). Patients were randomized 2:1 to olaparib tablet monotherapy (300 mg bd) or single-agent TPC (capecitabine, eribulin or vinorelbine). Cox proportional hazard models were used for these *post-hoc* analyses. **Results:** The study was not powered to detect differences in treatment effect between subgroups, and results should be interpreted with caution due to modest patient numbers and baseline imbalances. Key baseline characteristics and PFS by site of metastases are shown in the table. Within these subgroups, overall ORR in evaluable patients was: lung/pleura, 61.2% vs 22.2%; liver, 59.5% vs 25.8%; and brain/CNS metastases, 64.7% vs 20.0%, for olaparib vs TPC, respectively. **Conclusions:** Among patients with HER2-negative mBC and a g*BRCA*m who had metastases in the lung/pleura, liver or brain/CNS, the benefit for olaparib vs TPC appeared consistent with that seen overall, for both PFS and ORR. Clinical trial information: NCT02000622.

The association of early toxicity and outcomes for patients treated with abemaciclib. *First Author: Hope S. Rugo, University of California San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

Background: Abemaciclib is a CDK4 & 6 inhibitor dosed on a continuous schedule and has demonstrated efficacy with an acceptable safety profile in patients (pts) with hormone receptor-positive, human epidermal growth factor receptor 2-negative advanced breast cancer as monotherapy and in combination with endocrine therapy in the MONARCH 1, 2, and 3 trials. Early onset, low grade diarrhea was the most common toxicity and was typically manageable and reversible with antidiarrheal medication and/or dose reduction. Neutropenia was the most frequent grade 3/4 toxicity in the abemaciclib arms, typically occurring in the first 2 cycles. Here we provide an assessment of the association between these early toxicities, dose adjustment, and progression-free survival (PFS). **Methods:** Enrollment criteria, study designs, and endpoints were previously reported (Dickler et al. 2017; Sledge et al. 2017; Goetz et al. 2017). To examine the impact of dose reductions on efficacy, a time-dependent covariate analysis of dose level versus PFS was performed. A landmark analysis was performed for pts with/without toxicity occurring early in treatment (diarrhea: 7 days; neutropenia: 56 days) by comparing PFS for each of these arms to the placebo arm using a Cox model. **Results:** Discontinuation of abemaciclib due to diarrhea or neutropenia were each < 3% in the abemaciclib arms. Management of toxicity included dose adjustment as necessary. An exploratory time-dependent covariate analysis showed no difference in PFS for pts who dose-reduced compared to those who did not. Compared to placebo, pts in the abemaciclib arms received benefit whether or not diarrhea or neutropenia was observed early in treatment. **Conclusions:** The dose adjustment strategy used in the MONARCH trials appeared to be an effective way to manage toxicity without compromising efficacy. Clinical trial information: NCT02102490, NCT02107703, NCT02246621.

The tumor-immune microenvironment (TME) in HR+/HER2- metastatic breast cancer (mBC): Relationship to non-metastatic (met) tumors and prior treatment (tx) received. *First Author: Adrienne Gropper Waks, Dana-Farber Cancer Institute, Boston, MA*

Background: HR+/HER2- primary breast tumors demonstrate less anti-tumor immune activity than HER2+ or triple-negative BC. However, minimal data exist about the TME of HR+/HER2- met tumors, particularly in the tx-refractory setting. Prior analyses also have not looked at macrophages (macs), which may be important in HR+ BC. **Methods:** We obtained met tumor biopsies (bx) from HR+/HER2- mBC patients (pts) on a prospective tissue collection protocol. Tumor-infiltrating lymphocytes (TILs) were scored histologically, and cytokeratin, CD68, CD163, and PD-L1 on tumor cells (tPD-L1) were assessed by multiplex immunofluorescence (IF). Correlation between biomarkers and prior lines of tx was assessed by Spearman coefficient. A previously presented cohort of HR+/HER2- non-met tumors is included for comparison. Biomarker differences between non-mBC and mBC samples were assessed by Wilcoxon rank sum (TILs) and chi2 (tPD-L1) tests. **Results:** 33 HR+/HER2- mBC bx were analyzed from 30 pts (31 assessed for TILs, 21 by IF). Bx sites were 17 (52%) liver, 8 (24%) breast, and 8 (24%) other. Bx were obtained after a mean of 3.9 (range 0-10) lines of tx. Median TILs were 1% (range 0-20%). Ratio of M2 (CD68+CD163+) to M1 (CD68+CD163-) macs was ≥1 in 19/21 samples, suggesting dominance of M2 (immunosuppressive) macs. tPD-L1 was < 1% in 20/21 (95%) pts. There was no significant correlation between level of any cell type (TILs, M1 or M2 macs) and lines of hormonal tx, chemotx, or both received before bx. There was a trend toward lower TILs and lower tPD-L1 in mBC bx compared to a separate cohort (N = 55) of HR+/HER2- non-mBC (Table). Analysis of additional samples, IF stains, and RNA/exome sequence is in process and will be presented. **Conclusions:** HR+/HER2- mBC tumors show a trend toward lower TILs and tPD-L1 than unmatched non-met bx, which may help explain low response rates to checkpoint inhibitors. Immune biomarker levels did not change significantly based on a tumor's degree of pre-tx.

Plasma and tumor genomic correlates of response to BYL719 in *PI3KCA* mutated metastatic ER-positive breast cancer (ER+/HER2- BC). *First Author: Sarah-Jane Dawson, Peter MacCallum Cancer Centre, Melbourne, Australia*

Background: Mutations of genes involved in the PI3K signalling pathway occur frequently in BC. We performed a phase II study of BYL719, a selective PI3Kα inhibitor, in BC to evaluate its efficacy and identify biomarkers that correlate with tumor response. **Methods:** Eligible patients had advanced ER+/HER2- BC and documented genetic alteration of the PI3K pathway detected in either tumor or plasma. Patients received BYL719 350mg orally daily. The primary end point was RECIST objective response rate (ORR). Secondary endpoints were clinical benefit rate (CBR) including stable disease for ≥24 weeks, progression-free survival (PFS) and efficacy according to baseline and week 8 change in ctDNA levels. ctDNA analysis was performed through droplet digital PCR. **Results:** Of the total 17 patients treated, 16 (94%) had a *PIK3CA* mutation (mt) and 1 had a *PTEN* deletion. Of the *PI3KCA* mutant patients, 8 (47%) had a kinase domain mt, 7 (41%) had a helical domain mt and 1 (6%) patient had 2 *PIK3CA* mts. 16/17 (94%) patients had their alteration detected in plasma at baseline; concordance between plasma and tumor was 94% (15/16). Median age was 60 years (45-77). Patients had received a median of 3 prior treatment lines (1-7) in the metastatic setting; 16 (94%) had received prior endocrine therapy and 14 (82%) prior chemotherapy. 15 (88%) had visceral disease. The ORR (centrally reviewed) was 41% (7/17) and CBR was 59% (10/17). Median PFS (mPFS) was 5.49 months (mo) (95% CI, 3.63 – 13.78). The most common grade ≥ 3 adverse event was hyperglycaemia (5/17; 29%). Co-existent *MAP3K1* or *ESR1* mt (N = 7, 41%) had a longer clinical benefit (mPFS 11.02 mo (95%CI, 5.44-NR) with 3 (18%) ≥1 yr) compared with co-existent *TP53* mt, *CCND1* or *FGFR1* amplification (N = 10, 59%) (mPFS 3.66 mo (95%CI, 3.63-NR)). Patients who achieved clinical benefit had a significantly greater decrease in ctDNA levels at week 8 from baseline (median 97.34% vs 9.14% decrease, p = 0.04). **Conclusions:** BYL719 in previously treated advanced ER+/HER2- BC with *PIK3CA* mt detectable in plasma at baseline demonstrated robust clinical benefit. This biomarker should be considered in the Phase III setting. Clinical trial information: NCT02506556.

1056 Poster Session (Board #137), Sat, 8:00 AM-11:30 AM

Ribociclib (RIBO) + letrozole (LET) in patients (pts) with hormone receptor-positive (HR+), human epidermal growth factor receptor 2-negative (HER2–) advanced breast cancer (ABC) with no prior endocrine therapy (ET) for ABC: Preliminary results from the phase 3b CompLEEment-1 trial. *First Author: Michelino DeLaurentiis, National Cancer Institute "Fondazione G. Pascale", Napoli, Italy*

Background: CDK4/6 inhibitor RIBO has been approved for use in combination with LET for the treatment of HR+, HER2– ABC in postmenopausal women with no prior therapy for advanced disease, based on the significantly prolonged PFS versus placebo + LET observed in the pivotal phase 3 MONALEESA-2 trial (Hortobagyi et al. *NEJM* 2016). Here, we report baseline characteristics and early safety results for the first 1,000 pts enrolled in CompLEEment-1, an open-label, phase 3b trial evaluating RIBO+LET as first-line therapy in an expanded pt population. **Methods:** Pts (N≈3,000) with HR+, HER2– ABC, ≤1 line of prior chemotherapy, and no prior ET for ABC received RIBO (600 mg/day, 3 wk on/1 wk off) + LET (2.5 mg/day); men and premenopausal women received concomitant goserelin (3.6 mg subcutaneous implant every 28 days). The primary outcome was safety and tolerability. A pre-planned interim analysis was conducted ~12 months after first pt first visit. **Results:** Demographics and baseline characteristics for the first 1,007 pts enrolled in the study were captured in the database snapshot (January 17, 2018) and are summarized in Table 1. Details on safety results from the interim database lock (February 2018) will be presented. **Conclusions:** Initial population characteristics from CompLEEment-1 demonstrate a diverse group of pts, more reflective of those seen in a real-world setting. NCT02941926 Clinical trial information: NCT02941926.

Mutation signature of patients with ER+ metastatic breast cancer who received endocrine therapy. *First Author: Fei Ma, National Cancer Center/ Cancer hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Approximately eighty percent of breast cancer patients are estrogen receptor alpha (ER-α) positive. Although women initially respond well to endocrine therapies, resistance often emerges. In this study we try to analyze the mutations in ER+ metastatic breast cancer patients (MBC) who have received endocrine therapies. **Methods:** Using next-generation sequencing (NGS)–based gene panel test (NGS), we analyzed the mutation profiling in 194 patients (pts) with MBC who were treated by endocrine therapies. **Results:** Somatic genomic alterations in ctDNA including copy number variants and point mutations were identified in 179 of 194 patients (92.3%). *ESR1* activating point mutations or amplifications were identified in 28.9% (56/194) patients, which has been described to be associated with resistance to tamoxifen and AI therapies in patients with ER+ MBC. The most described hotspot activating mutations Y537C/S/N and D538G were detected in 26 and 21 patients, and other described mutations E380Q (13 pts), S463P (2 pts), L536R/H (2 pts), *ESR1* amplifications (2 pts) were also detected. Additionally, nine novel point mutations were identified in *ESR1* (including A58T, T311M, P406A, F435L, R436H, H488N, Q580L, V560E, Y526C). Polyclonal *ESR1* mutations were identified in 13 patients. Another mechanism of resistance to endocrine therapy *FGFR1* amplification was identified in 10 patients and one co-occurring with *ESR1* mutation. For other genes associated with target therapies, *PIK3CA* mutations or *PTEN* deficiency were more common detected in patients with *ESR1* mutation than *ESR1 WT* (50.0% *vs* 35.5%, p= 0.01). *CDKN2A* deficiency/*CCND1* amplification were detected in 4 (7.1%) and 15 (10.9%) patients with or without *ESR1* mutation. In addition, *HER2* amplifications were less common detected in patients with *ESR1* mutation than *ESR1 WT* (3.6% *vs* 14.5%, p= 0.03). **Conclusions:** In ER+ MBC patients with endocrine therapies, *ESR1* and *FGFR1* activating variants were common resistance to endocrine therapies and other targetable variants were also detected. Thus, These patients may benefit from combined treatment, such as endocrine therapies combined with mTOR inhibitors, CDK4/6 inhibitors when other pathways activating together.

1058 Poster Session (Board #139), Sat, 8:00 AM-11:30 AM

Phase IB trial of ACY-1215 (Ricolinostat) combined with nab-paclitaxel in metastatic breast cancer. *First Author: Kevin Kalinsky, Columbia University Medical Center, New York, NY*

Background: HDAC6, a cytoplasmic histone deacetylase, plays an important role in cell-cell interactions, motility, chaperone function, and protein degradation. ACY-1215 is an orally active, selective HDAC6 inhibitor. Preclinical studies have demonstrated ACY-1215 to have synergistic activity with taxanes. We have developed an algorithm (HDAC6 score) based on mRNA expression profiling to evaluate the HDAC6 activity of individual tumor samples. **Methods:** In this open-label phase Ib, patients (pts) received ACY-1215 daily for 21 days of each 28-day cycle with nab-paclitaxel 100 mg/m2 on days 1, 8, and 15 until progression of disease or unacceptable toxicity. The primary objective was to establish the maximum tolerated dose of ACY-1215 with nab-paclitaxel. Dose escalations were performed according to the time to event continual reassessment method (TITE-CRM), starting at 120 mg to a maximum dose of 240 mg daily (qd). The TITE-CRM used an empirical dose-toxicity model, with a sample size of 15 evaluable patients. HDAC score was performed retrospectively on primary and/or metastatic tissue. **Results:** 17 pts were accrued between 3/16-2/18: 15 were evaluable. Of evaluable pts, 3 had triple negative BC and 12 hormone receptor (HR)+/HER2-. The mean number of prior lines was 4 (range: 0-9). The first pt started at 120 mg qd, the second at 180 mg qd, and the rest at 240 mg qd. No dose limiting toxicities were seen. The only grade 3 event thought to be medication-related was syncope in 1 pt. No grade IV events were seen. In evaluable pts, the following were best responses: 1 partial response (PR), 9 stable disease (SD), and 3 progressive disease (PD: 2 TNBC, 1 HR+/HER2-). Two pts recently started and were too early to report. In the first 6 evaluable pts, the HDAC6 score (network size = 243) could significantly dichotomize those with PD vs. SD/PR (p = 0.05). **Conclusions:** ACY-1215 240 mg qd is safe and tolerable with weekly nab-paclitaxel. Clinical activity has been observed, with the majority of pts demonstrating SD and 1 with a PR. Notably, the HDAC6 score appears to preliminarily predict activity. We plan on presenting updated data, including HDAC6 score on additional pts, with data maturity. Clinical trial information: NCT02632071.

1059 Poster Session (Board #140), Sat, 8:00 AM-11:30 AM

Updated efficacy, safety, & PD-L1 status of patients with HR+, HER2- metastatic breast cancer administered abemaciclib plus pembrolizumab. *First Author: Sara M. Tolaney, Dana-Farber Cancer Institute, Boston, MA*

Background: Abemaciclib is a selective inhibitor of CDK4 & 6 approved to treat HR+, HER2- metastatic breast cancer (MBC) patients (pts) as monotherapy and in combination with fulvestrant. In preclinical models, abemaciclib administered with anti-programmed death-ligand 1 (PD-L1) antibody therapy synergistically induced anti-tumor response and immunologic memory. A Phase I study (JPBJ, NCT02079636) of abemaciclib plus pembrolizumab (Merck & Co.), a programmed death receptor 1 (PD-1) antibody, demonstrated stable disease in 65% of pts with stage IV NSCLC along with a generally manageable safety profile. **Methods:** JPCE is a multicenter, nonrandomized, open-label, Phase 1b study of abemaciclib plus pembrolizumab in pts with HR+, HER2- MBC or stage IV NSCLC. Key eligibility criteria for the MBC cohort were: HR+, HER2- MBC with 1 - 2 prior chemotherapy regimens, measurable disease, adequate organ function, ECOG PS ≤1, and no prior treatment with CDK4 & 6 or PD-1 & PD-L1 inhibitors. The primary objective was to assess safety of the combination per CTCAE v4.0. Secondary objectives were: objective response rate (ORR), progression-free survival, duration of response, disease control rate, overall survival, pharmacokinetics and pt-reported disease-related symptoms. Pts received the maximum tolerated dose established in JPBJ; orally administered abemaciclib 150 mg twice daily plus IV administered pembrolizumab 200 mg, day 1 of each 21-day cycle. **Results:** Twenty-eight pts were enrolled in the MBC cohort. Abemaciclib plus pembrolizumab demonstrated a generally manageable safety profile in pts with HR+, HER2- MBC. Single agent toxicity profiles reported previously were not exacerbated, and no new safety signals were detected. Initial ORR was 14.3%. Patient PD-L1 status by IHC staining (positive ≥1%; negative < 1%), efficacy, and safety data from the 24-week analysis will be presented. **Conclusions:** Abemaciclib plus pembrolizumab demonstrated a generally manageable safety profile upon initial review (Rugo et al. SABCS 2017). Assessment of the effectiveness of this novel combination, with reference to PD-L1 status, for the treatment of pts with HR+, HER2- MBC is ongoing. Clinical trial information: NCT02779751.

1060 Poster Session (Board #141), Sat, 8:00 AM-11:30 AM

Hematologic adverse events following palbociclib (PAL) dose reduction in patients (pts) with hormone receptor–positive (HR+)/human epidermal growth factor receptor 2–negative (HER2–) advanced breast cancer (ABC): Pooled analysis from randomized phase 2 and 3 studies. *First Author: Sunil Verma, Tom Baker Cancer Centre, University of Calgary, Calgary, AB, Canada*

Background: A previous pooled analysis showed that 36.9% of pts receiving PAL required dose reduction, most occurring during the first 6 mo of treatment and with decreasing frequency during subsequent 28-d treatment cycles (C). Previous data have also shown that PAL dose reductions do not affect efficacy (Im S-A, et al. ESMO Asia 2017). **Methods:** This analysis evaluated the frequency of hematologic adverse events (AEs) 30 d before and after dose reduction (during each treatment C1–C6) among pts who required PAL dose reduction. Data were pooled from 3 randomized studies: PALOMA-1, a phase 2, open-label study of postmenopausal pts untreated for ABC receiving PAL+letrozole (L) or L alone; PALOMA-2, a phase 3, double-blind study of postmenopausal pts untreated for ABC receiving PAL+L or placebo (PBO)+L; PALOMA-3, a phase 3, double-blind study of pre- or postmenopausal pts who progressed on prior endocrine therapy receiving PAL+fulvestrant (F) or PBO+F. **Results:** A total of 311 pts with HR+/HER2– ABC required a PAL dose reduction (93.6% due to AEs) from 125 to 100 mg. Mean age was 59.9 y, and 46.9% of pts had visceral disease. Median time to dose reduction was 70 d. Incidences of grades 3/4 hematologic AEs were lower after dose reduction (Table), with decreased severity after dose reduction. **Conclusions:** A decrease in frequency and severity of hematologic AEs, including febrile neutropenia, following PAL dose reduction was observed, supporting the use of dose reduction in AE management. Funding: Pfizer (NCT00721409, NCT01740427, NCT01942135). Clinical trial information: NCT00721409, NCT01740427, NCT01942135.

1061 Poster Session (Board #142), Sat, 8:00 AM-11:30 AM

G1T38, an oral CDK4/6 inhibitor, dosed continuously in combination with fulvestrant for HR+ breast cancer: Preliminary phase 1b results. *First Author: Iurie Bulat, ARENSIA Exploratory Medicine Research Unit, Institute of Oncology, Chisinau, Moldova, The Republic of*

Background: CDK4/6 inhibition has demonstrated significant improvements in PFS when combined with fulvestrant (F) in patients with breast cancer (BC). G1T38 (38) is a potent, selective oral CDK4/6 inhibitor with best-in-class potential. Continuous daily dosing in preclinical models inhibits tumor growth and leads to a dose-dependent ANC decline and subsequent plateau. A completed Phase 1 trial supports this Phase 1b/2a trial (NCT02983071) in BC patients. **Methods:** Patients with metastatic or locally advanced HR+ HER2(-) BC who had progressed following endocrine therapy are eligible. Patients receive 38 QD or BID continuously with 500 mg F. Primary objectives are to evaluate DLTs, safety, and tolerability and to determine the RP2D and schedule of 38 administered with F. **Results:** To date, 24 patients (median age 55.5) have enrolled and received 38 doses ranging from 200-500 mg QD and 100-150 mg BID for up to 367 days. Dose escalation is ongoing. 38 is well tolerated: no 38-related SAEs have been reported and no patient has withdrawn due to an AE. 1 DLT of Grade 4 neutropenia occurred at 200 mg QD. The most common 38-related TEAEs are cytopenias and GI AEs. There have been no reports of VTE, QT prolongation, or DILI. Incidence/severity of diarrhea is less than abemaciclib, and similar to palbociclib and ribociclib. The degree of neutropenia is consistent with effective CDK4/6 inhibition with 79% all-grade neutropenia. Following an initial decline, ANCs plateau beginning at Week 5, which is consistent with preclinical findings. The % ANC change at Week 5 ranges from -48% (200 mg QD) to -74% (500 mg QD). Confirmed PR rate is 20% in evaluable patients, with a median time to response of 12 weeks. The CBR (CR + PR + SD $\geq$ 24 weeks) is 57%. **Conclusions:** G1T38 is a potential best-in-class CDK4/6 inhibitor. Continuous daily dosing with G1T38 + F is well tolerated with non-dose-limiting ANC decrease that plateaus at week 5, thus eliminating the need for a drug holiday. Early efficacy results are encouraging, and data support continued dose escalation and dose expansion. Combinations of G1T38 in other indications are anticipated; a Phase 1/2a trial of G1T38 + Tagrisso in EGFRm NSCLC will initiate in March 2018. Clinical trial information: NCT02983071.

1062 Poster Session (Board #143), Sat, 8:00 AM-11:30 AM

Everolimus exposure and early metabolic response as predictors for treatment outcomes in breast cancer patients treated with everolimus and exemestane. *First Author: Annelieke Willemsen, Radboud university medical center, Nijmegen, Netherlands*

Background: Treating breast cancer patients (BC pts) with everolimus and exemestane can be challenging due to toxicity and suboptimal treatment responses. We investigated whether everolimus exposure, elderly age, and early metabolic response are predictive of toxicity and effectiveness in these pts. **Methods:** We collected blood samples from BC pts, 14 and 35 days after starting everolimus and exemestane, to measure everolimus trough level (C_{min}). Toxicity, defined as dose interventions (reduction or discontinuation) $<$ 3 months, and progression free survival (PFS) according to RECIST 1.1 were recorded. 18F-FDG-PET was performed at baseline, and 14 and 35 days after start of therapy. SUV normalized by lean body mass was calculated for the maximum voxel and highest peak (SUL_{max} and SUL_{peak}), for up to 5 target lesions. **Results:** In 44 evaluable pts, the geometric mean (GM) C_{min} was higher in pts with dose interventions $<$ 3 months compared to pts without: 17.4 vs 12.3 μg/L (p = .02). The optimal cut-off value to predict toxicity was C_{min} $>$ 19.2 μg/L (AUC 0.71, sensitivity 0.55, specificity 0.92). Elderly pts ($>$ 70 years) compared to pts $<$ 70 years had a shorter median time to dose intervention: 42 vs 141 days (p = .001), but no significant difference in everolimus GM C_{min}: 17.6 vs 13.5 μg/L (p = .12). GM C_{min} of pts with and without progressive disease (PD) $<$ 3 months was not significantly different: 12.0 μg/L vs 15.2 μg/L, respectively (p = .12). FDG-PET scans of 30 pts were analyzed. The percentage decrease in SUL_{peak} of the lesion with highest avidity at day 14 ($SUL_{peak\ high}$ d14) was the best predictor of PD $<$ 3 months. Pts with $>$ 11% vs $<$ 11% decrease in $SUL_{peak\ high}$ at d14 had a median PFS of 411 days vs 90 days respectively (p = .001), and 11 vs 70% of these pts had PD $<$ 3 months. **Conclusions:** Our results show that everolimus toxicity is related to everolimus C_{min} and by monitoring everolimus C_{min}, toxicity might be prevented. We recommend diligent monitoring of elderly pts, as they have toxicity more frequently. No relation was observed between everolimus exposure and effectiveness. FDG-PET is able to early identify pts at high risk of early progression. Further validation of these results is required. Clinical trial information: NCT01948960.

1063 Poster Session (Board #144), Sat, 8:00 AM-11:30 AM

^{18}F-Fluoroestradiol (FES) and ^{18}F-Fluorodeoxyglucose (FDG) PET imaging in lobular breast cancer. *First Author: Poorni Manohar, University of Washington/ Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: The histology and pattern of spread in lobular breast cancer has presented challenges in estimating extent of disease by traditional imaging methods. ^{18}F-FES is an estrogen analogue PET imaging tracer which measures tumor ER expression at multiple tumor sites simultaneously. We compared quantitative FES-PET and clinical FDG-PET SUV uptake between patients with metastatic lobular and ductal carcinoma. **Methods:** We retrospectively compared FES and FDG SUV uptake between ER+ lobular and ductal metastatic breast cancer patients (199 ductal, 44 lobular) enrolled in various studies at our institution. Up to nine lesions in each patient were evaluated by FES SUVmax and/or FDG SUVmax for a total of 619 lesions in FES images (n = 509 ductal, n = 110 lobular) and 466 lesions in FDG images (n = 378 ductal, n = 88 lobular). Using linear mixed-effects models, we assessed differences between lobular and ductal histologies in both FES SUVmax and FDG SUVmax. Overall survival (OS), from time of FES-PET scan to death, was evaluated between histologies using Kaplan-Meier curves and the Log-Rank test. **Results:** Among metastatic breast cancer patients with positive FES scans, approximately 10% of patients with ductal histology and 9% with lobular histology had absent FES uptake in at least one lesion. Mean (range) SUVmax in FES and FDG respectively for ductal was 3.48 (0.32, 20.5) and 5.2 (1.1, 26.7) and for lobular was 3.34 (0.61, 9.62) and 4.42 (1.09, 20.0). Difference in FES and FDG SUVmax between histologies was marginal and non-significant. On the natural log scale, lobular carcinomas demonstrated a higher SUVmax (Difference = 0.05, 95%CI = [-0.16, 0.26], p = 0.63) and a lower FDG SUVmax (Difference = -0.53, 95%CI = [-1.61, 0.56], p = 0.34. Following FES-PET imaging, patients with ductal carcinomas had a lower, non-significant median survival time (2.97 vs. 3.03 years, p = 0.81). **Conclusions:** In the metastatic setting, FES and FDG uptake in multiple lesions in ER+ lobular breast cancer patients did not statistically differ from ductal breast cancer. Metastatic lobular breast cancers have similar FES and FDG avidity to metastatic ductal tumors, suggesting these patients may benefit from similar diagnostic and treatment algorithms.

1064 Poster Session (Board #145), Sat, 8:00 AM-11:30 AM

Outcome of everolimus based therapy in hormone receptor positive metastatic breast cancer patients after progression on palbociclib combination. *First Author: Ajay Dhakal, Roswell Park Cancer Institute, Buffalo, NY*

Background: BOLERO 2 trial showed improved progression free survival (PFS) with everolimus (EV) + exemestane combination over exemestane alone in hormone receptor positive, HER2 non-amplified metastatic breast cancer patients (HR+ HER2- MBC) who progressed on an aromatase inhibitor (AI). Recent studies have established CDK 4/6 inhibitors (CDKI) as front line therapy in HR+ HER2- MBC. There are no clinical outcome data of HR+ HER2- MBC on EV after they progress on CDKI. Objective of our study is to analyze clinical outcomes of HR+ HER2- MBC on EV after progression on palbociclib (PA) & compare them with BOLERO 2 results. **Methods:** This is a retrospective, two-institute review of HR+ HER2- MBC from Jan 2015-July 2017 treated with EV after progression on PA. Women who received EV or PA $<$ 4 weeks were excluded. PFS was defined as the time from the initiation of EV to the date of progression as determined by treating physician based on radiological, biochemical and/or clinical criteria. Response rates were determined based on available radiological data. **Results:** 26 women with median age 61 (33-70) were identified. 76% had prior sensitivity to endocrine therapy, 69% had adjuvant chemo/hormonal therapy, 54% had visceral disease, 23% had 3 or more metastatic sites, 100% had ECOG performance status 0 or 1, 92% had prior AI, 65% had received chemotherapy, 35% had received chemotherapy for metastatic disease, 81% had 3 or more lines of prior therapy. Kaplan Meier estimate showed median PFS (95% CI) of 4.4 months (3.3-6.1) and median overall survival (OS) of 18.7 months (9.0- not reached). Median PFS and OS of EV cohort of BOLERO 2 (EV BOL) were 6.9 months (6.4-8.1) and 31.0 months (28.0-34.6). Fisher's exact test comparing current study cohort vs. EV BOL showed significant difference in objective response (complete + partial responses) of 6/26 (23%) vs. 46/485 (9.5%), p = 0.04. **Conclusions:** EV showed shorter PFS and OS but significantly higher objective response in HR+ HER2- MBC who have progressed on PA compared to EV BOL. This small study, for the first time, suggests that EV has evidence of clinical benefit after progression on PA in HR+ HER2- MBC. Larger studies are needed to confirm the results.

1065 Poster Session (Board #146), Sat, 8:00 AM-11:30 AM

Phase II study of Ra-223 combined with hormonal therapy and denosumab for treatment of hormone receptor-positive breast cancer with bone-dominant metastasis. *First Author: Naoto T. Ueno, Morgan Welch Inflammatory Breast Cancer Research Program and Clinic, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Radium-223 dichloride (Ra-223) is a targeted alpha therapy that induces a localized cytotoxic effect on bone metastases. We evaluated the efficacy of combined Ra-223, hormonal therapy, and denosumab in patients with hormone receptor (HR)-positive, bone-dominant metastatic breast cancer. **Methods:** In this single-center phase II study (NCT02366130), patients received Ra-223 (55 kBq/kg intravenously) on day 1 and then every 4 weeks for 6 cycles. Patients also received a hormonal agent (i.e., tamoxifen, aromatase inhibitor, or fulvestrant) at standard dosage and denosumab (120 mg) every 4 weeks. One non-bone metastatic site was allowed. There was no limit on the number of prior hormonal therapies, and one prior chemotherapy was allowed for metastasis. Response was evaluated by PERCIST on FDG PET-CT at baseline, 6 and 9 months (mo). Primary objective was disease control rate at 9 mo. Secondary objectives were tumor response rate at 6 mo and safety. **Results:** After patient accrual (n = 36), the first 30 patients who had 6 mo follow-up or progression prior to 6 mo were analyzed. The median number of prior therapies for metastasis was 1 (range, 0-4). Five patients (16%) received chemotherapy and 7 (23%) a CDK4/6 inhibitor. The median follow-up time was 12.2 mo (95% confidence interval [CI], 9.6–31.7). The disease control rates were 60% at 6 mo and 48% at 9 mo (5 patients had complete response). The median progression-free survival (PFS) was 7.4 mo (95% CI, 4.8–not reached [NR]). The bone-PFS was 15.9 mo (95% CI, 7.4–NR). The median PFS was significantly superior in patients with bone only metastasis than bone with other metastatic site at baseline (NR vs 4.4 mo; $p < 0.0001$). There were no grade 3 or 4 adverse events (AEs). The hematologic AEs were neutropenia (23%), anemia (20%), and thrombocytopenia (13%). **Conclusions:** Our results suggest that addition of Ra-223 to a hormonal agent and denosumab is a potentially effective approach in patients with HR-positive breast cancer with bone metastasis, with no major toxic effects. The impact of metastatic site outside of the bone at baseline must be factored into future clinical trial designs. We will report the updated result. Clinical trial information: NCT02366130.

1066 Poster Session (Board #147), Sat, 8:00 AM-11:30 AM

Sperm associated antigen 5 (SPAG5) as a predictor and monitor for response and distant relapse risk (DRR) to endocrine (ET) and chemo-therapies (CT) in oestrogen receptor positive (ER+) breast cancer (BC). *First Author: Tarek Mohamed Ahmed Abdel-Fatah, Nottingham University City Hospital NHS Trust, Nottingham, United Kingdom*

Background: SPAG5 is an ultimate proliferation marker and important driver that is commonly amplified in "luminal B" BC. **Methods:** SPAG5 copy number aberrations (CNAs), mRNA and protein expression and their association with BC specific survival (BCSS) were determined in 4998 cases of ER+ BC. The association between the pathological complete response (pCR) to neoadjuvant anthracycline based CT (NACT) and SPAG5 expression was evaluated in 1073 (mRNA) and 332 (protein) patients with ER+ BC . The association between the dynamic response to the neoadjuvant ET (NAET) and SPAG5 mRNA expression was evaluated in 101 cases of ER+ BC. The association between distant relapse risk (DRR) and SPAG5 expression were tested in ER+/HER2- patients who received (if eligible) NACT or adjuvant CT in addition to 5-year tamoxifen (mRNA: n = 2819; protein: n = 2501). **Results:** SPAG5 amplification (CNA) and overexpression (SPAG5+, mRNA, protein) were all associated with shorter BCSS (HR: 1.55, 1.31, and 1.90, ps $<$ 0.001); respectively). After receiving NACT, multivariable logistic regression analyses confirmed that SPAG5+ mRNA and protein expression were independently associated with higher pCR (OR: 1.90; p = 0.041 and 23.03; p $<$ 0·0001; respectively). Downregulation of SPAG5 has been observed after 2-weeks on NECT and this predicted the dynamic clinical response ($p < 0.01$). In patients received Tamoxifen alone with either lymph node positive (LN+) or LN negative disease, SPAG5+ BC (mRNA, protein) exhibited a two-fold increase in DRR compared to patients with SPAG5- disease (ps $<$ 0·0001). In contrast, in patients received CT+Tamoxifen with LN+ or LN-disease, SPAG5+ (mRNA, protein) exhibited a similar DRR to that with SPAG5- disease. ER+ patients with SPAG5+ mRNA tumours receiving CT+Tamoxifen has improved 5-year-DRFS by 28% for those with LN- disease (89% vs., 67%; p $<$ 0·001) and 22% for those with LN+ disease (76% vs., 54%; p $<$ 0·001), as compared to receiving Tamoxifen alone. **Conclusions:** SPAG5 could be used as a prognostic and predictive tool for selecting systemic therapies and monitoring response to the selected therapy in patients with ER+ BC.

1067 Poster Session (Board #148), Sat, 8:00 AM-11:30 AM

Healthcare medical costs among post-menopausal women with hormone receptor positive and human epidermal growth factor receptor 2 negative (HR+/HER2-) metastatic breast cancer (mBC) managed with systemic therapy following CDK 4/6 inhibitor (CDKi) in the real-world setting. *First Author: Nicole Princic, Truven Health Analytics, an IBM Company, Cambridge, MA*

Background: To examine US healthcare costs among HR+/HER2- women with mBC having systemic therapy with chemotherapy, endocrine therapy, or everolimus following CDKi. **Methods:** This population-based analysis used MarketScan Commercial and Medicare administrative claims data to select post-menopausal women diagnosed with HR+/HER2- mBC between 1/1/2012-10/31/2017 (index = first evidence of metastatic disease). Eligible patients had ≥1 line of systemic therapy on a chemotherapy, endocrine only, or everolimus-based regimen following a CDK4/6i-based line. All-cause and BC-related medical (excluding pharmacy) costs were measured per-patient per-month (PPPM) during each line of therapy. Generalized linear models were used to compare costs for post-CDKi systemic therapy lines after adjusting for key patient characteristics, including health status and line of therapy. **Results:** In total, 193 chemotherapy,186 endocrine only, and 70 everolimus-based lines following CDKi-based therapy were included. Patients with everolimus-based therapy had significantly ($p < 0.001$) lower all-cause (Δ = \$6,462 PPPM) and BC-related (Δ = \$5,706 PPPM) medical costs compared with chemotherapy and similar medical costs (all-cause and BC-related) compared with endocrine therapy after accounting for BC-related office administered treatment (Table). Results were consistent after adjusting for patient characteristics. **Conclusions:** Patients with HR+/HER2- mBC on everolimus-based therapies relative to chemotherapy following treatment with a CDKi incurred lower medical costs, after accounting for observable confounders.

	Chemotherapy	Endocrine	Everolimus	Everolimus vs. Chemotherapy	Everolimus vs. Endocrine
Total medical	\$11,505	\$6,767	\$5,043	$<$ 0.001	0.083
Total medical without BC-related office administered treatment	\$9,075	\$5,254	\$4,970	0.005	0.767
Total BC- related medical	\$8,506	\$4,899	\$2,800	$<$ 0.001	0.004
Total BC-related medical without office administered treatment	\$6,076	\$3,387	\$2,727	$<$ 0.001	0.311

1068 Poster Session (Board #149), Sat, 8:00 AM-11:30 AM

A phase I study of palbociclib (PALBO) plus everolimus (EVE) and exemestane (EXE) in hormone-receptor positive (HR+)/HER2- metastatic breast cancer (MBC) after progression on a CDK4/6 inhibitor (CDK4/6i): safety, tolerability and pharmacokinetic (PK) analysis. *First Author: Romualdo Barroso-Sousa, Dana-Farber Cancer Institute, Boston, MA*

Background: Although adding a CDK4/6i to endocrine therapy (ET) has proved to prolong progression-free survival in patients (pts) with HR+/HER2- MBC, it is unclear if continuing a CDK4/6i, together with subsequent lines of ET, is beneficial. Preclinical data showed that the combination of PI3K inhibitors and CDK4/6i are synergistic, and could restore sensitivity to both CDK4/6i and ET. We present phase Ib data of PALBO + EVE + EXE in pts with HR+/HER2- MBC. **Methods:** In this phase Ib/II study (NCT02871791), pts received escalating doses of PALBO (once daily, days 1–21 of 28-day cycle) + EVE (5 mg/d) + EXE (25 mg/d). Eligible pts had HR+/HER2- MBC, with measurable disease, and prior progression on any CDK4/6i and a non-steroidal aromatase inhibitor. Pts may have received any number of prior lines of ET, and 0-1 prior line of chemotherapy. Exclusion criteria included prior intolerance to 125mg of PALBO and prior use of mTORi or EXE. The primary objective of the phase Ib was to evaluate the safety, tolerability, and to define the maximal tolerated dose (MTD)/recommended Phase II dose (RP2D) of the triplet. Secondary objectives included PK analyses and characterization of genomic alterations by circulating tumor DNA (ctDNA). **Results:** 9 pts were treated on the phase 1 portion of the trial. In the first dose level of PALBO (100mg), 1 out of 3 pts experienced a DLT (G3 neutropenia and G2 mucositis). None of the 3 pts subsequently enrolled had a DLT. PALBO dose was escalated 125mg, and all the 3pts had a DLT (all had G3 neutropenia). PALBO 100mg/d (21 of 28 days) was declared the MTD. Most common G3/4 treatment-related adverse events were neutropenia (77%), and thrombocytopenia (22%). Five pts developed G2 oral mucositis; prophylactic oral dexamethasone rinse was not mandatory. The RP2D was PALBO 100mg/d (21 of 28 days), EVE 5mg/d, and EXE 25mg/d. PK analysis and genomic alterations seen in ctDNA will be presented. **Conclusions:** The triplet combination of PALBO 100mg/d (21 of 28 days) + EVE 5mg/d + EXE 25mg/d is safe in pts with HR+/HER2- MBC. The phase II portion of this trial is ongoing. Clinical trial information: 02871791.

1069 Poster Session (Board #150), Sat, 8:00 AM-11:30 AM

EMBRACA: Efficacy outcomes in clinically relevant subgroups comparing talazoparib (TALA), an oral poly ADP ribose polymerase (PARP) inhibitor, to physician's choice of therapy (PCT) in patients with advanced breast cancer and a germline *BRCA* mutation. *First Author: Hope S. Rugo, UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

Background: TALA is a dual-mechanism PARP inhibitor that traps PARP on DNA, preventing DNA damage repair and causing cell death in *BRCA1/2*-mutated cells. **Methods:** EMBRACA (NCT01945775) is an open-label, randomized, 2-arm, phase 3 trial comparing the efficacy and safety of TALA (1 mg/day) with standard single-agent PCT (capecitabine, eribulin, gemcitabine, or vinorelbine) in pts with advanced breast cancer (aBC) and a germline *BRCA1/2* mutation (g*BRCA*^{mut}). PFS by blinded independent central review (BICR) and ORR by investigator were investigated in clinically important subgroups. **Results:** Of 431 pts randomized, 287 were assigned to receive TALA and 144 to PCT. PFS and ORR are shown (Table). **Conclusions:** In pts with advanced g*BRCA*^{mut} breast cancer, TALA demonstrated a statistically significant improvement in both ORR and PFS in clinically relevant subgroups compared with PCT, including pts with CNS metastases, poor performance status, younger age, and visceral disease. Clinical trial information: NCT01945775.

1070 Poster Session (Board #151), Sat, 8:00 AM-11:30 AM

Analysis of germline *BRCA1/2 m*utated (g*BRCA*^{mut}) hormone receptor-positive (HR+) and triple negative breast cancer (TNBC) treated with talazoparib (TALA). *First Author: Wolfgang Eiermann, Interdisziplinäres Onkologisches Zentrum München, München, Germany*

Background: TALA is a dual-mechanism PARP inhibitor that traps PARP on DNA in *BRCA1/2*-mutated cells, preventing DNA damage repair and causing cell death. **Methods:** EMBRACA (NCT01945775) is a randomized phase 3 trial comparing TALA (1 mg/day) with physician's choice of therapy (PCT) (capecitabine, eribulin, gemcitabine, vinorelbine) in patients (pts) with g*BRCA*^{mut} advanced breast cancer (aBC). Pts had HR+ BC or TNBC (HER2+ BC pts were excluded). An analysis was conducted to determine if TALA had different efficacy and safety based on receptor expression. **Results:** Of 431 pts randomized, 241 had HR+ BC and 190 had TNBC. TNBC pts had a lower median age compared to HR+ pts (43 vs 50 years); only HR+ pts included males (n = 7). More TNBC pts had received prior platinum therapy (26% vs 11% HR+); both groups had received a median of 1 prior cytotoxic regimen for aBC. Duration of TALA therapy was longer for pts with HR+ compared to TNBC (7.3 vs 5.4 months); 19% of both TNBC and HR+ pts received 12+ months of TALA. The hazard ratio for PFS was similar between the 2 groups, but the median estimates for TALA were different: 0.596 (0.406, 0.874) for TNBC pts, with mPFS of 5.8 months; 0.474 (0.318, 0.708) for HR+ pts, with mPFS of 9.4 months. ORR for TALA was similar for the 2 groups: 61.8% for TNBC vs 63.2% for HR+. Duration of response median for TALA was longer for HR+ (6.8 months) compared to TNBC (4.3 months); both groups included a subset with a prolonged response to TALA (28% HR+ and 17% TNBC had a continued response at 12 months; no PCT patient had a continued response at 12 months). The majority of both HR+ and TNBC TALA pts achieved a CBR24 (74.5% vs 61.5%). The primary toxicity for both groups was hematologic: for HR+ and TNBC, grade 3+ anemia (38.5% vs 40.0%), neutropenia (16.7% vs 26.2%), and thrombocytopenia (12.8% vs 16.9%). Drug-related grade 3+ nonhematologic toxicities were rare in both groups. Serious AEs were similar (30.8% HR+ vs 33.1% TNBC). Few pts experienced an AE that resulted in permanent discontinuation (5.8% HR+ vs 6.2% TNBC). **Conclusions:** Talazoparib demonstrated improved PFS and ORR in pts both with g*BRCA*^{mut} HR+ BC and TNBC. The safety profile in these 2 groups was similar. Clinical trial information: NCT01945775.

1071 Poster Session (Board #152), Sat, 8:00 AM-11:30 AM

Clinical evaluation of germline polymorphisms (SNPs) associated with disease response to capecitabine in metastatic breast cancer (MBC) (TBCRC 015). *First Author: Noura Choudhury, The University of Chicago, Chicago, IL*

Background: Capecitabine is an effective therapy for advanced breast cancer; however, response prediction is imprecise. In this study, we aimed to identify potential SNPs associated with response in MBC pts treated with capecitabine. **Methods:** Women with MBC about to receive single-agent capecitabine were enrolled and then dosed at 2000 mg/m^2/day for 14 d on/7 d off, until unacceptable toxicity or disease progression. Pts were assessed by RECIST criteria. Primary analysis was a genome-wide association study (GWAS) analysis conducted with best response during treatment (PD vs. PR/CR) and stratified for the presence of liver metastases (mets) and estrogen receptor (ER) status. Genotyping was performed on the Illumina Human OmniExpress chip. Analysis was restricted to Caucasian pts to remove confounding by population stratification. **Results:** 258 pts from 14 institutions were enrolled. Pt characteristics included median age 57 yrs (range 25-85), 47.4% with liver mets and 74% were ER+. 30 pts were excluded due to incomplete response data. Final analysis was conducted on 136 Caucasian pts. Response was as follows: 4 (1.9%) CR, 27 (13.1%) PR, 104 (50.4%) SD, 71 (34.4%) PD. While no SNPs reached genome-wide significance ($< 6.9 \times 10^{-8}$), top GWAS signals included a novel SNP upstream of *BP1FB2* (p = 0.0007, OR 27.6), an intronic variant SNP in *ADAMTS3* (p = 0.0007, OR = 51.6), and an intronic variant in *Wnt7a* (p = 0.0009, OR 28.4) as associated with response to capecitabine treatment. *Wnt7a* has been shown to promote tumor aggressiveness through fibroblast activation, and *ADAMTS3* is downregulated in breast cancer compared to normal mammary tissue. *BP1FB2* has not been previously implicated in breast cancer. **Conclusions:** We identified several promising markers of disease response in women with MBC treated with capecitabine. Although these SNPs did not achieve genome-wide significance and may be due to false discovery, further investigation is merited to discern whether *Wnt7A* and *ADAMTS3* are merely markers of aggressive MBC or have a more specific role in influencing capecitabine response. Clinical trial information: NCT00977119.

1072 Poster Session (Board #153), Sat, 8:00 AM-11:30 AM

Anti-tumor activity of PM1183 (lurbinectedin) in combination with capecitabine in metastatic breast cancer patients: Results from a phase I trial. *First Author: Ahmad Awada, Medical Oncology Clinic, Institut Jules Bordet, Université Libre de Bruxelles, Brussels, Belgium*

Background: PM1183 (lurbinectedin, Zepsyre) is a new anticancer drug that blocks transcription, induces DNA double-strand breaks, and modulates the tumor microenvironment. Single-agent PM1183 has antitumor activity in various solid tumors, including metastatic breast cancer (MBC), and pre-clinical synergism/additivity with fluoropyrimidines. A phase I trial determined the recommended dose (RD) for the oral fluoropyrimidine capecitabine (XEL) as 1650mg/m^2 BID Day (D) 1 to D14 plus PM1183 2.2 mg/m^2 D1, every 3 weeks. Here we present results of the MBC patients (pts) treated in this trial. **Methods:** MBC pts with adequate organ function and < 3 prior chemotherapy lines for advanced disease were treated with PM1183+XEL until disease progression, or unacceptable toxicity. Stable asymptomatic brain metastases were allowed. **Results:** A total of 28 female MBC pts were treated between April 2013 and September 2016; 15 at RD. At cut-off, 5 pts (3 at RD) were still on treatment. Baseline characteristics and efficacy data are shown in Table 1. At RD, hematological toxicities consisted of neutropenia [40% grade (G) 3; 7% G4] and anemia (13% G3). No febrile neutropenia was observed. Non-hematological toxicities were generally mild to moderate, including nausea, fatigue, palmar-plantar erythrodysesthesia syndrome, diarrhea, and decreased appetite. All AEs were reversible and manageable with dose reductions, omissions and/or delays. Main dose-limiting toxicities (DLTs) at maximum tolerated dose were hematological. **Conclusions:** The PM1183+XEL combination showed encouraging clinical activity in MB. Further development is warranted in this indication. Clinical trial information: NCT02210364.

Baseline characteristics and efficacy of PM1183+XEL.

	All dose levels (*n*= 28)	RD (*n*= 15)

1073 Poster Session (Board #154), Sat, 8:00 AM-11:30 AM

Concordance of genomic alterations (GA) in synchronous tumor biopsies (tBx) and circulating tumor (ct) DNA from metastatic breast cancer (MBC) patients (pts). *First Author: Mafalda Oliveira, Medical Oncology Department, Breast Cancer Group, Vall d'Hebron University Hospital, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain*

Background: Next generation sequencing (NGS) of tBx is the basis for precision medicine. Most tBx used for NGS are archival primary tumors, often acquired several years before starting matched treatment. Analysis of ctDNA may better capture the GA landscape of MBC. We aimed to compare the concordance of GA detection by NGS in synchronously acquired tBx and ctDNA in MBC pts. **Methods:** MiSeq Amplicon-based NGS (panel of 59 cancer-related genes) was performed in both tBx and ctDNA at disease progression. The concordance of GA in tBx vs ctDNA was determined at patient level and at mutation (mut) level in clinically actionable genes (*PIK3CA, AKT1, ERBB2, ESR1, PTEN).* False negative result in ctDNA (FN-ctDNA) defined as mut detected in tBx but not in ctDNA. **Results:** 28 pts identified (luminal [lum] 21, HER2+ 5, triple negative 2), median prior lines of therapy 4.5 (0-15). Most pts had visceral metastasis (71%); most biopsies were from non-visceral sites (67%), mainly breast/nodes/skin (59%). In 16 pts (57%), tBx and ctDNA had complete concordant results (4 were wild-type). Concordance was 100% in non-lum and 43% in lum pts (P=0.01). Clinically actionable GA were found in 20/28 (71%) pts. FN-ctDNA rate was 25%; these pts had a trend towards having non-visceral metastasis (OR 3.1, P=0.32). Focusing in clinically actionable genes, concordance was 52% at mut level, being lower for *ESR1* mut (Table). Interestingly, ctDNA analysis identified 6 *ESR1* mut that were not detected in tissue, including 3 pts with a double *ESR1* mut. **Conclusions:** NGS in ctDNA is feasible and the results may be informative for pts management. Our results suggest that ctDNA may be useful for assessing GA in non-lum MBC and the emergence of *ESR1* mut in lum MBC. Double *ESR1* mut in ctDNA suggests a mechanism of convergent evolution in acquired resistance to endocrine treatment. Causes of discordant tBx/ctDNA (e.g. tumor burden / heterogeneity, technical issues related to ctDNA isolation / processing), warrant further study in larger datasets.

	N mut detected			Concordant mut
	tBx	ctDNA	Overall	N (%)
ERBB2	1	1	1	1 (100)
PIK3CA	9	7	9	7 (78)

1074 Poster Session (Board #155), Sat, 8:00 AM-11:30 AM

Efficacy of olaparib monotherapy in patients (pts) with HER2-negative metastatic breast cancer (MBC) with germline *BRCA* mutation (g*BRCAm*) or lesional *BRCA* mutation (l*BRCAm*). *First Author: Eleanor Meisner, University of Illinois at Rockford, Rockford, IL*

Background: A recent Phase III study in MBC with g*BRCA*m, olaparib monotherapy provided a statistical significant and clinically meaningful PFS benefit compared to standard physician of choice treatment. (Robson M, NEJM 2017) Recently, olaparib was FDA approved for MBC with g*BRCAm*. **Methods:** IRB-approved analysis of pts underwent to genomic or genetic analysis. Retrospective review charts for pts with MBC who had received ≥2 chemotherapy lines for MBC were tested with genomic or genetic studies. The objective of this analysis was to determine the PFS2/PFS1 ratio. [von Hoff DD, 2014]. l*BRCAm* were detected in 12 out 19 pts [8 Foundation One, 3 Foundation Act and 1 Guardant 360] where somatic versus germline nature was not determined and g*BRCAm* 7 out 19 pts. **Results:** From 03/2014 to 08/2017, 319 pts with advanced cancer were treated with targeted therapy based on molecular abnormality. Overall 19 out 319 (6%) consisted on olaparib for MBC with g*BRCAm* or l*BRCAm*. Median age 45.1 years (range, 31-67), 18 out 19 pts were female, 14/19 were Caucasians, median number of previous lines of treatment for MBC was 4 (range, 2-8). Olaparib was dosed at 300 mg po bid until disease progression. A total of 12 out 19 pts (63%) the PFS ratio was ≥ 1.3, with a Wilson score 95% CI of (0.7, 3.). Nine out 12 pts (75%) with l*BRCAm* had increased PFS ratio. The 6-month PFS was 69.4% [95% CI: (40%, 86.4%)], and the 6-month OS was 88.8% [95% CI: (62.1%, 97.1%)] There was no Grade 3-4 toxicity. **Conclusions:** Olaparib monotherapy provided a statistically significant increment of PFS in almost 2/3 (63%) of heavily pretreated MBC pts harboring g*BRCAm* and l*BRCAm*. Interestingly, 75% of patients with l*BRCAm* resulted in improvement the PFS with minimal toxicity. Further research is necessary to extend the olaparib approval for l*BRCAm* in MBC pts.

1075 Poster Session (Board #156), Sat, 8:00 AM-11:30 AM

Differences of TILs, hormone receptor, and HER2 status between primary and metastatic tumors. *First Author: Makiko Ono, Department of Medical Oncology, The Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo, Japan*

Background: Tumor-infiltrating lymphocytes (TILs) are reported to be associated with response to chemotherapy in early breast cancer. However, it is uncertain whether immunological microenvironment alters when tumors recur. The purpose of this study is to compare TILs and HR and HER2 status between paired primary and recurrent tumors. **Methods:** The patients were eligible if they had primary surgery at our institute and their breast cancer recurred, and specimens of recurrent disease were available. High TILs were defined as ≥10%. **Results:** Among 173 recurrent tumors, specimens were metastatic lesion to liver, lung, bone, skin or soft tissue, lymph nodes, and others in 19%, 27%, 16%, 15%, 14%, and 8%, respectively. In primary tumors, 89% were HR positive and 11% were HER2 positive. ER, PgR and HER2 status changed from positive in primary tumors to negative in recurrent tumors in 8%, 40%, and 6%, and changed from negative to positive in 15%, 15%, and 7%, respectively. Accordingly, breast cancer subtype change between primary and recurrent tumors was seen in 13%. High TILs in primary tumors were seen in 22% of patients and significantly associated with breast cancer subtype; HR+HER2-, HR+HER2+, HR-HER+, and HR-HER- in 16%, 36%, 67%, and 62%, respectively ($p < 0.001$). On the other hand, high TILs in recurrent tumors were not correlated with breast cancer subtype, but the site of metastasis; high TILs in 6%, 39%, 12%, 8% and 19% of liver, lung, bone, skin or soft tissue, and lymph node metastases, respectively ($p = 0.002$). In 71% of recurrent tumors, TILs did not change or decreased compared with primary tumors, whereas in 29% TILs increased in recurrent tumors. Among recurrent tumors with increased TILs, most frequent metastatic lesions were lung (40%), and bone metastases were less likely to have tumors with increased TILs (7%). High TILs in recurrent tumors were a positive prognostic marker after recurrence, whereas those in primary tumors were not. **Conclusions:** TILs as well as hormone and HER2 status altered between primary and metastatic tumors. Immunological tumor microenvironment may depend on the site of recurrence and evaluation of recurrent tumors is required in the immunotherapy era.

1076 Poster Session (Board #157), Sat, 8:00 AM-11:30 AM

Poly(ADP-Ribose) Polymerase Inhibitors (PARPi) for patients (pts) with locally advanced or metastatic breast cancer (BC): A meta-analysis. *First Author: Martin Tio, Royal North Shore Hospital, St Leonards, Australia*

Background: We performed a quantitative meta-analysis of randomized clinical trials of PARPi in pts with BC. **Methods:** 2 registries (ClinicalTrials.gov, WHO ICTRP) and 4 electronic databases (CBCG SR, CENTRAL, Medline, EMBASE) were searched from 2008 to 1/2018 for randomized clinical trials (RCTs) of PARPi therapy vs. control in BC. RCTs that reported overall survival (OS) or progression-free survival (PFS) were included. Pooled hazard ratios (HR) and 95% confidence intervals (95% CI) were calculated using a fixed effects model. **Results:** We identified 418 citations, of which 2 RCTs with a pooled sample size of n = 733 were included. There was a low/moderate risk of bias in both RCTs (Table). Both RCTs compared a PARPi to physician's choice of chemotherapy in pts with germline BRCA mutated HER2-negative BC in first or later line setting, with PFS as the primary outcome. The pooled analysis of PFS showed a statistically significant improvement with PARPi therapy, with an HR 0.56 (95% CI 0.45-0.68). The pooled analysis of OS did not show a statistically significant improvement, with an HR of 0.82 (95% CI 0.64-1.05). There was an acceptable safety profile with PARP therapy in both RCTs, with a grade $\geq$ 3 adverse event rate of 25.5% and 36.6% in the 2 RCTs respectively. **Conclusions:** The use of PARPi in pts with germline BRCA mutated HER2-negative BC offers a PFS benefit compared to physician's choice of chemotherapy in the first or later line setting, with an acceptable adverse events rate. Lack of OS benefit may be explained by availability of further lines of therapy, relative immaturity of the trials and not being powered to assess OS. This systematic review is part of a planned Cochrane Breast Cancer Group protocol.

1077 Poster Session (Board #158), Sat, 8:00 AM-11:30 AM

Multi-omic profiling of metastatic lesions to guide treatment selection: The Side Out 2 trial experience. *First Author: Mariaelena Pierobon, George Mason University, Manassas, VA*

Background: The aim of this prospective pilot study, the Side Out 2 trial (NCT01919749), was to explore if treatment selection based on Multi-omic Profiling (MoP) provides clinical benefits superior to empiric treatment selection in progressive metastatic breast cancers (MBC). **Methods:** Fresh core biopsies were collected from the metastatic lesions of 32 MBC patients. Samples underwent genomic and proteomic profiling, including: exome sequencing, RNA-Seq, IHC, and quantitative phosphoprotein-based protein pathway activation mapping by Reverse Phase Protein Microarray (RPPA). Whole tissue lysates were used for the exome sequencing, RNA-Seq and IHC; the RPPA data were obtained from microdissected tumor epithelia. A sample size of 25 evaluable patients was determined a priori according to the exact single-stage design for phase II studies, using a type I error rate of 5% (one-sided) and a power of 90%. Clinical benefit was defined as Growth Modulation Index (GMI) $\geq$ 1.3 assuming that MoP selected therapy would warrant further investigation if $\geq$ 35% of the patients demonstrate a PFS ratio of $\geq$ 1.3. GMI was calculated as a ratio between PFS on MoP selected therapy versus PFS on prior therapy (PMID:25209003). **Results:** Between 2014 and 2016, four US sites enrolled 32 previously treated MBC patients. Of the 32 patients enrolled, 29 received treatment based on their MoP and 25 met the follow-up criteria established by the trial protocol. Of the 25 patients, 14 (56%) met or exceeded a GMI of 1.3. The most frequently selected treatments were irinotecan based on TOPO1 expression (n = 12; single agent n = 6) and capecitabine based on TS expression (n = 9; single agent n = 3). Of the 7 patients that received endocrine therapy, 3 were treated with exemestane+ everolimus. Based on HER2 amplification/pathway activation, HER2 targeted agents were given to 4 patients. **Conclusions:** This study confirmed the unique role of MoP to select effective treatments for MBC. This approach provided clinical benefit for 56% previously treated MBC patients, which met the primary objective of the study. Thus, this approach merits further investigation. This study also suggests that irinotecan may be an under-developed drug for MBC patients. Clinical trial information: NCT01919749.

1078 Poster Session (Board #159), Sat, 8:00 AM-11:30 AM

Efficacy of mirtazapine in preventing delayed nausea and vomiting induced by highly emetogenic chemotherapy: An open-label, randomized, multicenter phase III trial. *First Author: Jun Cao, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: We examined the efficacy of mirtazapine for the prevention of delayed nausea and vomiting in patients who received highly emetogenic chemotherapy (HEC). **Methods:** Patients with breast cancer who experienced delayed emesis after receiving AC or cisplatin containing regimens, and would subsequently accept at least 3 cycles of the same chemotherapy were randomly assigned to a mirtazapine group (15 mg daily on days 2 to 4) or control group, both with aprepitant, a 5-HT3 receptor antagonist and dexamethasone (7.5 mg on day 2 to 4). Primary end point was complete response (CR) to vomiting (no emesis and no rescue treatments) in the delayed phase (25 to 120 h). Secondary end points included CR during acute (0 to 24 h) and overall (0 to 120 h) periods, complete control (CC) (no emesis, no rescue medication use, and no more than grade 1 nausea) during the 3 periods above. **Results:** The study was closed early in January, 2018 due to the slow enrollment. Of 95 patients, 46 in the mirtazapine group and 49 in the control group. Compared with control group in the 1st cycle, delayed and overall CR rates were significantly higher with mirtazapine: 78.3% versus 49.0% (P = 0.003) and 58.7% versus 34.7% (P = 0.019), respectively. Similar result was observed in the 3rd cycle, which showed that delayed CR rates was significantly higher with mirtazapine: 88.2% versus 55.0%, respectively (P = 0.010). Delayed and overall CC rates were significantly higher with mirtazapine both in the 1st and 2nd cycles: 76.1% versus 49.0% (P = 0.006) and 56.5% versus 32.7% (P = 0.019), respectively in the 1st cycle and 70.0% versus 45.7% (P = 0.049) and 50.0% versus 25.7% (P = 0.043), respectively in the 2nd cycle. In the 3rd cycle, delayed CC rates was significantly higher with mirtazapine: 88.2% versus 50.0% (P = 0.010). Adverse effects were mild to moderate. The mirtazapine group had increased somnolence and weight gain. **Conclusions:** Mirtazapine with aprepitant, a 5-HT3 receptor antagonist and dexamethasone significantly improved HEC-induced delayed nausea and vomiting prevention in patients with breast cancer who experienced delayed emesis in the same chemotherapy previously. Clinical trial information: NCT02336750.

1079 Poster Session (Board #160), Sat, 8:00 AM-11:30 AM

Breast cancer stem cell autoantibodies to identify women with advanced breast cancer. *First Author: Sasha E. Stanton, University of Washington, Seattle, WA*

Background: Cancer stem cells have properties of self-renewal, inducing drug resistance, and metastases. Breast cancer stem cells (BCSC) are associated with epithelial to mesenchymal transformation (EMT), increased invasiveness, and metastases. We identified a panel of BCSC proteins involved in EMT that predicted aggressive disease and could be targets for breast cancer vaccines. A therapeutic vaccine of five of the BCSC antigens is currently in a phase 1 clinical trial (NCT02157051) in breast cancer patients. We now demonstrate that autoantibodies of eight BCSC proteins (CDC25b, YB1, CD105, SOX2, CDH3, HIF1alpha, Survivin, and MDM2) identify women with increasing disease in breast cancer and may be a marker of progression of disease. **Methods:** Autoantibodies were evaluated by ELISA from sera of 253 individuals, 100 individuals with no breast atypia, 124 individuals with stage I and II invasive breast cancer (IBC), and 29 individuals with stage III and IV IBC. A positive autoantibody response was greater than 2 standard deviations above the mean of individuals with no IBC (control). **Results:** The percentage of individuals with a positive autoantibody response increased between control and stage I/II IBC and/or stage III/IV in 6 of the 8 autoantibodies. For example with CDC25b, there was 2% positive autoantibody response in control individuals, 13.7% in individuals with stage I/II IBC (p = 0.0014), and 17.2% of individuals with stage III/IV breast cancer (p = 0.0064). There were no differences in mean autoantibodies between breast cancer subtypes except increased autoantibodies to HIF1 alpha in ER+ HER2- disease as compared to HER2+ disease (p = 0.01). The panel of 8 autoantibodies predicted patients with stage I/II IBC from control individuals with AUC of 0.66 (95% CI 0.589 to 0.732, $p < 0.0001$). The panel could predict patients with III/IV IBC from control individuals with AUC of 0.84 (95% CI 0.0.753 to 0.931, $p < 0.0001$). **Conclusions:** These data demonstrate an increasing humoral immune response against 8 BCSC proteins at higher stages of breast cancer and suggests that these autoantibodies indicate more aggressive disease. Future studies will prospectively evaluate the antibody panel as a biomarker for breast cancer progression.

1080 Poster Session (Board #161), Sat, 8:00 AM-11:30 AM

Detection, dynamic monitoring, and resistance mechanism exploration of genomic alterations in circulating cell free tumor DNA (ctDNA) in Chinese metastatic breast cancer (mBC). *First Author: Huiping Li, Peking University Cancer Hospital and Institute, Beijing, China*

Background: Circulating DNA fragments (ctDNA) are using to longitudinal non-invasive molecular monitoring and resistance mechanism interrogation of the disease by detecting genomic alteration change and clonal evolution including somatic mutation and copy number alteration. **Methods:** We performed a retrospective analysis of blood samples from mBC patients (pts) collected at pre-treatment, on-treatment, and disease progression. A highly sensitive, plasma-derived ctDNA-based NGS assay was conducted to detect somatic mutations and copy number variations using pre-specified algorithms. Descriptive statistics and hypothesis tests were performed in R. **Results:** Total 350 blood samples were collected from 160 mBC pts who undertook therapy at Beijing cancer hospital after approved by Research Ethics Committee. Among these pts, the percent of HR+, HER2+ and triple-negative pts is 45%, 27% and 28% respectively. FFPE tissue slides at initial diagnosis were also available for a subset of pts. The most frequent mutations detected are TP53 (40%), PIK3CA (30%), and CDKN2A (12.5%). 24% showed mutations in DNA damage repair such as BRCA1, BRCA2 and ATM. HER2 copy number amplifications was detected amplification events in all IHC-based HER2 positive cases, resulted in 100% specificity and overall 91% accuracy in predicting HER2 amplification status for pre-treatment baseline samples, only a few on-treatment/disease progression samples detected HER2 amplifications. The result is further confirmed and validated by ddPCR assay. The study also identified additional genomic alterations that change dynamically along with the course of treatment or associate with drug response and/or resistance. **Conclusions:** This study showed ctDNA-based genomic analysis was highly sensitive, and consistent with sequencing data generated from matched tissues. it provides comprehensive mutation information of individual pts, enables molecular monitoring of disease and targeted therapy, suggesting that HER2 copy number variations could serve as a value tool for monitoring of treatment effect and disease progression.

1081 Poster Session (Board #162), Sat, 8:00 AM-11:30 AM

Racial disparity in breast cancer immune microenvironment. *First Author: Ahmed Elkhanany, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: Racial disparity in breast cancer (BC) goes beyond access to care. Biology of HER2- and Triple Negative (TNBC) tumors has been shown to differ between African Americans (AF) and Caucasians (CF), contributing to survival difference. Additionally, tumor infiltrating lymphocytes (TILs) incurred favorable response to neoadjuvant therapy in ER- and TNBC. We hypothesized that TIL composition of immune microenvironment (IME) differs between AF and CF, potentially explaining such biologic disparity. **Methods:** Using The Cancer Genome Atlas (TCGA), we applied recently described gene expression deconvolutional algorithm CIBERSORT, estimating 22 IME cell proportions. Clinical and PAM50 data were accessed from XENA. Cytolytic activity appended from Rooney et al. **Results:** 183 AF Pts had worse disease-free survival (5-year DFS 21% vs. 26%, HR 1.67[1.02-2.73]) and cumulative incidence of disease (sHR 1.75 [1.09-2.81]) compared with 752 CF Pts, adjusted for age and stage. DFS gap was most prominent in Basal subtype (HR 3[1.03-9.1]). Certain TILs impacted DFS and OS. Higher CD8 T cell fractions improved DFS and OS (HR 0.75[0.59-0.9] and 0.8[0.65-0.95]). Higher activated NK and γδT cell fractions predicted better DFS (HR 0.64 and 0.06). M2 macrophages incurred poor DFS (HR 11.6[1.07-126]). On adjusting for race, activated NK, γδT and M2 macrophage retained respective outcome, but not CD8 T cells. Regulatory T cells (Tregs) did not impact DFS or OS. Comparing AF to CF IME, CD8 T cells were higher in ER+ Pts only. Tregs were higher in whole cohort, Basal and TNBC subtypes. T follicular helper cells were higher in TNBC/Basal, and activated dendritic cells were higher in ER +/Luminal subtypes. Higher memory B, Plasma cells and Macrophages were seen in all subtypes except Basal ($p < 0.01$). Cytolytic activity was similar between AF and CF. It correlated with γδT cells (r^2 0.41, 0.49 in AF) and memory CD4 cells (r^2 0.4, 0.3 in AF), but not DFS or OS. **Conclusions:** IME in BC significantly differs by race, with AF having more Tregs in Basal/TNBC, and more CD8 T cells only in Luminal subtypes. This IME in Basal subtype (and TNBC phenotype) can explain independent worse outcome for this cohort. Incomplete deconvolution of heterogenous Tregs might explain lack of outcome correlation.

1082 Poster Session (Board #163), Sat, 8:00 AM-11:30 AM

Overall survival following locoregional surgery of the primary tumor in de novo stage IV breast cancer patients. *First Author: Herui Yao, Guangdong Provincial Key Laboratory of Malignant Tumor Epigenetics and Gene Regulation, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China*

Background: Current guidelines lack definitive evidences about the relative benefits of locoregional surgery for the primary tumor in de novo stage IV breast cancer. The aim of this study was to comprehensively investigate the role of locoregional surgery for primary tumor in de novo stage IV breast cancer. **Methods:** We conducted a Chinese multicenter real-world study of patient-level data to investigate the effect of locoregional surgery versus no surgery of the primary tumor in de novo stage IV breast cancer. We used propensity score matching to compare similar patients who underwent locoregional surgery and no surgery. Overall survival (OS) was estimated using the Kaplan-Meier method and the log-rank test. A meta-analysis also was performed of prospective and retrospective studies, respectively. **Results:** Among 353 patients, 189 (53.6%) received locoregional surgery and 164 (46.4%) underwent no surgery. We matched 202 patients treated with locoregional surgery with similar patients who received no surgery. The median follow-up time was 22.1 (95%CI, 18.8 to 25.9) months, 5-year overall survival was 62.4% in the locoregional surgery group versus 60.3% in the no surgery group, and there was no significant difference in OS (Hazard ratio [HR] 0.88, 95%CI 0.49 to 1.57, $P = 0.66$). In stratified analysis, the association between locoregional surgery and improved survival was particularly marked in patients with Ki67 $\geq$ 20% (HR 0.47, 95%CI 0.22 to 0.97). In addition, pooled results from 42 retrospective studies with 130,153 individuals indicated that locoregional surgery resulted into a significantly prolonged OS (HR 0.65, 95% CI 0.61 to 0.69) compared with no surgery. In contrast, we analyzed the meta-analysis from five prospective trials with 857 participants, finding that there was no significant difference in OS (HR 0.84, 95% CI 0.61 to 1.15) between two groups. **Conclusions:** Based on the evidences of our real-world study, prospective and retrospective meta-analysis, we concluded that locoregional surgery of the primary tumor have no significant survival benefit in de novo stage IV breast cancer. Patients with Ki67 $\geq$ 20% improved survival while receiving locoregional surgery.

1083 Poster Session (Board #164), Sat, 8:00 AM-11:30 AM

Predictors of survival after loco-regional therapy (LRT) in stage 4 breast cancer (BC). *First Author: Anuhya Kommalapati, University of South Carolina, Columbia, SC*

Background: Recent randomized trials evaluating the role of surgery in de novo stage 4 BC yielded mixed results indicating that patient/tumor characteristics might influence the survival. We analyzed the predictors of survival after LRT in stage 4 BC by using National Cancer Data Base (NCDB). **Methods:** Retrospective analysis of histologically confirmed infiltrative ductal (IDC), lobular (LC) and metaplastic stage 4 BC patients from 2004-2015 using NCDB. The study cohort was divided into 2 subsets based on the therapy received: no LRT and LRT (surgery ± radiation). The LRT subset was randomized into training and validation cohorts. In the training cohort, Cox proportional method was used to calculate HRs based on which a 17 point survival prediction scoring system was developed (Table). Both the cohorts were stratified into 3 groups based on the scores- group (G)1 (0-3), G2 (4-7) and G3 (8-17). Kaplan Meier (KM) method and log-rank test were used to compare survival among the 3 groups. We validated the prognostic score by comparing the OS between the respective groups in each cohort. **Results:** A total of 67,978 patients met the inclusion criteria (median age 61 y). The patients in LRT subset (21,120) had significantly better survival (median: 45 vs 24 m) ($p < .0001$). The 3 groups in training cohort showed significant difference in the OS ($p < 0.0001$) – G1 having better prognosis. The 3-year OS rates of the groups were 84% (G1), 66% (G2), and 38% (G3). On validation, comparable OS was seen between the respective groups in each cohort ($p = 0.77$). **Conclusions:** LRT was associated with improved OS in de novo stage 4 BC. Based on the patient/tumor characteristics, we developed a prediction model to characterize the prognostication in patients undergoing LRT for stage 4 BC.

1084 Poster Session (Board #165), Sat, 8:00 AM-11:30 AM

Analysis of circulating tumor cells (CTCs) in patients across multiple metastatic breast cancer (mBCa) cohorts identifies marked inter- and intra-patient heterogeneity in CTC size, shape, and overall morphology. *First Author: Gordon Vansant, Epic Sciences, Inc., San Diego, CA*

Background: The choice between hormonal therapies and chemotherapy is a frequent decision in the care of mBCa pts. We previously developed quantitative measures of phenotypic CTC heterogeneity in mCRPC, and found higher heterogeneity was associated with better survival on chemotherapy vs. targeted hormonal therapies, and the reverse was true in low heterogeneity patients (Scher et al. 2017 Cancer Research). We sought to apply our previous heterogeneity quantitation methodologies to a cohort of mBCa patient CTCs to ascertain feasibility in mBCa. **Methods:** 295 blood samples from mBCa patients were processed for CTC analysis utilizing the Epic Sciences platform. Following enumeration, multi-dimensional phenotypic characterization analysis was performed utilizing protein expression and digital pathology features. Features from each CTC (3994 CTCs from 165 pts, 84 HR+, 19 Her2+, 8 HR+/Her2+, 54 TNBC) were compared by unsupervised clustering, Shannon Index and intra-patient variance analyses to assess the intra-patient heterogeneity among mBCa CTC phenotypes. **Results:** CTCs were detected in 76.9% (227/295) of mBCa patients (med = 2.4 CTC/mL, Range 0 - 747). Distinct CTC phenotypes were identified and associated with mBCa subtypes. Subset of CTCs from TNBC pts had larger nuclear area and higher CK expression vs. other subtypes. In addition, we observed marked differences in heterogeneity in CTCs across patients, with some patients having relative uniform CTC profiles, and others with high phenotypic diversity. mBCa subtypes had similar intra-patient heterogeneity level. **Conclusions:** Distinct CTC phenotypes can be visualized reproducibly across patients and associated with specific mBCa subtypes. Our analysis revealed significant heterogeneity between individual CTCs both between and within patients. Identification of patients with high heterogeneity may help to find patients unlikely to respond to targeted therapies. Studies to link heterogeneity to therapeutic efficacy and pt outcome are ongoing.

1085 Poster Session (Board #166), Sat, 8:00 AM-11:30 AM

Polymorphisms of MTHFR and TYMS to predict capecitabine-induced hand-foot syndrome in patients with metastatic breast cancer. *First Author: Shaoyan Lin, Department of Medical Oncology, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing 100021, P.R.CHINA, Beijing, China*

Background: Breast cancer is a global problem, and 1.7 million new cases are diagnosed per year. Capecitabine, an oral prodrug of fluorouracil, has been reported to be effective in patients with metastatic breast cancer (MBC) and approved by the Unites States Food and Drug Administration for treatment of MBC. Hand-foot syndrome (HFS) is one of the most relevant dose-limiting adverse effects of capecitabine. If HFS is not handled well, it can deteriorate rapidly and lead to the treatment interruptions which may influence on the treatment efficacy. **Methods:** In our study, we investigated the association between single nucleotide polymorphism (SNP) and capecitabine-based HFS in patients with MBC in Chinese Han population, in an attempt to identify some predictive genetic biomarkers. We selected 3 genes involved in capecitabine metabolism and screened genetic variants in the target genes. We genotyped a total of 22 SNPs in the thymidylate synthase gene (*TYMS*), the methylene tetrahydrofolate reductase gene (*MTHFR*) and the ribonucleotide reductase M1 gene (*RRM1*) in 342 patients treated with capecitabine-based chemotherapy. **Results:** Logistic regression analyses showed that genotype AG of rs3737964 [odds ratio (OR) = 0.54,95% confidence interval (CI) = 0.31-0.97, P = 0.038] and genotype AG of rs4846048 (OR = 0.54,95%CI = 0.30-0.98,P = 0.042) in *MTHFR* were protective factors for HFS. That was to say, patients with these two kinds of genotypes in the Chinese Han population might have 0.54-fold lower risk of suffering from HFS. Genotype GT of rs2606241 (OR = 1.27,95%CI = 0.73-2.23,P = 0.012) and genotype CT of rs2853741 (OR = 2.25,95%CI = 1.31-3.87,P = 0.012) in *TYMS* increased the incidence of HFS. Patients with genotype GT of rs2606241 and genotype CT of rs2853741 were found to have 1.27-fold and 2.25-fold higher risk of suffering from HFS. **Conclusions:** In summary, we have identified a panel of clinically useful pharmacogenetic markers predicting capecitabine-induced HFS in MBC patients.

1086 Poster Session (Board #167), Sat, 8:00 AM-11:30 AM

Role of circulating miRNAs in detecting metastasis and having prognostic significance in metastatic breast cancer. *First Author: Sofia Agelaki, Department of Medical Oncology, University General Hospital of Heraklion, Heraklion, Greece*

Background: Metastasis is the leading cause of breast cancer associated death. In the current study we evaluated the expression of (a) micro-RNA (miR)-23b and miR-190 which are involved in tumor dormancy (b) miR-21 which is involved in metastasis and (c) miR-200b and miR-200c which are involved in EMT and metastasis, in the plasma of patients with early and metastatic breast cancer (BC) in order to investigate whether they could distinguish the two disease states. Furthermore the prognostic significance of the above miRNAs was investigated in patients with metastatic disease. **Methods:** Plasma samples were obtained from patients with early (n = 84) or metastatic (n = 57) BC before adjuvant or 1st-line treatment, respectively. Plasma miR-21, miR-23b, miR-190, miR-200b and miR-200c expression levels were assessed by RT-qPCR and expression was classified as high or low according to the median values. **Results:** miR-21 ($p < 0.001$), mir-23b ($p = 0.012$), miR-200b ($p < 0.001$) and miR-200c ($p = 0.001$) were higher and miR-190 ($p = 0.013$) was lower in metastatic compared to early BC patients. ROC analysis showed that miR-21 (AUC = 0.772; $p < 0.001$), miR-23b (AUC = 0.625; $p = 0.012$), miR-190 (AUC = 0.629; $p = 0.013$), miR-200b (AUC = 0.744; $p < 0.001$) and miR-200c (AUC = 0.668; $p = 0.001$) could distinguish between patients with metastatic and early BC. However, logistic regression and combined ROC analysis revealed that a panel of four miRs (miR-21, miR-190, miR-200b and miR-200c) discriminated with higher accuracy (AUC = 0.857; $p < 0.001$) between the two disease states. In patients with metastatic disease, miR-21 high was correlated with premenopausal ($p = 0.013$) and HER2 status ($p = 0.017$). The combined expression of miR-23b high and miR-190 high was correlated with progressive disease at the end of treatment ($p = 0.034$). Patients with miR-23b high had shorter PFS and OS ($p = 0.024$ and $p = 0.031$, respectively). **Conclusions:** Circulating micro-RNAs discriminate between patients with metastatic and early breast cancer. In addition, their expression holds predictive information in patients undergoing first-line chemotherapy.

1087 Poster Session (Board #168), Sat, 8:00 AM-11:30 AM

Androgen receptor expression in circulating tumor cells of metastatic breast cancer patients. *First Author: Ingeborg Elisabeth de Kruijff, Department of Medical Oncology, Erasmus MC Cancer Institute, Erasmus University Medical Center, Rotterdam, Netherlands*

Background: The androgen receptor (AR) is of clinical relevance in metastatic breast cancer (mBC): AR has been associated with resistance to endocrine therapy and could be a potential target for therapy, especially in the triple negative (TN) subtype. A minimal-invasive way to determine AR expression is by characterization of circulating tumor cells (CTCs). We therefore assessed *AR* mRNA expression in CTCs (CTC-*AR*) from mBC patients representing different breast cancer subtypes in relation to outcome on endocrine therapy and 25 genes related to the ER and AR pathways. Furthermore, we assessed *AR* in matched primary tumors and CTC samples taken at advanced disease. **Methods:** *AR* and AR- and ER-related gene expression levels were measured in CellSearch-enriched CTCs from 133 mBC patients with ≥5 CTCs and in 48 matched formalin-fixed paraffin embedded primary tissues using quantitative reverse-transcriptase PCR. *AR* was considered positive if the expression was 1 standard deviation higher than the expression measured in 12 healthy blood donors. mBC subtypes were established based on ER, PR and HER2-status of the primary tumor (9 unknowns). **Results:** 31% of the CTC samples were *AR*-positive (*AR*+). The HER2+ subtype had most frequently *AR*+ CTCs (4/8, 50%), which was significantly higher than observed in the TN subtype (2/16, 13%) ($p = 0.046$). The ER+/HER2- subtype had 35% (27/78) *AR*+ samples and the ER+/HER2+ 23% (5/22). There was no significant difference between PFS in ER-targeting treated patients and CTC-*AR*-status (17 *AR*+ / 41 *AR*-negative (AR-) cases, $p = 0.991$). 65% of the matched CTC samples and primary tissues were discordant with respect to *AR*, observing both switches from *AR*+ to *AR*- and vice versa. **Conclusions:** *AR* can be determined in RNA isolated from CTCs from different mBC subtypes, with in our set 31% *AR*-positive samples. Because there was a 65% discordancy between *AR* in CTC samples and the primary tumor, it seems that AR should be determined in CTCs, but more research should be conducted in a larger set. In our current analysis patients had similar outcome on ER-targeting therapy regardless of their CTC-*AR* status. Thus, determination of AR expression in CTCs might be a promising tool to select mBC patients for AR inhibiting agents.

1088 Poster Session (Board #169), Sat, 8:00 AM-11:30 AM

Benefits and risks from maintenance therapy after first-line chemotherapy in patients with metastatic breast cancer. *First Author: Yunfang Yu, Guangdong Provincial Key Laboratory of Malignant Tumor Epigenetics and Gene Regulation, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China*

Background: Current guidelines lack definitive evidence regarding the clinical outcomes associated with different maintenance strategies for metastatic breast cancer (MBC). We aimed to investigate the benefits and risks of different maintenance therapy after first-line treatment of MBC. **Methods:** We searched for randomized clinical trials (RCTs) investigating maintenance chemotherapy, endocrine therapy or immunotherapy after first-line chemotherapy in MBC. The primary endpoint was progression-free survival (PFS); overall survival (OS) and adverse events (AEs) were secondary endpoints. Direct and indirect evidence for data were combined using random-effects meta-analysis. The GRADE system was used to assess the quality of evidence. The PROSPERO registry number is CRD42017071858. **Results:** A total of 3,290 patients from 16 RCTs were included. Maintenance chemotherapy resulted into a significantly prolonged PFS (hazard ratio [HR] 0.63, 95% confidence interval 0.54 to 0.73, $P = 0.000$; high certainty) and OS (HR 0.87, 95% CI 0.78 to 0.97, $P = 0.016$; high certainty) compared with observation, although higher odds of G1-G2 AEs (moderate certainty). Among patients who developed an immune response, maintenance immunotherapy combined with chemotherapy extended PFS (HR 0.57, 95% CI 0.33 to 0.97, $P = 0.04$; low certainty) and OS (HR 0.71, 95% CI 0.52 to 0.97, $P = 0.029$; low certainty) than chemotherapy alone. Hormone-receptor-positive patients who received maintenance endocrine therapy might provide similar PFS (HR 1.0, 95% CI 0.70 to 1.50, $P = 0.998$; very low certainty) and OS (HR 1.15, 95% CI 0.59 to 2.22, $P = 0.679$; very low certainty) versus chemotherapy, but with lower odds of G1-G2 AEs (moderate certainty). **Conclusions:** Our study provided strong evidence for OS and PFS benefits of maintenance chemotherapy over observation after first-line chemotherapy in MBC patients. Limited prospective trial indicated that maintenance endocrine therapy was noninferior to chemotherapy with less treatment-related toxicity, which was worthy of a clinical recommendation. Support: ChiCTR-IIR-17014036, SYS-C-201801.

1089 Poster Session (Board #170), Sat, 8:00 AM-11:30 AM

Phase II study of cabazitaxel as second-line treatment in patients with HER-2 negative metastatic breast cancer previously treated with taxanes. *First Author: Angelos Koutras, Hellenic Cooperative Oncology Group (HeCOG), Athens, Greece*

Background: Cabazitaxel is a new taxoid efficient in stabilizing microtubules against depolymerization. Preclinical and limited clinical data indicate that cabazitaxel might be effective in breast cancer patients resistant to first-generation taxanes. **Methods:** The purpose of the current multicenter phase II trial was to evaluate the activity and safety of cabazitaxel as 2nd-line treatment, given on day 1 of a 21-day cycle, in patients with HER-2 negative metastatic breast cancer (mBC), previously treated with taxanes. Prophylaxis with G-CSF was recommended to all patients. The primary endpoint was the objective response rate (ORR), while secondary endpoints included overall survival (OS), progression-free survival (PFS), duration of response (DOR) and the safety profile. **Results:** Eighty-four patients were enrolled between 2012 and 2016. Among them, 3 patients (3.6%) were ineligible but received at least two cycles of treatment. In total, 499 cycles of cabazitaxel were administered (median 4; range 1-39). Median relative dose intensity was 0.99 (range 0.79-1.49). Seven patients were not evaluated for tumor response. In the 77 patients with evaluable treatment response, the ORR was 24.7% (1 complete and 18 partial responses). The disease-control rate was 58.4%, while the median DOR was 5.6 months (range 0.7-51.3). Within a median follow-up of 32.2 months, the median PFS was 3.7 months (95% CI 2.23-4.36), whereas the median OS was 15.2 months (95% CI 11.21-21.54). Regarding toxicity, grades 3-4 neutropenia and febrile neutropenia were reported in 22.6% and 6.0% of patients, respectively. Two fatal events were reported (1 febrile neutropenia; 1 sepsis) related to study treatment. Most frequent non-hematological events were fatigue, diarrhea, nausea (grade 1-3). There were no unexpected serious AE, and no new safety signal was revealed. **Conclusions:** This phase II trial suggests that cabazitaxel is active (disease control rate of almost 60%) with a manageable toxicity profile as 2nd-line treatment in taxane-pretreated patients with HER-2 negative mBC. Clinical trial information: NCT01693549.

1090 Poster Session (Board #171), Sat, 8:00 AM-11:30 AM

Dynamic changes of interleukin 2 (IL-2) and circulating tumor cells (CTCs) in patients with advanced breast cancer (BCa) after systemic therapies. *First Author: Qiang Zhang, Northwestern University, Department of Medicine, Division of Hematology/Oncology, Chicago, IL*

Background: CTCs play a critical role in BCa metastasis and worse prognosis even after systemic treatments such as chemotherapy and biological therapy. The mechanisms that contribute to CTCs migration and tumor aggressiveness remain unknown. Herein, we report a novel finding of the correlation between plasma IL-2 and the changes of CTC for BCa patients after therapies. **Methods:** Duplicate whole blood samples (7.5ml/each) were collected in EDTA tubes from 43 patients with stage III/IV BCa patients before (baseline, BL) or 3 months after (first evaluation, FE) systemic therapies respectively from patients treated at NMH. CTC enrichment and enumeration were performed in FDA approved CELLTRACKS ANALYZERII System and were linked with clinical database. The CTCs were classified as CK^+, $EpCAM^+$, $DAPI^+$ and $CD25^-$. ELISA for IL-2 was performed by using patients' plasma. Kruskal-Wallis test was used for statistics. **Results:** CTCs were detected in 23 patients at BL and 21 patients at FE of blood draws respectively. CTCs count increased in 12 patients (Group 1: from 102.9 to 213.3), decreased in 14 patients (Group 2: from 23 to 13.6) and remained unchanged as 0 in 17 patients (Group 3) respectively when BL was compared to the FE. The corresponding changes of IL-2 were -17.4pg/ml, 8.04pg/ml and -4.59pg/ml in Group 1, 2 and 3 respectively. The BL level of IL-2 in Group 1 is significantly higher than the other two groups ($p = 0.027$), and decreased of CTCs is associated with increased IL-2 ($P < 0.01$), while decreased IL-2 in FE level is associated with increased of CTCs after therapy in whole population ($p < 0.001$). More important, IL-2 dropped significantly in patients with CTC stably ≥ 5 or who experienced a rise in CTC ≥ 5 at the FE compared to the BL time point ($p < 0.001$). **Conclusions:** The study demonstrated for the first time a reverse correlation between IL-2 level and CTCs count. The data suggest that the more aggressive BCa (CTC≥ 5) induce the immune response (high levels of IL2 at baseline), but subsequently the IL2 level will decrease in patients that fail to benefit from treatment. We propose that surveillance of immune cytokine will help to understand advanced BCa prognosis and predict treatment benefit.

1091 Poster Session (Board #172), Sat, 8:00 AM-11:30 AM

Prognosis in young women under 40 with brain metastasis from breast cancer. *First Author: Ariana Mustillo, CHUM, Montreal, QC, Canada*

Background: Breast cancer brain metastases in young women is doubly devastating as both quality of life and life expectancy are significantly reduced. With new radiation technology and drugs that have emerged survival of these young women is expected to increase **Methods:** Using OACIS and SARDO patient databases, we identified 121 patients diagnosed with breast cancer and brain metastasis at CHUM between 2006 and 2016. We divided our group into Group A: patients whose first metastasis was in the brain and Group B: patients who developed a brain metastasis during the evolution of the metastatic breast cancer. Then, we compared young patients < 40 to those ≥ 40 for each category. **Results:** For the 121 patients with brain metastasis, the < 40 had a significantly longer mOS 18 mo compared to 4 mo for ≥ 40 ($P < 0.001$). With respect to timing of brain metastasis, group A had also a significantly longer survival (7 months) than group B (4 months) ($P = 0.032$). For group A, 2years OS was 57% for patients < 40 vs 12% for patients ≥ 40 (mOS NR vs 7 months; $P = 0.259$). For group B, patients < 40 had a significantly longer mOS 18mo than patients ≥ 40y 3 mo ($P = 0.0089$). There was no statistically difference in groups regarding time to first metastasis. BRCA 1/2 mutations were known for only 23 of 121 patients (19%). The BRCA 1/2 positive patients (8/23 = 35%) were well distributed between both age groups and none were treated with PARP inhibitors. **Conclusions:** Young women with brain metastasis from breast cancer have a better prognosis than women≥ 40. Patients who had their first metastasis to the brain also had a longer survival than patients whose metastasis to the brain developed later in the disease course.

1092 Poster Session (Board #173), Sat, 8:00 AM-11:30 AM

What are the drivers of healthcare cost among patients with metastatic breast cancer (mBC)? Total cost of care analysis to inform value-based reimbursement. *First Author: Chakkarin Burudpakdee, IQVIA, Fairfax, VA*

Background: Given the move toward value-based payment in oncology, total cost of care data are needed to evaluate value. The objective of this study was to quantify cost of care and identify key drivers of healthcare cost in patients (pts) with mBC. **Methods:** Adults with systemic treatment for mBC from 1/1/2014 – 12/1/2016 were identified from IQVIA's claims database. Pts were indexed on the first mBC treatment, had ≥2 diagnoses for both breast and metastatic cancer, ≥12 months of continuous medical and drug coverage before and ≥30 days after index. Healthcare resource use and costs were measured during follow up, standardized as per patient per month (PPPM), and compared between overall and high cost (defined as top 10%) pts. **Results:** 7,032 pts with mBC were included; mean (±SD) age was 55.5 ± 9.6; mean follow up was 14.0 ± 9.1 months. Total cost of care is shown in Table 1. The mean total PPPM cost of high cost pts (n = 703) was 3.7-fold higher than that of the overall population. The largest difference in cost between overall and high cost pts was for outpatient drugs ($7,348 PPPM); 76% was related to breast cancer medications. Other cost drivers in high cost pts included hospitalization ($6,152 PPPM higher), radiology procedures ($2,238 PPPM higher), and pharmacy services ($1,755 PPPM higher). The proportion of total costs due to outpatient surgery, office visits, lab services, and ED visits was lower in high cost pts compared to the overall population (10.5% vs. 7.1%). **Conclusions:** Our findings suggest that medications, hospitalizations, and radiology services are the main drivers of high costs in mBC pts. Further research is needed to identify if there are services and costs that are unintended and avoidable. Findings from this study can help inform evidence-based decisions when developing alternative payment models for cancer care.

Total cost of care.

	Mean cost PPPM	
	All (N = 7,032)	High cost (N = 703)
Total	$7,828	$28,776
Pharmacy	$1,341	$3,096
Medical	$6,487	$25,680
Inpatient	$1,337	$7,489
Outpatient	$5,150	$18,191
Drug	$2,189	$9,538
Radiology	$1,133	$3,371
Other outpatient service	$1,001	$3252
Surgery	$320	$742
Office visit	$269	$564
Laboratory	$183	$544
ED visit	$55	$180

1093 Poster Session (Board #174), Sat, 8:00 AM-11:30 AM

Updated survival data and biomarker assessment of the CBCSG006 trial: A randomized phase III trial of cisplatin plus gemcitabine compared with paclitaxel plus gemcitabine as first-line therapy for patients with metastatic triple-negative breast cancer. *First Author: Jian Zhang, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: It was previously reported in CBCSG006 trial that patients with metastatic TNBC were more likely to have higher response rate and longer PFS to cisplatin plus gemcitabine (GP) than to paclitaxel plus gemcitabine (GT) treatment. Here, we reported the updated survival data and the explorations of biomarkers for higher sensitivity to platinum doublet. **Methods:** 132 Blood and 114 archival tissue samples were collected prospectively. gBRCA1/2 genotyping and germ-line HRD panel status were detected by NGS. Core basal markers and PD-L1 expression were detected immunohistochemistry. Tumor-infiltrating lymphocytes (TILs) evaluation was performed on HE–stained sections. A model of composite measure of progression risk was developed to analyze the absolute survival benefits between two arms in CBCSG006 trial by a nonparametric sliding-window subpopulation treatment effect patter plot (STEPP) methodology. **Results:** Median PFS was 7.73 months (95% CI 6.46-9.00) for GP arm and 6.07 months (5.32-6.83) for GT arm (p = 0.005). No significant differences in OS were observed. Patients with gBRCA1/2 mutations had numerically higher ORR and prolonged PFS in GP than GT arm. Patients with germ-line HRD panel mutations had significantly higher ORR and longer PFS in GP than GT arm. Core basal subtype, lymphocyte-predominant breast cancer subtype and positive PD-L1 expression were not correlated with ORR or PFS. In STEPP analysis, patients with lower composite measure of progression risks had more absolute PFS benefits than those with high composite measure of progression risks, with absolute difference in 6-month PFS rates ranging from approximately 40% to none. **Conclusions:** gBRCA1/2 and germ-line HRD mutations are possible markers for platinum-based regimens. A composite risk model was developed to guide patient selection for GP treatment in TNBC. Clinical trial information: NCT01287624.

1094 Poster Session (Board #175), Sat, 8:00 AM-11:30 AM

Phase II (INSPIRE) trial of pembrolizumab (pembro) with serial immune and genomic profiling in patients (pts) with metastatic triple negative breast cancer (mTNBC). *First Author: Zachary William Neil Veitch, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Pembro is a PD-1 immune checkpoint inhibitor with a low response rate in pretreated mTNBC. In this biomarker driven, investigator-initiated trial we evaluate changes in immune and genomic landscapes of mTNBC pts treated with pembro monotherapy. **Methods:** Pts with mTNBC, ECOG 0-1, progressing after or ineligible for standard therapy were treated with Pembro 200mg IV q3w. Imaging (RECIST v1.1) was performed every 9 weeks. Pre- and on-treatment (week 6-9) tumor biopsies (bx) were assessed by IHC (C223 antibody) for PD-L1 expression; single cell suspensions were pooled for exome/RNA-sequencing and immunophenotyping (IP) by flow cytometry. Serial blood samples were collected for IP, cytokines, and ctDNA. **Results:** Of 20 mTNBC pts enrolled, median age was 40 years, 35% had ≥3 lines of therapy, 35% had LDH ≥1.5xULN, 60% had visceral metastases (liver 25%, lung 44%) and 30% had PD-L1+ (> 1%) tumors. Best response was 1 PR, 3 SD, and 16 PD. One pt discontinued Pembro after 3 cycles due to grade 3 pneumonitis and nephritis with 29% target lesion reduction (near PR). No other grade 3/4 AEs were observed. Grade ≤2 AEs were fatigue (30%), nausea (25%), and diarrhea (20%). After median follow-up of 6.5 months (range 1.8-19.8), mPFS was 2.1 months (95% CI 1.5-3.1) and mOS was 7.4 months (95% CI 6.2-10.7). Pre-/post-treatment bx were performed on 20 and 10 pts respectively, but at time of analysis only 8/20 had sufficient tumor cell content for IP, and 5/20 had genomic analysis. The two pts with PR/near-PR showed T-cell stimulation with increasing CD8 4-1BB levels on blood IP from baseline to cycle 2 (1.96 to 7.95 [% of CD3]; 10.1 to 13 [% of CD3]) relative to non-responders (4.06 to 3.13 [% of CD3]). A third patient with 26% reduction in target lesions but confirmed progression of non-target lesions had *POLE* (G1750E) mutation with germline *BRCA2* mutation. **Conclusions:** Consistent with previous reports, the response rate to Pembro monotherapy in pre-treated mTNBC was low. Increased expression of 4-1BB on peripheral blood CD8 cells was observed in patients with target lesion reduction. Further analyses are ongoing. Clinical trial information: NCT02644369.

1095 Poster Session (Board #176), Sat, 8:00 AM-11:30 AM

An open label, pilot study of veliparib (ABT-888) and lapatinib in patients with metastatic, triple negative (ER, PR, and HER-2 negative) breast cancer. *First Author: Erica Michelle Stringer-Reasor, University of Alabama at Birmingham, Birmingham, AL*

Background: Triple-negative breast cancer (TNBC) is an aggressive subtype of breast cancer (BC), often resistant to standard of care therapies. We previously showed an induced synthetic lethal interaction with combined EGFR (epidermal growth factor receptor) and PARP (Poly (ADP-ribose)-polymerase) inhibition in TNBC cells. Therefore, we tested a pilot clinical trial using lapatinib and veliparib in patients with locally advanced unresectable or metastatic TNBC. Here we report safety results and clinical activity of the combination of veliparib and lapatinib. **Methods:** Key eligibility criteria include histologically confirmed TNBC (ER negative, PR negative, HER-2-Neu negative), measurable disease, failed anthracyclines and taxanes in the neoadjuvant, adjuvant, or metastatic setting, left ventricular ejection fracture ≥ 50, and ECOG PS of 0-2. Patients with known germline BRCA 1 or 2 mutations were excluded. Eligible patients received continuous doses of lapatinib 1250 mg PO daily and veliparib 200 mg PO twice daily. Dose limiting toxicity (DLT) evaluation period was 28 days (cycle 1). Adverse events (AEs) were assessed by CTCAE v4.03 and best objective response per RECIST v1.1. **Results:** Twenty patients were enrolled and 17 were evaluable for response. The median number of prior therapies for advanced BC was 1 (range 0-2). Fifty percent of the patients enrolled were Caucasian, 45% African-American, and 5% Hispanic. Of the evaluable patients, 4 had a partial response and 2 had stable disease. There were no dose-limiting toxicities. The majority of toxicities occurred during cycles 2 and 3. Toxicities were manageable. Most adverse events (AEs) were limited to grade 1 or 2 (no grade 5). Common treatment-related AEs were fatigue (6.4%), diarrhea (5.1%), constipation (5.5%), insomnia (4.5%), vomiting (2.9%), anemia (2.6%), headache (2.6%), dizziness (2.3%), dyspnea (2.3%), and rash (2.3%). **Conclusions:** Lapatinib plus veliparib in the treatment of advanced TNBC resistant to SoC has a manageable safety profile and promising antitumor activity. Further investigation of EGFR inhibition in combination with a PARP inhibitor is needed. Clinical trial information: NCT02158507.

1096 Poster Session (Board #177), Sat, 8:00 AM-11:30 AM

Mechanisms of immune evasion in triple-negative breast cancer patients. *First Author: Javier Ignacio Orozco, John Wayne Cancer Institute at Providence Saint John's Health Center, Santa Monica, CA*

Background: Immunotherapy has shown promising results in enhancing response rates for patients with triple-negative breast cancer (TNBC). The success of immunotherapy is affected by poor tumor antigen presentation. This immune evasion is facilitated by genetic and epigenetic alterations, including aberrant RNA splicing (AS). Here we examined the role of PTBP1, a key RNA splicing factor related to immune evasion in TNBC. **Methods:** Clinical and gene expression data from 3,614 breast cancer patients included in the METABRIC and TCGA projects were evaluated to identify the impact of PTBP1 on TNBC. Univariate and multivariate statistical modeling was performed to test the association of PTBP1 expression with relapse-free survival (RFS), disease-free survival (DFS), and overall survival (OS). CRISPR-Cas9 technology, followed by RNA sequencing (RNA-Seq) was utilized to identify differentially activated pathways in a TNBC cell model (MDA-MB-231). A portrait of infiltrating immune cells was compiled using the xCELL algorithm. Immunofluorescence (IF) and immunohistochemistry (IHC) were employed to validate our findings in TNBC cell lines, tissue microarrays, and FFPE specimens (n = 110). **Results:** We found that PTBP1 is significantly upregulated in patients with TNBCs ($P < 0.001$). TNBC patients with high PTBP1 presented significantly shorter RFS ($P = 0.018$; HR = 1.66, 95%CI 1.1-2.5; n = 255), DFS ($P = 0.017$; HR = 3.2, 95%CI 1.16-8.3; n = 151), and OS ($P = 0.037$; HR = 1.48, 95%CI 1.02-2.15; n = 162). To explore potential mechanisms linking PTBP1 expression and poor survival, CRISPR-guided knockout of *PTBP1*, followed by RNA-seq identified a significant enhancement on antigen presentation pathways, confirmed by IF staining. xCELL analysis showed that TNBC tumors with high PTBP1 present an immune infiltration profile compatible with immune evasion (low CD4+ naïve and memory T cells, low CD8+ T cells, low tumor-associated macrophages, and high suppressor T cells). These observations were further confirmed by IHC evaluation of TNBC clinical specimens. **Conclusions:** This study suggests an important and relatively unexplored role of AS in immune evasion, identifying new prognostic and potentially therapeutic targets for patients with aggressive TNBC.

1097 Poster Session (Board #178), Sat, 8:00 AM-11:30 AM

Preliminary report of a phase 1b/2a trial, an oral inhibitor of phosphorylated P68 (P-p68) which mediates β-catenin nuclear translocation in advanced triple-negative breast cancer (TNBC). *First Author: Jennifer Robinson Diamond, University of Colorado, Aurora, CO*

Background: RX-5902 is a novel oral anti-cancer compound targeting phosphorylated p68 (P-p68) (RNA helicase DDX5, a member of the DEAD box family of RNA helicases) affecting the Wnt canonical pathway. P-p68 may play a role in cell proliferation and cancer progression by blocking the nuclear translocation of β-catenin. RX-5902 inhibits tumor growth and enhances survival in numerous xenograft animal models, including breast, melanoma and ovarian. **Methods:** This is a Phase 1b/2a trial in patients with previously treated advanced triple-negative breast cancer. Eligible subjects received 250 mg of RX-5902 orally for 5 consecutive days followed by 2 days off and continued until unacceptable toxicity or disease progression. Primary objectives include efficacy and safety of the recommended phase 2 dose and schedule, as was previously determined in the phase 1 study. A pre-planned interim analysis will be performed when 10 response evaluable subjects have been enrolled and have completed 4 cycles of therapy or have discontinued therapy due to progressive disease. Tumor imaging is performed every 2 cycles. If at least 2 objective responses are seen in the first 10 evaluable patients, enrollment will continue to stage 2 of the Phase 2a portion of the study. **Results:** As of Feb 2018, 11 subjects with TNBC were enrolled and treated in Stage 1 of the Phase 2a component. These subjects had received a median of 3 prior therapies (range 2 to 6). Preliminary evidence after 2 cycles of therapy showed 5 subjects with stable disease as the best overall response; 3 subjects had progressive disease, 2 subjects stopped therapy early and 1 subject just started treatment. One subject had a tumor reduction of 18.2% and 1 subject remains on study with stable disease for 5 cycles. The most common related adverse events, were Grade (G)1/2 nausea (2.8%), G1 vomiting (1.8%), G1/G2 diarrhea (1.8%) and G1/G2/G3 fatigue (4.6%). **Conclusions:** Preliminary evidence suggests that oral administration of RX-5902 at 250 mg/day appears safe and well tolerated. Early anti-tumor activity was observed in 1 patient. Recruitment to Phase 2 is ongoing. Clinical trial information: NCT02003092.

1098 Poster Session (Board #179), Sat, 8:00 AM-11:30 AM

An open label, single arm, prospective phase II study to evaluate the efficacy and safety of bevacizumab with gemcitabine and carboplatin as first-line treatment for metastatic triple negative breast cancer patients. *First Author: Sudeep Gupta, Department of Medical Oncology, Breast Disease Management Group, Tata Memorial Centre (TMC), Mumbai, India*

Background: There is a higher burden (29.2%-46%) of TNBC patients in India. This single arm, phase II trial evaluated the efficacy and safety of bevacizumab in combination with gemcitabine and carboplatin as first line treatment in Indian patients with metastatic TNBC. **Methods:** TNBC patients with prior adjuvant anthracycline and taxane therapy and no prior treatment for metastatic disease received bevacizumab (15mg/kg) with gemcitabine and carboplatin, every three weeks until disease progression or unacceptable toxicity. **Results:** Forty patients were accrued at 10 Indian centers between February 2011 to April 2013. At median follow-up of 12 (0.5 –59.3) months there were 27 disease progressions and 23 deaths. Using EORTC QLQ-30 questionnaire, improvements were observed in physical function ($P = 0.0435$), emotional function ($P = 0.002$) and pain perception ($P = 0.0243$) domains from baseline to cycle 6. Median duration of study treatment was 4.6 (0.3 – 18.4) months. Overall, 24 (60%) patients reported 133 adverse events (99 non-serious, 34 serious) including proteinuria, rectal hemorrhage (grade 3) and fatigue (grade 4) in 1 patient each. A total of 34 serious adverse events were reported in 17 (42.5%) patients. No new safety signals were identified and bevacizumab was found to be well tolerated by Indian patients. **Conclusions:** Bevacizumab in combination with gemcitabine and carboplatin as first line treatment in metastatic TNBC, resulted in favorable survival outcomes with acceptable toxicity. The patients also experienced significant improvement in several domains of health related QoL during the first 6 cycles of this treatment. Efficacy results Clinical trial information: NCT01201265.

Primary Endpoint	N = 40
Median PFS	8.5 months (95% CI: 5.2 – 15.3)
Secondary Endpoints	N = 40
Median OS (protocol-defined end of study)	15.8 months (95% CI: 11.8 – 24.9)
Updated Median OS (additional 14.5 months follow-up)	23.1 months (95% CI: 9.6 – 36.0)
TTP	8.9 months (95% CI: 6.0 – 18.1)
Complete Response (CR)	2 (5%)
Partial Response (PR)	18 (45%)
Stable Disease (SD)	17 (42.5%)
Overall Response Rate (CR+PR)	20 (50%)
Clinical Benefit Rate (CR+PR+SD)	37 (92.5%)

1099 Poster Session (Board #180), Sat, 8:00 AM-11:30 AM

Characterization of the inflammatory infiltrate and association with expression of PD-1, PDL1 and PDL2 and survival in triple-negative mammary carcinoma. *First Author: Monique Celeste Tavares, Hospital A.C. Camargo, Sao Paulo, Brazil*

Background: However, recent evidences suggest that lymphocyte infiltration in tumors (LIT), which is presented in breast cancer prior to the treatment, may predict response to the therapy and a better prognosis. Not only the intensity of lymphocyte infiltration, but also the phenotype of that infiltrate, determine the clinical outcome.Objectives:To evaluate the intensity and composition of the LIT in an operated TNBC and its association with the expression of PD-1, PD-L1 and PD-L2. **Methods:** This is an observational, descriptive and a retrospective cohort study. The studied population consisted of patients diagnosed with invasive TNBC. **Results:** LIT was evaluated in 165 patients. The mean intensity of the inflammatory infiltrate was 20%. We observed that 47 (28%) had inflammatory infiltrate $\leq 5\%$, 86 (52%) between 5 and 50% and 32 (19%) $> 50\%$. The average OS in each group was, respectively, 85 months, 104 months and 148 months ($p = 0.002$). We established an ideal cutoff point of 5% of LIT for OS analysis, so that average overall survival was 85 months for patients with LIT$\leq 5\%$ and 136 months for those with infiltrate $> 5\%$ ($p = 0.001$) . We included 76 cases in the TMA for IHC analysis. We established an optimal cutoff point of 5% in this group, we observed that the majority 56 (78.87%) had an inflammatory infiltrate $> 5\%$. With a tendency to benefit in specific cancer survival, for patients with inflammatory infiltrate $> 5\%$, but with no statistical significance. We found an average of 4 and 12% expression of tumor-free PD-L1 and no stroma, respectively. The cutoff point for the labeling of PD-L1 in the stroma was 5%, with 17 (22.4%) presenting $> 5\%$ and 31 (40.8%) $\leq 5\%$; and in tumor was 1%, with 11 (14.5%) $> 1\%$ and 51 (67%) $\leq 1\%$. There was no association between PD-L1 expression and OS. We found a positive and statistically significant correlation of LIT with labeling PD-L1 in stroma ($p = 0.001$) and in tumor ($p = 0.028$). **Conclusions:** In TNBC, TII above 5% is associated with the increasing of OS. TII is associated with a number of cells labeled positively for PD-L1 both in stroma and in tumor. PD-L1 was not associated with OS. Increased number of FOXP3+ and of PTEN marking cells are associated with better OS.

TPS1100 Poster Session (Board #181a), Sat, 8:00 AM-11:30 AM

A phase II study of atezolizumab (Atezo) combined with pertuzumab (P) and high-dose trastuzumab (H) for the treatment of central nervous system (CNS) metastases in patients with Her2-positive (HER2+) metastatic breast cancer (MBC). *First Author: Romualdo Barroso-Sousa, Dana-Farber Cancer Institute, Boston, MA*

Background: There is no clear standard of care to address the management of refractory CNS metastases in HER2+ MBC. The ongoing study (NCT03417544) is evaluating the efficacy of the combination of Atezo with P and high-dose H for the treatment of CNS metastases in patients (pts) with HER2-positive MBC. **Methods:** This is a phase II, single arm, multi-center trial assessing the efficacy of Atezo with Pertuzumab plus high-dose H for the treatment of CNS metastases in HER2+ MBC. Participants will receive Atezo [1200mg every 3 weeks (q3w)], P (840-mg loading dose, then 420mg q3w), and high-dose H (6 mg/kg weekly for 24 weeks, and then q3w). Eligibility Criteria include pts with HER2+ MBC, at least one measurable CNS metastasis ($\geq$10 mm), unequivocal evidence of new and/or progressive CNS metastases, and left ventricular ejection fraction (LVEF) $\geq$ 50%. Exclusion criteria include CNS complications for whom urgent neurosurgical intervention is needed; known leptomeningeal/brainstem metastases; and treatment with dexamethasone $>$ 2mg/day or bioequivalent within 7 days of initiating therapy. The primary endpoint is objective response rate (ORR) in the CNS per Response Assessment in Neuro-Oncology Brain Metastases (RANO-BM) criteria. Secondary endpoints include the duration of CNS response, bi-compartmental progression-free survival according to RANO-BM, and the extracranial ORR according to RECIST 1.1. Tumor biopsies, peripheral blood, and cerebrospinal fluid will be obtained at baseline, on treatment and at progression. In the first stage, 19 pts will be enrolled. If there are at least 4 CNS responses, accrual will continue to the second stage where up to 14 additional pts will be enrolled. If at least 8 of these 33 pts have CNS response, the regimen will be considered worthy of further study. With this design, if the true response rate is 15%, the chance the regimen is declared worthy of further study is less than 10% (exact alpha = 0.096). If the true response rate is 35%, the chance that the regimen is declared worthy of further study is 90.4%. The trial opened in February 2018, with a target accrual of 33 pts. Clinical trial information: 03417544.

TPS1101 Poster Session (Board #181b), Sat, 8:00 AM-11:30 AM

SOLTI-1303 PATRICIA: A phase II study of palbociclib and trastuzumab (HR+ with or without letrozole) in trastuzumab-pretreated, postmenopausal patients with HER2-positive metastatic breast cancer. *First Author: Patricia Villagrasa, SOLTI Breast Cancer Research Group, Barcelona, Spain*

Background: Despite the high efficacy of anti HER2-agents, HER2-positive (HER2+) metastatic breast cancer (BC) remains incurable and in need of additional options. In this context, CDK4/6 inhibition combined with anti-HER2 therapy is currently being explored in phase II/III trials. Preclinical evidence from different HER2+ BC models have shown that CDK4/6 inhibition leads to deep cytostatic arrest and inhibition of its invasive properties, underlining the role of CDK4/6 in HER2 signaling. Moreover, Identification of the luminal subtype in HER2+/HR+ disease might be important since the median IC50 of palbociclib (P) in HER2+ BC cell lines falling into the luminal subtype is lower than in non-luminal HER2+ cell lines (47.5 vs. 300 nM). We have recently reported that PAM50 luminal subtype predicts progression-free survival (PFS) in HER2+/HR+ advanced BC treated with P and trastuzumab (T) compared to non-luminal disease (10.37 vs. 3.53 months, p-value = 0.023). PATRICIA is a Simon 2-Stage study to evaluate the efficacy of combining T plus P, +/- letrozole (L), assessed by PFS in heavily pretreated HER2+ patients. **Methods:** Postmenopausal HER2+ patients who had received 2-4 prior lines of anti-HER2-based regimens are included in 3 cohorts: A: HR-negative; B1: HR+, receiving both T and P; B2: HR+, receiving T, P and L. P is administered at 200 mg/day for 14 days of 21-day cycles. T and L are administered at usual doses. The primary objective is to assess clinical efficacy measured as PFS at 6 months (PFS6). Assuming an increase of at least 20% in PFS6 by the addition of P +/- L to T, PFS6 should be $\geq$30% for a cohort to be successful and proceed to stage 2. Thus, it will be necessary to include 15 patients in each cohort in stage 1. In stage 2, each cohort may continue recruitment for up to 46 patients. Translational research for predictive biomarkers will be implemented. To date, 55 patients, 15 in A and 20 in each B cohort, have been included in 14 sites across Spain. The 1st stage efficacy analysis was performed for B cohorts, leading 2nd stage accrual began in September 2017. Cohort A stage 1 effectiveness analysis is intended for June 2018. Clinical trial information: NCT02448420.

TPS1102 Poster Session (Board #182a), Sat, 8:00 AM-11:30 AM

A phase 2, multicenter, open-label study of trastuzumab deruxtecan (DS-8201a) in subjects with HER2-positive, unresectable and/or metastatic breast cancer previously treated with T-DM1. *First Author: Jose Baselga, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: There is no standard of care for HER2-positive breast cancer refractory to T-DM1. DS-8201a is a novel HER2-targeted antibody-drug conjugate with a humanized HER2 antibody attached to a topoisomerase I inhibitor payload by a cleavable peptide-based linker (deruxtecan), and with a high drug-to-antibody ratio of 7 to 8. In the ongoing phase 1 DS8201-A-J101 trial, DS-8201a showed a manageable safety profile and promising antitumor activity in HER2-positive breast cancer subjects previously receiving T-DM1 (confirmed objective response rate [ORR] of 61.4%; Oct 2017 data cutoff) (Modi et al, SABCS 2017). In August 2017, the FDA granted breakthrough therapy and fast track designations. **Methods:** The phase 2, open-label, multicenter, 2-part, DESTINY-Breast01 study will assess the efficacy and safety of DS-8201a in subjects with HER2-positive (confirmed by centralized testing) unresectable and/or metastatic breast cancer previously treated with T-DM1. Part 1 will enroll 120 subjects and includes pharmacokinetic (PK) and dose finding stages to identify the recommended phase 2 dose (RP2D). The PK stage will randomize 60 subjects (1:1:1) to 1 of 3 DS-8201a doses (7.4, 6.4, and 5.4 mg/kg; once every 3 weeks). In the dose finding stage, an additional 60 subjects will be randomized (1:1) to 1 of 2 doses selected in the PK stage. Part 2a will continue to enroll approximately 100 subjects at the RP2D. Part 2b will enroll an open-ended number of subjects who discontinued T-DM1 for reasons other than progressive disease. Overall, enrollment of $\geq$100 subjects with a history of prior pertuzumab treatment for metastatic breast cancer is planned at the RP2D. The primary endpoint, ORR, will be assessed in all subjects enrolled in parts 1 and 2a who received the RP2D and who had baseline measurable tumors assessed by an independent central imaging facility. Secondary endpoints include duration of response, disease control rate, progression-free survival, and overall survival. Enrollment began in August 2017. As of Feb. 12, 2018, 35 of approximately 230 subjects have been enrolled. Clinical trial information: NCT03248492.

TPS1103 Poster Session (Board #182b), Sat, 8:00 AM-11:30 AM

A multicenter, phase I/II trial of anastrozole, palbociclib, trastuzumab and pertuzumab in HR-positive, Her2-positive metastatic breast cancer. *First Author: Krystal Pauline Cascetta, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Overexpression or amplification of HER2 occurs in approximately 15 – 20% of patients and about half of these tumors are hormone receptor (HR) positive. Studies suggest that this 10% of all breast cancer cases may derive less benefit from endocrine therapy than those with HR+ disease without HER2 overexpression. The use of aromatase inhibitors in the metastatic setting is well established while significant improvement in overall survival has been established with the use of trastuzumab or pertuzumab in HER2-overexpressing tumors. To date, no studies have examined the combination of endocrine therapy, palbociclib, and dual HER2 therapy with pertuzumab and trastuzumab in this patient population. Trial Design: Multicenter, Phase I/II Trial of Anastrozole, Palbociclib, Trastuzumab and Pertuzumab in HR-positive, Her2-positive Metastatic Breast Cancer. Eligibility Criteria: Stage IV HR+, HER2+ breast cancer patients. Specific Aims: Phase I: To determine the maximum dose tolerated of palbociclib. Phase II: To determine the clinical benefit rate (CBR) of treatment with anastrozole, palbociclib, trastuzumab, and pertuzumab in HR+, HER2+ metastatic breast cancer patients. Exploratory: Examine potential biomarkers of response to palbociclib including expression of cyclin D1, cyclin E1 and E2, retinoblastoma, phosphorylated retinoblastoma, and p16 levels. RNA sequencing will be used to assess for other predictors of response in an unbiased manner to assess for correlation with inhibition of Ki-67 and phosphorylated retinoblastoma expression as well as evaluate for potential mechanisms of resistance. **Methods:** This study will evaluate the maximum tolerated dose (MTD) of the Anastrozole, Palbociclib, Trastuzumab and Pertuzumab. If $\geq$ 33 % of patients experience a dose limiting toxicity (DLT) at any dose level, the dose level below that level will be considered the MTD. Or, if the highest level has been reached and $<$ 33% of patients have experienced DLT, that will be considered the MTD. Once the MTD is reached, we will assess the clinical benefit rate using a Simon's II stage design among a maximum 30 patients. Accrual: Maximum of 36 subjects. Clinical trial information: NCT03304080.

TPS1104 **Poster Session (Board #183a), Sat, 8:00 AM-11:30 AM**

Palbociclib after CDK and endocrine therapy (PACE): A randomized phase II study of fulvestrant, palbociclib, and avelumab for endocrine pre-treated ER+/HER2- metastatic breast cancer. *First Author: Erica L. Mayer, Dana-Farber Cancer Institute, Waban, MA*

Background: CDK4/6 inhibition (CDK4/6i) has a well-established role in the management of hormone receptor positive/HER2 negative (HR+/HER2-) metastatic breast cancer (MBC). The addition of a CDK4/6i to endocrine therapy (ET) in HR+/HER2- MBC leads to prolongation of progression-free survival in the first-line and pre-treated settings. Mechanisms of resistance to CDK4/6i are not well described, and it is not known if continuation of CDK4/6i with subsequent lines of ET improves outcomes over ET alone. Further, preclinical data suggest combination therapy with ET, CDK4/6i, and anti-PDL1 may provide synergistic efficacy. The PACE trial was designed to determine optimal subsequent line of therapy in patients (pts) with HR+ / HER2- MBC that has progressed despite prior CDK4/6 inhibition and endocrine therapy. **Methods:** PACE is a multicenter phase II trial randomizing pts 1:2:1 to Arm A: fulvestrant alone (with option for palbociclib monotherapy crossover at time of progression); Arm B: fulvestrant and palbociclib; or Arm C: fulvestrant, palbociclib, and avelumab. The primary objective is to evaluate progression-free survival (PFS) with the combination of fulvestrant and palbociclib vs. fulvestrant alone; secondary objectives include overall response (OR) and PFS comparisons for other arms; assessment of outcomes in predefined molecular subgroups including ESR mutation, PI3K mutation, loss of Rb; safety and tolerability; and comparing OR by RECIST vs irRECIST. Extensive analysis of tissue, ctDNA, and CTC for markers of response and resistance to therapy is planned. Eligible pts have HR+/HER2- MBC, with prior response to and subsequent progression on CDK4/6i and ET, defined as at least 6 months of prior treatment, with confirmed subsequent progression, and no more than one prior P dose reduction for toxicity. Pts may have had 1-2 prior ET, and 0-1 prior lines of chemotherapy. A sample size of 220 patients is planned. NCT03147287.

TPS1105 **Poster Session (Board #183b), Sat, 8:00 AM-11:30 AM**

PADA-1: A randomized, open label, multicentric phase III trial to evaluate the safety and efficacy of palbociclib in combination with hormone therapy driven by circulating DNA *ESR1* mutation monitoring in ER-positive, HER2-negative metastatic breast cancer patients. *First Author: Francois Clement Bidard, Institut Curie, Paris, France*

Background: Palbociclib (Pal) combined with an aromatase inhibitor (AI) is a standard of care as first line therapy in estrogen receptor-positive (ER+) HER2-negative (HER2-) metastatic breast cancer (MBC). The efficacy of Pal +AI may be however limited by the onset of *ESR1* mutations during therapy as a mechanism of resistance to AI, while pre-clinical and retrospective clinical data suggest that *ESR1*-mutated clones remain sensitive to fulvestrant (Ful). Rising *ESR1* mutation levels might be detected in ctDNA several months before actual tumor progression. This clinical utility trial tests whether switching from AI-Pal to Ful-Pal after the onset of rising *ESR1* mutations will turn into a clinical benefit for patients; the safety of these treatments will also be evaluated. **Methods:** Main inclusion criteria are patients with ER+ HER2-MBC with no prior systemic treatment for metastatic disease, no visceral crisis and theoretical AI-sensitivity. In the first step, all patients (N=800) are treated with Pal+AI; *ESR1* mutations in ctDNA are tracked by ddPCR (targeting E380, L536, Y537 and D538 ER hotspots) at baseline, after 1 cycle of treatment and then every other cycle. Upon the detection of rising *ESR1* mutation(s) in blood, patients without RECIST tumor progression proceed to the second step and are randomized (1:1) between the continuation of the same regimen or a switch to Pal+Ful. In a third step, patients that were randomized in standard regimen arm may crossover to Pal+Ful following tumor progression. The co-primary objectives of this ethically approved trial (NCT03079011), conducted in France by UCBG with GINECO, are (i) treatment safety (steps 1 to 3) and (ii) PFS in the two treatment arms (step 2). The 1st patient was included in March 2017; as of January 2018, 426 patients have been included. Clinical trial information: NCT03079011.

TPS1106 **Poster Session (Board #184a), Sat, 8:00 AM-11:30 AM**

Contessa: A multinational, multicenter, randomized, phase 3 registration study of tesetaxel in patients (Pts) with HER2-, hormone receptor + (HR+) locally advanced or metastatic breast cancer (MBC). *First Author: Joyce O'Shaughnessy, Texas Oncology - Baylor Charles A. Sammons Cancer Center and The US Oncology Network, Dallas, TX*

Background: Chemotherapy treatments that offer improved quality of life are needed. Tesetaxel (T) is a novel, oral taxane that has potential advantages over currently available taxanes, including: oral administration with a low pill burden and Q3W dosing; no history of hypersensitivity reactions; and improved activity against chemotherapy-resistant tumors (Shionoya 2003; Chan 2006). 555 pts have been treated with T in clinical studies (492 monotherapy; 63 in combination with capecitabine (C)). In MBC, T had robust single-agent activity in 2 multicenter, Phase 2 studies. In TOB203, 38 pts with HER2-, HR+ MBC received single-agent T Q3W for MBC; the confirmed ORR per RECIST 1.1 in all 38 pts was 45% (95% CI: 29% - 62%); the median PFS was 5.7 mo (95% CI: 4.1 – 9.8 mo). In a Phase 1 study, the combination of T plus a reduced dose of C was associated with a tolerable AE profile with minimal overlapping toxicity. C is a preferred agent for pts with MBC. Combining the approved dose of C with currently available taxanes results in robust efficacy but significant toxicity, while preclinical and clinical studies suggest that reducing the dose of C in combination with a taxane may result in reduced toxicity without a reduction in efficacy. CONTESSA investigates T plus a reduced dose of C as an all-oral regimen in HER2-, HR+ MBC. **Methods:** CONTESSA is a 600-pt, multinational, multicenter, randomized (1:1), Phase 3 registration study comparing T (27 mg/m^2 on Day 1 of a 21-day cycle) plus a reduced dose of C (1,650 mg/m^2/day on Days 1-14 of a 21-day cycle) to the approved dose of C alone (2,500 mg/m^2/day on Days 1-14 of a 21-day cycle) in pts with HER2-, HR+ MBC previously treated with a taxane in the (neo)adjuvant setting. Where indicated, pts must have received endocrine therapy with or without a CDK 4/6 inhibitor. The primary endpoint is PFS assessed by an Independent Radiologic Review Committee (IRC). CONTESSA is 90% powered to detect a 42% improvement in PFS (HR = 0.71). Secondary endpoints are OS, ORR assessed by IRC, disease control rate assessed by IRC and patient reported outcomes. Enrollment was initiated in Dec 2017. Clinical trial information: NCT03326674.

TPS1107 **Poster Session (Board #184b), Sat, 8:00 AM-11:30 AM**

BYLieve: A phase II study of alpelisib (ALP) with fulvestrant (FUL) or letrozole (LET) for treatment of *PIK3CA* mutant, hormone receptor-positive (HR+), human epidermal growth factor receptor 2-negative (HER2–) advanced breast cancer (aBC) progressing on/after cyclin-dependent kinase 4/6 inhibitor (CDK4/6i) therapy. *First Author: Hope S. Rugo, University of California San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

Background: Endocrine therapy (ET) is the standard of care for treatment of HR+, HER2– aBC. However, ET resistance occurs frequently due to dysregulation of the PI3K/AKT/mTOR pathway, specifically mutations in *PIK3CA,* the gene encoding the p110alpha subunit of PI3K. In a phase 1 study, ALP, a PI3Kα-specific inhibitor, in combination with FUL has shown antitumor activity in patients (pts) with *PIK3CA* mutant, HR+, HER2– aBC. The ongoing phase 3 SOLAR-1 trial (NCT02437318) is evaluating ALP + FUL combination in HR+, HER2– aBC. The present BYLieve study aims to assess the efficacy and safety of ALP + FUL/LET in *PIK3CA*-mutant, HR+, HER2– aBC progressing on/after prior CDK4/6i combination therapy. **Methods:** BYLieve is a phase 2, multicenter, open-label, 2-cohort, non-comparative study. Men and women (pre-menopausal and post-menopausal; $\geq$18 years) with *PIK3CA*-mutant, HR+, HER2– locally advanced or metastatic breast cancer that has progressed on/after prior CDK4/6i combination therapy are eligible. Other eligibility criteria include $\geq$1 measurable lesion (RECIST v1.1) or predominantly lytic bone lesion; ECOG PS $\leq$2; $\leq$1 line of prior chemotherapy in the advanced setting; and no prior PI3K inhibitor therapy. Pts are allocated to 2 cohorts; cohort A (pts who had received CDK4/6i + aromatase inhibitor): oral ALP (300 mg QD) + intramuscular FUL (500 mg) and cohort B (pts who had received CDK4/6i + FUL): oral ALP (300 mg QD) + oral LET (2.5 mg QD). The primary end point is the proportion of pts who are alive without disease progression at 6 months (RECIST v1.1; local assessment), and will be evaluated separately in each cohort. Evidence of treatment effect will be demonstrated if the lower bound of the 90% CI is greater than 30% with a planned sample size of 80 pts in each cohort. Secondary end points include progression-free survival (PFS), PFS on next-line treatment (PFS2), overall response rate, clinical benefit rate, duration of response, safety, and tolerability. Recruitment of the planned 160 pts is currently ongoing. Clinical trial information: NCT03056755.

TPS1108 Poster Session (Board #185a), Sat, 8:00 AM-11:30 AM

Study TTC-352-101: Phase 1 study of TTC-352 in patients with metastatic breast cancer (BC) progressing on endocrine therapy. *First Author: Ruth O'Regan, University of Wisconsin Carbone Cancer Center, Madison, WI*

Background: 75% of all breast cancers (BC) are hormone receptor-positive (HR+). Despite the efficacy of endocrine therapies, HR+ BC develop resistance, and cytotoxic chemotherapy is ultimately the only option to treat these patients. TTC-352 is a selective human estrogen receptor (ER) partial agonist (ShERPA) that was developed for treatment of HR+ BC. ShERPAs mimic the effects of estradiol (E2) in hormone-independent, endocrine-resistant BC cells, but since it has only partial agonist activity in HR+ BC cells, it could have an improved side effect profile. Specifically, TTC-352 does not support the growth of HR+, hormone-dependent BC xenografts that normally require E2 for growth nor result in uterine proliferation in mouse xenograft models as does E2. PKCa is a predictive biomarker for response to TTC-352 in endocrine-resistant BC xenografts. Thus, TTC-352 could be a promising treatment option for endocrine-resistant BC. **Methods:** This is an open-label, accelerated dose escalation study that will evaluate up to five dose levels of TTC-352 in patients with HR+ endocrine-resistant metastatic BC. The maximum tolerated dose (MTD) of TTC-352 will be determined using initial single-patient cohorts until grade 2 toxicity, then expansion to a modified-Fibonacci dose-escalation 3+3 design. Patients enrolled at each cohort must complete the first 28-day cycle before enrollment to the next dose cohort can start. The MTD dose level cohort will be expanded to a total of 9 patients, to further evaluate safety. The secondary objectives are: to determine patient best response (BR) to treatment, progression-free survival (PFS), overall survival (OS), treatment tolerability of TTC-352, and to establish the pharmacokinetic profile of TTC-352 in patients with metastatic ER+ BC. Correlative objectives include: tumor PKCa expression, steady-state values for Cmax, and AUC0-12 correlation with BR, PFS and OS. Patient population: patients with metastatic HR+ BC that has progressed on at least two lines of endocrine therapy, with one that included a CDK4/CDK6 inhibitor, and with adequate hepatic, renal, and bone marrow function at screening. This study is currently enrolling patients. Clinical trial information: NCT03201913.

TPS1109 Poster Session (Board #185b), Sat, 8:00 AM-11:30 AM

AIPAC (Active Immunotherapy PAClitaxel): A randomized, double blind, placebo controlled, multinational phase IIb trial evaluating the efficacy of eftilagimod alpha (a soluble LAG-3 fusion protein) in combination with paclitaxel in hormone receptor positive metastatic breast cancer. *First Author: Luc Dirix, Sint-Augustinus Hospital Oncology Center, Medical Oncology, Antwerpen, Belgium*

Background: Eftilagimod alpha (efti, previously IMP321) is a recombinant LAG-3Ig fusion protein that binds to MHC class II and mediates antigen-presenting cell (APC) activation followed by CD8 T-cell activation. The activation of the dendritic cell network with efti injected s.c. the day after chemotherapy at a time when these APC are loaded with tumor antigens may lead to stronger anti-tumor CD8 T cell responses. AIPAC (Active Immunotherapy PAClitaxel; NCT02614833) is a Phase IIb trial in hormone receptor-positive stage IV metastatic breast carcinoma patients receiving eftilagimod alpha (efti; also named IMP321) or placebo as adjunctive to weekly paclitaxel as a first-line chemotherapy. The safety run-in stage (stage 1) has been completed in 2016 and the randomized part (stage 2) is recruiting. **Methods:** This clinical trial is a placebo-controlled, double-blind, 1:1 randomized Phase IIb study aiming to enroll 226 patients at multiple centers across 7 different European countries. Patients with metastatic receptor positive breast adenocarcinoma receiving first line chemotherapy with weekly paclitaxel and with measurable disease according to RECIST 1.1 are enrolled. Patient eligible to Her2/neu targeted therapy are excluded from the trial. In the first treatment phase, paclitaxel (80 mg/m^2 IV at D1, D8, D15 plus efti (30 mg) or placebo at D2, D16 (i.e. injected SC the day after paclitaxel, every two weeks) will be administered for 6 cycles (1 cycle = 4 weeks). This is followed by a maintenance phase in which stable or responding patients will receive efti or placebo for up to additional 52 weeks (12 injections). The primary endpoint is progression-free survival. Secondary endpoints include overall survival, tumor response according to RECIST 1.1., time to and duration of response, duration of stable disease and quality of life. Clinical trial information: NCT02614833.

TPS1110 Poster Session (Board #186a), Sat, 8:00 AM-11:30 AM

Phase II study of a combination therapy of nivolumab, bevacizumab and paclitaxel in patients with HER2-negative metastatic breast cancer as a first-line treatment (WJOG9917B, NEWBEAT trial). *First Author: Yukinori Ozaki, Toranomon Hospital, Tokyo, Japan*

Background: In recent years, an immune checkpoint inhibitor, anti-PD-1 antibody, has been developed for various cancer types including breast cancer. The synergic effect of combination of nivolumab, paclitaxel and bevacizumab has been anticipated based on various preclinical data. Therefore, we initiated this investigator-initiated trial to evaluate the efficacy and safety of nivolumab + paclitaxel + bevacizumab therapy as a first-line treatment in patients with metastatic or recurrent HER2-negative breast cancer. **Methods:** This is a Phase II, multi-center, single-arm study to evaluate the efficacy and safety of nivolumab + paclitaxel + bevacizumab combination therapy as a first-line treatment for HER2-negative advanced metastatic or inoperable recurrent breast cancer. Patients will receive nivolumab 240 mg/body on day 1, 15, paclitaxel 90 mg/m^2 on day1, 8, 15, and bevacizumab 10 mg/kg on day1, 15 every 4 weeks until the protocol treatment is determined to be ineffective or may not be continued. The primary endpoint is the objective response rate (ORR) and key secondary endpoints include progression free survival, overall survival, and the toxicity of the protocol treatment. The threshold and expected ORR are 55% and 70%, respectively, and 47 patients are needed to ensure a statistical power of 80% (α = 0.10). A total of 51 patients will be enrolled and duration of enrollment will be one year. Tumor tissue will be evaluated for the amount and phenotypes of TILs, PD-L1 expression, and gene expression analysis. Peripheral blood will be evaluated for immune status and cytokine profiling. This trial opened to accrual in February 2018. Clinical trial information: UMIN000030242.

TPS1111 Poster Session (Board #186b), Sat, 8:00 AM-11:30 AM

ATTAIN: Phase 3 study of etirinotecan pegol (EP) vs. treatment of physician's choice (TPC) in patients (pts) with metastatic breast cancer (MBC) who have stable brain metastases (BM) previously treated with an anthracycline, a taxane, and capecitabine (ATC). *First Author: Debu Tripathy, Department of Breast Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: EP is a next-generation topoisomerase I inhibitor-polymer conjugate that provides continuous exposure to SN-38, the active metabolite. A BM mouse model showed high penetration and retention of SN-38 in CNS lesions, resulting in decreased size of CNS lesions and improved survival at concentrations achieved at the recommended dose in pts (Adkins BMC Cancer 2015). Although a phase 3 trial (BEACON) of EP vs TPC in 852 pts with advanced BC did not meet its primary endpoint of overall survival (OS) (HR 0.087; P = 0.08), a subset of 67 pts with stable BM showed improved OS (HR 0.51 [95% CI 0.30-0.86]; $P < 0.01$) (Perez Lancet Oncol 2015). The current phase 3 trial (ATTAIN) was designed for this subpopulation of pts having high unmet medical need. **Methods:** Pts with MBC with locally treated stable BM will be randomized 1:1 to EP or TPC in an open-label phase 3 study. Eligibility includes: ECOG PS 0 or 1; adequate organ function; prior ATC therapy (neo/adjuvant or locally advanced/MBC setting); $\geq$1 prior cytotoxic regimen for pts with triple negative MBC; $\geq$2 prior cytotoxic regimens for pts with HR+ or HER2+ BC (pts with HR+/HER2+ BC must have received prior hormone therapy/HER2 targeted therapy); prior definitive local therapy of BM (whole brain radiation [RT], stereotactic RT or surgical resection as single-agent or combination); and stable signs/symptoms of BM with steroids (ie, unchanged or decreasing $\geq$7 days prior to randomization). Primary endpoint is OS. Key secondary endpoints are ORR and PFS by RECIST v1.1 and RANO-BM, clinical benefit rate (ORR+SD $\geq$ 6 months) and QoL. Pts randomized to TPC will receive 1 of 7 cytotoxic IV agents. Pts are stratified by region, PS and receptor status. 350 pts will be randomized to obtain the number of events required at 90% power to detect a statistically significant improvement in OS (hypothesizing HR = 0.67); 1 interim analysis is planned at 50% of deaths (130 events). PK sampling and UGT1A1 testing will be performed in the EP arm; plasma ctDNA will be assessed for potential predictive markers of efficacy. Enrollment began early 2017. Clinical trial information: NCT02915744.

TPS1112 Poster Session (Board #187a), Sat, 8:00 AM-11:30 AM

An open-label, phase II study of rucaparib, a PARP inhibitor, in HER2- metastatic breast cancer patients with high genomic loss of heterozygosity. *First Author: Anne Patsouris, Institute of West Cancerology Paul Papin, Angers, France*

Background: Rucaparib, a potent oral PARP-1, -2 and -3 inhibitor, has shown activity in a phase 3 study in patients (pts) with ovarian carcinoma (ARIEL 3) harbouring a *BRCA* mutation or an homologous recombination deficient (HRD) profile defined by high percentage of genome-wide loss of heterozygosity and in a phase 1 study that included breast cancer pts with germline *BRCA* mutation (Kristeleit *et al*, *Clin Can Res*, 2017). High genomic LOH score identified HRD tumors (also known as BRCAness tumors), including both known *BRCA1* methylation and unknown genetic/epigenetic mechanisms and somatic *BRCA1/2* mutations. This single arm, open-label, multicenter phase II RUBY study (NCT02505048) is evaluating the efficacy and safety of rucaparib in pts with HER2- metastatic breast cancer (MBC) associated with a "high tumor genomic LOH" score and/or a somatic *BRCA* mutation (excluding *BRCA1* and/or *BRCA2* germline mutation). **Methods:** Women with HER2- MBC with a HRD phenotype who received at least 1 prior chemotherapy regimens are eligible. ECOG PS 0-1 and adequate organ function is required. HRD phenotype is defined by a "high tumor genomic LOH" score, generated from the CytoScan HD SNP array, which is available from the SAFIR02 (NCT02299999) or SAFIR-TOR (NCT02444390) protocols. Pts received oral rucaparib 600 mg BID continuously in 21-day cycles until disease progression. The primary endpoint is clinical benefit rate (CBR), defined by complete and partial response and stable disease lasting for at least 16 weeks. If CBR is significant the objective response rate (ORR) will be considered as well. Secondary endpoints include progression-free survival, overall survival, safety, and the prognostic value of the HRD signature. This trial design is intended to establish proof-of-concept that rucaparib can improve ORR in HER2- MBC with HRD. Targeted enrollment is 41 pts using a Simon two-stage design, 19 pts in the first step and 22 pts in the second one. The prespecified goal of the first step was achieved; enrollment into the second step is ongoing. Clinical trial information: NCT02505048.

TPS1113 Poster Session (Board #187b), Sat, 8:00 AM-11:30 AM

A randomized phase II study of pembrolizumab, an anti-PD (programmed cell death) 1 antibody, in combination with carboplatin compared to carboplatin alone in breast cancer patients with chest wall disease, with immunologic and genomic correlative studies. *First Author: Neelima Vidula, UC San Francisco, San Francisco, CA*

Background: Chest wall disease from breast cancer has limited treatments. Given the inflammatory nature of this disease and the increased expression of PD-1 seen with lymphocytic infiltration, we hypothesize that pembrolizumab may be effective. Combining immunotherapy with platinum chemotherapy may facilitate anti-tumor immunity, as demonstrated in lung cancer. This study is evaluating the combination of pembrolizumab and carboplatin in breast cancer patients with chest wall disease. **Methods:** This is a randomized phase II multicenter trial in the Translational Breast Cancer Research Consortium. Eighty-four patients with breast cancer (hormone resistant, triple negative, or refractory HER2+) with chest wall disease will be enrolled. Patients may have had prior surgery but prior radiation is not required, and patients may have distant metastases. Patients will be randomized 2:1 to treatment with pembrolizumab 200 mg IV and carboplatin AUC 5 every 3 weeks for at least 6 cycles followed by pembrolizumab 200 mg IV alone (n = 56, Arm A) or carboplatin AUC 5 every 3 weeks (n = 28, Arm B) until progression. Patients in Arm B may cross over to pembrolizumab 200 mg IV every 3 weeks (Arm Bx) on progression. After 18 patients are enrolled in Arm B, an interim analysis for futility will be performed, to allow for early closure if lack of efficacy. The primary objective is to determine the disease control rate in both arms at 18 weeks of treatment; the study is powered to detect a 20% difference between arms, with a hazard ratio of 0.52 (α = 0.10, β = 0.20). The secondary objectives are to determine toxicity, progression free survival, and response based on irRECIST and PD-L1 expression. Exploratory objectives, using tumor biopsy and peripheral blood testing before and after treatment, include correlations of response with biomarkers including tumor PD-L1 expression, tumor and peripheral blood immune composition, circulating tumor cells, circulating tumor DNA, soluble PD-L1 and tumor MYC expression. This study is open to accrual; the first patient was enrolled in 11/17. Clinical trial information: NCT03095352.

TPS1114 Poster Session (Board #188a), Sat, 8:00 AM-11:30 AM

A phase II clinical trial to analyze olaparib response in patients with *BRCA1* and/or *BRCA2* promoter methylation with advanced breast cancer (GEICAM/2015-06 COMETA-Breast study). *First Author: Juan De La Haba, Biomedical Research Institute Maimonides.Hospital UniversitarioReina Sofia,Universidad de Cordoba, Spain.Centro de Investigación Biomédica en Red de Oncología, CIBERONC-ISCIII. GEICAM, Spanish Breast Cancer Group, Spain, Cordoba, Spain*

Background: Identification of targeted therapies for advanced triple negative breast cancer (TNBC) remains as an important clinical challenge. TNBC frequently shows BRCA dysfunction and 80% of germline *BRCA1* mutation (g*BRCA*m) carriers with BC diagnosis are TNBC patients (pts). In addition to germline mutations, epigenetic silencing by aberrant methylation of *BRCA1/2* promoters can be responsible for a dysfunctional BRCA protein. Methylation of *BRCA1* promoter occurs in 15-57% of TNBCs. Interestingly, *BRCA1*-methylated sporadic breast tumors display pathologic features and gene expression profiles similar to those of g*BRCA*m carriers, a phenotype called "*BRCA*ness". Olaparib (O) is an oral poly (ADP-ribose) polymerase (PARP) inhibitor approved by the FDA for treatment of g*BRCA*-mutated HER2-negative metastatic BC. Tutt et al. have shown antitumor activity in g*BRCA*-mutated advanced TNBC (54% Objective Response Rate [ORR]). We report an ongoing phase II clinical trial to analyze the O efficacy in advanced TNBC pts with *BRCA1/2* promoter methylation (NCT03205761). **Methods:** Eligible pts are advanced TNBC cases with $\geq$ 1 prior treatment for advanced disease, without germline *BRCA1*/2 mutations and centrally confirmed somatic *BRCA1/2* promoter methylation in metastatic lesions. Pts receive O 300 mg b.i.d. orally. Primary objective is to analyze O efficacy in terms of ORR according to RECIST 1.1 by investigator assessment. Secondary objectives include safety, other efficacy endpoints, and biomarker analyses. Sequential tumor and blood samples are collected to a) explore changes in methylation status, b) correlate *BRCA*-methylation status both in blood vs. tumor and in primary vs. metastatic counterpart lesions, and c) correlate methylation status with *BRCA1/2* expression and outcome. Thirty-four evaluable pts are required based on an optimal two-stage Simon model (α error = 0.05, power = 80%, dropout rate = 10%). Recruitment started in October 2017, with 17 pts screened for methylation status, 3 pts enrolled by 31th January 2018, and 14 active sites out of 16 participants. Primary endpoint analysis is planned for Q2 2020. Clinical trial information: NCT03205761.

TPS1115 Poster Session (Board #188b), Sat, 8:00 AM-11:30 AM

IMpassion132: A double-blind randomized phase 3 trial evaluating chemotherapy (CT) $\pm$ atezolizumab (atezo) for early progressing locally advanced/metastatic triple-negative breast cancer (mTNBC). *First Author: Rebecca Dent, National Cancer Center, Singapore, Singapore*

Background: Atezo blocks the interaction of PD-L1 with receptors PD-1 and B7.1, restoring anti-tumor immunity. PD-L1 pathway inhibitors may be synergistic with CT. In a phase 1b study in mTNBC, atezo + nab-paclitaxel showed durable confirmed responses [Adams 2016]. The IMpassion130 and 131 randomized phase 3 trials are evaluating atezo combined with nab-paclitaxel and paclitaxel, respectively, as 1st-line therapy for mTNBC. Both exclude patients (pts) with disease progression (PD) within 12 mo of CT for early breast cancer (eBC). IMpassion132 (NCT03371017) compares atezo + CT vs placebo + CT in pts with PD $\leq$12 months after completing CT for eBC, and combines atezo with 2 commonly used non-taxane CT regimens. **Methods:** In this multinational placebo-controlled randomized phase 3 trial, pts with recurrent (inoperable locally advanced/metastatic) TNBC treated with standard (neo)adjuvant anthracycline and taxane CT and relapsing $\leq$12 months after the last treatment with curative intent for eBC are eligible if they have received no prior CT for advanced/metastatic TNBC. PD-L1 status (for stratification) and TNBC status are confirmed centrally before randomization. Investigators select CT (gemcitabine 1000 mg/m^2 + carboplatin AUC 2, d1 & 8 q21d [GC] or capecitabine 1000 mg/m^2 bid d1–14 q21d [X]) before randomization. All pts with prior platinum for eBC must receive X. At least 30% of ~350 planned pts will receive X. Stratification factors are: visceral (lung and/or liver) metastases (yes vs no); tumor PD-L1 status (IC 0 vs 1/2/3); and selected CT (GC vs X). Pts are randomized to either atezo or placebo 1200 mg q21d with the chosen CT, continued until PD, unacceptable toxicity or pt/physician decision. Tumors are assessed q8w for the 1st year and q12w thereafter until PD. The primary endpoint is overall survival (OS). Secondary endpoints include 12- and 18-mo OS rates, progression-free survival, objective response rate (RECIST v1.1), duration of response, clinical benefit rate, pt-reported outcomes (PROs; EORTC QLQ-C30) and safety. Exploratory endpoints include further PROs, pharmacokinetics and translational research. Clinical trial information: NCT03371017.

TPS1116 Poster Session (Board #189a), Sat, 8:00 AM-11:30 AM

VIOLETTE: A randomized phase II study to assess DNA damage response inhibitors in combination with olaparib (Ola) vs Ola monotherapy in patients (pts) with metastatic, triple-negative breast cancer (TNBC) stratified by alterations in homologous recombination repair (HRR)-related genes. *First Author: Andrew Tutt, Breast Cancer Now Toby Robins Research Centre The Institute of Cancer Research, and Breast Cancer Now Research Unit, King's College London Division of Cancer Studies, King's Health Partners Academic Health Sciences Centre, London, United Kingdom*

Background: Invasive BC is diagnosed in > 255,000 pts in the US annually, and TNBC comprises ≈15% of cases. Alterations in *BRCA1/2* are associated with ≈5% of all BCs. Ola (a poly ADP-ribose polymerase inhibitor [PARPi]) is approved in the US for treating pts with HER2-negative metastatic BC with germline *BRCA* mutation (g*BRCA*m). Pts treated with Ola had significant and clinically meaningful improvements in progression-free survival (PFS) vs pts treated with "physician's choice" of chemotherapy. Similarly, alterations in other non-*BRCA1/2* HRR genes (non-*BRCA* HRRm) may confer sensitivity to Ola therapy in pts with TNBC. Ola, AZD1775 (a WEE1 checkpoint inhibitor) and AZD6738 (an ataxia telangiectasia and Rad3-related protein inhibitor) target DNA damage repair and cell cycle regulation. Both Ola + AZD1775 and Ola + AZD6738 had synergistic antitumor effects vs Ola monotherapy in preclinical studies, supporting the clinical evaluation of these combinations vs Ola monotherapy in pts with TNBC. **Methods:** In this global, multicenter, open-label, phase II study (NCT03330847), 450 pts with advanced TNBC will be randomized (1:1:1) to 3 treatment arms 1) Ola 200 mg bid + AZD1775 175 mg bid, 2) Ola 300 mg bid + AZD6738 160 mg qd, or 3) Ola 300 mg bid. All pts will undergo centralized tumor molecular testing to detect mutation(s) in 15 HRR genes and ≈150 pts will be assigned to each of the 3 biomarker strata (A: *BRCA*m; B: non-*BRCA* HRRm; C: non-HRRm). All pts will be stratified by prior platinum exposure. Eligible pts will have received ≤2 prior lines of chemotherapy for metastatic disease, including an anthracycline or taxane. Exclusion criteria include prior PARPi therapy. The primary endpoint is PFS (each combination vs Ola alone) analyzed by blinded, independent central review (RECIST v1.1). Secondary endpoints are objective response rate, duration of response, change in tumor size, and overall survival for comparisons between combinations and for each combination vs Ola alone; drug exposure; and safety and tolerability. Enrollment is ongoing. Clinical trial information: NCT03330847.

TPS1117 Poster Session (Board #189b), Sat, 8:00 AM-11:30 AM

IPATunity130: A pivotal randomized phase III trial evaluating ipatasertib (IPAT) + paclitaxel (PAC) for *PIK3CA/AKT1/PTEN*-altered advanced triple-negative (TN) or hormone receptor-positive HER2-negative (HR+/HER2–) breast cancer (BC). *First Author: Rebecca Dent, National Cancer Center, Singapore, Singapore*

Background: In the LOTUS trial in advanced TNBC, adding IPAT to first-line PAC improved progression-free survival (PFS; primary endpoint), particularly in patients (pts) with *PIK3CA/AKT1/PTEN*-altered tumors [Kim, Lancet Oncol 2017]. The pivotal double-blind placebo (PBO)-controlled randomized phase III IPATunity130 trial (NCT03337724) aims to confirm and build on findings from LOTUS. **Methods:** Eligible pts have ECOG performance status 0/1 and RECIST-measurable locally advanced/metastatic BC not amenable to resection with curative intent. Pts are allocated to either cohort A (TNBC; n≈249) or cohort B (HR+/HER2– not suitable for endocrine therapy; n≈201) according to their most recent locally assessed receptor status (in recurrent/metastatic tumor if available). In cohort A, any prior systemic therapy for advanced TNBC is prohibited, whereas cohort B pts may have received prior systemic therapy except chemotherapy for advanced BC. Tumor *PIK3CA/AKT1/PTEN* eligibility is tested centrally by next-generation sequencing (Foundation Medicine). Stratification factors are prior (neo) adjuvant chemotherapy, geographic region, and either tumor *PIK3CA/AKT1*-activating mutation status (cohort A) or prior PI3K/mTOR inhibitor therapy (cohort B). Pts in both cohorts are randomized 2:1 to 28-day cycles of PAC 80 mg/m^2 (d1, 8, & 15) combined with either oral IPAT 400 mg/day (d1–21) or PBO until disease progression, intolerable toxicity, or withdrawal. Crossover to IPAT after progression on PAC + PBO is prohibited. The primary endpoint is investigator-assessed PFS by RECIST v1.1. Secondary endpoints include overall survival (key secondary), objective response rate (RECIST v1.1), duration of response, clinical benefit rate, EORTC QLQ-C30 global health status/health-related quality of life, and safety. Cohorts A and B will be analyzed separately. For each cohort, PFS will be compared between treatment arms using a stratified log-rank test. The trial is actively accruing pts. Clinical trial information: NCT03337724.

TPS1118 Poster Session (Board #190a), Sat, 8:00 AM-11:30 AM

A randomized phase II trial of carboplatin with or without nivolumab in first- or second-line metastatic TNBC. *First Author: Ana Christina Garrido-Castro, Dana-Farber Cancer Institute, Boston, MA*

Background: Triple negative breast cancer (TNBC) has an aggressive clinical course with higher relapse rates and shorter overall survival compared to patients with hormone receptor-positive or HER2-positive disease. Increasing data suggest that interaction with the immune system is critical for outcomes in TNBC. Tumor infiltrating lymphocytes (TIL) correlate with improved prognosis and response to several PD-1/-L1 inhibitors. However, response rates with single agent checkpoint inhibitors reach only ≈ 25% in first-line TNBC. Platinum agents are DNA crosslinkers that cause accumulation of genotoxic stress, which stimulates immune activation via IFN-γ signaling. In preclinical models, platinum has been shown to generate CD8-driven anti-tumor immune response, making the combination with nivolumab (PD-1 antibody) an attractive strategy to enhance the benefit of either agent alone. **Methods:** This Phase II open-label, multicenter trial will enroll 132 patients with metastatic TNBC randomized 1:1 to receive carboplatin (AUC 6) with or without nivolumab (360 mg) IV every 3 weeks. Eligible patients must have unresectable locally advanced or metastatic TNBC treated with 0 to 1 prior line of chemotherapy in the metastatic setting. Prior platinum exposure is allowed in the neo/adjuvant setting if ≥12 months elapsed since the end of adjuvant therapy to the development of metastatic disease. The primary objective is to compare the efficacy, defined as progression-free survival (PFS) per RECIST 1.1, of carboplatin in combination with nivolumab versus carboplatin alone. Key secondary objectives include objective response rate, overall survival, clinical benefit rate, and duration and time to objective response. Patients must be willing to undergo mandatory paired research biopsies, one at baseline and one after 2 cycles of therapy, if safely accessible, to assess the correlation between TIL and PFS, and to explore pharmacodynamic changes in TIL and other biomarkers of response and resistance to treatment. Additional correlative studies, including analyses of circulating tumor DNA, peripheral blood mononuclear cells and intestinal microbiome, are planned. Clinical trial information: NCT03414684.

TPS1119 Poster Session (Board #190b), Sat, 8:00 AM-11:30 AM

A phase II study of nivolumab in combination with cabozantinib for metastatic triple-negative breast cancer (mTNBC). *First Author: Romualdo Barroso-Sousa, Dana-Farber Cancer Institute, Boston, MA*

Background: Patients with mTNBC have a poor prognosis, and new therapies are needed. Vascular endothelial growth factor (VEGF)-A and myeloid-derived suppressors cells (MDSCs) have been recognized as critical players of tumor immune suppression of T-cell mediated responses. We hypothesize that cabozantinib, a multikinase inhibitor that blocks the VEGF receptor 2, and reduces MDSCs while increasing the number of T cells, will enhance the activity of the anti-PD-1 checkpoint blocker nivolumab in mTNBC. **Methods:** This is a phase II, single arm, single-center study assessing the efficacy of nivolumab (480 mg intravenously on day 1, every 28 days) plus cabozantinib (40 mg daily by mouth) in patients with mTNBC (NCT03316586). Eligibility Criteria include patients with mTNBC, or estrogen and progesterone receptor low positive (< 10%) breast cancer, with measurable disease, and who have received 0-3 prior lines of chemotherapy in the advanced setting. The primary aim is to evaluate the efficacy of the combination, as defined by ORR according to RECIST 1.1. Secondary objectives include to determine the ORR according to immune-related criteria, the progression-free survival, the clinical benefit rate, the safety and the tolerability of the combination. Tumor biopsies and peripheral blood will be obtained at baseline, on treatment and at disease progression for immunoprofiling and to examine biomarkers of treatment response. Using the Simons "optimal" method, in the first stage, 18 patients will be enrolled. If there are least 3 responses, accrual will continue to the second stage where up to 17 additional patients will be enrolled. If at least 7 of these 35 patients have an objective response the regimen will be considered worthy of further study. With this design, if the true response rate is 10%, the chance the regimen is declared worthy of further study is less than 5% (exact alpha = 0.047). If the true response rate is 30%, the chance that the regimen is declared worthy of further study is 90%. The trial opened in December 2017 and has accrued 5 patients with a target accrual of 35 patients. Accrual should be completed in 12 months. Clinical trial information: 03316586.

1500 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Low-fat dietary pattern and all cancer mortality in the Women's Health Initiative (WHI) randomized trial. *First Author: Rowan T. Chlebowski, City of Hope National Medical Center, Duarte, CA*

Background: In the Women's Health Initiative randomized (WHI) Dietary Modification (DM) primary prevention trial, after 16.1 years median follow-up, implementation of a low-fat dietary pattern significantly reduced deaths after breast cancer. Mortality from other cancer sites has not been reported. **Methods:** To determine low-fat dietary pattern influence on deaths from and after breast cancer and other cancers during 8.5 years (median) dietary intervention and now with 17.1 years (median) cumulative follow-up, 48,835 postmenopausal women with no prior cancer, aged 50-79, were randomized at 40 US clinical centers from 1993-1998 to dietary intervention (DM-I) (40%, n = 19,541) to reduce fat intake to 20% of energy and increase fruits, vegetables and grains intake, or usual diet comparison (DM-C) (60%, n = 29,294). DM-I influence on breast, colorectal, endometrium and ovarian cancers alone and as a composite were prospectively determined primary analyses. **Results:** During dietary intervention, deaths after breast cancer was the only statistically significant cancer mortality finding. During cumulative follow-up with 3,867 deaths after all cancers, significant reduction in deaths after breast cancer continued in the DM-I group (HR 0.85 95% CI 0.74-0.99, P = 0.03) especially in subgroup with waist circumference > = 88 cm (HR 0.78 95% CI 0.64-0.95). Deaths after pancreatic cancer were somewhat lower in the DM-I group (HR 0.89 95% CI 0.70 -1.13, not significant). In addition, in no other cancer or cancer composite group was a dietary intervention effect on death from or after cancer seen (see table). **Conclusions:** Adoption of a low-fat dietary pattern led to a lower incidence of deaths after breast cancer. No reduction in mortality from other cancer sites was seen. Clinical trial information: NCT00000611.

Deaths from cause after cancer	DM-I*	DM-C*	HR (95% CI)	P-value
Primary analysis				
Deaths after breast cancer	280(0.098)	507(0.12)	0.85(0.74,0.99)	0.03
Death after colorectal cancer	164 (0.057)	228(0.052)	1.10(0.90,1.35)	0.34
Death after ovarian cancer	92(0.032)	143(0.033)	0.98(0.75,1.27)	0.87
Death after endometrial cancer	69(0.042)	98(0.039)	1.07(0.79,1.46)	0.66

1501 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Pre- and post-treatment body weight and prognosis in a multiethnic cohort of breast cancer patients. *First Author: Lihua Shang, University of Chicago, Chicago, IL*

Background: Although pre-diagnosis obesity was found to be associated with worse outcomes in breast cancer patients, few studies have been conducted on weight change after diagnosis. African Americans have higher prevalence of obesity than other racial/ethnic populations, but it is unclear if obesity prevalence could explain mortality disparity between African Americans and whites. **Methods:** Data on body mass index (BMI) prior to, during, or after treatment were available in 3061 breast cancer patients enrolled in the Chicago Multiethnic Epidemiologic Breast Cancer Cohort (ChiMEC), including 1662 whites, 1183 African Americans and 216 other ethnicities. Multilevel random effects models were used to examine changes in body weight or BMI over time. Cox models were used to investigate the impacts of BMI on overall survival and disease-free survival. **Results:** At diagnosis, half of African Americans (51.5%) were obese, compared with 27.0% in whites. After 6 months, 1 year, 2 years, and 4 years from diagnosis, African Americans on average have lost 0.73 kg, 1.05 kg, 1.29 kg, and 2.47 kg, respectively ($P < 0.0001$), while there were only small weight changes in whites (< 0.31 kg). The impact of pre-treatment BMI on survival was stronger for estrogen receptor (ER) positive patients (hazard ratio [HR] 1.20 per 5 kg/m^2, 95% confidence interval [CI]: 1.06-1.36; p = 0.005) than for ER negative patients (HR 1.06 per 5 kg/m^2, 95% CI: 0.90-1.24; p = 0.52). African Americans had a 90% higher mortality risk relative to white patients after adjusting for age, stage and other clinical factors (HR 1.90, 95% CI: 1.41-2.55). Further adjusting for BMI at diagnosis, the HR for African Americans changed to 1.81 (95% CI: 1.34-2.43). In the landmark analysis of patients who were followed > 2 years, the multivariable HR for African Americans was 1.64 (95% CI: 1.05-2.58) without adjusting for post-treatment BMI and 1.55 (95% CI: 0.97-2.48) after adjusting for post-treatment BMI. Similar results were observed in the analysis of disease-free survival. **Conclusions:** African American patients had higher obesity prevalence but had substantial weight loss during and after treatment. The impact of BMI on survival differs by ER status.

1502 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Cardiorespiratory fitness and incident lung and colon cancer: FIT-Cancer Cohort. *First Author: Catherine Handy, Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD*

Background: Cardiorespiratory fitness (CRF), an objective measure of exercise tolerance, is a strong predictor of cardiovascular disease and mortality yet its relationship with cancer incidence is unclear. The goal of this analysis was to assess the relationship between CRF and lung and colon cancer in a large, multi-ethnic clinical cohort. **Methods:** From The FIT Project, a retrospective cohort of 69,885 consecutive patients who underwent physician referred treadmill testing using the Bruce protocol in the Henry Ford Health System (HFHS) between 1991 and 2009, we created the FIT-Cancer Cohort by linkage with the HFHS Tumor Registry. We included patients aged 40-70 years who were cancer free at baseline. Multivariable adjusted Cox proportional hazard models were used to evaluate the association between CRF (measured in peak metabolic equivalents [METs]) and incident lung and colon cancer. **Results:** 49,143 individuals (46% women, 64% White), with a mean age of 54 years, were included. During a median follow up of 8.3 years (IQR 7.1 years), there were 388 and 238 incident lung and colon cancers. Compared to those with the lowest level of CRF, individuals in the highest CRF category had a 77% (CI: 63-85%) decreased risk of developing lung cancer and a 60% (CI: 33-75%) decreased risk of colon cancer in multivariable adjusted models. There was a significant, inverse METs-incident cancer dose response relationship (Table 1, p trend for lung and colon < 0.01). Subgroup analyses in smokers, by sex and race showed similar results. **Conclusions:** In the largest study of its kind, CRF measured during exercise testing is a strong predictor of future lung and colon cancer risk. Our study provides another important reason for optimizing CRF.

Adjusted risk of incident lung and colon cancer, per category of CRF.

1503 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Inherited mutations in breast cancer patients with and without multiple primary cancers. *First Author: Kara Noelle Maxwell, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA*

Background: Women with breast cancer have a 5-12% lifetime risk of a second primary cancer. Whether mutations in genes other than *BRCA1/2* are enriched in patients with breast and another primary cancer (MP-BC) over those with a single breast cancer (S-BC) is unknown. **Methods:** We identified pathogenic germline mutations in cancer susceptibility genes in *BRCA1/2* negative patients in two differently ascertained cohorts: Cohort #1, high risk breast cancer program (MP-BC, n = 551 vs S-BC, n = 464) and Cohort #2, familial breast cancer research study (MP-BC, n = 340 vs S-BC, n = 1464). Mutation rates in patients of European descent were compared to ExAC. **Results:** Overall pathogenic mutation rates for cancer panel testing genes were two-fold higher in patients with MP-BC versus S-BC in both cohorts (8.7% vs 4.1%, p = 0.003 and 8.2% vs 4.2%, p = 0.003, respectively). However, there were differences in individual gene mutation rates between cohorts (Table). In comparison to a race and ethnicity matched control group, mutations in *TP53* and *MSH6* were statistically significantly enriched in MP-BC but not S-BC patients. Mutations in *ATM*, *CHEK2* and *PALB2* were statistically significantly enriched in both MP-BC and S-BC patients relative to controls. **Conclusions:** These data demonstrate that mutations in high risk genes are typically found in patients with multiple primary cancers; whereas rates of moderate penetrance gene mutations are similar. Patients with multiple primary cancers should be offered multiplex panel testing.

Mutation rates in MP-BC vs S-BC patients in two cohorts.

1504 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Frequency of actionable cancer predisposing germline mutations in patients with lung cancers. *First Author: Semanti Mukherjee, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Most of the heritability for lung cancer, estimated at 18% in population studies, remains unexplained. Utilizing a tumor-normal screening, we determined the prevalence of clinically actionable germline cancer-susceptibility mutations in patients with lung cancer, and correlated findings with clinical, tumor associated, and family history characteristics **Methods:** Tumor/normal samples from lung cancer patients (pts) enrolled from 1/14 until 5/16 underwent sequencing analysis for 468 genes by MSK IMPACT [PMID: 28481359], with pathogenicity assessment for 76 cancer predisposition genes by ACMG guidelines. Selected patients with a strong family history of cancer, multiple primary tumors, or early age of diagnosis (≤50) were offered return of germline findings. As per IRB protocol, germline results were anonymized for all cases except those consenting to return of results. Frequencies of pathogenic/likely pathogenic (P/LP) germline mutations were compared to population databases. **Results:** 1118 pts consented to tumor-normal sequencing and 42 to return of germline findings; the median age of the two groups was 68 and 59 , respectively ($p < 0.05$). For the 42 pts receiving germline findings, 24% had early onset and 52% multiple cancer diagnosis, and 31% had P/LP mutations in 10 genes (3 *BRCA2*, 2 *MEN1*, 1 *APC*, 1 *ATM*, 1 *BAP1*, 1 *BLM*, 1 *CHEK2*, 1 *FH*, 1 *FLCN*, 1 *RAD51D*). Among 1118 pts, 8% had P/LP mutations in 16 genes (20 *APC*, 15 *CHEK2*, 13 *MUTYH*, 7 *BRCA2*, 6 *BRCA1*, 5 *FH*, 4 *ATM*, 4 FANCC, 4 *RECQL4*, 3 *FANCA*, 3 *TP53*, 2 *RAD50*, 2 *RAD51C*, 1 *BRIP1*, 1 *NBN*, 1 *PMS2*). 45% of the P/LP mutations of *CHEK2, APC, MUTYH, BRCA1* were population "founder" mutations. There was no statistically significant increase in burden of these pathogenic variants in the lung cancer cases studied. The 31% prevalence of germline variants in pts enriched for family history of cancer was greater than the 8% prevalence in patients unselected for family history ($p < 0.0002$). **Conclusions:** Our preliminary findings demonstrate an increased prevalence of clinically actionable germline mutations in patients with lung cancer with either a family history of other cancers, early age at onset, or multiple cancer diagnosis, compared to unselected lung cancer patients.

1505 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Pathogenic somatic mutation (SM) of mismatch repair (MMR) genes and associations with microsatellite instability (MSI), tumor mutational burden (TMB) and SM in other DNA repair pathways in 24,223 tumor genomic profiles. *First Author: Joseph Nicholas Bodor, Fox Chase Cancer Center, Philadelphia, PA*

Background: SM disabling DNA repair mechanisms is common in cancer. SM in MMR genes (MLH1, MSH2, MSH6, PMS2) contribute to MMR deficiency and the MSI phenotype. Biallelic SM (bSM) of an MMR gene can cause MMR deficiency in colorectal (CRC) and endometrial cancers (EC), but the frequency of monoallelic SM (mSM) and bSM of MMR genes in other tumors is unknown. Clinical/molecular correlates of MMR gene mSM/bSM are not well described. **Methods:** The Caris Life Sciences database was queried for tumors with ≥1 SM of an MMR gene by NGS (Illumina NextSeq 592 gene panel). Association of mSM or bSM with clinical factors, MSI, TMB, and SM in non-MMR DNA repair pathways was examined. Associations were tested by Fisher's exact test and logistic regression. **Results:** Of 24,223 tumors queried, 470 had ≥1 SM, of which 80 had bSM in an MMR gene. MSH6 had the highest frequency of bSM (n = 46) primarily due to recurrent SM at F1088fs, a coding microsatellite. Tumors with bSM were more common in younger pts, median age 57.5 yrs bSM vs. 63 yrs mSM ($p = 0.003$). bSM was associated with high TMB ($p < 0.001$), and with SM in nucleotide excision repair (NER) genes ($p = 0.003$), and homologous recombination (HR) genes ($p = 0.01$), e.g. ATM (62/470, 13.2%) and BRCA1/2 (n = 91/470, 19.4%). At the single gene level, mSM in MSH2 ($p = 0.001$) and MSH6 ($p = 0.01$) were positively associated with TMB, but inversely with PMS2 ($p < 0.001$). MSI was only associated with mSM in MLH1 ($p < 0.001$). Further, SMs in HR genes were associated with mSM in MLH1, MSH2, and MSH6 (all $p < 0.01$), but SM in NER were associated only with mSM in MSH6 ($p = 0.004$). By tumor type, mSM were common in EC (n = 84), CRC (n = 80) and lung (n = 45), but nearly all bSM (98%) were in LS-spectrum tumors. Differences in bSM frequency in left vs. right CRC (30.0% vs 12.5%) were not seen ($p = 0.10$). **Conclusions:** MMR gene mSM occur in diverse tumors, but bSM occur almost exclusively in LS-spectrum tumors. Younger age suggests germ-line mutations may precede some bSM events. Association of MMR mSM/bSM to high TMB, MSI, and SM in other DNA repair pathways suggests cascade effects of DNA repair deficiency and reveals possible treatment targets.

1506 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

A breast cancer risk model as a predictor of interval cancer rate and tumor characteristics. *First Author: Nickolas Dreher, University of California, San Francisco, San Francisco, CA*

Background: The Breast Cancer Surveillance Consortium (BCSC) Risk Calculator is a validated and widely used risk model that predicts five- and ten-year risk of developing invasive breast cancer for women age 40-75. However, little research has been conducted to determine if women with high BCSC risk are also more likely to develop any particular type of cancer. These women may be at elevated risk to develop interval cancers, those that present symptomatically following a normal screening mammogram and are often faster-growing. If this were the case, women with high BCSC risk (defined here as the top 2.5% by age) may merit increased screening frequency. **Methods:** We calculated BCSC 5-year risk scores for female breast cancer patients who completed an online intake survey distributed by the Athena Breast Health Network before being seen at the UCSF Breast Care Center, and whose BI-RADS density category was available. We reviewed charts of patients who were in the top 2.5% of risk for their age according to national averages estimated by the BCSC, and we compared them to an equal number of female breast cancer patients from the lower 97.5%. We then compared the proportion of interval, ER-negative, node-positive, and high-grade cancers between each group using a Chi-squared test (two-sided alpha = .05). **Results:** Of 5253 female breast cancer patients who completed an intake survey, 1880 had BI-RADS data available. 131 of these patients fell in the top 2.5% of breast cancer risk for their age. Compared to 131 breast cancer patients from the lower 97.5% of risk, more high-risk patients developed an interval cancer within one year of a normal screening mammogram, with preliminary rates of 24.1% vs 4.1% respectively ($p = 0.003$). There was no significant difference between the rates of ER-negative, node-positive, or high-grade cancers between the two groups. **Conclusions:** Breast cancer patients in the top 2.5% of breast cancer risk according to the BCSC model are more likely to develop interval cancers, which may warrant tailored screening strategies.

1507 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Validation of a combined residual risk score for healthy unaffected women presenting to breast cancer (BC) screening centers. *First Author: Kathryn Dalton, Cape Cod Healthcare, Mashpee, MA*

Background: Recent studies have identified single-nucleotide polymorphisms (SNPs) that individually confer modest risk but together explain genetic BC predisposition in many women testing negative for monogenic mutations. We have previously developed and validated an 86-SNP residual risk score (RRS) and a combined residual risk score (cRRS) that incorporates version 7.02 of the Tyrer-Cuzick (TC) model in large consecutive cohorts of women who tested negative for mutations in known BC predisposition genes during hereditary cancer testing. Here, we describe validation of the cRRS in a consecutive cohort of women enrolled from BC screening centers. **Methods:** This was a prospective, IRB-approved study conducted according to a case-control design. The primary objective was to demonstrate that cRRS offers significantly improved discriminatory accuracy compared to TC alone. A consecutive series of unaffected controls and recently diagnosed BC-affected cases of European ancestry who presented to screening centers were enrolled. Consented patients provided blood or saliva samples for SNP and multi-gene panel testing, and clinical information for the TC model. Discriminatory accuracy of cRRS and TC were evaluated with age-adjusted weighted logistic regression models. P-values were based on likelihood ratio chi-squared test-statistics, and reported as two-sided. **Results:** 518 patients (256 BC cases; 262 unaffected controls) who met study eligibility criteria were enrolled from 4 screening centers: Elizabeth Wende Breast Care (123); The Breast Center of NWA (145); Bethesda Health (113); CUDA/CCHC (137). Patients with mutations in BC genes were excluded from analysis. Both cRRS and TC significantly discriminated BC cases from unaffected controls in terms of remaining lifetime (cRRS $p < 10^{-11}$; TC $p < 10^{-5}$) and 5-year (cRRS $p < 10^{-10}$; TC $p < 10^{-4}$) risk estimates. The cRRS showed significantly improved discriminatory accuracy compared to TC alone (lifetime $p < 10^{-7}$; 5-year $p < 10^{-7}$). **Conclusions:** The cRRS offers superior risk stratification compared to TC alone, and may improve prevention and screening strategies for unaffected women testing negative for monogenic BC mutations. Clinical trial information: NCT03067389.

1508 Oral Abstract Session, Sun, 8:00 AM-11:00 AM

Polygenic risk score for breast cancer in high-risk women. *First Author: Mary Helen Black, Ambry Genetics, Aliso Viejo, CA*

Background: While assessment of genetic contribution to breast cancer (BC) risk was once limited to high-penetrance genes such as *BRCA1/2*, additional genes conferring two- to five-fold increased risks of BC, as well common SNPs with relative risks ranging 1.03-1.57, have recently been identified. Although several reports suggest that a score based on combined genotypes across a large number of SNPs may have substantial predictive value for risk stratification in the general population, few studies have examined the performance of such a score in high-risk women. **Methods:** We genotyped 102 BC-associated SNPs using next-generation sequencing in order to examine whether a risk score based on these SNPs was predictive of BC in 2,910 women (1,758 cases with no other cancer primaries and 1,152 controls unaffected with any cancer) referred for genetic testing at a single diagnostic laboratory. All women were self-reported Caucasian, 18-85 years of age and provided family history information at the time of testing, and tested negative for pathogenic variants in BC-related genes (mean$\pm$SD age at testing 52$\pm$13 years). We constructed a polygenic risk score (PRS), with each SNP weighted by per-allele relative risks in Caucasians from large genome-wide association studies and population-specific allele frequencies, and tested PRS association with BC using logistic regression. **Results:** The PRS was significantly higher in cases than controls (mean$\pm$SD 1.41$\pm$0.86 vs. 1.06$\pm$0.66, $p < 0.0001$). Compared to women in the 1st quartile of PRS, those in the 2nd, 3rd and 4th quartile were 1.65 (95% CI: 1.34-2.05), 2.12 (95% CI: 1.71-2.64) and 2.75 (95% CI: 2.20-3.44) times as likely to have BC (all $p < 0.0001$). PRS predictive performance was consistent with prior literature (AUROC = 0.61). **Conclusions:** These data suggest that a 102-SNP PRS assessed in high-risk patients performs similarly to risk scores reported in the broader population, and has direct implications for their clinical management. Our ongoing analysis of the ability of the PRS to discriminate among specific pathologic subtypes, as well as validity and utility of a PRS combined with clinical models to estimate residual lifetime risk, has the potential to further inform screening guidelines and improve patient care.

LBA1509 Clinical Science Symposium, Mon, 8:00 AM-9:30 AM

Pan-cancer microsatellite instability to predict for presence of Lynch syndrome. *First Author: Alicia Latham Schwark, Memorial Sloan Kettering Cancer Center, New York, NY*

The full, final text of this abstract will be available at abstracts.asco.org at 7:30 a.m. ET on Saturday, June 2, 2018, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2018, issue of the *Journal of Clinical Oncology*. On-site at the Meeting, this abstract will be printed in the Monday edition of *ASCO Daily News*.

1510 Clinical Science Symposium, Mon, 8:00 AM-9:30 AM

Disclosure of secondary germline findings from clinical tumor-normal paired somatic mutation profiling. *First Author: Molly S. Daniels, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Accurate identification of cancer somatic mutations is facilitated by tumor-normal subtractive analysis. Tumor-normal paired testing (TNPT) can also lead to significant secondary germline findings. We report the secondary germline outcomes from clinical TNPT of 4923 patients at a single institution. **Methods:** TNPT via the Oncomine platform was performed in-house when ordered by patients' clinicians. Potential secondary germline findings were flagged and sent to clinical cancer genetics (CCG) for review. Pathogenic germline mutations in high penetrance hereditary cancer genes were selected by database and literature review. Medical records were reviewed to determine whether standalone germline testing (SGT) had already identified the mutation. If not, CCG contacted the patient and offered confirmatory SGT via outside reference laboratory. **Results:** From January 2016 to January 2018, 62/4923 (1.3%) of TNPTs were flagged for CCG review. 41/62 (66%) mutations were selected for follow-up (see table). 16/28 (57%) of patients with previously unknown mutations returned for confirmatory SGT. In 28/29 (97%) cases where both TNPT and SGT results were available, they were concordant. The exception was an *MSH2* mutation found on TNPT but not on SGT; further analysis revealed that the TNPT result had been a low confidence call. **Conclusions:** Clinical TNPT identified germline mutations in 0.8% of tested patients, many of which were not already known to patients and/or occurred in cancers outside the typical spectrum for that gene. Effective communication between pathology and CCG facilitates classification of mutations as well as patient notification. Offering secondary germline findings from clinical TNPT to patients is feasible and affords families the opportunity to benefit from predictive genetic testing.

Gene	Mutation previously found on SGT (13)	Mutation newly identified on TNPT (28)
BRCA1	Ovary (4)	Sebaceous(1), ovary (1), lung (2), colon (1)
BRCA2	Breast (1), ovary (3), prostate (2), lung (1), pancreatic (1)	Ovary (1), colon (5), lung (4), prostate (3), glioma (1), ampullary (1)
TP53	0	Sarcoma (2), colon (1), thymoma (1), pancreatic (1)
EGFR T790M	0	Lung (1), colon (1)
MSH2	Ovary (1)	Kidney (1)

1511 Clinical Science Symposium, Mon, 8:00 AM-9:30 AM

Genetic counseling (GC) and germline (GL) testing rates after adoption of an integrated clinical cancer genetics (CCG) approach to genomics tumor board (GTB). *First Author: Stefan Klek, Cleveland Clinic, Cleveland, OH*

Background: The clinical impact of addressing potentially GL alterations (PGA) from somatic next-generation sequencing (NGS) is not well characterized. We hypothesize that the addition of screening for PGA by genetics professionals at GTB increases GL findings in those who underwent NGS. **Methods:** In a prospectively accrued cohort with tumor NGS via FoundationOne (F1), we quantified (1) patients with $\geq$1 GC visit, (2) whether GC occurred pre- or post-F1 testing, (3) GC referrals due to F1 reports, (4) which had GL testing, and (5) results of GL testing. We analyzed these variables across 4 sub-cohorts: patients whose F1 reports were presented at GTB (C1) before and (C2) after the addition of screening for PGA by genetics professionals at GTB. C2 was further subdivided: (C2A) after the addition of GL screening at GTB and (C2B) after the addition of GL screening at GTB plus a formal CCG workflow to coordinate post-GTB GC. P-values were determined using a 2-sample, one-tailed z-test. **Results:** 907 F1 reports were reviewed at GTB from 2013 to 2017 ($n_{C1} = 281$, $n_{C2} = 626$, $n_{C2A} = 493$, and $n_{C2B} = 133$). Overall, the number of GC visits showed an increasing trend from C1 to C2A (14.6 to 19.9%, $P = .066$) with significance from C1 to C2B (14.6 to 33.1%, $P = .0012$). Incidence of GC visits post-F1 rose from C1 to C2 (7.3 to 41.6%, $P < .0001$) with visits specifically due to F1 increasing from C1 to C2A (7.3 to 32.7%, $P < 0.0001$) and even more from C1 to C2B (7.3 to 40.9%, $P < 0.0001$). Incidence of GL testing showed an increasing trend from C1 to C2A (11.0 to 14.4%, $P = 0.091$) with significance from C1 to C2B (11.0 to 27.8%, $P < 0.0001$). Finally, the number of pts found positive for GL mutation showed an increasing trend from C1 to C2A (1.4% to 2.2%, $P = .22$) with significance from C1 to C2B (1.4% to 6.0%, $P = .0046$). **Conclusions:** Integrating CCG with somatic NGS testing review significantly increased not only GC utilization but also the discovery of positive GL results. Although this approach should not substitute for documentation of a detailed family history, positive GL findings can be a direct consequence of somatic NGS and should be considered an independent clinical benefit of somatic NGS testing apart from therapeutic uses.

Implementing universal genetic counseling (GC) and multigene germline testing (MGT) for pancreatic cancer (PC) patients (pts). *First Author: Matthew B. Yurgelun, Dana-Farber Cancer Institute, Boston, MA*

Background: MGT will identify cancer susceptibility gene variants in 4-10% of unselected PC pts. Such data have prompted calls for universal GC and MGT of all PC pts, but the real-world benefits and barriers to implementing such systematic testing are unknown. This study's aim was to study the implementation of universal hereditary cancer risk assessment for all PC pts seen in an academic oncology practice. **Methods:** All gastrointestinal medical oncologists at the Dana-Farber Cancer Institute (DFCI) were recommended to refer all PC pts for GC and MGT beginning 12/2016. A special referral sheet was placed in new PC pt charts to remind providers and streamline GC referral workflows. Clinical and germline data were collected on a consecutive cohort of PC pts undergoing GC and MGT from 3/1/2017-1/31/2018. **Results:** Over the 11-month study period, 443 (43.9/month) PC pts were seen for medical oncology new patient visits at DFCI, 114 (10.4/month) were referred for GC, and 92 (8.4/month) eligible PC pts underwent GC and consented to MGT and study enrollment. Among the 92 participants, median time from first DFCI appointment to GC was 44 days (IQR 23-142 days), 33 (35.9%) underwent MGT within 30 days of their first DFCI appointment, and 4 (4.3%) died within 30 days of receiving MGT results. 8/92 (8.7%; 95% CI 2.9-14.5%) were found to carry germline mutations (2 *BRCA1*, 2 *BRCA2*, 1 *ATM* and *PALB2*, 1 *NBN*, 1 *PMS2*, 1 *STK11*) on MGT. There were no significant differences in patient age, sex, race, personal cancer history, family history of PC, or family history of other cancers between mutation carriers and non-carriers. 4/8 (50%) carriers received targeted therapy (eg, PARP inhibitors) based on MGT results (2 remain on 1st line chemotherapy; 2 died without undergoing targeted therapy) and 5/8 (63%) have family members who are actively pursuing cascade testing for the identified mutation. **Conclusions:** Clinical implementation of universal GC/MGT in PC pts is potentially feasible and results in the detection of mutations that are actionable for PC pts and their at-risk family members. In spite of streamlined workflows, lack of oncologist referral is a critical barrier to the real-world efficacy of universal GC/MGT in PC. Clinical trial information: NCT03060720.

Long-term (7-year) outcomes of universal mismatch repair screening (uMMR) of 1156 colorectal (CRC) and endometrial cancers (EC) in an academic setting. *First Author: Michael J. Hall, Fox Chase Cancer Center, Philadelphia, PA*

Background: uMMR of CRC/EC for Lynch syndrome (LS) is recommended to identify the 2-3% of incident CRC/EC with germline MMR mutations in MLH1, MSH2, MSH6, and PMS2. Many US centers use a positive immunohistochemical (IHC+) tumor test to prompt further evaluation such as genetic counseling (GC). Efficacy of uMMR is established, but real-world performance is not. W/recent Blue Ribbon Panel recommendations for broad implementation, we reviewed uMMR effectiveness in an academic cancer center. **Methods:** Outcomes of all CRC/EC undergoing uMMR from 9/2011 (start of uMMR at Fox Chase Cancer Center) to 12/2017 were reviewed. uMMR results are reported in the surgical pathology report and by email to providers w/a PDF test report meant for pts. Results [IHC, MSI, BRAF, MLH1 promoter methylation, gene testing] and clinical data were extracted from a clinical genetics database and the EMR. Associations were tested by chi-square and T-test (2-sided). **Results:** From 1156 screened tumors, 278 (24.0%) had +IHC: 112 (40.3%) CRC vs 166 (59.7%) EC. Mean age was 64.7 yrs, and 117/278 (42.4%) reported family history (FamHx) of a LS cancer. After BRAF V600E testing, 91.0% (253/278) warranted GC. Only 98/253 (38.7%) pts warranting GC have to date completed GC (mean follow-up 3.0 yrs)—most common pt-reported reason for non-compliance w/GC was low interest (46.7%). Pts who completed GC were younger (47.9% vs 29.6% were $<$ 60 yrs, p = 0.004), and had stronger FamHx (55.1% vs 34.8%, p = 0.006), while differences in GC uptake by race (40.6% White vs 28.2% non-White, p = 0.14) were not significant. Of the 67 pts who sought counseling and warranted a germline test, 91.8% completed testing. LS was diagnosed in 20.9% (14/67) or 1.1% of the uMMR population—nearly 1 in 4 tested (24.6%, 17/67) were clinically suspicious for LS but test results were inconclusive. **Conclusions:** uMMR effectiveness is limited by low uptake of GC as well as high rates of non-diagnostic test results. Among uMMR IHC+ pts, low interest is the foremost patient barrier to GC uptake, and is strongly influenced by personal (age) and familial risk factors. Molecular testing alone (IHC+ screen) may be insufficient to achieve desired uMMR outcomes.

Identification and referral of women at risk for *BRCA* mutations. *First Author: Cecelia Bellcross, Emory University, Atlanta, GA*

Background: It is estimated that less than 10% of *BRCA*1/2 mutation carriers have been identified, despite well-documented evidence of reduced cancer morbidity and mortality with targeted screening and prevention. The United States Preventive Services Task Force endorsed the Breast Cancer Genetics Referral Screening Tool (B-RST) as one of several validated screening tools to assist clinicians in identifying women appropriate for cancer genetics referral. The purpose of this study was to implement B-RST in mammography clinics to determine the most effective means of follow-up for screen positive women. **Methods:** Women undergoing routine screening mammography at one of four Emory clinics were approached to complete the B-RST. Participants were given written information about their results and appropriate resources. Those who screened positive, indicating increased risk for a *BRCA1/2* mutation, were randomized to one of three follow-up groups: self-referral (Group 1), electronic health record (EHR) messaging (Group 2), or direct contact (Group 3). We compared genetic counseling (GC) appointment scheduling and completion rates by group. Those who did not schedule an appointment were invited to participate in an online survey. **Results:** Of 2,422 participants, 610 (25.2%) screened positive. Demographic factors did not differ between the three groups. GC appointments were scheduled by 9.2% of Group 1 participants, 19.7% of individuals in Group 2, and 12.5% of Group 3 participants (p = 0.001). Challenges to scheduling included lack of physician response to EHR messages and unsuccessful direct contact. Among those scheduled (n = 76) 69.7% completed the appointment. with no difference in completion rate between the three groups. The most common barriers to scheduling reported by survey respondents (n = 97) were lack of physician recommendation (71%), health insurance concerns (67%) and indecision about GC (66%). However, 52% reported interest in future GC contact. **Conclusions:** B-RST can be used effectively in mammography settings to identify high-risk women for cancer genetics referral. While follow-up via EHR was the most effective, additional strategies are needed to facilitate completion of the GC process in routine clinical practice. Clinical trial information: NCT02786147.

Inherited defects in checkpoint kinase 2 (CHEK2) to confer increased susceptibility to testicular germ cell tumors. *First Author: Saud H. Aldubayan, Department of Medical Oncology, Dana Farber Cancer Institute, Boston, MA*

Background: Although up to 50% of testicular germ cell tumor (TGCT) risk is predicted to be inherited, no Mendelian TGCT predisposition genes have been so far identified. Recently, we showed that TGCTs are uniquely enriched for somatic DNA double-strand breaks. We hypothesized that inherited DNA repair gene (DRG) defects may drive TGCT susceptibility. **Methods:** A case-control germline mutation enrichment analysis was first used to screen 56 Mendelian DRGs in 205 unselected TGCT patients and 27,173 ancestry-matched cancer-free adults. Significant findings were then validated in independent cohorts of 448 unselected and 221 familial TGCT patients and matched controls. **Results:** Of 205 unselected TGCT patients in the discovery cohort, 24 pathogenic germline DRG mutations were identified in 22 patients (10.7%; 95% CI = 6.85-15.8). Unexpectedly, one-third of detected DRG mutations involved *CHEK2,* which ranked first as the most commonly mutated gene in TGCT patients. Unselected TGCT patients from the discovery cohort were almost four times more likely to carry a germline loss-of-function (LOF) mutation in *CHEK2* compared with ancestry-matched controls (OR = 3.87; P = 0.0055). A similar degree of enrichment was also seen in an independent cohort of 448 unselected Croatian TGCT patients *vs.* 442 matched controls (OR $>$ 1.4; P = 0.03) and a cohort of 221 familial TGCTs probands *vs.* 3,090 matched controls (OR = 6.12; P = 0.0014). In addition, the low-penetrance *CHEK2* mutation (p.Ile200Thr) was found to be a Croatian founder TGCT risk mutation (OR = 4.03; P = 0.001). Finally, *CHEK2* mutation carriers developed TGCTs at an earlier age compared with mutation-negative patients (8.43 years; P = 0.017). **Conclusions:** Our multicenter case-control analysis of 874 TGCT patients and matched controls provides validated evidence for *CHEK2* as a novel moderately-penetrant TGCT susceptibility gene, making it the first clinically informative molecular biomarker that can be offered to TGCT patients and their at-risk relatives. In addition to providing an important insight into potential mechanisms driving TGCT susceptibility, our analysis also provides new avenues to explore TGCT preventive strategies in high risk patients.

DNA damage repair (DDR) germline mutations in patients (Pts) with urothelial carcinoma (UC). *First Author: Maria Isabel Carlo, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: We previously reported on germline mutations in cancer predisposition genes in 113 pts with UC, with a 19% rate of pathogenic or likely pathogenic (P-LP) variants in DDR genes. Here we report on an expanded cohort of 176 pts and on a separate cohort of 327 anonymized specimens devoid of clinical annotation. **Methods:** Pts with UC malignancies were prospectively enrolled to a matched tumor-germline DNA sequencing protocol from 3/2013 to 9/2017; starting in 2014, patients could opt in to receive germline results. Germline analysis was done with an institutional, CLIA-certified next generation sequencing (NGS) platform (IMPACT) and analyzed for germline mutations. This analysis includes pts seen in medical oncology clinics who consented to receive germline results (Cohort 1), and additional pts seen in urology and medical oncology clinics who had anonymized germline testing (Cohort 2) with an extended DDR panel. **Results:** Cohort 1 consisted of 176 pts, 90% with muscle invasive or metastatic disease, median age 63 (31-87), 76% male. Primary sites were bladder (B) (70%), upper tract (UT) (28%), or unknown (2%). 8% had early onset (≤45 yrs at diagnosis), 9% had a family history of UC, 19% had documented non-UC cancers. 30 P-LP DDR gene mutations were identified in 28 patients. The most frequent mutations are shown in the Table. P-LP mutations were present in 29% of pts with UT and 13% of pts with B primaries. Of pts with DDR germline mutations, 29% did not have additional somatic DDR mutations. Cohort 2 consisted of 327 anonymized pts. 32 P-LP DDR germline mutations, including in *ERCC2* and *ERCC3*, were identified in 30 pts. Including both cohorts, 77% of mutations were of high or moderate penetrance. **Conclusions:** Germline predisposition genes are common in UC pts and may be greater in higher stage disease, further investigation into mutation frequency by stage is warranted. Most mutations are highly penetrant and have profound implications for both pts and family members. Clinical trial information: NCT01775072.

Gene	Mutations Cohort 1 (%) Total n = 176	Mutations Cohort 2 (%) Total n = 327
Total DDR	30 (17)	32 (9.8)
MSH2	5 (2.8)	4 (1.2)
BRCA1	5 (2.8)	3 (0.9)
CHEK2	4 (2.2)	3 (0.9)
BRCA2	3 (1.7)	5 (1.5)
MSH6	2 (1.1)	0

Clinical factors associated with urinary tract cancers (UTCs) among Lynch syndrome (LS) patients (Pts). *First Author: Jonathan W. Wischhusen, Beth Israel Deaconess Medical Center, Boston, MA*

Background: LS is the one of the most common inherited causes of cancer and predisposes to a wide variety of cancers. UTCs (kidney, renal pelvis, ureter, and bladder cancer) are collectively the second- and fourth-most common LS-associated cancers in male and female LS pts, respectively. This study's aim was to identify clinical factors associated with UTC among LS pts. **Methods:** The study population was a cohort of 52758 consecutively ascertained patients undergoing germline LS testing from 6/2006-7/2013 at a commercial laboratory. Clinical data, including age at genetic testing, personal history (PHx) of cancer, and family history of cancer in first- and second-degree relatives (FDRs and SDRs, respectively) were obtained from test request forms completed by the ordering provider. Multivariable logistic regression was performed to identify clinical factors associated with PHx of UTC among LS carriers. **Results:** Data from 51086 pts was analyzed after excluding 1672 pts without clinical data (N = 1664) or > 1 LS mutation (N = 8). Of these, 3828 carried pathogenic LS mutations (1346 *MLH1*, 1639 *MSH2*, 670 *MSH6*, 145 *PMS2*, and 28 *EPCAM*). 158/3828 (4.1%; 95% CI 3.5-4.8%) LS pts had a PHx of UTC (49 kidney; 62 ureter/renal pelvis; 67 bladder; 21 multiple UTCs) and 369 (9.6%; 95% CI 8.7-10.6%) had any family history of UTC. Compared to non-carriers, LS pts were significantly more likely to have a PHx of any UTC (4.1 vs 1.2%; $P < 0.0001$), kidney cancer (1.3% vs 0.7%; $P = 0.0003$), ureter/renal pelvis cancer (1.6% vs 0.1%; $P < 0.0001$), bladder cancer (1.8% vs 0.4%; $P < 0.0001$), and any family history of UTC (9.6% vs 6.5%; $P < 0.0001$). By multivariable logistic regression, PHx of UTC among LS pts was significantly associated with male sex (OR 2.04; 95% CI 1.73-2.41), age at genetic testing (OR 1.97 per 10 years; 95% CI 1.86-2.09), *MSH2* mutation carriage (OR 4.03; 95% CI 3.29-4.94; ref: non-*MSH2* LS mutations), and family history of UTC (OR 2.07 for each FDR/SDR with UTC; 95% CI 1.80-2.40). **Conclusions:** Increasing number of FDR/SDR with UTC, male sex, age, and *MSH2* mutations are each independently associated with PHx of UTC among LS pts. LS pts with these clinical features should be considered for UTC screening/prevention strategies.

Adapted physical activity and recommendations for second cancers prevention for adolescents and young adults with cancer. *First Author: Julien Carretier, Centre Léon Bérard, Lyon, France*

Background: While long term survival is about 80%, adolescents and young adults (15-25 years old) with cancer (AYAC) are at increased risk of second primary cancer (SPC). Risk depends on first cancer type, treatment and prevalence of risk factors (smoking, overweight, sedentary lifestyle, environmental exposures...). AYAC have reduced physical activity (PA) and decreased motivation for PA. The objective of this study is to implement a supervised program based on adapted PA (APA) and cancer prevention for AYAC. **Methods:** AYAC attended supervised APA sessions during the treatment period (4-6 months). Physical activity (IPAQ), quality of life (QLQ-C30) and physical functioning (six-min walk test) were assessed at baseline (T1) and at the end of treatment (T2). They then participated in individual information meetings on SPC risk prevention. At 1 year (T3), they were questioned by phone on pursuit of physical activity and adoption of cancer prevention behaviors. **Results:** 63 AYAC (39 boys, 24 girls; median age = 19 years) completed T1 and T2; 37 AYAC completed T3. On average, they participated in 4 supervised sessions at the hospital and 16 unsupervised sessions at home during 3.5 months [min 2-max 6]. Preliminary results indicate an increase in the PA level between T1 and T2 (median scores of 360 and 1059 MET-min/week, respectively; $P < .0001$) and in the six-min walk test from T1 to T2 (median distances of 391 and 464 m, respectively; $P < .0001$). Median sedentary time decreased from 53.3 h/week at T1 to 37.5 h/week at T2 ($P < .01$). Global QOL score significantly increased between T1 and T2 ($P < .001$). **Conclusions:** This APA program responds to AYAC's needs for support and information regarding PA and SPC prevention and shows increased PA, physical functioning and QOL for AYAC undergoing cancer treatment. Results will be validated in a multicenter study. Clinical trial information: NCT03336905.

Nutrition assessment among men undergoing genetic counseling for inherited prostate cancer: A teachable moment. *First Author: Veda N. Giri, Sidney Kimmel Cancer Center, Thomas Jefferson University, Philadelphia, PA*

Background: Genetic counseling (GC) for men with or at-risk for prostate cancer (PCA) is growing with advancements in genetic testing (GT). GC provides a unique opportunity to promote a healthy lifestyle and is understudied in men. We conducted a targeted dietary analysis of men with or at-risk for PCA who have undergone GC and GT in the Genetic Evaluation of Men (GEM) study at two academic centers. **Methods:** GEM participants completed a structured lifestyle questionnaire (QA) which included dietary behaviors. QA included frequency of consuming six different types of foods (rich in vitamins C, A and D, cruciferous vegetables, rich in lycopene, smoked and/or salted meats) and daily servings for specific food groups (red meat, seafood, chicken, legumes/other protein sources, vegetables, fruit, grains, milk products, foods high in saturated fat) and alcohol. Diet intake was compared to USDA's dietary recommendations for cancer survivorship. Distributions of dietary consumption were assessed by PCA status, PCA aggressiveness (Gleason > 7, T3, or metastatic disease), family history (FH), and body mass index (BMI) with Chi-Square contingency analyses and adjusted residuals (adj resid). Alpha levels were set *a priori* at $p < .05$. **Results:** Self-reported dietary data among men with PCA (n = 239) and at-risk for PCA (n = 81) who underwent GC was included. Overall, 84% were overweight/obese per CDC guidelines. Consumption of Vitamin C 1-2 times per week was significantly lower among men with aggressive PCA (adj resid = -1.9) vs. less aggressive PCA (adj resid = 1.9). Men with aggressive PCA also reported eating more red meat vs less aggressive PCA ($p = 0.011$). A higher percentage of men with aggressive PCA and higher weight did not meet the recommended guideline for vegetables ($p = 0.047$) and red meat ($p = 0.015$) than expected per contingency analyses. **Conclusions:** In this sample, specific dietary patterns were associated with aggressive PCA. A high proportion of men receiving GC for inherited PCA were overweight and/or obese, affording a teachable moment for lifestyle intervention. Key focus areas to develop diet intervention include consumption of less red meat and more vegetables among men at-risk or in survivorship.

Risk of second primary HPV-associated cancers after index HPV-associated cancers. *First Author: Ryan Suk, University of Florida, Gainesville, FL*

Background: For the HPV-associated index cancer survivors, persistent HPV infection may remain a risk factor for preventable HPV-associated second primary cancer (HPV-SPC). However, the risk of HPV-SPCs among HPV-associated index cancer patients has not been well documented. **Methods:** Longitudinal data from 9 cancer registries of the Surveillance, Epidemiology, and End Results (SEER) database were used to identify cases of HPV-associated cancers diagnosed from 1973 to 2014. The HPV-SPC risk was quantified using standard incidence ratios (SIRs) and excess absolute risk (EAR) per 10,000 person-years at risk (PYR). **Results:** The SIRs for second primary HPV-related cancers after index HPV-related cancers among women and men were 3.3 (95% CI 3.2 to 3.4) and 15.8 (95% CI, 15.0 to 16.7), respectively; the EAR was 6.0 and 51.4 for women and men, respectively. When the same site second primary cancers were excluded, the risk remain significant both among women (SIR = 2.7) and men (SIR = 2.3). The risk of HPV-SPC was highest for oropharyngeal cancer both among women (SIR = 20.6; EAR = 83.8) and men (SIR = 18.8; EAR = 64.3), and lowest for cervical (SIR = 2.0; EAR = 2.4) and penile (SIR = 7.0; EAR = 20.7) cancer. **Conclusions:** The risk of developing HPV-SPC among HPV-related cancer survivors is significant, implying that HPV might be a cause for developing HPV-SPC. Our findings have the potential to inform surveillance recommendations among HPV-related cancer survivors.

SIRs for HPV-SPCs after index HPV-related cancers.

	Women				Men			
	All HPV-SPC		All HPV-SPC (same site excluded)		All HPV-SPC		All HPV-SPC (same site excluded)	
Index HPV Cancers	SIR (95% CI)	EAR	SIR (95% CI)	EAR	SIR (95% CI)	EAR	SIR (95% CI)	EAR
All HPV-related cancers	3.3 (3.2-3.4)	6.0	2.7 (2.5-2.8)	2.3	15.8 (15.0-16.7)	51.4	2.3 (1.8-2.9)	1.6

Dietary inflammatory index and breast cancer risk by menopausal status and histological subtype. *First Author: Adela Castello, National Center for Epidemiology, Instituto de Salud Carlos III, Consortium for Biomedical Research in Epidemiology & Public Health (CIBERESP). Instituto de Salud Carlos III.Faculty of Medicine, University of Alcalá, Madrid, Spain*

Background: Inflammation plays an important role in cancer development. The Dietary Inflammatory index (DII) reflects the inflammatory potential of diet. We examined the association between the DII and breast cancer (BC) risk by menopausal status and histological subtype. **Methods:** Epi-GEICAM is a nation-wide case-control study that collected epidemiologic information, including diet, of 973 BC cases from 23 hospitals individually matched to 973 controls by age and residence. Cases were sub classified by tumor subtype: 1) Estrogen Receptor(ER)+ or Progesterone Receptor(PR)+ with Human Epidermal Growth Factor Receptor 2(HER2)-; 2) HER2+; and 3) ER-,PR-&HER2-. The association of the calorie density adjusted DII score (0-10) with BC risk was evaluated using conditional logistic regression models, adjusted by alcohol, body mass index, age at menarche, physical activity, smoking habit, education, history of breast alterations, family history of BC, age at first delivery and menopausal status. Heterogeneity of the effects by menopausal status was tested including an interaction term between this variable and the DII. Multinomial logistic regression models -adjusted for age, hospital, and the same set of potential confounders described above- were used to evaluate the association of the DII score with each of the intrinsic BC subtypes. In all cases associations were analyzed both, as categorical (grouping the DII into quartiles of its distribution among controls) and continuous (1-point increase) variables. **Results:** Women whose diet was more pro-inflammatory showed higher BC risk ($OR_{4th\ quartile(Q4)vs\ 1st\ quartile(Q1)}$= 1.39; 95%CI = 1.05-1.84; p-trend = 0.023). This effect seemed to be confined to premenopausal women (OR_{Q4vsQ1}= 1.52; 95%CI = 1.05-2.21; p-trend = 0.030) and it was stronger for HER2+ (OR_{Q4vsQ1}= 1.46; 95%CI = 0.92-2.32; p-trend = 0.050) and ER-,PR-&HER2- (OR_{Q4vsQ1}= 2.72; 95%CI = 1.45-5.10; p-trend = 0.006) tumors than for ER+/PR+&HER2- (OR_{Q4vsQ1}= 1.24; 95% CI = 0.92-1.67; p-trend = 0.145) tumors. **Conclusions:** A diet that promotes inflammation might be associated with higher BC risk, especially among premenopausal women and for the most aggressive tumors (HER2+ and ER-, PR-&HER2-).

Value of EGD for gastric cancer surveillance in patients with hereditary non-polyposis colorectal cancer (HNPCC) or Lynch syndrome (LS). *First Author: Swetlana Ladigan, Department of Medicine, Knappschaftskrankenhaus, Ruhr-University Bochum, Bochum, Germany*

Background: Gastric cancer (GC) is the second most common non-gynecologic malignancy in patients with LS. Due to an absence of prospective randomized data, the value of esophago-gastro-duodenoscopy (EGD) for GC surveillance in LS patients remains a controversial issue. According to German guidelines regular EGDs beginning at the age of 35 are recommended for LS patients. The focus of this study was to evaluate the effectiveness of EGD as an instrument for early GC detection. **Methods:** Data of HNPCC and LS patients diagnosed with GC was retrieved from the German Consortium for Familial Intestinal Cancer Registry. Individuals from 3 groups were included: pathogenic germline mismatch repair gene mutation carriers (n = 47), untested patients from families with known germline mutations (putative carriers; n = 8) and individuals fulfilling at least the revised Bethesda criteria without a mutation but with microsatellite instability (MSI group; n = 47). Statistics were calculated using Fisher's exact test. **Results:** Overall a total number of 107 GCs were observed in 102 patients (male/female: 60/42) with 71 (69%) having a negative family history of GC. Among germline mutation carriers, *MLH1* (n = 21) and *MSH2* (n = 24) mutations were the most prevalent; *EPCAM* and *MSH6* mutations were rare with only one case each. The median age at diagnosis was 54.4 years (28.9-81.4) for the whole cohort, with mutation carriers being diagnosed at a younger age (51.8 years) than individuals from the MSI group (63.1 years). Of all GC patients, two were diagnosed at an age younger than 35 years and 7 patients were younger than 40 years. The GCs in patients undergoing surveillance were diagnosed significantly more often with an early stage disease (UICC I) than GCs detected through symptoms (77.8% vs. 23.5%; p = 0.0046). **Conclusions:** To our knowledge this is the largest study investigating the effectiveness of EGD surveillance for early GC detection in HNPCC or LS patients. This study indicates a benefit for patients undergoing regular EGDs and supports the recommendation of regular gastroscopic surveillance for HNPCC and LS syndrome patients beginning not later than at the age of 35.

"What if I keep my breasts?" Extended follow-up of unaffected *BRCA* mutation carriers diagnosed with breast cancer (BC) in the Toronto magnetic resonance imaging (MRI) screening study. *First Author: Ellen Warner, Odette Cancer Centre, Sunnybrook Health Sciences Centre, University of Toronto, Toronto, ON, Canada*

Background: The addition of MRI to mammography for screening *BRCA* mutation carriers detects significantly earlier stage BC but, with median follow-up of < 10 years in all reports to date, the long-term prognosis of these cancers is uncertain. Moreover, while the short-term risk of ipsilateral recurrence for carriers who opt for breast conservation (BCT) are reported to be similar to that of non-carriers, the risk of late new breast primaries may be substantially higher. We report the long-term ipsilateral, contralateral, and distant recurrence as well as survival results for the previously unaffected women with BC diagnosed in the Toronto MRI screening study. **Methods:** From 07/1997 to 06/2009, 380 *BRCA* mutation carriers with no history of BC or ovarian cancer completed 1 to 9 rounds of annual screening with MRI and mammography; 41 cancers (30 invasive) were detected (38 by MRI, 5 by mammography) in 40 women (20 *BRCA1, 20 BRCA2*), median age at diagnosis 48 (32 to 68), followed annually for recurrence and survival by mailed questionnaire. 10-year results were calculated using the Kaplan-Meier method. **Results:** As of 01/2018, median follow up was 13.5 (8 to 19) years with none lost to follow-up. Of the 27/40 (68%) who initially had BCT, 6 (22%) had an ipsilateral recurrence/new primary at 3, 3, 6, 15, 16 and 19 years, with 2 of the latter 3 opting for repeat lumpectomy and re-irradiation. Of the 34 who did not have bilateral mastectomy initially, only 1 developed a metachronous contralateral cancer at 1 year. Of the 40 women, 34 (85%) are alive with no evidence of disease, and 6 have died: 2 (5%) of peritoneal cancer, 1 of ovarian cancer, 1 of suicide, and only 2 (5%) of ER+ BC, with distant recurrences 6 and 7 years after diagnosis. 10-year BC-specific survival was 94.6% for all 40 patients and 92.6% for those with invasive disease. **Conclusions:** MRI-detected BC in *BRCA* mutation carriers has a 10-year BC-specific distant recurrence-free survival rate of 95%. Distant recurrences occur relatively early, likely due to the known faster growth rate of these cancers. MRI-based breast screening has proven to be a very reasonable alternative to risk-reducing mastectomy.

Expanding *BRCA1/2* testing criteria to include other confirmed breast and ovarian cancer susceptibility genes. *First Author: Fergus Couch, Mayo Clinic, Department of Laboratory Medicine and Pathology, Rochester, MN*

Background: The National Comprehensive Cancer Network (NCCN) has expanded its breast and ovarian cancer (BC and OC) genetic testing and management recommendations to address the broader spectrum of cancer predisposition genes. However, management recommendations are pending for some candidate BC genes (e.g. *BARD1*, *RAD51D*) and OC genes (e.g. *ATM*, *NBN*) due to insufficient evidence of increased cancer risk, and indications for multi-gene panel testing (MGPT) remain vague overall. We aimed to further characterize BC and OC risks for 21 candidate susceptibility genes and explore the potential utility of *BRCA1/2* testing criteria as an indication for MGPT. **Methods:** Gene-specific pathogenic variant (PV) frequencies among Caucasian BC and OC patients (unadjusted for other personal/family cancer history) ascertained from a cohort of > 175,000 patients referred for MGPT were compared to non-Finnish European reference controls from the genome aggregate database (gnomAD). Clinical histories of BC and OC patients were also reviewed to assess whether NCCN *BRCA1/2* testing criteria were met (version 2.2017). **Results:** We confirmed the association of 15 genes with increased risk (> 2.0-fold) of BC (*ATM*, *BARD1*, *BRCA1/2*, *CDH1*, *CDKN2A*, *CHEK2 (excluding p.I157T)*, *MLH1*, *MSH2*, *MSH6*, *NF1*, *PALB2*, *PTEN*, *RAD51D*, *TP53*). The pooled frequency of PVs in these genes was 9.2% among BC patients of all ethnicities (3.5% in *BRCA1/2* and 5.7% in other genes) and 8.6% among BC patients meeting *BRCA1/2* testing criteria (3.4% in *BRCA1/2* and 5.2% in other genes). Eleven genes were associated with increased risk of OC (> 2.0-fold, *ATM*, *BRCA1/2*, *BRIP1*, *MSH2*, *MSH6*, *NBN*, *PMS2*, *RAD51C*, *RAD51D*, *TP53)*. PVs in these genes were detected among 13.0% of OC patients of all ethnicities (8.0% for *BRCA1/2* and 5.0% for other genes combined). Therefore, inclusion of additional risk genes increases detection rate for BC and OC patients meeting *BRCA1/2* testing criteria by 152.9% and 62.5%, respectively. **Conclusions:** These results further characterize gene-specific BC and OC risks, which can be used to refine management recommendations for at-risk patients. Current testing criteria fail to capture a substantial proportion of women with increased risk of BC and OC.

1526 Poster Session (Board #97), Sat, 1:15 PM-4:45 PM

Towards personalised risk assessment and clinical management: A worldwide study of age-, sex-, geographic region-, gene- and cancer-specific risks for Lynch syndrome. *First Author: Aung K. Win, The University of Melbourne, Parkville, Victoria, Australia*

Background: Lynch syndrome is a cancer predisposition caused by inherited mutations in mismatch repair genes *MLH1, MSH2, MSH6* and *PMS2,* or *EPCAM*. Accurate cancer risk estimates are required for mutation carriers and their family members to develop appropriate genetic counselling guidelines and targeted screening and clinical management. Cancer risks for Lynch syndrome may differ not only by age, sex and the gene mutated but also by the genetic variant and geographic region of the carrier. **Methods:** We analysed pedigree data (age, sex, cancer histories and mutation status of family members) of Lynch syndrome families that were submitted by researchers and clinicians from 23 countries to the International Mismatch Repair Consortium (IMRC) (http://www.sphinx.org.au/imrc). For each cancer, we estimated age-specific cumulative risk (penetrance) and hazard ratios for carriers compared with the general population. We estimated penetrance by: cancer site, sex, the gene mutated, type of mutation, and geographic region. **Results:** IMRC has already received pedigree data from 6651 families with a mismatch repair gene mutation (2214 *MLH1,* 2717 *MSH2,* 1118 *MSH6*, 558 *PMS2,* 44 *EPCAM*) throughout the world (2482 in North America, 101 in South America, 3307 in Europe, 431 in Asia, 330 in Australasia). Preliminary analyses suggest that the risk of colorectal cancer to age 70 is highest for both male and female carriers in Australasia and North America and lowest for carriers in South America and Asia. **Conclusions:** Preliminary results from this world's largest study on Lynch syndrome penetrance suggest that cancer risks for people with Lynch syndrome differ by geographic region, which is consistent with existence of environmental modifiers for the disease and might justify region-specific screening guidelines.

Gene	Region	Hazard ratio	Risk to age 70 males	Risk to age 70 females
MLH1	Europe	19 (14–26)	50%	32%
	North America	32 (26–38)	61%	48%
	Australasia	32 (22–46)	68%	55%
	South America	6 (1.5–22)	12%	10%
	Asia	7 (4.5–15)	20%	14%
MSH2	Europe	14 (11–16)	39%	24%
	North America	33 (28–40)	61%	50%
	Australasia	36 (24–54)	73%	59%
	South America	70 (10–490)	82%	75%
	Asia	8 (4.8–17)	21%	15%

1527 Poster Session (Board #98), Sat, 1:15 PM-4:45 PM

Evaluation of whole body MRI for early detection of cancer in TP53 mutation carriers: Final results of the LIFSCREEN study. *First Author: Olivier Caron, Gustave Roussy Cancer Campus, Villejuif, France*

Background: Li Fraumeni syndrome (LFS) is a rare cancer predisposition caused by TP53 germline mutation associated with a broad tumor spectrum making surveillance very complex. Whole body MRI (WBMRI) is an attractive strategy. The LIFSCREEN nation-wide trial was designed to evaluate the impact of adding WBMRI as a screening tool on the overall survival (OS) of LFS patients. **Methods:** Participants (pts) were TP53 mutation carriers, > 5 and < 71 y, with/without cancer personal history. Pt were randomized in standard surveillance arm ("A": clinical exam, brain MRI, abdomino-pelvic US, CBC, and breast MRI/US and breast US for women over 20), or in "B" arm (A + WB diffusion MRI). Each pt repeated annually the process for at least 3 years. Acceptability and psychological impact were evaluated throughout the study. **Results:** 105 pts (mean age 33y [5-67]) were randomized in one of the 19 French centers. In 318 screening rounds, 24 pts presented 31 new primary cancers (NPC): 20 in A arm and 11 in B arm. 12 NPC were diagnosed at the first round. Cancer-free survival (NPC and relapses) was similar at 3 years in both arm (p = 0.23). 27 Biopsies were carried out in A arm and 20 in B arm. 157 WBMRI were performed, with a sensitivity and specificity of 0,8 and 0,89, respectively (10% false positive). Their centralized review showed a 31% discordance rate (44/141). The 3 years OS was 90% [81-95], with no difference between the 2 arms (p = 0.58). The 3- years OS with NPC was 54.8% [32-75]. 10 pts voluntarily left the study. Psychological impact was similar in both arms, with low screening-related distress. **Conclusions:** This first randomized study performed on one of the largest TP53 carrier series did not show WBMRI efficiency on OS. Nevertheless, it displayed correct sensitivity and specificity, with few biopsy generation. Long-term follow-up was acceptable and feasible in each participating center. Despite its tricky interpretation, WBMRI was the only modality to detect lung cancer, whose incidence was surprisingly high. TP53 mutation carrier surveillance might be completed with WBMRI, in a multimodality setting. The very high short-term mortality in pt with new cancer makes prevention and treatments improvement mandatory. Clinical trial information: NCT01464086.

1529 Poster Session (Board #100), Sat, 1:15 PM-4:45 PM

Differences between screen-detected and interval breast cancers among BRCA mutation carriers. *First Author: Melissa Louise Pilewskie, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: BRCA mutation carriers have an elevated lifetime and interval breast cancer risk. We sought to compare BRCA mutation carriers with screen-detected versus clinically detected, interval breast cancers. **Methods:** Women with a known BRCA mutation prior to a breast cancer diagnosis were identified. Clinical and pathologic factors, and imaging within 18 months of diagnosis were compared among screen-detected vs clinically detected/interval cancers. Clinically detected tumors were those detected by physical exam regardless of screening history, whereas interval cancers were those detected by physical exam among women undergoing regular screening. **Results:** Of 115 breast cancers, 93 were screen and 22 clinically detected, of which 11 were interval cancers among regular screeners. Women with clinically detected/interval cancers were younger, had lower BMIs, and were more likely to be Black than those with screen-detected cancers ($p < 0.05$). Clinically detected/interval cancers were all invasive, were larger, more likely to be node positive and to have lymphovascular invasion, and were more likely to require axillary lymph node dissection and chemotherapy ($p < 0.05$). No significant differences were seen by BRCA mutation, mammographic density, MRI background parenchymal enhancement, tumor grade, or receptor status between cohorts. Women screened with both mammogram and MRI had significantly lower rates of clinically detected/interval cancer rates compared to women screened with only mammogram or MRI alone ($p < 0.05$)(Table). **Conclusions:** Clinically detected/interval breast cancers among BRCA mutation carriers have worse clinicopathologic features than screen-detected tumors, and require more aggressive medical and surgical therapy. Imaging with mammogram and MRI is associated with lower interval cancer development and should be utilized among this high-risk population.

Imaging	Screen-Detected	Clinically Detected	P value	Screen-Detected	Interval Cancers	P value
	All Women			Regular Screeners		
Alternating q6 Month Mammo/MRI	34 (89%)	4 (11%)	0.003	32 (91%)	3 (9%)	0.014
Synchronous Mammo/MRI	38 (90%)	4 (10%)		25 (93%)	2 (7%)	
Mammo Only	18 (58%)	13 (42%)		7 (58%)	5 (42%)	
MRI Only	3 (75%)	1 (25%)		1 (50%)	1 (50%)	

1530 Poster Session (Board #101), Sat, 1:15 PM-4:45 PM

Effect of breastfeeding on the risk of breast cancer in Li-Fraumeni syndrome. *First Author: Payal Khincha, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: Li-Fraumeni syndrome (LFS) is an autosomal dominant inherited cancer predisposition syndrome associated with germline pathogenic variants in *TP53*. It is characterized by early-onset cancer and a high lifetime risk for multiple cancers. Although women with LFS are at very high risk of pre-menopausal breast cancer some women will perhaps never develop the disease. This may be due to non-genetic factors that may modify the risk. **Methods:** The aim of this retrospective cohort study was to evaluate the impact of female reproductive factors such as age at menarche, parity, breastfeeding (BF) and use of oral hormonal contraceptives (OCP) on the risk of breast cancer (BC) in LFS patients. **Results:** We enrolled 154 *TP53* mutation-positive women from the NCI's LFS protocol, 86 of whom had at least one breast cancer. Median age at first breast cancer diagnosis was 32 years (range 20-54 years), 32 women had a second BC. Sixty percent of first breast cancers were ER/PR+; and 57% were HER2/neu+. Our data showed that breastfeeding (BF) reduced the risk of breast cancer in LFS, most notably reduced in patients with over 6 months of BF (Odds Ratio (OR) 0.36, $p = 0.04$, OR at 12 months of BF 0.32, $p = 0.02$). The association was strongest in ER+ BC *versus* BC-free women, but was not significant when comparing odds of developing ER+ to ER- BC. Controlling for age and parity, women with BF $>$ 12 months had a lower risk of BC *versus* BF $<$ 12 months ($p = 0.02$). Neither parity nor OCP independently altered BC risk significantly, a finding limited by limited sample size of the comparator group of OCP non-user LFS women. **Conclusions:** Our data show that while BF for any duration reduces risk of BC, the risk is significantly reduced with BF for at least 6 months, a protective effect similar to previous studies of BF and BC risk in the general population and *BRCA1* cohorts. Neither parity nor OCP independently altered BC risk significantly. This is the first study to evaluate BC reproductive risk modifiers in LFS patients. Larger, prospective case-control studies are needed to validate these findings. If confirmed, women with LFS would warrant education regarding BF's protective effect to inform management decisions.

1531 Poster Session (Board #102), Sat, 1:15 PM-4:45 PM

Interest in and outcomes with web-based education for return of genetic research results for inherited susceptibility to breast cancer. *First Author: Angela R. Bradbury, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA*

Background: How frequently research participants are interested in receiving genetic individual research results (IRR) and the best method for returning IRR remains unknown. **Methods:** Woman at three centers with a personal or family history of cancer, who provided a bio-sample for research, were offered the opportunity to receive IRR for 25 cancer susceptibility genes. Participants could complete pre-disclosure education by a self-directed web-education (WebED) or by telephone with a genetic counselor (GC). All participants received IRR by phone with a GC. Participants completed surveys at baseline, after pre-disclosure education and disclosure. We used t-tests and multiple linear regressions of change scores. **Results:** 1277 participants were contacted. Mean age was 61.4 years, 68% were white, 68% had a history of cancer and 56% had a college education. 393 (31%) enrolled to receive IRR, 120 (9%) actively declined, and 764 (60%) have not responded to multiple contacts. Age, education and race/ethnicity were not significantly associated with interest in IRR. To date, 211 (81%) completed pre-disclosure education by WebEd and 50 (19%) by GC. Younger age was associated with completing WebEd v GC. 250 (95%) received IRR; 12 (4%) declined. 12 (5%) received a positive result and 56 (22%) a VUS. Knowledge increased significantly after pre-disclosure education and disclosure of IRR, and was not associated with WebEd v. GC pre-disclosure. Depression, anxiety, cancer specific distress and perceived utility declined significantly after pre-disclosure education and disclosure. Change in knowledge, anxiety, cancer-specific distress and uncertainty did not differ from baseline to post-disclosure between WebEd v. GC education. After IRR, having WebEd and receiving a positive result were associated with greater reduction in depression as compared to GC pre-disclosure. **Conclusions:** Among participants interested in receiving genetic IRR, there was high interest in a web-based pre-disclosure education. Web-education was not associated with negative outcomes after receipt of IRR with a genetic counselor, suggesting a potential alternative resource reducing model for return of IRR.

1532 Poster Session (Board #103), Sat, 1:15 PM-4:45 PM

Development of HOPE-Genomics: An IT platform for patient-directed cancer genome sequencing education and return of results. *First Author: Ilana Solomon, City of Hope, Duarte, CA*

Background: Profiling of somatic/germline tissue has the potential to improve outcomes for patients with cancer. However, the realization of precision medicine is hindered by patients' limited understanding of genetics and their own tumor/germline results. Innovations to improve patient education and care engagement are urgently needed. **Methods:** We recruited patients at a comprehensive cancer center to help develop a web-based, patient-directed cancer genomic sequencing education and reporting tool: HOPE-Genomics. We obtained clinical data through patient surveys and chart reviews. We obtained feedback on the tool from patients, family members, and clinicians via focus groups. **Results:** 40 patients (mean age 40, 92% White, 8% Asian, 15% Hispanic, 15% $\leq$ high school) completed the survey; 93% had advanced disease and 30% had lung, 25% breast, 10% ovarian, 18% colon, and 17% other cancers. Although 98% had tumor and/or germline profiling on chart review, 33% of patients were unaware this tested occurred. All breast and gastric cancer patients knew they had *HER2* testing whereas only 20% of CRC patients knew they had *KRAS* testing. The majority of participants wanted to see, or their patients to see, "patient-friendly" reports. When presented with HOPE-Genomics, themes identified in patient/family focus groups included the opinion that the tool could help patients prepare questions, a desire for all types of information (e.g., prognostic, uncertain), and favorable attitudes about including genetic counseling information. Themes identified in clinician focus groups included the opinion that the tool could help patients share information with family and decrease patient confusion. Clinicians had mixed feelings about tool implementation (e.g., provider control vs. time-dependent release of report, concern over disclosure of some types of information). **Conclusions:** Many patients do not recall having molecular/genomic testing but are interested in learning their results. Early development of a web-based education and reporting tool appears to be acceptable to patients, family members and clinicians. We plan to refine the tool and develop processes for optimal clinical integration.

1533 Poster Session (Board #104), Sat, 1:15 PM-4:45 PM

Genomic profiling of tumors from patients with germline *BRCA* mutations. *First Author: Anne-Vibeke Laenkholm, Department of Surgical Pathology, Zealand University Hospital, Slagelse, Denmark*

Background: Gene expression profiling assays are not commonly used for therapy selection for breast cancer patients with germline *BRCA* mutations but a complete molecular characterization could lead to identification of novel subgroups where therapy modification may be considered. We hypothesized that the PAM50 intrinsic subtypes and ROR score in combination with characterization of the immune response could provide biological insights to guide the next generation of treatment strategies for *BRCA*-mutated tumors. **Methods:** The Danish Breast Cancer Group database was used to identify a cohort of 584 *BRCA*-mutated breast cancer patients diagnosed between 1977 and 2011. Tumor RNA from archived FFPE tissue samples was analyzed on the NanoString platform using a 770-gene Breast Cancer Panel and the PAM50 intrinsic subtypes were determined using the Prosigna gene signature algorithm. The immune response was evaluated with the Tumor Inflammation Signature (TIS) score. **Results:** Of the 532 samples assessable for PAM50 subtype, 54% were Basal-like, 7% Her2-Enriched, 23% Luminal B, and 16% Luminal A, with significant heterogeneity between *BRCA1* and *BRCA2* tumors. *BRCA1* tumors were primarily Basal-like while *BRCA2* tumors were enriched for Luminal subtypes. There was a wide range of Prosigna ROR scores with 15% of the Luminal tumors identified as low-risk (ROR$\leq$40). Similarly, there was a broad spectrum of immune response with *BRCA1* tumors demonstrating a higher average TIS score ($P < 0.001$). However, the heterogeneity of TIS by *BRCA* mutant was explained by intrinsic subtype with basal-like tumors exhibiting higher inflammation. **Conclusions:** To our knowledge, this is the largest study of a prognostic signature on *BRCA*-mutated tumors presented to-date. We observed heterogeneity in the intrinsic subtypes and a wide range of inflammation response with differences between *BRCA1* and *BRCA2* tumors being explained by intrinsic subtype. Additional analyses are ongoing including evaluation of signatures associated with DNA Damage, immune profile, and HRD as well as association of expression signatures with outcomes.

	Intrinsic Subtypes: N (%)			
	Basal-like	**Her2-Enriched**	**Luminal B**	**Luminal A**
BRCA1	241 (73)	19 (6)	38 (12)	30 (9)
BRCA2	48 (24)	18 (9)	84 (41)	54 (26)

Risk of pediatric malignancy in families known to carry *BRCA1/2* mutations. *First Author: Kevin Thomas Nead, University of Pennsylvania Perelman School of Medicine Hospital, Philadelphia, PA*

Background: Inherited mutations in cancer predisposition genes typically associated with adult-onset cancers, including *BRCA1/2*, have been found in children with cancer. However, it is unknown whether such mutations are causative. Our objective is to determine whether there is an increased risk of pediatric malignancy in families known to carry *BRCA1/2* mutations. **Methods:** We utilized the Cancer Risk Evaluation Program (CREP), a registry of high-risk breast and ovarian cancer families undergoing *BRCA1/2* testing. We compared the proportion of pediatric malignancies (age $\leq$ 18 years) among families tested positive vs negative for *BRCA1/2* mutations in 1) the proband's siblings and 2) other potential at risk relatives of the proband (siblings, children, nieces and nephews). We used generalized estimating equations to account for familial clustering. We compared pediatric malignancy rates in *BRCA1/2* mutation positive families from CREP to the general population from SEER (Surveillance, Epidemiology and End-Results) using an incidence rate ratio (IRR). **Results:** We compared 1,313 *BRCA1/2* mutation negative and 1,402 *BRCA1/2* mutation positive families. 3,168 siblings had 10 pediatric malignancies (0.3%) in *BRCA1/2* negative families and 3,185 siblings had 9 pediatric malignancies (0.3%) in *BRCA1/2* positive families. When examining at-risk family members there were 30 *BRCA1/2* negative families (2.3%) with a pediatric malignancy (31 malignancies) and 24 *BRCA1/2* positive families (1.7%) with a pediatric malignancy (25 malignancies). We found no evidence for an increased risk of pediatric malignancy in *BRCA1/2* positive vs *BRCA1/2* negative families in the sibling (OR = 0.69, 95% CI, 0.25-1.92; p = 0.482) or family based (OR = 0.76; 95% CI, 0.42-1.35; p = 0.342) multivariable adjusted analyses. The pediatric malignancy rates (per 100,000 person-years) among *BRCA1/2* positive families in CREP (incidence rate [IR] = 16.1, 95% CI, 10.9-23.9) and SEER (IR = 16.1, 95% CI, 16.0-16.3) were similar (IRR = 1.00; 95% CI, 0.65-1.48). **Conclusions:** We find no evidence for an increased risk of pediatric malignancy in *BRCA1/2* mutation positive families. Our data supports delaying *BRCA1/2* testing in *BRCA1/2* mutation positive families until adulthood.

1536 Poster Session (Board #107), Sat, 1:15 PM-4:45 PM

Feasibility of perioperative multi-gene panel testing (MGPT) in cancer patients eligible for hereditary genetic evaluation (GE): The PROTECT pilot. *First Author: Michael J. Hall, Fox Chase Cancer Center, Philadelphia, PA*

Background: Uptake of genetic evaluation (GE) remains limited in cancer pts. MGPT is recommended for GE of women with ovarian cancer (OC), but many will never be tested. For pts w/incident colorectal (CRC) and endometrial cancer (EC), universal mismatch repair screening (uMMR) for Lynch syndrome (LS) precedes GE and is also standard of care, but the limited scope of uMMR screening may obscure actionable mutations in non-LS genes, which are more prevalent than LS. We hypothesized that the opportunity to receive MGPT as part of GE would be favorably received by pts having cancer surgery, when relevance is highest. Additionally, to explore variation in timing/approach, we examined completion of a modified GE approach beginning w/MGPT immediately post-op (i-MGPT) vs completion of GE/MGPT when offered via a usual care (UC) pathway (MD- or self-referral). **Methods:** Women (F)/men (M) w/CRC (n = 20), women w/EC (n = 28) or ovarian cancer/OC (n = 6) were recruited 1-3 days pre/postop (6/2017-1/2018). Interested pts consented and were randomized to i-MGPT vs UC. Those on i-MGPT arm watched a brief pre-testing video about MGPT w/standard genetic counseling available at request. Results were phoned to i-MGPT pts; in-person counseling was encouraged for pathogenic (PV) and uncertain variants. Feasibility was measured by study consent rate (goal $>$ 50%). **Results:** 56/110 (50.9%) eligible pts consented. Most (89%) reported family history (FHx) of cancer. All pts on i-MGPT arm completed GE: 11% (3/27) had actionable PVs—a BRCA2 PV in a 60F w/EC and FHx pancreas cancer; a BRIP1 PV in a 70F w/OC and FHx breast cancer; a MUTYH PV in a 52M w/CRC. On UC arm, only 40.7% (11/27) have completed GE—PVs in MSH6 (70M w/CRC) and BRCA1 (44F w/OC) were found. Another 29.6% (8/27) on the UC arm with strong cancer risks have not sought GC, including 3 pts with cancer $<$ 50 yrs, a 54F w/OC, and a 70F w/IHC+ CRC and a strong FHx cancer. **Conclusions:** Perioperative I-MGPT lead to 100% completion of GE while uptake of GE on the UC arm was lower (40.7%). Of the 5 PVs discovered by MGPT, 4 were in non-LS genes. Peri-op MGPT to evaluate hereditary cancer risk is feasible in CRC, EC, and OC pts.

1537 Poster Session (Board #108), Sat, 1:15 PM-4:45 PM

Importance of genetic counseling referrals for high-risk women with endometrial cancer despite intact mismatch repair immunohistochemistry. *First Author: Jessica Lee, New York University School of Medicine, New York, NY*

Background: Lynch syndrome (LS) accounts for most inherited endometrial cancers (EC). The identification of probands presents a chance to prevent other cancers and enable cascade testing. Professional organizations have released guidelines for genetic counseling referrals (GCR) based on high-risk (HR) criteria including loss of mismatch repair (MMR) protein expression on tumor immunohistochemistry (IHC). **Methods:** All women diagnosed with EC from 2012 to 2017 were retrospectively identified and evaluated. Comparative analyses were performed with appropriate two-sided statistical tests. HR criteria were defined as age $\geq$50 at diagnosis, significant family or personal histories of LS-related cancers or positive MMR IHC. **Results:** A total of 716 women were diagnosed with EC and of these, 230 (32%) had at least one HR criteria. Of the HR women, 51% were given GCR and 13 (19%) were found to have LS. Mid-2015, we implemented universal MMR IHC. GCR rates among HR women were higher after January 2016 (72% vs 52%, $p = 0.01$). Among women with positive MMR IHC, there were higher rates of GCR after January 2016 that trended towards significance (94% vs 67%, $p = 0.08$). Table 1 lists GCR and LS rates. Of the 13 women with LS, 11 underwent MMR IHC. Of the 11 women, six (55%) had loss of MMR expression and one (9%) had intermediate MSH6 expression. Three (27%) had retained expression and one (9%) had loss of MLH1 and PMS2 expression but positive MLH1 promoter methylation; these four women all had significant family histories. All LS women had $\geq$ one HR criteria to warrant GCR Table 1. **Conclusions:** The initiation of universal MMR IHC correlates with a time of increased awareness for GCR among HR women, resulting in higher GCR rates. Although retained MMR expression is regarded as an indication to forgo GCR, almost 40% of LS women had MMR IHC findings which were not suggestive of LS. It is important to consider all HR characteristics even with intact MMR IHC to capture all LS cases.

Cohort	GCR / Cohort	LS / GCR women
All HR women	118 / 230 (51%)	13 / 118 (11%)
Before 2016	69 / 133 (52%)	8 / 69 (12%)
After 2016	49 / 68 (72%)	5 / 49 (10%)
+ MMR IHC women	39 / 52 (75%)	8 / 39 (21%)
Before 2016	24 / 36 (67%)	5 / 24 (21%)
After 2016	15 / 16 (94%)	3 / 15 (20%)

1538 Poster Session (Board #109), Sat, 1:15 PM-4:45 PM

Investigation of discordant sibling pairs from hereditary breast cancer (HBC) families. *First Author: Kara Landry, University of Vermont, Burlington, VT*

Background: Women who undergo testing for hereditary breast cancer (HBC) may be offered a panel of up to 40 genes but the majority of women tested have no mutation identified on these panels. This implies the existence of additional genes associated with HBC. Using a family-based design, our goal is to identify novel gene(s) or variants associated with HBC. **Methods:** We enrolled discordant sister pairs (one with and one without breast cancer) from families with $\geq$3 breast cancers (one diagnosed $\leq$50) on an IRB approved study. Germline DNA was extracted and whole exome sequencing performed. In order to highlight variants identified by our sequencing analysis as putative risk alleles, we used publicly available bioinformatics tools and genomic databases. By combining information across these resources, we generated a list of candidate risk alleles. Discordant allele scores were calculated for each of the variants (from genes with known cancer associations, and variants likely to alter function) seen in $\geq$1 case but no controls. Variants were flagged for further study if they were 1. predicted to alter function (using publicly available data bases), 2. located in a cancer associated gene, and 3. seen at low frequency ($<$ 1%) in the general population. **Results:** We enrolled 22 sister pairs with a mean age of diagnosis for sisters with breast cancer being 44 (range 34-60, only 1 $>$ 55). More than 50% of families have $>$ 3 cases of breast cancer. We have sequence data from germline exomes from 14 sib-pairs. Analysis has revealed several rare variants in genes not previously associated with HBC (ECO1, RECQL4, PMS1, MYC, UBE2D4). Additionally, 8 rare variants in three known HBC genes (BRCA1, CTNNA1, PMS2), but not reported in current databases (i.e. ClinVar), were identified. Co-segregation analysis of these families is underway. **Conclusions:** Using a family-based design we have identified both novel genes and novel variants in known HBC associated genes, in affected sisters from HBC families. These findings may represent private variants associated with HBC or support emerging hypotheses that accumulation of variants in cancer risk associated genes may account for HBC. Future studies will evaluate the functional significance of these variants.

1539 Poster Session (Board #110), Sat, 1:15 PM-4:45 PM

Genetic testing and clinical management practices for variants in non-*BRCA1/2* breast (and/or ovarian) cancer susceptibility genes: An international survey by the Enigma Clinical Working Group. *First Author: Sarah Nielsen, The University of Chicago Medical Center, Chicago, IL*

Background: Advances in massively parallel sequencing technologies have made multigene panels affordable and have revolutionized genetic testing for hereditary breast and ovarian cancer. Through the Evidence-Based Network for the Interpretation of Germline Mutant Alleles (ENIGMA) consortium, we conducted a survey regarding non-*BRCA1/2* genes to assess international testing practices and risk management approaches for breast cancer (BC) and ovarian cancer (OC) susceptibility. **Methods:** Data were collected via in-person and paper/electronic surveys. ENIGMA members from around the world were invited to participate. Additional information was collected via country networks in the UK and in Italy. **Results:** Responses from 61 cancer genetics centers across 20 countries showed that 16 genes were tested by more than 50% of the centers, but only 6, *PALB2, TP53, PTEN, CHEK2, ATM,* and *BRIP1,* were tested regularly. US-based centers tested those genes most often, while UK and Italian centers (not directly affiliated with ENIGMA at the time of the survey) were the least likely to regularly test them. Most centers tested the 16 genes through multigene panels; some centers tested *TP53, PTEN* and other cancer syndrome-associated genes individually. The majority of centers reported pathogenic variants to patients and would test family members for such variants. Gene-specific guidelines for BC/OC risk management were limited and differed between countries, especially with regard to starting age and type of imaging techniques and risk-reducing surgery recommendations. **Conclusions:** Only a few genes beyond *BRCA1/2* are currently routinely analyzed and related management guidelines are limited and largely based on expert opinion. To achieve clinical application of multigene panel testing through evidence-based management practices, clinicians and patients should be encouraged to participate in international initiatives aimed at sharing information from panel testing, interpreting sequence variants, and collecting prospective data to underpin risk estimates and evaluate the outcome of risk intervention strategies.

1540 Poster Session (Board #111), Sat, 1:15 PM-4:45 PM

Non-BRCA hereditary gene mutations and breast cancer phenotype: An ISC-RAM Consortia study. *First Author: Banu Arun, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The use of multi-gene panel testing (MGP) for hereditary breast cancer has been increasing. Currently, the indications for MGP depend on personal and/or family history of cancer, as tumor phenotype and patient characteristics for non-BRCA related cancers are not well described. The present study analyzed tumor characteristics of breast cancers associated with non-BRCA hereditary mutations. **Methods:** Institutional IRB-approved prospective databases from the International Society of Cancer Risk Assessment and Management (ISC-RAM) members were queried for patients with invasive breast cancer who underwent MGP between 2013-2017. Clinical and tumor characteristics for mutation carriers were analyzed using descriptive statistics and Pearson's and Fisher's Chi-Square analyses. **Results:** Of a total of 1,854 patients with invasive breast cancer who underwent MGP, 374 (20%) had a positive pathogenic gene mutation. Median age at diagnosis was 46 years (range: 22-85). Positive testing results were as follows: BRCA1: 77 (21%); BRCA2: 76 (20%); ATM: 45 (12%); CHEK2: 47 (12.5%); PALB2: 32 (8.5%); TP53: 16 (4.3%); MUTYH: 13 (3.5%); 68 (18.2%) patients tested positive for other genes (APC, BRIP1, BARD1, PTEN, STK11, CHD1, MLH, MSH, PMS, CDKN2A, NBN, NF1, RAD50, RAD51, SDHD, AXIN2, MITF, GALNT12, XRCC2). As expected, BRCA1 mutation was associated with triple negative breast cancer ($p < 0.0001$). The tumor characteristics of all other carriers were similar to those seen in BRCA2 carriers with two exceptions: MUTYH carriers were more likely to have invasive lobular cancers ($p < 0.0001$) and TP53 carriers were younger at diagnosis ($p < 0.001$) and more likely to have HER-2/neu positive cancers ($p = 0.006$). **Conclusions:** Our collected series of patients with non-BRCA hereditary breast cancers demonstrates specific tumor characteristics associated with TP53 and MUTYH mutations. Further exploration is warranted to expand this data set and further characterize cancers that are associated with low frequency genetic mutations. The frequency of ER positive tumors in these patients suggests that chemoprevention may be an important strategy in this population.

1541 Poster Session (Board #112), Sat, 1:15 PM-4:45 PM

Integrative clinical genomics of early-onset breast cancer. *First Author: Lixi Li, National Cancer Centre/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College Cancer Hospital, Beijing, China*

Background: The peak onset age of breast cancer in China is about 10 years ahead of Europe and the United States. Early-onset breast cancer has more aggressive clinicopathological characteristics and worse prognosis. The spectrum of germline mutation among unselected patients with early-onset breast cancer is largely uncertain, and it has never been studied among women under 25 years old. Exploring the mutation spectrum of early-onset breast cancer can help identify molecular markers and provide therapeutic targets for clinical treatment. **Methods:** About 20,000 women with breast cancer visited National Cancer Center between 2000 and 2015, and nearly 5% of those patients were 35 years old or younger, of whom 242 women were included in this study. Peripheral blood samples were collected and germline DNA was sequenced with a 139-gene panel using next generation sequencing. Clinicopathological characteristics were assessed by age at diagnosis and mutation status. **Results:** In this study, 58 of the 242 (24.0%) women with early-onset breast cancer had at least one pathogenic germline mutation. The cumulative frequency of pathogenic germline mutations increased with decreasing age at diagnosis ($P < 0.001$). In addition to most of genes previously implicated in breast cancer (BRCA1, BRCA2, CHEK2, TP53, PALB2, MSH2, MSH6, MLH1, RAD51D, RAD51B, ATM), a number of novel mutated genes were identified, including APC, SLX4, TSC2, TGFBR2, RET, SBDS and FANCE. Germline mutation differed according to clinicopathological characteristics. Similar to the association between BRCA1 and TNBC, BRCA2 germline mutation was enriched in luminal B subtype and predicted worse prognosis, and CHEK2 p.H371Y mutation predicted HER2 negativity. **Conclusions:** The cumulative frequency of germline mutations increased with decreasing age at diagnosis. Hereditary susceptibility could account for 50% of breast cancer in ultra-young patients ($\leq$25 years). Germline mutation could predict clinical characteristics and prognosis in early-onset breast cancer. Because of the high frequency and wide spectrum of pathogenic mutations, early-onset breast cancer should be offered genetic testing with a multigene panel.

1542 Poster Session (Board #113), Sat, 1:15 PM-4:45 PM

Beyond *BRCA1* and *BRCA2*: Implementation of a multigene panel for the upfront testing of germline mutations in ovarian cancer. *First Author: Maria Beatriz Mira, Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisboa, Portugal*

Background: Germline mutations impacting homologous recombination repair have been associated with predisposition to breast (BC) and ovarian cancer (OC). OC, even if no family history (FH) confers a 10% combined probability of *BRCA1/2* mutations, being a criteria for testing. *BRCA1/2* detection rate may vary FH and pathology. Besides *BRCA1/2,* other genes have also been associated with hereditary OC. **Methods:** all index, consecutive, OC patients (pts) counselled between September 2016-December 2017 were tested upfront for a panel testing (PT) including *BRCA1*, *BRCA2*, *RAD50*, *RAD51C*, *RAD51D* and *BRIP1 (*BRCA Hereditary Cancer MASTER Plus methodology). All pts were required to have a pathology confirmation of OC (mucinous cases excluded). In here, we analyze the molecular results and discuss the clinical potential of PT for OC. **Results:** 109 female pts consented to PT (108 OC pts and 1 BC pt with a first degree relative with OC). Medium age at testing was 58.1 years (26-83). Pathogenic variants were found in 20 pts (18.3%): *BRCA2* – 8 (40%), *BRCA1* – 5 (25%), *RAD51C* – 3 (15%), *RAD51D* – 2 (10%), *RAD50* – 1 (5%), *BRIP1* – 1 (5%). Of the 8 *BRCA2* pts, 2 were diagnosed with the c.156_157insAlu mutation. 13 pts (65%) had high grade serous OC and 4 pts endometrioid OC (20%). 2 pts had low grade OC, both stage III at diagnosis – one with a *RAD51C* mutation (c.404G > A, p.C135Y) and other with a pathogenic *BRCA2* variant (c.156_157insAlu). All of these pts (except the one with *BRIP1* mutation) had a personal history of OC and 3 of them had had BC and OC (1 *BRCA1,* 2 *BRCA2*). The pt with the *BRIP1* mutation (c.484C > T; p.Arg162Ter) was the only one without OC: she was as BC survivor with a FH of OC. **Conclusions:** With this panel, and without restrictions relating to non-mucinous pathology, we observed a high (18%) germline mutation detection rate for OC. Adding 4 genes to *BRCA1/2* testing increased the mutation detection rate by 53.8%. Even if counselling is complex in families harbouring variants in moderate penetrance genes, our results suggest clinical utility for OC prevention. Other genes will be included in our upfront OC panel.

1543 Poster Session (Board #114), Sat, 1:15 PM-4:45 PM

Prospective Registry of Multiplex Testing (PROMPT): Feasible and sustainable. *First Author: Heather Symecko, Basser Center for BRCA, University of Pennsylvania, Philadelphia, PA*

Background: Prospective Registry of Multiplex Testing (PROMPT) is an online registry for individuals who completed multiplex panel testing for cancer susceptibility. The overall objective of this registry is to ascertain families to allow penetrance calculations for mutations in less characterized genes. **Methods:** Since September 2014, health care providers and commercial laboratories have provided PROMPT information to eligible participants and ordering providers with the test results. The PROMPT registry has self-enrolled those with pathogenic mutations and variants of unknown significance (VUS) in cancer susceptibility genes. Registrants consent to full participation (FP), permitting study investigators to have contact information, or partial participation (PP), with de-identified information only. In 2016, we expanded to Phase II, targeting enrollment by genes of interest for family co-segregation, and collecting additional risk factor data and saliva samples. **Results:** Over 4500 individuals have enrolled into PROMPT. Using initial recruitment goals, to date we have reached 250% of our initial recruitment. 94% of enrollees are women, representing 33 countries (96% from the United States). 63% of participants reported at least one cancer (67% breast cancer) and 23% reported two or more cancers. 29% report likely pathogenic/pathogenic alteration, 25% VUS, and the remaining are in the process of being verified. The most frequently reported genes are ATM (13%), CHEK2 (12%), PALB2 (7%), BRIP1 (4%), and BARD1 (4%). 58% of participants have participated more than 1 year, and of those, 28% completed the first annual follow-up survey. A gene-specific survey sent to participants with CDH1 genetic alterations had a 61% response from FP and a 32% response rate from PP. **Conclusions:** The continued linear enrollment since the inception of PROMPT and the willingness of participants to respond to survey studies, annual follow-up, and PROMPT II enrollment, supports the feasibility and sustainability of a prospective registry for the collection of genetic epidemiology data. Strategies to increase follow up participation are underway, including gene-specific surveys and transitioning PP to FP, for those who are willing.

1544 Poster Session (Board #115), Sat, 1:15 PM-4:45 PM

Treatment failure: Why patients with BRCA mutations are declining risk-reducing surgery. *First Author: Olivia R Khouri, New York University Medical Center, New York, NY*

Background: The NCCN guidelines recommend risk-reducing bilateral salpingo-oophorectomy (RRBSO) for patients with BRCA mutations by age 35-40 or upon completion of childbearing. We previously reported high rates of non-compliance with these guidelines, with many women pursuing RRBSO after 40, if at all. We sought to evaluate patients' reasons for declining RRBSO to identify areas for improvement in counseling and prevention. **Methods:** We conducted a retrospective chart review to identify patients with BRCA mutations (diagnosed 2006–2017). Data were abstracted from electronic medical records and analyzed using descriptive and two-tailed statistics. **Results:** There were 345 women with BRCA mutations identified (57% BRCA1, 43% BRCA2), with median age 32(16–49) at the time of diagnosis. Eighty-seven percent (303) were Caucasian and 50% (172) were of Ashkenazi descent. A majority (87%, 287) had a family cancer history and 25% (88) had a personal cancer history. Thirty-eight percent (132) underwent risk-reducing mastectomy (RRM) and 32% (102) underwent RRBSO. Among those noncompliant with RRBSO, 21% cited menopausal symptoms, 56% fertility preservation, 15% "other," and 8% were lost to follow up. Undergoing RRBSO was associated with age > 40 ($p < 0.0001$), personal cancer history ($p = 0.02$), family cancer history ($p < 0.0001$), and previous RRM ($p = 0.04$). Patients > 40 more often cited menopausal symptoms in declining RRBSO ($p < 0.0001$), while patients < 40 were more likely to cite fertility preservation ($p < 0.0001$). **Conclusions:** Patients with a personal or family history of cancer, history of RRM, or age > 40 were more apt to undergo RRBSO. The majority of women who declined RRBSO reported fertility or menopause as primary concerns. As the age of childbearing increases, counseling of BRCA patients should address early childbearing, assisted reproductive technology, and hormonal therapy to facilitate timely RRBSO for prevention of ovarian cancer and mortality reduction.

1545 Poster Session (Board #116), Sat, 1:15 PM-4:45 PM

Identification and characterization of germline pathogenic variants using matched tumor-normal next-generation sequencing in 7363 pan-cancer patients in China. *First Author: Yuting Yi, Geneplus-Beijing Institute, Beijing, China*

Background: Comprehensive NGS panel based genetic testing is becoming more common to help clinicians provide personalized cancer care. Matched tumor-normal sequencing is recommended primarily to detect tumor-specific variants. Previously under-explored, it could also detect pathogenic germline alterations in cancer patients. Using targeted matched tumor-normal NGS, we identified and characterized germline variants in a large pan-cancer patient cohort in China. **Methods:** We surveyed the germline variants in 7363 Chinese patients across more than 18 diverse cancer types. Germline variants in 62 cancer-susceptibility genes were called from a 1021 gene NGS panel analyzing matched normal DNA. Following AMCG guidelines, variants were classified into pathogenic, likely pathogenic, variant of unknown significance, likely benign, or benign. **Results:** 385 germline pathogenic and likely pathogenic variants (GPVs) were identified in 374/7363 (5.1%) patients. Ovarian cancer (27.6%, 37/134) represented the highest prevalence. Breast cancer (11.3%, 92/813), colorectal cancer (8.3%, 66/791), pancreatic cancer (6.2%, 8/130), renal cell cancer (6%, 5/84), and gastric cancer (5.1%, 14/273) displayed relatively high rates of GPVs in line with expectations. Interestingly, NSCLC (2.5%, 88/3572) and hepatocellular cancer (2.3%, 5/214) also showed such events. In total, only 192/385 (49.9%) participants presented with GPVs in cancer-susceptibility genes in the expected cancer types. *BRCA2* and *BRCA1* were the top two common genes, which were found in 146 patients across 15 cancer types including 27/3572 (1%) NSCLC and 3/214 (1.4%) hepatocellular cancer patients. 285/385 (74%) of the GPVs were actionable for targeted therapy. **Conclusions:** Germline variants can be identified on routine targeted matched tumor-normal NGS and commonly exist in patients with cancers of diverse tissue origin. Recognition of germline variants may be valuable in therapeutic interventions and genetic risk analysis. We are currently performing retrospective family history analysis and genetic counseling for those patients with unreported GPVs.

1546 Poster Session (Board #117), Sat, 1:15 PM-4:45 PM

Population health and cancer testing pilot protocol (PHACT). *First Author: Mallika Sachdev Dhawan, University of California San Francisco, San Francisco, CA*

Background: There is considerable uncertainty on cancer risk and recommendations for genetic testing in various populations. The purpose of this study is to test types and frequencies of cancer risk mutations in large, unaffected multiethnic populations, as well as feasibility and acceptance of general population germline testing. **Methods:** After consent, germline genetic testing via Color Genomics Multigene Cancer Risk panel with personal and family cancer history assessment, was offered to at least 500 participants residing in the San Francisco Bay Area. Participants were older than 21 and without a known personal history of a cancer risk mutation. Recruitment occurred at random and by various community events. Genetic counseling through a genetic counselor at UCSF was offered to all participants. **Results:** 457 total samples have been submitted by 535 consented participants. 28 participants in 440 finalized tests were found to have a cancer risk mutation (6.4%). The majority of these have been in moderate risk cancer mutations including CHEK2 (1.4%), APC (0.9%), MUTYH (1.6%) and NBN (0.4%); higher risk mutations were found in BRCA1 (0.4%), BRCA2 (0.4%), BRIP1 (0.2%), PMS2 (0.2%) and PALB2 (0.2%). 4 additional participants were found to have mutations (3 BRCA1, 1 ATM) but had a known family history of a cancer risk mutation. Ancestry data via self-reporting and SNP testing via the Color Genomics platform was collected to contextualize these results. Rates of VUS (variants of uncertain significance) differed among the various ethnic groups ($p = 0.029$) with the lowest rates in Europeans (18% vs. 31% $p = 0.002$). **Conclusions:** The PHACT study demonstrates that large population screening of cancer risk mutations is feasible. The number of participants found to have mutations was greater than expected although the majority of these were in moderate risk genes. We found high rates of VUS in non-Europeans, which supports the need to broaden genetic testing in minority populations to better understand the significance of these variants. This is to our knowledge the largest study of cancer risk mutations in an unaffected multiethnic population and serves as a pilot to a much larger 10,000-person study of the prevalence of cancer risk mutations across California.

1547 Poster Session (Board #118), Sat, 1:15 PM-4:45 PM

Evaluating empowerment in genetic counseling using patient reported outcomes. *First Author: Suat Ying Lee, National Cancer Centre, Singapore, Singapore, Singapore*

Background: Despite the demand for cancer genetic services, patient-derived benefits remain poorly captured due to a paucity of validated tools. The Genetic Counselling Outcome Scale (GCOS-24), a genetics-specific Patient Reported Outcome Measure (PROM), has been adapted to evaluate our local cancer genetic service (CGS). We aim to evaluate the psychometric properties of GCOS-24 using Rasch analysis. **Methods:** 155 patients who attended CGS at National Cancer Centre Singapore (May 2016-2017) were recruited. The questionnaire was interviewer-administered pre- and post-counselling. Responses were subjected to Rasch analysis, comparing individual Rasch item scores pre and post. Multiple regression analysis was used to assess the association of baseline characteristics with changes in scores. **Results:** GCOS-24 questionnaire displayed good precision (person separation index > 2.0) and targeting (difference between person and item means < 1.0). Cognitive Control [post-intervention: median 1.23 (IQR -0.3-6.2); pre-intervention: median 0.46 (IQR -1.1-3.6)] and Emotional Control [post-intervention: median 0.99 (IQR -1.1-6.4); pre-intervention: median 0.61 (IQR -1.1-3.9)] scores showed significant improvement. All components of cognitive control consistently showed improvement. Notably, aspects of Emotional Control such as alleviating feelings of being upset ($p = 0.88$) and hopelessness ($p = 0.2$) did not reflect significant improvement. Family history ($p = 0.047$) and genetic testing ($p = 0.002$) were significantly correlated with cognitive control. As for emotional control, genetic testing ($p = 0.002$) and the female gender ($p = 0.033$) were also significantly correlated. **Conclusions:** This study shows that GCOS-24 is well adapted and validated in our population. Significant improvements in cognitive and emotional control are concordant with previous adaptations, demonstrating the value of empowerment through genetic counselling. This study highlights the need for further emphasis to be placed on improving hope and addressing emotions, through hope-based interventions and a systems-based approach to identifying and alleviating negative emotions associated with genetic conditions and testing.

1548 Poster Session (Board #119), Sat, 1:15 PM-4:45 PM

The effect of Genetic Cancer Risk Assessment (GCRA) on the uptake of risk-reducing surgeries (RRS) in Hispanic women with breast cancer (BC). *First Author: Yanin Chavarri Guerra, Instituto Nacional de Ciencias Médicas y Nutrición, Salvador Zubirán, Mexico City, Mexico*

Background: The management of women with BC includes GCRA for those at risk of carrying deleterious *BRCA* mutations. GCRA can aid decisions regarding RRS, including contralateral risk reducing mastectomy (CRRM) and risk reducing salpingoophorectomy (RRSO). The uptake of RRS among Hispanic women with BC is unknown, partly due to disparities in access to GCRA. We hypothesized that these disparities may be accentuated in Latin America (LA). **Methods:** Hispanic women from the US & LA (Mexico, Colombia, Peru & Puerto Rico) with history of BC who underwent GCRA, enrolled in the Clinical Cancer Genomics Community Research Network registry from 1997-2016 were included. Demographic characteristics and data regarding RRS were obtained from chart reviews and self-reported surveys. Data was analyzed using Fisher's and x2 tests. An adjusted logistic regression model including a set of selected factors was used to predict the likelihood of undergoing RRS. **Results:** RRS data was collected on 1,517 Hispanic women with BC. 270 (17.7%) were *BRCA* carriers and 1247 (82%) non-*BRCA* carriers. Median age at GCRA was 44 years (y)(range 17-87). Median follow-up was 2.6 y. RRS were more common among *BRCA* carriers (34% CRRM and 27.7% RRSO) compared to non-*BRCA* carriers (18.6% CRRM and 4.1% RRSO). Of those that had CRRM, it occurred after GCRA for 79% of *BRCA* carriers and 50% of non-*BRCA* carriers. Factors associated with CRRM in *BRCA* carriers were: $\geq$1 pregnancies (OR 0.3, p 0.01), and living in the US (OR 5.2, $p < 0.01$). Factors associated with CRRM among non-carriers were: older age (OR 0.9, $p < 0.01$), $\geq$1 pregnancies (OR 1.4, p 0.4), family history of cancer (OR 1.9, $p > 0.1$), living in the US (OR 30.6, $p < 0.01$) and previous ipsilateral mastectomy (OR 2.9, $p < 0.01$). **Conclusions:** RRS uptake among Hispanic women with BC in LA was lower than previously reported in other populations. GCRA may influence risk appropriate RRS uptake, especially for *BRCA* carriers. CRRM and RRSO can prevent new primary cancers, and RRSO can improve survival for *BRCA* carriers, so a better understanding of behavioral factors is needed to inform interventions to improve risk appropriate uptake of RRS among Hispanics.

1549 Poster Session (Board #120), Sat, 1:15 PM-4:45 PM

Influence of vitamin D (Vit D) on mammographic density (MD) and insulin like growth factor 1 (IGF1): Results of CALGB (Alliance) 70806. *First Author: Marie Wood, University of Vermont, Burlington, VT*

Background: Vitamin D is safe and has breast cancer prevention properties. CALGB 70806 was a randomized phase II trial evaluating the effect of vit D on several breast cancer biomarkers (including MD and serum IGF1). **Methods:** Premenopausal women were assigned to receive either 2000IU of Vit D or placebo for 12 months, stratified by baseline (BL) vit D level (sufficient vs insufficient). Eligible women were premenopausal, age < 55, with at least 25% dense breast tissue. Biomarker specimens were collected at baseline and 12 months. MD was determined using the Breast Imaging Reporting and Data System (BIRADS), semi-automated and automated methods. Serum IGF1 was determined by ELISA. Biomarkers were compared between arms using Wilcoxon and t-tests. **Results:** 300 women were recruited from 41 institutions across the US between 1/11 -12/13. The mean age was 42.6 years with 14% Hispanic, 12% African American, 74% European. 62% of participants were vitamin D deficient at enrollment and 49% of women had MD between 25-50% with only 12% over 50% dense. 216 (72%) of participants completed treatment, 8 withdrew due to side effects, and 76 for other reasons (28% withdrawal rate). A significant increase in Vit D was seen with treatment with 99% and 72% of experimental and control subjects having sufficient levels at 12 months($P < 0.0001$)). MD decreased 2.2% over 1 year for the entire cohort, with no significant difference between arms (Table 1). Similarly, no significant change in IGF1 levels was seen with Vit D. **Conclusions:** Vit D supplementation resulted in a significant increase in serum Vit D (from a mean of 35.5 to 49.7 ng/mL, $p = < 0.0001$). However, no significant change in MD was observed with treatment; potentially due to small change in MD seen at 1 year, the low percentage of high MD or that Vit D works by another mechanism. Further study with longer Vit D exposure is warranted. Support: UG1CA189823, U24CA196171. Clinical trial information: NCT01224678.

Biomarker changes over 12 months.

Biomarker	Placebo	Vit D	P-value
25(OH)D (ng/mL)	-0.9 (12.5)	+14.3 (12.9)	< 0.0001
IGF1 (ng/mL)	-0.1 (0.6)	-0.1 (0.6)	0.3699
MD	-2.4% (7.9%)	-1.9% (9.8%)	0.7048

1550 Poster Session (Board #121), Sat, 1:15 PM-4:45 PM

Randomized double-blind placebo-controlled biomarker modulation study of vitamin d in premenopausal women at high risk for breast cancer (SWOG S0812). *First Author: Katherine D Crew, Columbia University Medical Center, New York, NY*

Background: Observational studies have reported an inverse association between vitamin D status and breast cancer risk. We examined whether high-dose vitamin D supplementation among high-risk premenopausal women reduces mammographic density (MD), a strong predictor of breast cancer risk. **Methods:** We conducted a multicenter randomized double-blind placebo-controlled trial among premenopausal women at high risk for breast cancer [5-year Gail risk score $\geq$1.67%, lobular carcinoma *in situ*, prior stage 0-II breast cancer, hereditary breast cancer syndrome, or high MD (heterogeneously/extremely dense)] and with a baseline serum 25-hydroxyvitamin D [25(OH)D] $\leq$32 ng/mL. Subjects were randomized 1:1 to 1 year of vitamin D3 20,000 IU/week or matching placebo. All received standard-dose vitamin D 600 IU/day. The primary endpoint was change in MD from baseline to 1 year as assessed by the Cumulus technique. Secondary endpoints were serial blood biomarkers [25(OH)D, 1,25(OH)D, parathyroid hormone, insulin-like growth factor (IGF)-1, IGF binding protein-3] and MD change at 2 years. **Results:** Among 208 subjects registered from December 2011 to April 2014, median age was 44.6 years (range, 21-50); 84% were white; 33% had a baseline serum 25(OH)D < 20 ng/mL; 78% had a high baseline MD. At 1 year, we observed a significant mean change in serum 25(OH)D in the active vs. placebo group (+18.9 vs. +2.8 ng/mL, $p < .01$), but non-significant change for IGF-1 (-9.8 vs. -1.8 ng/mL, $p = 0.28$). Mean absolute change in MD at 1 year and 2 years after randomization was -0.3% and -1.2%, respectively, in the active arm and +1.5% and +1.6%, respectively, for the placebo arm ($p > 0.05$). At 1 year, MD correlated with serum IGF-1 and IGF-1/IGFBP-3 ($p < .01$). High-dose vitamin D3 was well-tolerated. **Conclusions:** Changes in MD at 1-2 years were small and did not significantly differ between high-dose and standard-dose vitamin D. Longer exposure may be required to detect a difference. The relationship between vitamin D, IGF-1, and MD are hypothesis-generating. Understanding the relationship between vitamin D and biomarkers of breast cancer risk may inform future clinical trials. Clinical trial information: NCT01097278.

1551 Poster Session (Board #122), Sat, 1:15 PM-4:45 PM

Case-only analyses for identifying genotypes that modify the effect of finasteride in the Prostate Cancer Prevention Trial (PCPT): SWOG S9217. *First Author: James Dai, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: The Prostate Cancer Prevention Trial (PCPT) reported decreased risk of all prostate cancers but increased risk of high-grade prostate cancer in the finasteride arm. The aim of the present analysis was to identify genotypes that modify the effect of finasteride using case-only methods for estimating gene-treatment interactions. **Methods:** Germline genetic data from 1157 prostate cancer cases in the Prostate Cancer Prevention Trial (PCPT, NCT00288106) were analyzed by case-only methods. Genotypes included 357 single nucleotide polymorphisms (SNPs) from 83 candidate genes in androgen metabolism, inflammation, circadian rhythm and other pathways. Univariate case-only analysis was conducted to evaluate whether individual SNPs modified the finasteride effect on the risk of high-grade and low-grade prostate cancer. Case-only classification trees and random forests, which are powerful machine learning methods with resampling-based controls for model complexity, were employed to identify a predictive signature for genotype-specific treatment effects. **Results:** Accounting for multiple testing, a single SNP in *SRD5A1* gene (rs472402) significantly modified the finasteride effect on high-grade prostate cancer (Gleason score > 6) in PCPT (p-value = 8×10^{-5}, family-wise error rate < 0.05). Men carrying GG genotype at this locus had a 55% reduction of the risk in developing high-grade cancer (RR = 0.45, 95% C.I. [0.27, 0.75]). Additional effect-modifying SNPs with moderate statistical significance were identified by case-only trees and random forests. A prediction model built by the case-only random forest method classified 36% of PCPT men to have reduced risk of high-grade prostate cancer when taking finasteride, while the others have increased risk. No SNP-finasteride interaction was found for low-grade prostate cancer. **Conclusions:** Case-only methods identified SNPs that modified the effect of finasteride on the risk of high-grade prostate cancer in PCPT and predicted a subgroup of men who had reduced cancer risk by finasteride. Clinical trial information: NCT00288106.

1552 Poster Session (Board #123), Sat, 1:15 PM-4:45 PM

Chest x-ray (CXR) screening to improve outcomes in lung cancer: Reanalysis of the lung cancer component of the Prostate-Lung-Colorectal-Ovary (PLCO) randomized controlled trial. *First Author: John Paul Flores, Virginia Mason Medical Center, Seattle, WA*

Background: CXR screening for lung cancer is considered ineffective because no randomized trial demonstrated a lung cancer mortality reduction. However, in the Mayo Lung Project, CXR screening has been reported to produce significant survival advantages not attributable to overdiagnosis or other screening biases (JCO: 20: 1973-83, 2002). PLCO compared CXR to no screening and reported no lung cancer mortality reduction after 13 years. Lung cancer survival was not reported. That analysis included all lung cancers diagnosed over 13 years, though active screening lasted only 3 years. Since screening is unlikely to benefit individuals diagnosed many years after screening is discontinued, we evaluated lung cancer outcomes among cases diagnosed only within 4 years of randomization. **Methods:** PLCO randomized 77,445 subjects to an experimental group (EG) undergoing a prevalence CXR and 3 annual incidence CXRs and 77,456 to an unscreened control group (CG). Lung cancer survival and mortality were calculated for all lung cancers diagnosed during the 13-year follow-up and those diagnosed only within 4 years of randomization. **Results:** After 13 years, 1,838 and 1,737 lung cancers were detected in EG and CG (RR = 1.06; 95%CI 0.99-1.13; p = 0.09). Five year survival was 24% vs. 19% in EG and CG ($p < 0.001$). There were 1,217 and 1,203 lung cancer deaths, indicating no mortality reduction (p = 0.77). Within 4 years of randomization, 658 and 582 lung cancers were detected in EG and CG (RR = 1.13; 95%CI 1.01-1.13; p = 0.030). Five-year survival was 27% vs. 18% in EG and CG ($p < 0.001$). Among these, there were 463 and 481 lung cancer deaths, a difference not statistically significant (p = 0.58). **Conclusions:** In PLCO, randomization to CXR screening produced a significant improvement in lung cancer survival, an advantage not attributable to any screening bias, including overdiagnosis as lung cancer incidence was not statistically different. The benefit is diminished when lung cancers diagnosed well beyond the active screening interval are included. This analysis supports that CXR screening did save lives in PLCO among patients diagnosed during the active screening period.

1553 Poster Session (Board #124), Sat, 1:15 PM-4:45 PM

Long-term effectiveness and immunogenicity of quadrivalent HPV vaccine in young men: 10-year end-of study analysis. *First Author: Stephen Goldstone, Laser Care Surgery, New York, NY*

Background: The quadrivalent human papillomavirus (qHPV) vaccine prevented HPV6/11/16/18-related persistent infection and external genital lesions in young men in an international, randomized, placebo-controlled pivotal efficacy study. We report the end-of-study analysis of a long-term follow up (LTFU) extension study that assessed the effectiveness and immunogenicity of the qHPV vaccine through 10 years after the first dose. **Methods:** In the 3-year base study, young men (16-26 years old) were randomized 1:1 to receive a 3-dose regimen of qHPV vaccine or placebo; we report results from those who received 3 doses of qHPV vaccine in the base study and participated in the LTFU. The entire study population was assessed annually in the 7-year LTFU for HPV6/11-related genital warts and HPV6/11/16/18-related external genital lesions (EGL), and a subpopulation was assessed for HPV6/11/16/18-related anal intraepithelial neoplasia (AIN) or anal cancer. Persistence of anti-HPV6/11/16/18 antibodies was evaluated from serum samples collected 48-72 months (first LTFU visit) and 10 years post-Dose 1. **Results:** A total of 917 participants were followed for effectiveness for up to 11.5 years (median: 9.5 years) post-Dose 3. There were no new cases of HPV6/11-related genital warts, HPV6/11/16/18-related EGL, or HPV6/11/16/18-related high-grade AIN during the LTFU (Years 3 to 10 of the study) in the per-protocol population. One case of low-grade AIN (AIN1) with positive PCR results for HPV6 and HPV58 was reported. Seropositivity rates assessed by competitive Luminex immunoassay (cLIA) were $> 97\%$ at Month 7 (1 month post-Dose 3); remained high over time for HPV6, 11, and 16; and decreased over time for HPV18 (40.2% at Month 120 by cLIA). Seropositivity rates at Month 120 assessed by IgG Luminex immunoassay (a more sensitive assay) were $> 90\%$ for all 4 HPV types. **Conclusions:** The qHPV vaccine provides durable protection from vaccine-type–related anogenital disease and elicits persistent HPV antibody responses through 10 years post-vaccination onset in 16-26–year-old men. Clinical trial information: NCT00090285.

1554 Poster Session (Board #125), Sat, 1:15 PM-4:45 PM

Breast cancer risk perception and adherence to u.s. cancer prevention guidelines. *First Author: Jillian Eckroate, Yale University, New Haven, CT*

Background: In the United States, nearly 300,000 cancer diagnoses each year are attributed to poor diet and physical inactivity. We sought to determine whether perceived personal breast cancer risk was associated with adherence to healthy lifestyle habits. **Methods:** The National Health Interview Survey (NHIS) is conducted annually by the CDC, designed to broadly represent the U.S. civilian population. We utilized data from the 2010 and 2015 NHIS adult and cancer supplements to evaluate fruit/vegetable intake, alcohol use, and exercise habits among women who perceived themselves to be at high risk of developing breast cancer, as compared to those women who perceived themselves to be at average or low risk. **Results:** In 2010 and 2015, 12,055 and 14,542 women without a history of cancer were surveyed, representing 94,990,140 and 98,404,285 people, respectively. In 2010, those who perceived themselves to be at higher risk of breast cancer were more likely to follow the fruit/vegetable and physical activity guidelines, but less likely to follow the alcohol intake guidelines than those at low to average risk, but these differences were not statistically significant (p = 0.57, 0.15, 0.31 respectively). In 2015, those who perceived themselves to be at high risk were significantly more likely to follow the fruit/vegetable guidelines (p = 0.02) as their low/average risk counterparts, but had similar rates of following alcohol and physical activity guidelines (p = 0.58 and 0.67 respectively). In general, guideline adherence did not improve from 2010 to 2015 (see table). **Conclusions:** Less than a third of women adhere to nutrition and physical activity guidelines regardless of self-perceived breast cancer risk, a trend that has remained stable over time and indicates a need to educate patients on healthy lifestyle habits.

	2010	2015	p-value
High Risk—% meeting guidelines			
Fruit/Veg Intake (³ 5 servings/daily)	4.90%	6.25%	0.25
Alcohol Intake (£ 7/week)	94.22%	95.80%	0.16
Physical Activity (75-150 min vig-mod activity/week)	30.11%	28.97%	0.64
Low/Avg Risk—% meeting guidelines			
Fruit/Veg Intake (³ 5 servings/daily)	4.42%	3.92%	0.11
Alcohol Intake (£ 7/week)	95.13%	95.35%	0.53
Physical Activity (75-150 min vig-mod activity/week)	27.74%	29.79%	0.01

1555 Poster Session (Board #126), Sat, 1:15 PM-4:45 PM

Clinical characteristics and EGD surveillance in Lynch-syndrome patients with small bowel/duodenal carcinomas. *First Author: Deepak B. Vangala, Department of Medicine, Knappschaftskrankenhaus, Ruhr-University Bochum, Bochum, Germany*

Background: Small bowel carcinomas (SBC) account for less than 5% of all gastrointestinal malignancies in the general population. However in patients with Lynch-Syndrome (LS) the life-time-risk for SBC is reported as high as 10%. The aim of this study was to evaluate the effectiveness of esophagogastro-duodenoscopy (EGD) surveillance for early detection of proximal SBCs. **Methods:** The *German Consortium for Intestinal Cancer* database was screened for patients with a diagnosis of SBC. General tumor characteristics such as mutational status and age specific incidence where analyzed. Tumor stage at diagnosis was used as a surrogate parameter for prognosis and correlated to patients being diagnosed by symptoms compared to patients diagnosed by EGD-surveillance. Furthermore, adherence to EGD-surveillance after SBC diagnosis was correlated to survival. Statistics were calculated using Fisher's exact test. **Results:** A total of 125 SBC in 112 patients were included in the study (45.6% duodenal, 32% jejunal, 10.4% ileal, 9.6% unclassified). The median age at diagnosis was 51.7 years (15.1 – 80.7) with 62% of patients being male. MLH1 and MSH2 germline mutations were most prevalent with 37 % each. Of all SBCs, 10.4% of patients were younger than 35 years at diagnosis (8.8 % of duodenal cancers). Duodenal cancer patients undergoing surveillance were diagnosed with early stage disease (UICC I-IIa) significantly more often than patients diagnosed because of symptoms (69.2 % vs 26.6%; $p = 0.0089$). In non-duodenal SBC there was no stage difference between these groups. Adherence to EGD surveillance was better after SBC diagnosis with significantly less cancer deaths among patients undergoing surveillance after SBC. **Conclusions:** To our knowledge, this is the largest study regarding the role of EGD surveillance for early detection of SBC in LS patients. Our data support the use of EGD as a surveillance instrument for duodenal cancer, which make up nearly half of SBC in LS patients. In contrast to current practice in Germany, the results of this study suggest an earlier beginning of EGD surveillance than at the age of 35.

1556 Poster Session (Board #127), Sat, 1:15 PM-4:45 PM

Effects of U.S. Preventive Services Task Force (USPSTF) guidelines on cervical cancer screening, incidence, and mortality. *First Author: Alexander Melamed, Massachusetts General Hospital, Boston, MA*

Background: To evaluate the consequences of USPSTF recommendation to stop pap testing in well-screened women age ≥65 years on cervical cancer incidence and mortality. **Methods:** In 2003, the USPSTF recommended that women age ≥65 years with prior normal cervical cancer screening could discontinue screening. Using nationally-representative survey data from the Behavioral Risk Factor Surveillance System, we constructed a joinpoint model to evaluate if the guideline affected pap smear discontinuation (defined as no pap for ≥5 years). We performed interrupted time-series to evaluate whether guideline-related pap-smear discontinuation affected stage-specific cervical cancer incidence and mortality in women ages ≥65, using women ages 30-64 as controls. Incidence and mortality rates were obtained from the Surveillance, Epidemiology, and End Result program, and adjusted for age and hysterectomy prevalence. **Results:** After declining from 1992 to 2004, the proportion of women reporting no pap smear for ≥5 years increased from 2004 to 2014 among women age ≥65 years and 30-64 years ($p < 0.001$ for both). However, the proportion of women who discontinued screening was greater in those age ≥65 years (10.7 versus 2.7 percentage points from 2004 to 2014, $p < 0.001$). Despite this, women age ≥65 had greater-than-expected declines in the incidence of localized (-2.3% per year, $p = 0.05$) and regional (-3.0% per year, $p = 0.03$) cervical cancer after 2004, compared with 30-64-year-old women. Incidence of distant cancer increased slightly in both groups, but the magnitude of the change did not differ between groups ($p = 0.23$). Cervical cancer mortality rates declined in both groups throughout the study period ($p < 0.001$), and there was no evidence that guideline-related pap-smear discontinuation led to excess mortality among women ≥65 compared to those 30-64 years. **Conclusions:** Compared to women unaffected by the USPTF guidelines, women age ≥65 years had larger declines in the incidence of locally- and regionally-confined cervical cancer, and no difference in the incidence of metastatic cancer. Recommendations to stop pap testing in women age ≥65 did not appear to have led to increased cervical cancer mortality.

1557 Poster Session (Board #128), Sat, 1:15 PM-4:45 PM

Profile of cancer-screening resistant individuals (EDIFICE 6). *First Author: Thibault De La Motte Rouge, Groupe Hospitalier Pitie Salpetriere, Paris, Cedex 13, France*

Background: The efficacy of cancer screening (cost effectiveness, reduced mortality) relies on a minimum threshold uptake rate. Target populations are asymptomatic with only average risk, and thus likely to avoid screening. We studied the characteristics of cancer-screening resistant individuals. **Methods:** The French nationwide observational survey, EDIFICE 6, was conducted online from 26 June-28 July 2017 on a core sample of 12 046 individuals (age 18-69 y). Representativeness was ensured by quota sampling on age, gender, profession, and stratification by geographical area and type of urban district. Multivariate stepwise logistic regression analyses were conducted with a common set of variables to identify factors likely to explain non-uptake of cancer screening. The analysis focused on individuals in the age range of target populations for organized programs: 50-69 y for breast (BC) and colorectal cancer (CRC) (N = 1954 and N = 4300, respectively) and 25-65 y for cervical cancer (CC) (N = 4499). **Results:** Of those who had never taken part in a screening program, 6% (N = 108) were in the target population for BC screening, 12% (N = 539) for CC, and 38% (N = 1625) for CRC screening. Items associated with not undergoing screening included: for BC, the statement "progress is accomplished through clinical research" rated as unimportant (OR = 2.14, 95% CI = [1.16-3.82]); social vulnerability (OR = 2.09, [1.36-3.25]); rating BC prevention programs as ineffective (OR = 1.60, [1.01-2.51]). For CC: living alone (OR = 2.31, [1.89-2.82]); manual worker (OR = 1.95, [1.21-3.05]); social vulnerability (OR = 1.83, [1.49-2.26]). For CRC: self-employed (OR = 1.83, [1.24-2.71]); rating CRC prevention programs as ineffective (OR = 1.76, [1.48-2.08]); current smoker (OR = 1.45, [1.25-1.68]); manual worker (OR = 1.40, [1.05-1.87]). **Conclusions:** Mistrust in clinical research—possibly linked to medical skepticism—and social vulnerability play major roles in resistance to BC screening. A disadvantaged socioeconomic profile has a negative impact on CC screening uptake and yet is an acknowledged risk factor for the disease. Self-employed people who mistrust cancer prevention are resistant to CRC screening. Our findings highlight the need for tailored education campaigns.

1558 Poster Session (Board #129), Sat, 1:15 PM-4:45 PM

A health system experience with an electronic medical record based application to increase lung cancer screening. *First Author: Brandon Weckbaugh, UMKC School of Medicine, Kansas City, MO*

Background: Screening high risk patients for lung cancer with Low Dose Computed Tomography (LDCT) reduces lung cancer-specific mortality, however its adoption in routine clinical care has been limited. We designed an Electronic Medical Record (EMR) based application to identify patients for screening in the primary care setting. **Methods:** A two-step screening application was created to identify patients meeting CMS criteria for LDCT screening in a visit to a primary care provider (PCP). First, the application directs medical assistants to complete a patient's smoking history. If the patient meets eligibility for LDCT screening, step-by-step direction for PCPs to complete the screening process, including reviewing smoking history, shared decision making and ordering the LDCT scan, is initiated. We compared the number of referrals for screening LDCT in the 12-month periods before and after implementation of the screening application. **Results:** During the 12-month period prior to implementation of the screening application in a 18-person PCP group, there were a total of 198 referrals for LDCT screening. Of these, 162 (81.8%) were negative (CAT 1 and 2), 20 (10.1%) required follow up CT (CAT 3), 16 (8.1%) were positive (CAT 4), 3 (1.5%) required an invasive diagnostic procedure (bronchoscopy with biopsy, endobronchial ultrasound, CT guided biopsy, thoracic surgery). Cancer was diagnosed in 2 patients (1.0%), both of whom received cancer treatment. In the 12 months after implementation, referrals increased by 40% to 278. Of these, 241 (86.7%) were negative, 19 (6.8%) required follow up CT, 18 (6.5%) were positive, 4 (1.4%) required an invasive diagnostic procedure, and 3 (1.1%) were diagnosed with cancer and are receiving treatment. Major challenges include variable user compliance in completing accurate smoking history and providers ignoring alerts to initiate lung cancer screening. **Conclusions:** To our knowledge this is the first report on the use of an EMR based application to identify patients at risk for lung cancer. Implementation of the EMR based application correlated with an increase in referrals for LDCT screening and led to the identification of high risk lung lesions including lung cancer.

1559 Poster Session (Board #130), Sat, 1:15 PM-4:45 PM

Attributable failure and costs associated with continued smoking by cancer patients. *First Author: Graham W. Warren, Medical University of South Carolina, Charleston, SC*

Background: Smoking by cancer patients causes adverse outcomes including increased cancer specific mortality, but there are no estimates of the effects of continued smoking in cancer patients on costs of continued medical care for cancer. **Methods:** Attributable failure (AF) was modeled across expected first-line cancer treatment failure in non-smoking patients (ns-FLF), prevalence of current smoking, risk for escalated first-line cancer treatment failure caused by smoking, and cost of subsequent treatment after failure of first-line cancer treatment. **Results:** As smoking prevalence increases, AF increases with peak AF in cancer treatment conditions where ns-FLF ranged from 30-50%. In disease sites with 90% ns-FLF, the AF caused by smoking was lower than in patients with 10% ns-FLF, supporting a more significant effect of continued smoking in patients with higher expected cure rates. Using a conservative 60% increased risk of treatment failure caused by smoking across all cancer patients and cancer treatments published from median cancer related mortality estimates of risk from the 2014 Surgeon General's Report, the conditions of 20% smoking prevalence and 30% ns-FLF resulted in 10.7 AF per 100 smoking patients. Cost per smoking patient per $100,000 incremental cost of ns-FLF cancer treatment was $10,675, Extending results to 1.6 million cancer patients, treatment of AF due to continued smoking by cancer patients cost $3.4 billion for every $100,000 increment of cost of cancer treatment per AF. **Conclusions:** Treatment of AF caused by continued smoking in cancer patients results in significant costs. Because estimates did not include costs associated with medical care not related to cancer progression, results are expected to underestimate the true costs of medical care caused by smoking in cancer patients.

1560 Poster Session (Board #131), Sat, 1:15 PM-4:45 PM

Overweight and breast cancer risk in the International Breast Cancer Intervention studies I and II. *First Author: Samuel G Smith, University of Leeds, Leeds, United Kingdom*

Background: Overweight increases breast cancer risk in population risk postmenopausal women. Data from the National Surgical Adjuvant Breast and Bowel Project (NSABP) P1 and P2 chemoprevention trials indicate premenopausal overweight, but not postmenopausal overweight, increases breast cancer risk in high risk women. We estimated the relationship between overweight and breast cancer risk in the International Breast Cancer Intervention Studies (IBIS) I and II. **Methods:** The IBIS prevention trials compared tamoxifen (IBIS-I) and anastrozole (IBIS-II) vs. placebo in women at increased risk of breast cancer. Baseline body mass index (BMI) was calculated for premenopausal (n = 3138) and postmenopausal (n = 3733) women in IBIS-I and postmenopausal women in IBIS-II (n = 3783). BMI change ($<$ 5%, 5-9.9%, $>$ 10%) was available for 2504 IBIS-I women. There were 542 (IBIS-I) and 168 (IBIS-II) invasive breast cancer events and median follow-up was 19.6 years (IQR 17.8–21.1) and 9.3 years (IQR 7.2–11.4), respectively. We used Cox proportional hazards regression to calculate Hazard Ratios (HRs) for invasive breast cancer risk after adjusting for previous trial participation (IBIS-II only), age, diabetes, hormone therapy use, smoking and menopausal status (IBIS-I only). **Results:** Higher BMI was associated with increased invasive breast cancer risk in IBIS-I (HR = 1.02, 95% CI = 1.00-1.03, p = 0.044) and IBIS-II (HR = 1.06, 95% CI = 1.03-1.09, $p < 0.001$). In IBIS-I, the association between BMI and breast cancer risk was restricted to postmenopausal women (HR = 1.03, 95% CI = 1.01-1.05, p = 0.004). Among IBIS-I postmenopausal women, compared with healthy weight, HRs were 1.20 (95% CI = 0.92-1.56) for overweight and 1.29 (95% CI = 0.97-1.72) for obese women. In IBIS-II HRs were 1.15 (95% CI = 0.75-1.75) for overweight and 1.90 (95% CI = 1.27-2.84) for obese women. There was no interaction between BMI and treatment group in either trial. Weight gain did not affect breast cancer risk. **Conclusions:** Contrary to NSABP P1 and P2 data, we found no evidence for increased breast cancer risk among overweight premenopausal women. IBIS-I and IBIS-II data suggest higher BMI increases breast cancer risk in postmenopausal women with elevated breast cancer risk. Clinical trial information: ISRCTN91879928 and ISRCTN31488319.

1561 Poster Session (Board #132), Sat, 1:15 PM-4:45 PM

Smoking cessation after a cancer diagnosis and survival in cancer patients. *First Author: Graham W. Warren, Medical University of South Carolina, Charleston, SC*

Background: Extensive literature confirms that continued smoking by cancer patients and survivors increases overall mortality, but the benefits of smoking cessation specifically after a cancer diagnosis has not been well described. **Methods:** Comprehensive evaluation of all Pubmed studies identified using "smoking" and "cancer" published since 2000 was performed to identify all studies with at least 100 patients reporting on the effects of smoking cessation after a cancer diagnosis on overall mortality. Studies that evaluated the exclusive or combined effects of smoking cessation before a cancer diagnosis were not included. **Results:** Ten (10) studies were identified that met all inclusion criteria including 7 prospective and 3 retrospective studies. The effects of smoking cessation were evaluated for lung cancer patients in 4 studies, head/neck cancer patients in 3 studies, breast cancer patients in 1 study, and multiple cancers in 2 studies. In 3 prospective studies, continued smoking increased risk of overall mortality as compared with never smoking and quitting smoking had an intermediate risk between continued smoking and never smoking. In 7 studies comparing smoking cessation with continued smoking, the median risk of overall mortality in patients who quit smoking was 0.55 (range 0.19-0.92) as compared with continued smoking including 6 of 7 studies with statistically significant reductions in overall mortality risk. Only 1 study reported on overall mortality in cancer patients who were actively enrolled in a smoking cessation program after a cancer diagnosis, and quitting smoking was observed to reduce overall mortality by 44% (HR 0.56, 95% CI 0.36-0.89). **Conclusions:** Of larger contemporary studies evaluating the effects of smoking cessation after a cancer diagnosis on overall mortality, most demonstrate a significant benefit of quitting smoking.

1562 Poster Session (Board #133), Sat, 1:15 PM-4:45 PM

Community based lung cancer screening program: Evaluation of the initial lung cancer screening CT scan. *First Author: Tripurari Mishra, Advocate Lutheran General Hospital, Park Ridge, IL*

Background: Low-dose chest CT for lung cancer screening has shown to have a significant impact on the early diagnosis of lung cancer. In the initial trials, approximately a 20% decrease in lung cancer mortality was found. Patients enrolled in a community-based lung cancer screening program initiated in March 2013 at Lutheran General Hospital and Illinois Masonic Hospital were evaluated for initial outcomes. **Methods:** All patients who completed an initial consultation in oncology clinic from March 2013-June 2017 were included in the analysis. Eligibility criteria for the program included patients within the age range of 55-77, with a $>$ 30 pack year history, and that were current smokers or quit tobacco less than 15 years ago. Individuals between 50-55 years old were also included if they had $>$ 20 pack year smoking history and at least one additional risk factor. All patients with significant abnormalities were discussed at a multidisciplinary conference prior to embarking on any invasive procedures. Also, they underwent a low-dose chest CT for lung cancer screening and were subsequently seen in consultation by a thoracic surgeon. All patient data was entered into a REDCap database and subsequently evaluated. **Results:** 392 patients were enrolled during the study timeframe. Majority of the patients were caucasian (88%) and male (60%). They were referred by their primary physician (95%). The average age of the sample was 64 years ($\pm$6.6). 211 (53.8%) patients were found to have pulmonary nodules. A total of 506 pulmonary nodules were found with an average size of 4.9 ($\pm$ 4.3) mm. Of the 392 patients who underwent lung cancer screening, a total of 11 lung cancers were found (2.8%). Of the 11 patients, 6 (55%) patients were Stage I, 1 (9%) patient was Stage II, 2 (18%) patients were Stage III, and 1 (9%) patient was Stage IV. There was also 1 (9%) patient with limited stage small cell carcinoma. **Conclusions:** Of the 11 cancer patients identified, 64% presented with early stage lung cancer on initial lung cancer screening. In fact, 55% of the patients presented with Stage I lung cancer. These data suggest that lung cancer screening is a viable tool in discovering early stage lung cancer with the potential to improve lung cancer survival.

1563 Poster Session (Board #134), Sat, 1:15 PM-4:45 PM

Herpes zoster vaccine and varicella zoster virus infection among cancer patients having chemotherapy. *First Author: Lisa Y. Law, Kaiser Permanente, Davis, CA*

Background: Varicella zoster virus (VZV) infection is an opportunistic infection among immunocompromised patients. The herpes zoster (HZ) vaccine is a live vaccine not approved for administration to oncology patients receiving chemotherapy. We aimed to assess the association between HZ vaccine given prior to cancer diagnosis and VZV infection in this population. **Methods:** In this retrospective cohort study conducted in Kaiser Permanente Northern California (KPNC) we assessed the association between prior HZ vaccination and VZV infection in cancer patients age 60-89 years having chemotherapy January 1, 2010-December 31, 2014. Subjects were followed until death, loss of membership, or end of study (December 31, 2016). Multivariable analyses were performed using adjusted relative risk models. Variables controlled for included age, sex, hematological vs. non-hematological cancers, high dose steroid therapy, prior immunomodulation therapy, and antiviral prophylaxis. Subanalyses were performed for subjects with and without hematological cancers. **Results:** Our study consisted of 13,069 subjects having cancer and chemotherapy; of these 5090 (39.9%) had prior administration of the HZ vaccine. Median follow-up time was 26.0 months (IQR: 10.6-42.9). Of vaccinated subjects 198 (3.9%) developed VZV infection compared to 410 (5.1%) of unvaccinated subjects (Adjusted Relative Risk [ARR] 0.73, 95% CI 0.62-0.86). Hematological cancers were associated with VZV infection (referent: other cancers, ARR 2.76, 95% CI 2.32-3.29); antiviral prophylaxis was not (ARR 1.00, 95% CI 0.72-1.40). In subanalyses the HZ vaccine was more protective against VZV infection in subjects with hematological cancers (ARR 0.62, 95% CI 0.47 – 0.83) than in those with other cancers (ARR 0.81, 95% 0.66-0.99). There were 7965 deaths (60.9%) during follow-up. The HZ vaccine was protective against all-cause mortality in all subjects (ARR 0.76, 95% 0.74-0.79). **Conclusions:** The live HZ vaccine is protective against VZV infection in oncology patients receiving chemotherapy; this effect is greater in subjects having hematological cancers. The vaccine is also associated with decreased all-cause mortality.

1564 Poster Session (Board #135), Sat, 1:15 PM-4:45 PM

Occupational exposure to pesticides and prognosis of diffuse large B-cell lymphoma: A cohort study. *First Author: Sylvain Lamure, Department of Clinical Hematology, Montpellier University Hospital, Montpellier, France*

Background: Professional use of pesticides is a risk factor for non-Hodgkin lymphoma. The main biological mechanisms of both pesticides and chemotherapy are genotoxicity and reactive oxygen species generation. Cellular adaptation among patients exposed to low doses of genotoxic and oxidative compounds may hinder chemotherapy efficiency in lymphoma patients. We aim to determine the influence of occupational exposure to pesticides on response to immuno-chemotherapy and survival of patients treated for Diffuse Large B Cell Lymphoma (DLBCL). **Methods:** The ProLyPhy study is a retrospective cohort of patients treated between 2010 and mid-2015, for DLBCL, with a least 2-year follow-up. The study took place in 6 hospitals of central southern France. We screened 404 patients with newly-diagnosed DLBCL treated with anthracycline-based immuno-chemotherapy (R-CHOP like). Occupational history was reconstructed for 244 patients. Occupational data were analysed with the Pestipop French job-exposure matrix to determine probability of occupational exposure to pesticides. We have compared treatment failure rate, 2-year event-free survival (EFS) and overall survival (OS) between exposed and non-exposed patients, after adjustment. **Results:** Mean age was 61.3 years (range 19-90), 62.7% of patients were male, 67 had occupational exposure to pesticides, of which 38 from farming activities. Occupational exposure did not impact clinical and biological characteristics at diagnostic. We observed that exposed patients had significantly higher treatment failure rate: 22.4% versus 11.3% ($p = 0.027$), OR = 3.2 (1.8-11.5, $p = 0.007$); this difference was higher among farmers: 31.4% CR versus 12.8%, $p = 0.005$, OR = 4.6 (1.8-11.5, $p = 0.001$). Two-year EFS was 70% in the occupationally-exposed group versus 82%, HR = 2.1 (CI 95% 1.2-3.6, $p = 0.008$). Among farmers, the difference was more pronounced: 2-year EFS was 56% versus 83%, HR = 3.1 (CI 95% 1.7-5.6, $p < 0.001$). Similarly 2-year OS was lower in the farmer group: 81% versus 92%, HR = 3.9 (CI 95% 1.5-10.0, $p = 0.005$). **Conclusions:** This retrospective study suggests that agricultural occupational exposure to pesticides is an independent risk factor for treatment failure, EFS and OS in DLBCL.

1565 Poster Session (Board #136), Sat, 1:15 PM-4:45 PM

Risk of second malignancies in breast cancer patients who received chemotherapy: A SEER analysis. *First Author: Snigdha Nutalapati, Morehouse School of Medicine, Atlanta, GA*

Background: Chemotherapy agents used in breast cancer have carcinogenic potential and can cause malignancies. Patients with breast cancer could also be at risk for a second malignancy as well. We aimed at determining the risk of after adjuvant chemotherapy for breast cancer. **Methods:** We did an observational study of women who received a diagnosis of breast cancer from 1990 to 2009 using Surveillance, Epidemiology, and End Results (SEER) registries database 9 registries. Second malignancy(SM) was defined as any malignancy diagnosed 6 months after initial diagnosis of breast cancer (includes both chemotherapy-related malignancies and second primary malignancies). hormone receptor (HR) status into estrogen receptor (ER) and progesterone receptor (PR), positive (+) and negative (-). Standardized incidence ratios(SIR) were calculated based on United States population in 2000. p-value of < 0.05 is considered statistically significant. **Results:** Total of 245,235 cases (2,409,502 person-years) were identified, 36.3% received chemotherapy. 66.2% were ER+PR+, 11.9% were ER+PR-, 2.5% ER-PR+ and 19.5% were ER-PR-. Median follow up was 11.3 years (range 1-22.9 years), 36,005 (14.7%) cases eventually developed SM. In patients who received radiotherapy (RT), risk of developing SM was increased by 43% (SIR 1.43 [95%CI 1.39-1.46] in those who received chemotherapy (CT) compared to only 22% (SIR 1.22 [95%CI 1.20-1.24]) in those who did not receive chemotherapy (non-CT). In patients who were not treated with radiotherapy, those who got chemotherapy (CT) had an increased risk of developing SM: SIR 1.27 [95%CI 1.23-1.31]. Breast cancers represented 37% of all SM followed by digestive system (16.6%), uterine (14.3%), bronchopulmonary (12.7%), colorectal (9.4%), urinary system (4.6%), lymphoma (3.4%) and ovarian cancers (3.0%). Acute myeloid leukemia (AML) and salivary gland tumors represented only 1.3% and 0.3% of all SM. **Conclusions:** Risk of secondary malignancies, which includes second primary cancers is significantly higher for cases that received chemotherapy and the risk is increased irrespective of radiation status. Radiation therapy increases the risk for secondary malignancies.

1566 Poster Session (Board #137), Sat, 1:15 PM-4:45 PM

Impact of prophylactic bilateral salpingo-oophorectomy on bone health in *BRCA* mutation carriers: A prospective cohort study. *First Author: Elizabeth Hall, Women's College Research Institute, Toronto, ON, Canada*

Background: Women who inherit a deleterious mutation in *BRCA1* or *BRCA2* face a high lifetime risk of ovarian cancer. Prophylactic bilateral-salpingo oophorectomy (PBSO) is recommended prior to natural menopause; however, the impact of abrupt hormonal withdrawal on bone health in this high-risk population is not known. We conducted a longitudinal study to evaluate the impact of PBSO on bone mineral density (BMD) in *BRCA* mutation carriers. **Methods:** The study population included women who underwent PBSO at the University Health Network (Toronto, Canada) between January 2000 and May 2013. Eligibility criteria included having a *BRCA* mutation, at least one ovary prior to surgery, and no personal cancer history other than breast cancer. Information regarding medical history, medication use, and lifestyle factors was collected via questionnaire. BMD measurements using dual x-ray absorptiometry were collected at baseline (prior to surgery) and follow-up. The % change in BMD from baseline to follow-up was calculated for the lumbar spine, femoral neck, and total hip. **Results:** A total of 103 women had baseline and follow-up BMD measurements available. Mean age at PBSO was 49 years (range 37-52). Mean time to first follow-up was 2.04 years (range 0.98-4.74). Among women premenopausal at the time of surgery ($n = 58$), there was a significant change in BMD from baseline to first follow-up in the lumbar spine (-5.32%; 95% CI -7.17 to -3.48), femoral neck (-2.94%; 95% CI, -4.62 to -1.26), and total hip (-2.75%; 95% CI, -3.82 to -1.68) respectively. Among the women who were postmenopausal at the time of surgery ($n = 45$), there was a significant change in BMD across the lumbar spine (-2.41%; 95% CI, -4.41 to -0.41), and femoral neck (-2.73%; 95% CI, -4.86 to -0.60), but not for total hip (-0.78%; 95% CI, -2.40 to 0.85). **Conclusions:** These preliminary findings suggest significant post-operative bone loss, particularly among women who were premenopausal prior to PBSO. Targeted interventions as well as routine BMD measurements may be needed to improve management of bone health in this population. Additional analyses evaluating the impact of supplement use, body mass index, as well as hormone replacement therapy are underway.

1567 Poster Session (Board #138), Sat, 1:15 PM-4:45 PM

Comparing the prevalence of non-AIDS defining cancers by HIV status in the Ohio Medicaid population. *First Author: Siran M. Koroukian, Case Western Reserve Univ, Cleveland, OH*

Background: Persons living with human immunodeficiency virus (PLWHV) are over-represented in low income and minority populations. This makes Medicaid data particularly relevant for evaluating cancer care needs and outcomes among PLWHV. As a first step, we compare the prevalence of non-AIDS defining cancers (NADCs) between PLWHV and their non-HIV counterparts, hypothesizing that, adjusting for age, race, and sex, PLWHV are more likely than others to have been diagnosed with NADCs. **Methods:** This is a cross-sectional of Medicaid beneficiaries 18-64 years of age, using the 2012 Ohio Medicaid Analytic eXtract (MAX) file. Demographics included age, race (White, Black, and Other), and sex (male, female). We identified HIV status, as well as cancer for the different anatomic sites based on ICD-9 diagnosis codes documented in inpatient and outpatient claims data. We conducted descriptive analysis, and multivariable logistic regression analysis to evaluate the association between HIV status and NADCs after adjusting for age, race and sex. Given that a large percentage of Medicaid beneficiaries are enrolled in Medicaid for only part of the year, we also adjusted for the length of enrollment in Medicaid in our multivariable analysis. **Results:** Our study population included 1,061,471 individuals; 0.28% were PLWHV. Men and Blacks represented 55.2% and 58.9% of PLWHV, respectively, compared with 35.7% and 28.5% of their non-HIV counterparts. Adjusting for age, race, and sex, the two NADCs with which PLWHV were significantly more likely to have been diagnosed were rectal cancer (adjusted odds ratio: 4.03 (95% confidence interval: 2.31 - 7.03)), and anal cancer (34.19 (21.82-53.57)). **Conclusions:** For some cancers, the burden is significantly higher in PLWHV than among others. The higher prevalence of rectal and anal cancer highlights the importance of cancer prevention through screening and safe sex practice.

1568 Poster Session (Board #139), Sat, 1:15 PM-4:45 PM

Global, regional, and national cancer incidence, mortality, years of life lost, years lived with disability, and disability-adjusted life-years for 29 cancer groups, 2006 to 2016: A systematic analysis for the Global Burden of Disease study. *First Author: Christina Fitzmaurice, University of Washington, Institute for Health Metrics and Evaluation, Division of Hematology, Seattle, WA*

Background: Increasing burden due to cancer poses a threat to human development, which has resulted in global political commitments reflected in the Sustainable Development Goals as well as the WHO Global Action Plan on NCDs. To determine if these commitments have resulted in improved cancer control, quantitative assessments of the cancer burden are required. In the Global Burden of Disease (GBD) study 2016 we assessed the cancer burden for 29 cancer groups in order to provide a framework for policy discussion, resource allocation, and research focus. **Methods:** Cancer incidence, mortality, years lived with disability, years of life lost, and disability adjusted life years were analyzed for 195 countries from 2006 to 2016 using the GBD estimation methods. Levels and trends were analyzed over time, and by Sociodemographic Index (SDI). Changes in incident cases were decomposed into changes due to the epidemiological versus the demographic transition. **Results:** In 2016, there were 17.2 million cancer cases worldwide and 8.9 million deaths. Incident cases increased by 28% between 2006 and 2016. The smallest increase was seen in high-SDI countries. Aging contributed 17%, population growth 12%, and changes in age-specific rates -1% to this change. The most common cancer globally for men was prostate cancer (1.4 million). The leading cause of cancer deaths and DALYs was tracheal, bronchus, and lung cancer (1.2 million deaths and 25.4 million DALYs). For women, the most common cancer and leading cause of cancer deaths and DALYs was breast cancer (1.7 million cases, 535 000 deaths and 14.9 million DALYs). Between 2006 and 2016, the average annual age-standardized incidence rates for all cancers increased in 154 of 285 countries. The average annual age-standardized death rates for all cancers decreased in 221 of 285 countries. **Conclusions:** Large disparities exist between countries in cancer burden. Scaling up cancer prevention and ensuring universal access to cancer care are required for health equity and to fulfill the global commitments for NCDs and cancer control.

1569 Poster Session (Board #140), Sat, 1:15 PM-4:45 PM

Milk intake and mammographic density in premenopausal women. *First Author: Yunan Han, Division of Public Health Sciences, Department of Surgery, Washington University School of Medicine, St. Louis, MO*

Background: Mammographic density (MD), which reflects the amount of epithelial and stromal tissues in relation to adipose tissue in the breast, is a strong risk factor for breast cancer. Although diet is associated with breast cancer risk, studies evaluating the associations of adult diet with MD have mainly reported null associations. Few studies have, however, investigated the associations of dairy intake with MD, with conflicting results. Therefore, we investigated the associations of milk intake with MD in premenopausal women. **Methods:** We recruited 375 premenopausal women, with no history of cancer, who had routine screening mammography at the Breast Health Center, Washington University in St. Louis in 2016. We used Volpara to measure MD: volumetric percent density (VPD), dense volume (DV) and non-dense volume (NDV). In addition to known breast cancer risk factors, all participants completed a detailed questionnaire on milk intake (skim milk and 1%/2% milk were categorized into 4 groups: $<$ once/week, once/week, 2-6 times/week, $\geq$once/day; whole and soy milk were categorized into 2 groups: $<$ once/week, $\geq$once/week, because fewer women consumed them). We used multivariable linear regression models (adjusted for age, body mass index (BMI), parity, oral contraceptive use, family history of breast cancer, race) to evaluate the associations between milk intake and log transformed VPD, DV and NDV. Beta coefficients (β) were evaluated and back transformed for easier interpretation. **Results:** The mean age was 47.5 years (range: 32-58 years), mean VPD was 9.48%, mean DV was 80.69 cm^3, and mean NDV was 1079 cm^3. Compared with women who drank 1%/2% milk $<$ once/week, VPD was 20% (p-value = 0.003) lower in the once/week group, 14% (p-value = 0.047) lower in the 2-6 times/week group, and 12% (p-value = 0.144) lower in the $\geq$once/day group. NDV was 19% (p-value = 0.039) lower among women who drank soy milk $\geq$once/week compared with women who drank $<$ once/week. There were no associations of skim and whole milk with MD. **Conclusions:** We observed that 1%/2% milk intake was inversely associated with VPD, while soy milk intake was inversely associated with NDV. Further studies on how 1%/2% and soy milk intake impact MD are needed, as this could have implications in breast cancer prevention.

1570 Poster Session (Board #141), Sat, 1:15 PM-4:45 PM

Association between pesticides use and incidence of diffuse large B cell lymphoma (DLBCL). *First Author: Alaa Altahan, University of Tennessee Health Sciences Center, Memphis, TN*

Background: Some studies have linked pesticide exposure to risk of developing cancers. However, these studies were limited to single or few pesticides. We analyze association between incidence of DLBCL and all chemicals reported by The United States Geological Survey (USGS). **Methods:** Using International Classification of Diseases for Oncology (ICDO-3) code 9680, patients (pts) diagnosed with DLBCL in 2012 were extracted from Lymphoma-leukemia dataset from The Surveillance, Epidemiology, and End Results (SEER) database. Pts were grouped by Federal Information Processing Standards (FIPS) code. United States Census data (www.census.gov) was used to obtain population estimates for each FIPS code in 2012. USGS data (www.usgs.gov) was used to extract quantitative pesticides use in the year of 1992 per FIPS code*. Incidence of DLBCL per FIPS code was calculated then matched to USGS data. SPSS software was used for statistical analysis. Association between level of pesticides use and incidence of DLBCL was analyzed using linear regression. Two tailed P value of <0.05 on Pearson correlation was used for statistical significance. **Results:** A total of 2258 pts with DLBCL in 167 counties were identified. Of the 290 chemicals reported by USGS, 65 were excluded due to lack of data. Of the remaining 225, forty showed statistically significant correlation (30 positive and 10 negative) with incidence of DLBCL. Of these chemicals, 8 have moderate or strong correlation with R coefficient $>$ 0.4 (table). **Conclusions:** Some agriculture chemicals have significant correlation with incidence of DLBCL. This warrants further evaluation of these chemicals as potential carcinogens or protective agents. Analysis of the underlying mechanisms may reveal some common mechanisms.

Chemical	R coeff	P - value	Median	Range	N**
BARIUM POLYSULFIDE	0.997	0.049	8.3	3.1-12.2	3

1573 Poster Session (Board #144), Sat, 1:15 PM-4:45 PM

The role of adiposity in the association between type 2 diabetes and the risk of breast cancer. *First Author: Maria Bota, University of Strathclyde Institute for Global Public Health at iPRI, Ecully, France*

Background: Studies have shown an increased risk of breast cancer (BC) among women with type 2 diabetes (T2D). This association could be causal, related to hyperglycaemia or hyperinsulinaemia, or could be triggered by other factors such as obesity and physical inactivity which are known risk factors for T2D and for BC in post-menopausal women. **Methods:** A meta-analysis was performed to assess the risk of BC in T2D patients compared to non-diabetic women, with special attention to changes in the risk of BC when the body mass index (BMI) was included in multivariate analyses. Studies were selected if they had a prospective design. Studies that compared BC incidence in T2D women to the incidence in the general population were excluded. Summary relative risks (SRR) and 95% confidence intervals (CI) were computed using random-effects models. **Results:** Eighteen studies were included in the meta-analysis, based on 28,230,143 person-years of follow-up and 320,111 BC cases. Compared to non-diabetic women, the SRR of BC among T2D women was 1.13 (95% CI: 1.04, 1.24). There was a large amount of unexplained heterogeneity of results across studies (I^2 = 95%), but no indication of publication bias. Three studies reported the risk of BC by BMI category, with a consistently higher risk of BC associated with increasing BMI. In the 9 studies that adjusted for adiposity, the SRR decreased to 1.05 (95% CI: 0.97, 1.14) while the heterogeneity of results across studies reduced to I^2 = 21%. Only two studies reported data by menopausal status. In contrast, in the 9 studies that did not adjust for adiposity, the SRR increased to SRR = 1.19 (95% CI: 1.01, 1.39), while the heterogeneity remained high (I^2 = 98%). Five studies reported data for post-menopausal women only, with a SRR of 1.13 (95% CI: 0.89; 1.44) and high heterogeneity (I^2 = 94%) with one study representing 82% of the weight in the meta-analysis. **Conclusions:** This analysis provides evidence for a moderately increased risk of BC in T2D women. The effect of the adjustment for BMI on the SRR and on the heterogeneity suggests that the higher risk of BC among women with T2D may not be due to the diabetes itself but to adiposity. New studies should examine the relationship between BC, T2D and adiposity in premenopausal women.

1574 Poster Session (Board #145), Sat, 1:15 PM-4:45 PM

Nasopharyngeal cancer in Alaska Native people: A cancer health disparity. *First Author: Matthew J. Olnes, Alaska Native Tribal Health Consortium, Anchorage, AK*

Background: Cancer is a leading cause of death in Alaska Native (AN) people. Significant cancer health disparities exist in both incidence and mortality between AN people and the US Whites. Nasopharyngeal cancer (NPC) is the leading cancer disparity among AN people, with an incidence rate 17.3 times higher (2009-2013) and a mortality rate that is 21 times higher (1992-2011) than those in US whites. The etiologic basis for these disparities has not been identified. **Methods:** To better understand this health disparity, we created an Alaska Native NPC patient database derived from the Alaska Native Tumor Registry and Alaska Native Medical Center Tumor Registry to characterize all cases of NPC in AN people over the last forty years. We identified 186 cases of NPC in AN people from 1976 to 2016 by merging electronic data sets from the Alaska Native Medical Center Tumor Registry and the Alaska Native Tumor Registry, and analyzed, baseline demographics, clinical and pathologic features, patterns of care, and treatment outcomes for this disease for which data were available for analysis. **Results:** The median age of AN NPC patients was 60 years, and 68% of patients were male. The regions with the highest numbers of NPC were Anchorage/Mat-Su, followed by Yukon-Kuskokwim and Norton Sound regions of Alaska. The histologic subtype of NPC by World Health Organization category were 55% of tumors type 3, 25% type 1, and 15% type were type 2. Most AN patients with NPC presented at advanced AJCC TNM clinical stages at the time of diagnosis with 2% diagnosed at stage I, 10% at stage II, 9% at stage III, and 43% at stage IV. Patients were treated with chemotherapy (62%), radiation (69%), and combinations of chemotherapy and radiation (58%). Median survival for all patients was 2.5 years (95% Confidence Interval 1.9-3.0). **Conclusions:** This study represents the first characterization of NPC in AN people that includes treatment and clinical outcome data, and it may serve as a useful database to develop treatment guidelines and future translational studies to better understand this cancer health disparity.

1575 Poster Session (Board #146), Sat, 1:15 PM-4:45 PM

Prevalence of HIV infection among cancer patients in a Haitian hospital. *First Author: Joseph Bernard, Université Notre Dame d'Haiti, Faculté de Médecine et des Sciences de la Santé, Port-Au-Prince, Haiti*

Background: Malignancies are nowadays among the main conditions affecting HIV-infected patients. The state of immunosuppression puts these patients at high risk of developing cancer in their lifetime. The objectives of this study were to determine the prevalence of HIV infection among cancer patients and compare the overall mortality rate between the HIV-positive and HIV-negative subpopulations. **Methods:** A two-year retrospective study was conducted in the cancer program of Innovating Health International (IHI). Were included all cancer patients with a known HIV status enrolled from January 1st, 2016 to December 31st, 2017. Date of admission, age, gender, cancer type, cancer stage, antiretroviral therapy status for HIV-infected patients and outcome were the main variables selected for this chart review. HIV infection was tested as a factor associated with mortality. **Results:** Among the 785 cancer patients selected for this study, 398 (50.7%) had a known HIV status. Thirty (7.5%) of them were HIV-infected, among them 19 women and 11 men. The mean age was 45.9 years [25-69] versus 49.5 years [16-87] for the HIV-negative patients (p = 0.15). There were 11 patients with AIDS-defining cancers (ADC) such as invasive cervical cancer (n = 8) and Non-Hodgkin lymphoma (n = 3). 18 patients had Non-AIDS-defining cancers (NADC) such as head and neck cancers (n = 8), among them 3 oral cancers and 3 ocular cancers, breast cancer (n = 4), penile cancer (n = 2), and one case each of Hodgkin's lymphoma, lung cancer, ovarian cancer and pancreatic cancer. 1 patient had a carcinoma of unknown primary (CUP). 22 of these 30 patients (73.3%) were already known HIV-infected before their admission and were on antiretroviral therapy. 75% of the staged patients were at stages III or IV of their cancer. The overall mortality rate was 33.3% [95% CI, 17.3% – 52.8%] versus 20.9% [95% CI, 16.9% – 25.4%] for the HIV-negative patients. HIV-infected cancer patients were more likely to die than HIV-negative ones. (Odds ratio = 1.9, p = 0.11). **Conclusions:** The prevalence of HIV infection among the cancer patients was 7.5% [95% CI, 5.1% - 10.6%], with a predominance of Non-AIDS-defining malignancies. HIV infection was not for this cancer cohort a significant factor associated with mortality.

1576 Poster Session (Board #147), Sat, 1:15 PM-4:45 PM

Non-AIDS defining malignancies among HIV-infected patients in a tertiary referral center in Hong Kong. *First Author: Daisy Wing-san Mak, Queen Elizebeth Hospital, Hong Kong, Hong Kong*

Background: Non-AIDS defining malignancy (NADM) is increasingly recognized as an important cause of death among human immunodeficiency virus (HIV)-infected individuals. This study describes the details and survival trend of NADM in this group of patients in a tertiary center in Hong Kong. **Methods:** We have investigated the occurrence of NADM in a retrospective observational study of 1,523 HIV-infected patients. Baseline demographics, immunological data, the use of highly-active anti-retroviral therapy (HAART), details of malignancy and their treatment were analyzed. Survival was analyzed by Kaplan-Meier and Cox proportional hazards model. **Results:** From November 1993 to March 2013, a total of 41 NADM was diagnosed in 39 HIV-positive patients. Lung cancer, anogenital cancer, head and neck cancer, and hepatocellular carcinoma were the most common malignancies among the NADM. Compared with the 65 patients diagnosed with AIDS-defining malignancy (ADM), patients with NADM were significantly older at cancer diagnosis (age 53 vs. 47, p = 0.01), had a significantly longer duration of HIV infection (94 vs. 2 months, $p < 0.0001$), were more likely to be recipients of HAART (92% of patients with NADM vs. 77% of patients with ADM, p = 0.028), and had a significantly higher CD4 count at cancer diagnosis (257 vs. 76 cells/ul, $p = < 0.0001$). Median survival of patients with NADM was 9 months (95% CI, 4.3-13.8 months), and was not dependent on age, CD4 count at diagnosis of malignancy, and treatment with HAART. **Conclusions:** This retrospective, observational study describes the pattern of NADM in a tertiary institution in Hong Kong. Together with the emerging body of literature on NADM, we have known that the general trend of NADM is rising in HIV-infected population, and the risk of these cancers is much beyond than seen in the general population. Frontline clinicians must recognize that these diseases strike a population at an age which still permits high functional capacity. The oncology community should add to the knowledge of how the immune system interplays with environmental factors and oncogenesis, work towards the goals of reducing the morbidity in these patients, and ultimately, prevent these diseases and revert the mortality.

1577 Poster Session (Board #148), Sat, 1:15 PM-4:45 PM

Prevalence of germline genetic alterations in colorectal cancer patients. *First Author: Andrea Cercek, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Although universal screening of all colorectal tumors for Lynch syndrome (LS) is recommended, the prevalence of other germline mutations, with potential clinical implications, in colorectal cancer (CRC) patients is less well-defined. We performed comprehensive germline testing (GT) in a prospective cohort of CRC patients in order to determine the proportion of clinically actionable germline mutations detected by universal tumor-normal sequencing. **Methods:** Between 11/2015 to 1/2018, 427 unselected CRC patients were prospectively consented to GT in 76-genes associated with cancer susceptibility using an IRB-approved protocol. Prevalence of likely pathogenic and pathogenic genetic alterations (PGAs) were reported and correlated with clinical and somatic findings. **Results:** Of 427 CRC patients, the median age was 52 years (range, 18-88 years), 54% were male. PGAs were present in 55 (13%) of CRC patients including 24 PGAs in high-penetrance (MLH1, MSH2, MSH6, EPCAM, PMS2) and 23 PGAs in moderate-low penetrance (CHEK2, mono-MUTYH, APC I1307K) CRC-associated risk genes. The prevalence of moderate/high PGAs was 12.5% (20/160) versus 6% (17/267) in patients with CRC age $\leq$50 versus age $>$ 50, respectively (p-value = 0.045). LS accounted for 12 (60%) and 5 (30%) of high or moderate mutations in the age $\leq$50 versus age $>$ 50 groups. All LS-associated tumors exhibited concordant tumor findings with high-frequency microsatellite instability, deficient mismatch repair protein expression, or high mutational load. Seventeen (31%) of patients with PGAs did not meet current guidelines for GT. PGAs not traditionally associated with CRC-risk were identified in 14 cases, including 7 high- (4 BRCA2, 1 FLCN, 1 NF1, 1SDHA) and 7 moderate-penetrance (3 BRIP1, 3 ATM, 1 HOXB13) genes. Correlative tumor data, including assessment of somatic mutations and loss of heterozygosity in the gene(s) corresponding to these germline mutations will be presented. **Conclusions:** Although the prevalence of PGAs is higher in patients with young-onset CRC($\leq$ 50), LS accounts for the vast majority of germline mutations in these patients. Analysis of PGAs not traditionally associated with CRC to evaluate for causality versus incidental findings will be performed.

1578 Poster Session (Board #149), Sat, 1:15 PM-4:45 PM

Genetic testing and results in population-based breast cancer patients and ovarian cancer patients. *First Author: Allison W. Kurian, Stanford School of Medicine, Stanford, CA*

Background: Genetic testing for cancer risk has expanded rapidly, with more genes tested. Little is known about test use or pathogenic variant (PV) prevalence among population-based cancer patients. **Methods:** Women aged $\geq$20 years, diagnosed with breast or ovarian cancer in 2013-14 and reported to SEER registries covering the entire populations of Georgia and California, were included. Registry data were linked to clinical genetic testing results, performed from 1/1/2012 through 4/30/2016, by 4 laboratories that did nearly all cancer genetic testing in these states. **Results:** There were 77,085 breast cancer and 6,001 ovarian cancer patients, with almost 30,000 patients of racial groups other than non-Hispanic (NH) White. One-quarter (24.1%) of breast and one-third (30.9%) of ovarian cancer patients had genetic test results. While test use was similar across racial groups for breast cancer, testing in ovarian cancer patients was lower in NH Blacks (21.6%, CI 18.2-25.4%, vs NH Whites: 33.8%, CI 32.3-35.4%). The most prevalent PVs in breast cancer patients were *BRCA1* (3.2%), *BRCA2* (3.1%), *CHEK 2* (1.6%), *PALB2* (1.0%), *ATM* (0.7%), *NBN* (0.3%) and *TP53* (0.3%); and in ovarian cancer patients were *BRCA1* (8.7%), *BRCA2* (5.8%), *CHEK2* (1.4%), *BRIP1* (0.9%), *MSH2* (0.8%), *ATM* (0.6%) and *RAD51C* (0.6%). Racial differences in PVs included *BRCA1* (ovarian cancer: NH Whites, 7.2%, CI 5.9-8.8%; Hispanics, 16.1%, CI 11.8-21.2%) and *CHEK2* (breast cancer: NH Whites, 2.3%, CI 1.8-2.8%; NH Blacks, 0.2%, CI 0-0.8%). Among those tested for all genes designated by the National Comprehensive Cancer Network as associated with their cancer type (breast: *ATM, BRCA1, BRCA2, CDH1, CHEK2, NBN, NF1, PALB2, PTEN, STK11, TP53*; ovarian: *BRCA1, BRCA2, BRIP1, EPCAM, MLH1, MSH2, MSH6, PMS2, STK11, RAD51C, RAD51D*), 7.7% of breast and 14.5% of ovarian cancer patients had a PV. **Conclusions:** Clinically tested, population-based breast cancer patients and ovarian cancer patients had 8-15% PV prevalence in guideline-designated cancer risk genes. *CHEK2* and *ATM* PVs were relatively prevalent in ovarian cancer patients: this merits further study because *CHEK2* and *ATM* are not known to be ovarian cancer risk genes. Racial testing disparities are targets for improvement.

1579 Poster Session (Board #150), Sat, 1:15 PM-4:45 PM

Impact of pre-surgical germline multigene panel testing on choice of surgery for breast cancer. *First Author: Elena Zarcaro, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Knowledge of hereditary risk-associated mutations may impact primary surgical decision-making for breast cancer(BC) patients (pts). Since 2015, all new pts seen in the Massachusetts General Hospital (MGH) multidisciplinary BC clinic have been screened by genetic counselors (GCs) for rapid GC consultation and multigene panel testing. We sought to determine the impact of pre-surgical BC multigene panel testing on the timing and type of surgery. **Methods:** All pts screened and tested by the MGH GCs from July, 2016 through December, 2017 were identified, and only those who had surgery at MGH were included. Pts may have had genetic testing prior to initial visit at our institution. Screening criteria for rapid GC consultation included personal or family history of BC with the following features: age $<$ 45, triple negative age $<$ 60, male, bilateral, Ashkenazi Jewish descent, or ovarian ca. Surgical and genetic testing outcomes were collected by retrospective chart review and Fishers exact test was used for statistical analysis. **Results:** During our study period, 1341 eligible pts were screened in the MGH multidisciplinary BC clinic. Of 628 pts who met genetic testing criteria, 588 (93.6%) were tested and 50 (8.5%) were positive for a germline mutation including 16 BRCA1, 10 BRCA2, 8 ATM, 8 CHEK2, 5 PALB2 and 1 each of TP53, BRIP1, and RAD51C. In 24 pts with BRCA1/2 mutations who had genetic results prior to surgery, 21 (87.5%) had upfront bilateral mastectomies (BM). In 21 pts who tested positive for other germline mutations before surgery, 14 (66%) had upfront BM. In a cohort of 120 pts with negative test results before surgery, only 37 (30.8%) had up front BM ($p < .05$ compared to BRCA1/2 and other germline mutations). **Conclusions:** Screening newly diagnosed BC pts for rapid GC consultation and testing prior to surgery successfully identified pts with germline mutations in our population. Pts with BRCA1/2 mutations had a higher rate of BM than gene-negative pts and pts with other germline mutations also had a higher rate of BM. Further studies should explore factors influencing pre-operative decision-making in the context of non-BRCA1/2 germline mutations to assess concordance with guideline recommendations.

1580 Poster Session (Board #151), Sat, 1:15 PM-4:45 PM

Mosaic *TP53* pathogenic variants on multi-gene hereditary cancer panel testing: Clinical characteristics and follow-up testing. *First Author: Sarah A. Jackson, GeneDx, Inc., Gaithersburg, MD*

Background: Li-Fraumeni Syndrome (LFS) is an autosomal dominant cancer susceptibility syndrome due to germline pathogenic variants in *TP53* and is associated with a significant risk for sarcomas, female breast, and other cancers. A subset of individuals undergoing germline *TP53* analysis will have a variant with an allele fraction (AF) less than that in heterozygous individuals, consistent with mosaicism. *TP53* mosaicism may be limited to hematopoietic cells, such as in age-related hematopoietic expansion, or may be constitutional, in which case the variant exists in additional tissues and may increase LFS-associated cancer risks. This study aims to characterize the clinical characteristics and follow-up results of cases with a *TP53* mosaic pathogenic or likely pathogenic variant (PV). **Methods:** We performed a retrospective review of all individuals undergoing multi-gene hereditary cancer panel testing at our diagnostic laboratory. Cases included those with mosaicism for one or more *TP53* PV, characterized as an AF of $<$ 35.0% on next-generation sequencing (NGS) on a blood or oral rinse specimen. Data were analyzed utilizing descriptive statistics and hypothesis tests, including Fisher s exact test. **Results:** We identified 117 *TP53* mosaic PV cases. Among 37 cases that had one or more relatives undergo testing for the mosaic PV, no relatives were positive. Among 21 cases that underwent subsequent fibroblast (FB) testing, 19.0% (4/21) correlated with the initial mosaic result, suggesting constitutional mosaicism. Of those that confirmed on FB, the mean AF for the original sample was 28.3% (n = 4; SD = 3.2%), whereas the mean for those negative on FB was 18.5% (n = 17; SD = 6.3%). Confirmation of mosaicism on FB was associated with an initial NGS AF $\geq$25.0% (p = 0.0276; FB Pos: 3/4, FB Neg: 2/17) and with a personal history of a breast cancer or sarcoma diagnosed $<$ 46 years (p = 0.0276; FB Pos: 3/4, FB Neg: 2/17). **Conclusions:** Although NGS is not purely quantitative, apparent constitutional mosaicism appears to correlate with higher AF on NGS. In addition, phenotypes of cases with *TP53* mosaicism confirmed via FB are more suggestive of LFS. Further studies are required to establish clinical correlation.

1581 Poster Session (Board #152), Sat, 1:15 PM-4:45 PM

Promoting breast cancer screening after multiplex genetic panel testing (MGPT) and genetic counseling. *First Author: Gregory Idos, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: Cancer screening guidelines recommend that germline carriers with a pathogenic variant (PV) in a breast cancer susceptibility gene undergo more intensive breast screening including breast magnetic resonance imaging (MRI). We assessed the impact of genetic counseling and MGPT on adherence to recommended screening. **Methods:** In a prospective cohort study of 2000 patients undergoing MGPT, patients completed self-adminstered questionnaires to document breast cancer screening within one year of testing. Patients were surveyed at 3, 6, and 12 months after genetic results disclosure. Multivariable logistic regression was used to analyze an association between MGPT result and breast MRI after adjusting for study center, personal history of breast cancer and personal history of breast surgery. **Results:** 2000 patients completed MGPT and 1532 (77%) completed at least one follow-up survey. 242 (12%) tested positive for at least 1 PV in any one of 25 (or 28) genes. MGPT identified a PV in the following increased risk breast cancer genes: *BRCA1* (n = 41), *BRCA2* (n = 36), *CHEK2* (n = 17), *ATM* (n = 16), *NBN* (n = 2), *PALB2* (n = 9), *TP53* (n = 6), and CDH1 (n = 1). Within 1 year, patients with a PV (OR = 2.1 95% CI [1.45-3.15], $p < 0.001$) were more likely to undergo MRI versus those testing negative. Patients with a PV in *BRCA1/2* (OR = 3.5 95% CI [1.96-6.33], $p < 0.001$) or a moderate risk breast cancer gene (CHEK2, ATM, NBN) (OR = 3.3 95% CI [1.30-8.15], p = 0.012) were three times more likely to have MRI versus those testing negative. Patients with a PV in other high risk breast cancer genes (*PALB2*, *TP53*, or *CDH1*) were three times more likely to undergo MRI (OR = 3.5 95%CI [0.76-15.97], p = 0.107) versus those testing negative, but the results did not reach statistical significance. There was no difference in Breast MRI (OR = 1.0 95%CI [0.78-1.37], P = 0.814) use among those with a variant of uncertain significance (VUS) versus those with negative results. **Conclusions:** MGPT and genetic counseling prompted patients with a *BRCA1/2* PV to appropriate adoption and adherence to breast cancer screening. There was no difference in screening between those with VUS or negative results. Clinical trial information: NCT 02324062.

1582 Poster Session (Board #153), Sat, 1:15 PM-4:45 PM

Promoting colorectal cancer (CRC) screening after multiplex genetic testing and genetic counseling. *First Author: Gregory Idos, USC Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: Cancer screening guidelines recommend that germline carriers with a pathogenic variant (PV) in a CRC susceptibility gene should undergo more frequent colonoscopy screening. We assessed the impact of genetic counseling and multiplex genetic panel testing (MGPT) on adherence to colonoscopy screening. **Methods:** In a prospective cohort study of 2000 patients undergoing MGPT, patients completed-self-adminstered questionnaires to document colon cancer screening within one year of testing. Patients were surveyed at 3, 6, and 12 months after genetic results disclosure. Multivariable logistic regression was used to analyze an association between MGPT result and colonoscopy after adjusting for study center, personal history of colorectal cancer and personal history of colorectal surgery. **Results:** 2000 patients completed MGPT and 1622 (81%) completed at least one follow-up survey. 242 (12%) tested positive for at least 1 PV in any one of 25 (or 28) genes. High risk CRC gene mutations were in *PMS2* (n = 11), *MLH1* (n = 10), *MSH2* (n = 10), *MSH6* (n = 8), *EPCAM* (n = 1), *TP53* (n = 6), Biallelic *MUTYH* (n = 2), *APC* (N = 3). Moderate risk CRC mutations were in monoallelic *MUTYH* (n = 41), *CHEK2* (n = 17), and *APC* I1307K (n = 16). Within 1 year of testing, patients with a PV were twice more likely (OR = 2.0, 95% CI [1.33, 2.92], $p < 0.001$) and patients with a VUS were as likely (OR = 1.2, 95% CI [0.86, 1.62], p = 0.312) to have a colonoscopy as compared to patients with a negative test result. Patients identified to carry a PV in a mismatch repair gene were 4x (OR = 3.6 95% CI [1.66-7.91], p = 0.001) or a PV in *APC,* Biallelic *MUTYH, or TP53* were 10x (OR = 10.1, 95% CI [1.80-57.29], p = 0.009) more likely to undergo colonoscopy. Those with a mutation in a moderate risk gene were 3x (OR = 3.3, 95% CI [1.79-5.95], $p < 0.001$) more likely to undergo colonoscopy. **Conclusions:** MGPT and genetic counseling prompted patients with a PV in a high risk CRC gene to appropriate adoption and adherence to screening colonoscopy. In contrast, there was no difference in colonoscopy screening among those with a VUS or negative results. These findings demonstrate genetic testing and counseling can encourage appropriate CRC screening. Clinical trial information: NCT 02324062.

1583 Poster Session (Board #154), Sat, 1:15 PM-4:45 PM

Examining patients' medical and psychosocial experiences following detection of a *CDH1* variant with multiplex genetic testing. *First Author: Jada Hamilton, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Germline *CDH1* mutations are associated with hereditary diffuse gastric cancer and lobular breast cancer. We conducted a cross-sectional, self-report survey to understand genetic testing experiences, medical management, and psychosocial adaptation among patients with a *CDH1* variant. **Methods:** We recruited participants from the Prospective Registry of Multiplex Testing (PROMPT), an online genetic registry. We invited individuals with a *CDH1* variant to complete a survey of validated and investigator-designed items. We computed descriptive statistics, and used *t* tests and chi-square tests to compare responses of individuals with pathogenic variants (PV) or variants of uncertain significance (VUS). **Results:** Data were available from 55 individuals (96% female, 89% white, 75% college graduate, age 32-78) with a *CDH1* PV (n = 16; 3 with a family history of gastric cancer) or VUS (n = 39; 12 with a family history of gastric cancer). Overall, 82% had received genetic counseling, 73% felt sufficiently informed when they had genetic testing, and participants reported low decisional regret about testing ($M \pm SD$= 12.6±20.1 on 0-100 scale); no differences were observed based on *CDH1* variant type. Those with VUS were less satisfied with healthcare providers' knowledge about their *CDH1* result than were those with PV (p= .02). Those with PV were more likely than those with VUS to have received a recommendation for prophylactic gastrectomy (44% vs 0%, p< .001). Only 2 participants, both with PV, had a prophylactic gastrectomy. Those with VUS had less knowledge about *CDH1* than those with PV (63% vs 93% correct knowledge; p <.001); yet, participants had similar perceptions of cancer risks (ps > .05). Those with PV reported greater testing-related distress (p <.001) and worry about genetic discrimination (p= .05); there were no differences between groups on other emotional outcomes including testing-related uncertainty, positive experiences, or quality of life (ps > .05). **Conclusions:** Many patients reported being well informed and satisfied with their *CDH1* genetic testing decision; yet, patients with VUS and PV each have unique informational and emotional needs warranting additional support.

1584 Poster Session (Board #155), Sat, 1:15 PM-4:45 PM

Impact of germline BRCA identification on subsequent breast cancer stage and therapy: Implications for routine screening. *First Author: Tal Hadar, Shaare Zedek Medical Center, Jerusalem, Israel*

Background: Screening healthy Ashkenazi Jews (AJ) for germline BRCA1/BRCA2 mutations (gBRCA) is not standard policy, despite high (2.5%) carrier rates. Most carriers are identified only after breast cancer diagnosis. We hypothesized that pre-symptomatic knowledge of carrier status would favorably affect breast cancer stage and management. **Methods:** We reviewed records of gBRCA carriers who did not undergo risk-reduction mastectomy and were diagnosed with breast cancer between 4/1996-4/2016. Patient age, parity, family history, genotype, screening compliance, method of breast cancer detection, disease characteristics and treatment (breast and axillary surgery, chemotherapy) were compared between carriers whose gBRCA was identified pre-breast cancer vs. post-breast cancer. **Results:** 165 females with gBRCA and breast cancer were identified, of whom carrier status was determined pre-breast cancer in 45 (27%) and post-breast cancer in 120 (73%); both groups had similar mean age at cancer diagnosis (50.6y vs. 50.5y, range 27-86) and BRCA1:BRCA2 distribution (64%:36% and 65%:35%). Pre-breast cancer carriers were significantly ($p < 0.001$) more likely to have a suggestive family history (90% vs. 62%), prior breast cancer screening (78% vs 60%), and breast cancer diagnosed by imaging (78% vs 25%) rather than clinical symptoms (19% vs 73%). Pre-breast cancer carriers had a higher DCIS: invasive breast cancer presentation (40%:60% vs. 2%:98% in post-breast cancer) and lower stage ($p < 0.005$). No differences in tumor grade, ER or Her2 status were identified. Pre-breast cancer carriers were more likely to undergo sentinel lymph node biopsy (91% vs 45%), less likely to receive chemotherapy, and more likely to elect bilateral mastectomies (62% vs 10%) than post-breast cancer carriers ($p \leq .001$ for all comparisons). Overall, pre-breast cancer gBRCA identification and routine screening predicted for early stage (0-I) breast cancer diagnosis ($p <$ 0.001, OR 16.8). **Conclusions:** Presymptomatic identification of gBRCA status is significantly associated with earlier stage breast cancer diagnosis, requiring less extensive treatment. This supports routine gBRCA testing in all healthy AJ women.

1585 Poster Session (Board #156), Sat, 1:15 PM-4:45 PM

Implementing genetic risk assessment in a community free clinic. *First Author: Leah Marsh, Cedars-Sinai Medical Center, Los Angeles, CA*

Background: Assessment of hereditary cancer risk plays an integral role in reproductive healthcare. ACOG and NCCN recommend that OB/GYNs assess hereditary cancer risk annually. The Saban Community Clinic is a Resident-run clinic in Los Angeles, California, serving a predominantly non-white, uninsured patient population of low socioeconomic status (SES) with no access to genetic counseling. Prior to this study, no formal cancer family history was elicited. **Methods:** We adapted a bilingual screening tool developed at the UCSF Cancer Risk Program that is compliant with NCCN and ACOG guidelines. It relies on fact recall that patients can complete independently assuming low health literacy. Clinic providers were briefed on the project and distribution commenced in April of 2017. The questionnaires were scored and entered into a secured database. **Results:** Between April 2017-January 2018, a total of 98 questionnaires were collected. Ages ranged from 19-67. Thirty-two percent (32%) of the patients identified as Hispanic. Of those who identified as non-Hispanic, only 3 of these identified as White, the others identified as Asian or Black. Twenty-one percent (21%) of the forms were completed in Spanish. First degree relative with ovarian cancer and/or multigeneration presence of breast cancer accounted for 11% of the patients who screened "positive" for referral to further genetic counseling. **Conclusions:** This study sought to 1) determine the feasibility of implementing a brief genetic risk screening tool and 2) assess the unmet need for referral to genetic counseling/testing in a community clinic serving predominantly non-white, low SES patients without health insurance. The preliminary data is promising that a patient administered survey can aid clinicians in identifying patients for referral. It also demonstrates the unmet need in this population, with 32% of these patients meeting criteria for referral. This tool identified an important area of health inequity in cancer prevention in this population.

1586 Poster Session (Board #157), Sat, 1:15 PM-4:45 PM

The incidence of germline cancer susceptibility mutations in primary CNS neoplasm patients. *First Author: Katharine Lord, Texas Oncology - Austin Brain Tumor Center, Austin, TX*

Background: Genomic profiling is performed on primary brain (CNS) tumors to identify somatic mutations. Several syndromes, (e.g. Neurofibromatosis) are well known causes of CNS neoplasms but data is limited on other germline cancer susceptibility mutations in CNS tumor patients. After a somatic mutation was unexpectedly found to be germline, we interrogated our database of somatic CNS tumor mutations. **Methods:** This IRB approved study reviewed patients at our center from May 2013 - November 2017. Tumors from 319 patients underwent next generation sequencing. At least 1 somatic mutation on a gene of interest was found in 208 tumors; 108 patients were deceased prior to study start. Of the remaining 100 patients, 28 were offered germline testing. **Results:** 26 patients completed germline testing: 12 had germline mutations (12%), 6 had germline variants of uncertain significance (6%) and 8 had negative germline testing (8%). Germline mutations were identified in the following genes: BRCA2 (3 patients), CHEK2 (4 patients), APC (3 patients), ATM (3 patients), MUTYH (2 patients), PMS2 (2 mutations in 1 patient). Of the 12 patients with germline mutations, five (41.6%) did not meet guidelines for hereditary cancer genetic testing. As a result of the germline findings, medical management was altered and additional family members with pathogenic mutations were identified. **Conclusions:** Based on somatic and germline mutational data from 319 CNS tumor patients, we estimate 5.8% of all CNS tumor patients (without an obvious CNS tumor syndrome) carry a germline cancer susceptibility mutation. Twelve percent of patients whose tumor contains a somatic mutation of possible "germline" interest carry a germline cancer susceptibility mutation. Pathogenic germline variants were identified in the following genes: BRCA2, CHEK2, APC, ATM, MUTYH and PMS2. Five patients (41.6%) did not meet recognized criteria for germline cancer genetic testing, thus without the somatic data, would have been overlooked. Nearly 50% of CNS tumor patients with germline cancer susceptibility mutations are overlooked when using routine testing criteria; tumor genomic profiling is the only means for identifying these undiscovered germline mutations.

1587 Poster Session (Board #158), Sat, 1:15 PM-4:45 PM

Value of germline multi-gene panel next generation sequencing (NGS) in identification of hereditary cancer syndromes (HCS) in colorectal cancer population (CRC). *First Author: Jing Gu, University of Southern California, Los Angeles, CA*

Background: Identification of HCS in probands (PB) provides a mechanism for cancer screening and prevention in 1st degree relatives (FDR). Lynch syndrome (LS) is the most common HCS in CRC. However, other HCS known to increase risk of breast and ovarian cancers (BC/OC) have been reported in CRC. We evaluated the value of NGS vs. tumor immunohistochemistry followed by MMR gene sequencing (T-MMR) in a CRC cohort with $>$ 5% probability of HCS based on a predictive model. **Methods:** In a modeled cohort of CRC patients, those with over 5% probability of HCS by MMRpro are assessed using either T-MMR or NGS. FDR of PB with a HCS are offered target genetic testing for the known mutation. The output of this population is input in a Markov model, which simulates the life history of FDR to calculate their costs and quality adjusted life years (QALYs). This model incorporates the effects & costs of cancer screening strategies, preventive procedures, and treatments. The model has 3 states: cancer free, diagnosed with cancer, and deceased; subjects transition among these states based on their known cancer risk and US life tables. Our model takes a US societal perspective and a 3% annual discount rate for both costs and QALYs. **Results:** For a cohort of newly diagnosed CRC with US epidemiology, 27,775 individuals had a MMRPro score $>$ 5%. T-MMR identified 2,584 (9.3%) PB with LS and subsequently 1,915 FDR with LS and 516 false negative relatives. With NGS, 8,076 (29.1%) PB with a HCS are identified, and 5,984 FDR tested positive for a HCS; including 3,814 with a mutation in a CRC associated gene and 2,170 with BC/OC associated gene mutation. The T-MMR arm failed to identify 2,929 PB and 4,393 FDR with a BC/OC associated gene mutation. Testing for T-MMR arm yields 645,874 QALYs while NGS arm yields 671,507 QALYs for CRC. Total costs are $1,215,670,597 for T-MMR tested group vs. $1,036,167,834 for NGS tested group, defining NGS as the dominant strategy for testing for HCS. One-way sensitivity analysis shows robust results. **Conclusions:** Compared to the T-MMR testing for LS, using a multi-gene NGS panel that included BC/OC cancer risk genes for HCS among CRC patients increases QALYs and saves costs.

1588 Poster Session (Board #159), Sat, 1:15 PM-4:45 PM

Multiplex germline testing in selected melanomas presenting to oncology clinic. *First Author: Pauline Funchain, Cleveland Clinic, Cleveland, OH*

Background: A recent twin study found melanoma to be the most heritable cancer with high twin-twin concordance (Mucci et al., JAMA 2016). Of melanoma patients presenting to oncology, 29% had a family history of $\geq$3 cancers, 59% had cancer in a 1st degree relative, and 17% had a family history of melanoma (Sussman et al., SMR 2017). The clinical utility of multiplex germline testing in the oncologic melanoma population has not yet been established. **Methods:** Consecutive patients who met criteria were offered germline testing with a multiplex panel (Invitae, San Francisco, CA) comprised of 12 genes related to melanoma and 69 additional cancer-related genes not known to be related to melanoma. Eligibility criteria included $\geq$ 2 melanomas in an individual or family; melanoma and other cancer(s) in an individual; melanoma and at least 2 other cancers in 1st- or 2nd-degree relatives, including a 1st-degree relative; age $\leq$35 at diagnosis; and limited family structure. **Results:** Of 81 patients with completed testing, 15 (18.5%) had a pathogenic/likely pathogenic mutation. 8 (53%) mutations were in genes previously associated with melanoma (*CDKN2A, BRCA1/2, BAP1, TP53*), and 7 (47%) were in genes from an extended pan-cancer panel (*CHEK2,PMS2,RAD51C, BLM, MUTYH*). Study eligibility met by mutation-positive individuals included 9 (60%) with a personal history of multiple cancers, 6 (40%) with multiple relatives with cancer, 4 (33%) with family history of $\geq$2 melanomas, 3 (20%) age $\leq$35 years, 2 (13%) with personal history of $\geq$3 melanomas, and 1 (7%) with limited family history. Melanoma subtypes of mutation-positive probands included 12 cutaneous, 1 mucosal, and 2 uveal. Other cancers observed in probands/families: bladder, brain, renal, pancreatic, carcinoid, thyroid, lymphoma, colon, breast, and ovarian cancers. **Conclusions:** Multiplex germline testing in a melanoma cohort selected by family or personal history of multiple cancers resulted in an 18.5% mutation-positive rate, nearly half identified in genes not previously associated with melanoma. Patients with melanoma, particularly with a personal or family history of other cancers, may benefit from germline testing. More data will be required to further refine testing guidelines for melanoma.

1589 Poster Session (Board #160), Sat, 1:15 PM-4:45 PM

Incidence of pathogenic variants in individuals with a personal or family history of pancreatic cancer. *First Author: Pashtoon Murtaza Kasi, Mayo Clinic, Jacksonville, FL*

Background: Genetic testing related to pancreatic cancer is expanding. Many companies offer a multi-gene panel with a focus on pancreatic cancer. The purpose of this study was to evaluate the incidence and types of pathogenic variants detected in individuals with a personal and/or family history of pancreatic cancer. **Methods:** The genetic test results of patients visiting a genetic counselor at Mayo Clinic Florida from January 2012 to February 2018 were examined. Clinical notes and three generation pedigree taken at the time of initial genetics consult were reviewed. **Results:** Of the 2038 patients that completed testing, 223 (10.9%) were diagnosed with a hereditary cancer syndrome. 59 were referred due to personal history of pancreatic cancer, of which 3 (5.1%) were found to carry a germline mutation discovered in *BRCA1/2*. One additional patient was found to carry a mosaic pathogenic variant in *ATM*. Of the 285 that reported any family history of pancreatic cancer, 35 (12.3%) carried a pathogenic variant. These variants were present in *APC* (3), *ATM* (4), *BRCA1* (5), *BRCA2* (13), *CHEK2* (5), *MSH6* (1), *NBN* (1), *PALB2* (3), and *PRSS1* (1). The incidence of pathogenic variants nearly doubled (21.4%) if the individual had at least two relatives with a history of pancreatic cancer. **Conclusions:** It has been difficult to determine who may benefit from pancreatic cancer screening, but identifying a pathogenic variant in an individual with a family history of pancreatic cancer is sometimes enough evidence to suggest surveillance. Gathering family history is an important piece of evaluating value of pancreas screening.

Number of individuals diagnosed with a hereditary cancer syndrome who had a personal and/or family history of pancreas cancer.

Category	Number of positives / Total (%)	Genes
Personal history of pancreas cancer	3-4/59 (5.1-6.8%)	*ATM*[1], *BRCA1 (2)*, *BRCA2*
Family history of pancreas cancer	36/285 (12.6%)	*APC*[2] *(3)*, *ATM (4)*, *BRCA1 (5)*, *BRCA2 (13)*, *CHEK2 (5)*, *MSH6*, *NBN*, *PALB2 (3)*, *PRSS1*
Family history of 2+ relatives with pancreas cancer ca	12/56 (21.4%)	*APC*[2] *(2)*, *ATM (2)*, *BRCA1 (2)*, *BRCA2 (4)*, *CHEK2 (2)*

1590 Poster Session (Board #161), Sat, 1:15 PM-4:45 PM

Implementation of strategies to increase genetic counseling referral rates for ovarian cancer patients. *First Author: Kara J. Milliron, University of Michigan, Ann Arbor, MI*

Background: Genetic counseling is recommended for all women diagnosed with epithelial ovarian cancer, independent of family history. Despite the potential benefits to the patient and her family, referral rates remain low. We sought to assess referral rates at our institution and implement two strategies to improve both the rate of referral and the completion of counseling and testing – (1) discussion of referral for all patients reviewed at multidisciplinary treatment planning conference and (2) option of telephone counseling. **Methods:** Patients with a diagnosis of epithelial ovarian, fallopian tube or primary peritoneal cancer since 10/1/14 were identified through pathology reports and chart review was performed to obtain demographic data and cancer details including histology, grade and stage. Personal and family history of cancer, date of genetic counseling referral, method of genetic counseling (in-person vs. telephone), date of genetic testing and the result of genetic testing were also abstracted. **Results:** The rate of genetic counseling referral was 63.5% (214/337 patients). Of those referred, 61% (131/214) underwent counseling, with 77% (165/214) in person and the 23% (49/214) via telephone after initiation of the telephone counseling program in September 2017. Overall, 90% of patients who received genetic counseling underwent testing, including 92.7% of the in-person counseling cohort and 67.9% of the telephone counseling cohort to date. In total, 24.1% of patients harbored a pathogenic gene mutation, with *BRCA1* mutations most common (16.5% of patients). Variants of undetermined significance were identified in 11.3% of patients. **Conclusions:** Telephone genetic counseling and mandatory discussion of referral at the time of treatment planning conference both appear to facilitate genetic counseling and ascertainment of actionable germline mutations. Overall, referral rates are high at our institution. The implementation of telephone-based genetic counseling programs has the potential to improve both counseling and testing rates, particularly when in-person counseling is not available or is delayed.

1591 Poster Session (Board #162), Sat, 1:15 PM-4:45 PM

Referral patterns and attrition rate for germline testing in pancreatic cancer (PC) patients. *First Author: Evan Justin Walker, University of California San Francisco, San Francisco, CA*

Background: Hereditary predisposition is estimated to account for 10% of all PC cases. Identification of pathogenic germline mutations can inform not only screening recommendations for family members but also, increasingly, treatment selection for pts. However, referral patterns and clinical workflow for germline testing in this disease differ significantly by institution, and many pts may not undergo recommended testing for a variety of reasons. **Methods:** We performed a retrospective review of all pts diagnosed w/ PC referred to our University of California, San Francisco Clinical Genetics program over a 3-yr period (1/2015 – 10/2017). Medical records were reviewed for demographic, medical/family history, and disease-specific data as well as genetic testing results. If testing did not occur, the reason was documented. Results were categorized as negative, variants of unknown significance (VUS), or established pathogenic mutations. Descriptive statistics included means with standard deviations (SD); associations were analyzed with t-test and Fisher's Exact Test. **Results:** ~29% (n = 137) of pts seen at UCSF w/PC dx were referred to Clinical Genetics during this time period. Of these, only 64% attended the appt and 60% ultimately underwent germline testing. Reasons for attrition inc. lack of pt f/u (n = 20), worsening disease severity (n = 11), insurance concerns (n = 7), and logistic/travel difficulties (n = 6). Pathogenic germline mutations were detected in 20% (n = 16) of pts tested [CFTR (n = 4), BRCA2 (n = 3), CHEK2 (n = 2), ATM (n = 2), MLH (n = 1), MUTYH (n = 1), other (n = 3)]; while 48% (n = 39) of pts had $\geq$1 VUS. Confirmed pathogenic mutations in our cohort were distributed across races/ethnicities, and assoc w/ younger age (mean age 53.3 vs 60.5 y. o.; p = 0.02) and FHx of breast cancer (p = 0.05). **Conclusions:** PC pts frequently do not undergo genetic counseling/germline testing despite appropriate referrals, highlighting the need to develop streamlined processes to engage more pts in testing, esp those w/ high-risk features such as young age and (+) FHx of cancer. Based on these data, our Center plans to pilot a genetic testing station for all new PC pt visits, incorporating both same-day testing and f/u remote counseling.

1592 Poster Session (Board #163), Sat, 1:15 PM-4:45 PM

The impact of genetic counseling on patients' knowledge about tumor genomic profiling. *First Author: Rebecca D. Pentz, Emory University School of Medicine, Atlanta, GA*

Background: Molecular testing is increasingly being integrated into cancer management. However, despite rapid advancements in this area, little work has been done to explore strategies for communicating genomic information to patients undergoing tumor profiling. This study evaluated the impact of an educational tool combined with genetic counseling on patients' understanding of key terms related to tumor genomic profiling. **Methods:** A genetic counseling intern designed a picture book to explain six words found in prior research to be difficult for patients to understand: mutation, germline mutation, somatic mutation, biomarker, molecular testing, and targeted therapy. The picture book was cognitively tested with oncology patients and revised. After consent, patients who had previously discussed molecular testing with their oncologist were asked to define the six words in their own terms. The same patients then received an explanation of each word from the intern using the picture book, and were asked to redefine each word directly afterwards. All definitions were scored for correctness by two independent coders. The proportion of patients who defined each term correctly and total knowledge scores were compared before and after genetic counseling. **Results:** Twenty-eight patients with melanoma, colon, lung, or breast cancer were recruited. Correct understanding rates improved for all six terms, with significant improvement for germline mutation ($p < 0.001$), somatic mutation ($p < 0.001$), biomarker ($p < 0.001$) and molecular testing ($p < 0.001$). Mean total knowledge score significantly improved from 30% to 83.3% ($p < 0.001$). **Conclusions:** Our data suggest that the use of a simple educational tool combined with genetic counseling in the setting of genomic tumor testing increases patient knowledge and may improve the process of informed consent. Future studies are warranted to determine the feasibility of providing in person genetic counseling in this setting and whether the picture book can be effectively used by other advanced practice providers with knowledge of genomics.

1593 Poster Session (Board #164), Sat, 1:15 PM-4:45 PM

Incidence and risk of second primary malignancy after an index potentially-human papillomavirus-associated cancer. *First Author: Eric Adjei Boakye, Saint Louis University Center for Health Outcomes Research, St. Louis, MO*

Background: Approximately 39,000 HPV-associated cancers are diagnosed annually in the US. Oncogenic HPV-infections are associated with virtually all cases of cervical, 95% of anal, 73% of oropharyngeal, 65% of vaginal, 50% of vulvar, and 35% of penile cancers. Cancer survivors are at increased risk of a second primary malignancy (SPM). We assessed the risk of developing a SPM after an index potentially-HPV-associated cancer (P-HPV-AC). **Methods:** This was population-based cohort study of patients with P-HPV-AC in the Surveillance, Epidemiology, and End Results registry (2000-2014). Only patients with invasive P-HPV-AC [cervical, vagina, vulva, penile, anal canal, and oropharynx] per International Classification of Diseases for Oncology, 3rd edition, were included. SPM was defined as the first subsequent primary cancer occurring at least 2 months after first cancer diagnosis. Excess SPM risk was quantified using standardized incidence ratios (SIRs) stratify by gender. **Results:** A total of 100,960 patients with an index P-HPV-AC were identified, and 7.37% developed a SPM overall. In all P-HPV-AC patients, the overall SIR was 1.72 (95% CI: 1.68–1.76). All index P-HPV-AC sites presented with a statistically significant increase in the risk of SPM. Among males, the greatest increase in risk of SPM was observed among patients diagnosed with an index P-HPV-AC oropharynx (SIR = 1.83; 95% CI, 1.76–1.90). Among females, the greatest increase in risk of SPM was observed among patients diagnosed with an index P-HPV-AC oropharynx (SIR = 2.47; 95% CI, 2.29–2.65, Table). **Conclusions:** HPV cancer survivors experience significantly excess risk of SPM; thereby calling for a more effective program for surveillance of patients with HPV-associated cancers.

			SIR	
	Cancers	Observed	Rate	95% CI
Overall	All potentially-HPV-associated cancers	7,447	1.72	1.68 – 1.76
Male and female	Oropharynx (head and neck)	3,240	1.91	1.84 – 1.98
	Anal	1,131	1.52	1.43 – 1.61
Male	Oropharynx (head and neck)	2,672	1.83	1.76 – 1.90
	Anal	453	1.48	1.35 – 1.62
	Penile	251	1.41	1.24 – 1.59
Female	Oropharynx (head and neck)	568	2.42	2.22 – 2.62
	Anal	678	1.55	1.44 – 1.67
	Cervical	2,017	1.51	1.44 – 1.58
	Vulvar	618	2.33	2.15 – 2.52
	Vaginal	190	1.78	1.54 – 2.06

TPS1594 Poster Session (Board #165a), Sat, 1:15 PM-4:45 PM

Evaluating intermittent dosing of aspirin for colorectal cancer prevention. *First Author: Katrina M. Alber, Northwestern University, Chicago, IL*

Background: Colorectal cancer (CRC) remains the 4th most common cancer in the United States. Thus the identification of effective and safe prevention methods remains important. While long-term use of COX-2 inhibitors, NSAIDs, and aspirin are associated with a reduced risk of CRC, the cardiovascular (CV) toxicity of COX-2 inhibitors and NSAIDs inhibits use in the prevention setting. Aspirin (ASA) does not confer risk of CV side effects and is a promising chemopreventive agent for CRC, but risks include gastrointestinal side effects and bleeding. Preclinical data suggest that intermittent dosing of aspirin would retain efficacy, with reduced toxicity [Mohammed, AACR 2018, NCI-N01-CN-250026]. **Methods:** This ongoing double-blind placebo-controlled randomized trial will enroll 90 subjects (men and women) to three arms: daily oral ASA 325 mg for 12 weeks (N = 40); intermittent aspirin 325 mg daily (4 cycles, alternating 3 weeks aspirin/placebo for a total of 12 weeks, N = 40); or daily placebo for 12 weeks (N = 10). The primary objective is to test for the equivalence of the two aspirin schedules, as demonstrated by similar changes in the ratio of cell proliferation to apoptosis in rectal biopsy samples (Ki67: Bax). Secondary endpoints include spectral markers of colon cancer risk and DNA methylation changes. Eligibility requirements include a history of colorectal adenoma (any grade), and no history of the following: invasive malignancy in the past 2 years; chronic renal or liver disease; unstable angina, hemorrhagic stroke or uncontrolled hypertension; anemia, peptic ulcer, gastrointestinal bleeding, active colitis, or inflammatory bowel disease. Participants must not have taken aspirin, other NSAIDs, or COX-2 inhibitors 3 weeks prior to the intervention; alcohol use $<$ 2 drinks/day. They will undergo blood draws and rectal biopsies at entry, at 9 weeks, and at end of intervention. A 3-month follow-up visit is planned. Statistical analyses will be based on 32 evaluable subjects in each of the two aspirin arms (allowing for drop-outs); we will have 81% power to detect a change in the Ki67:Bax ratio of -3.0 to +3.0, based on the standard deviation of similar data from an ongoing trial. Enrollment began in January 2018. Funding: NCI #HHSN2612201200035I. Clinical trial information: NCT02965703.

TPS1595 Poster Session (Board #165b), Sat, 1:15 PM-4:45 PM

A phase IIB pre-surgical trial of oral tamoxifen (TAM) versus transdermal 4-hydroxytamoxifen (4-OHT) in women with DCIS of the breast. *First Author: Kelly A. Benante, Northwestern University, Chicago, IL*

Background: Ductal carcinoma in situ (DCIS) is diagnosed in 60,000 women annually in the US. TAM is proven to reduce risk of local recurrence and new primary breast cancer in women with estrogen receptor (ER) positive DCIS. However, acceptance of TAM has been low, primarily because of toxicity related to systemic exposure. Local delivery to the breast is an attractive alternative as low systemic levels could minimize toxicity. 4-OHT is an active metabolite of TAM. When formulated as a gel and applied to the breast, it is well tolerated, and results in 4-OHT breast tissue drug levels comparable to oral TAM. In small pilot studies, its anti-proliferative effects on invasive breast tumors and DCIS are also similar to oral TAM [Lee O, et al. PMID 25028506]. The goal of our study is to validate these results in preparation for a Phase III trial of 4-OHT gel compared to oral TAM. **Methods:** We are conducting a randomized, double-blinded, placebo-controlled, Phase IIB pre-surgical trial to demonstrate that daily application of 4-OHT gel will result in a reduction in the Ki-67 labeling index of DCIS lesions that is not inferior to that seen in women receiving daily oral TAM. Ki-67 of the base-line diagnostic core needle biopsy will be compared to that of the therapeutic surgical excision sample after oral TAM or 4-OHT gel for 8 $\pm$ 2 weeks. Secondary endpoints include changes in Oncotype DCIS-Score, IHC markers, hormone levels, coagulation markers, drug concentration in the plasma and breast, and experienced symptoms. 100 women (assuming 20% non-evaluable samples or non-compliance) with DCIS (10% ER-positive) will be enrolled across 6 institutions into two intervention arms: oral TAM 20mg daily, placebo gel and 4-OHT gel 4mg daily (2mg/breast), placebo capsule. All participants will be evaluable for toxicity from first dose. To date 8 of 100 participants have been enrolled. Since study open, 39 potential participants have been contacted, 28 did not consent for screening, 9 consented, 2 are pending consent, and 9 have started study intervention. The most common reason potential participants chose not to consent is wanting to schedule surgery as soon as possible. Funding Source: NCI Contract # HHSN26122012000035I. Clinical trial information: NCT02993159.

2000 Oral Abstract Session, Fri, 2:45 PM-5:45 PM

GAPVAC-101: First-in-human trial of a highly personalized peptide vaccination approach for patients with newly diagnosed glioblastoma. *First Author: Wolfgang Wick, Neurology Clinic, DKFZ, DKTK, Heidelberg, Germany*

Background: The need for treatment personalization is obvious as every cancer is molecularly unique. In addition glioblastoma (GB) are immunologically regarded as resistant, "cold" tumor with few targetable antigens available from mutations, thus demanding new personalized immunotherapies. **Methods:** The GAPVAC consortium realized an immunotherapy, for which personalized selection of 2 peptide-based actively personalized vaccines (APVAC) per patient for treatment of newly diagnosed GB was based not only on whole-exome sequencing but also on human leukocyte antigen (HLA)-ligandome analyses providing insight into the actual presentation of relevant epitopes in the tumor. GAPVAC-101 (NCT02149225) enrolled 16 patients in a European phase I feasibility, safety and immunogenicity trial integrated into standard of care. For APVAC1, up to 7 peptides were selected from a trial specific warehouse based on individual biomarker data. Vaccination (i.d.) with GM-CSF and poly-ICLC in 15 patients started with the 1st adjuvant cycle of temozolomide (TMZ). For APVAC2, analyses revealed a median of 36 somatic, non-synonymous mutations in the patients' tumors. From the 4th TMZ cycle, 11 patients received APVAC2 with usually 2 *de novo* antigens per patient selected according to mutation, actual or putative HLA presentation and immunogenicity. Overall 20 APVAC2 antigens incl. 14 mutated were vaccinated. **Results:** Adverse events were largely reversible injection site reactions but also 2 anaphylactic reactions and one increase in cerebral edema. Short, non-mutated APVAC1 antigens induced sustained CD8 responses with memory phenotype, being with regard to CD8 immunogenicity rate (51%, *ex vivo* readout) numerically at least not inferior to long mutated antigens (45%, readout after *in vitro* culture). Mutated APVAC2 antigens induced predominantly CD4 responses of favorable TH1 type. Median PFS and OS were 14.2 and 29 months from diagnosis, respectively, in patients that received $\geq$1 APVAC vaccination (N = 15). **Conclusions:** Overall, the GAPVAC approach displayed expected safety profiles and high biological activity warranting further development. Clinical trial information: NCT02149225.

2001 Oral Abstract Session, Fri, 2:45 PM-5:45 PM

A mutation-specific peptide vaccine targeting IDH1R132H in patients with newly diagnosed malignant astrocytomas: A first-in-man multicenter phase I clinical trial of the German Neurooncology Working Group (NOA-16). *First Author: Michael Platten, Mannheim University Hospital, German Cancer Research Center (DKFZ), Mannheim, Germany*

Background: Hot-spot point mutations in the gene for isocitrate dehydrogenase type 1 (IDH1R132H) are a frequent founder event in gliomas and other tumors. Preclinical studies have defined IDH1R132H as a clonal neoantigen presented on MHC class II to induce tumor-specific therapeutic T helper cell responses. **Methods:** NOA-16 (NCT02454634) is a first-in-man, multicenter, phase I trial, which enrolled 33 patients with newly diagnosed WHO °III and °IV astrocytomas with IDH1R132H mutations. After completion of radiochemotherapy a total of eight vaccinations with an IDH1R132H peptide in incomplete Freund's adjuvant produced at a central GMP site was to be administered subcutaneously with topical imiquimod over a period of 32 weeks together with maintenance temozolomide. The primary end points were safety and immunogenicity. **Results:** The safety dataset comprised 249 vaccines administered to 32 patients. One patient withdrew after screening. 29 patients received all eight vaccines. Vaccine-related adverse events (AE) were restricted to grade 1 reactions, according to common toxicity criteria for AE(CTCAE v4.0). Two serious AE were observed in two patients; one probably related to the peptide vaccine. 28/30 patients (93.3%) evaluable for immunogenicity displayed IDH1R132H-specific T cellular (detected by ELISPOT assays in 24/30 (80%)) or humoral (detected by ELISA in 26/30 patients (87%)) immune responses not detectable before vaccination. Until end of study (EOS, week 32), 4/32 (12.5 %) patients had progressive disease (PD) according to RANO criteria, all other patients (N = 28, 87.5%) had stable disease (SD). 12/32 (37.5%) patients displayed pseudoprogressions. Single-cell T cell receptor (TCR) sequencing allowed for the identification of IDH1R132H-specific TCRs. **Conclusions:** NOA-16 met its primary endpoints by demonstrating safety and immunogenicity of a mutation-specific IDH1R132H peptide vaccine. Pseudoprogressions observed after the initiation of the vaccine may indicate intratumoral immune reactions warranting further development, including TCR cell therapy. Clinical trial information: NCT02454634.

2002 Oral Abstract Session, Fri, 2:45 PM-5:45 PM

Phase 1 study of AG-881, an inhibitor of mutant IDH1/IDH2, in patients with advanced IDH-mutant solid tumors, including glioma. *First Author: Ingo K. Mellinghoff, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Isocitrate dehydrogenase 1 and 2 mutations (mIDH1/2) occur in solid tumors including glioma, and result in production of the oncometabolite 2-hydroxyglutarate (2-HG), promoting tumorigenesis. AG-881 is an oral, potent, brain-penetrant inhibitor of mIDH1/2 that reduces 2-HG by up to 98% in glioma models. **Methods:** Patients (pts) with recurrent/progressive mIDH1/2 glioma (G) and non-glioma (NG) solid tumors were eligible to receive AG-881 daily in continuous 28-day cycles. Dose escalation cohorts for G and NG solid tumors enrolled using a Bayesian logistic regression model (BLRM) escalation guided by the overdose control (EWOC). Blood and tumor samples were evaluated for pharmacokinetics (PK)/pharmacodynamics (PD). Dose-limiting toxicity (DLT) was defined as a Grade (Gr) $\geq$3 AG-881-related event in Cycle 1 or by sponsor designation. **Results:** As of 1Dec2017, 93 pts had received AG-881 (G: 52; NG: 41) and 20 remain on AG-881 (G: 19, NG: 1). Demographics: M/F = 40/53; median age = 51; median no. prior systemic therapies = 3 (range 1–7). Seven initial dose levels were tested: 25mg QD (n = 10); 50mg QD (n = 12); 100mg QD (n = 21); 200mg QD (n = 22); 200mg BID (n = 5); 300mg QD (n = 5) and 400mg QD (n = 6). To further assess safety and PK in the G cohort, a 10mg dose level was tested (n = 6) and 6 additional pts enrolled in the 50mg cohort. PK showed less than dose-proportional plasma exposure with a mean effective half-life of 71$\pm$54 hrs. Common adverse events (AEs) across all pts regardless of attribution: fatigue (38.7%), nausea (35.5%), ALT/AST increase (34.4% each). Elevated ALT/AST AEs were dose-dependent (n = 0 at 10mg, n = 7 at $\leq$50mg, n = 10 at 100mg, n = 20 at $>$ 100mg). Five G pts experienced DLTs at 100mg and above: Gr $\geq$2 ALT/AST which resolved to Gr $\leq$1 with dose modification (n = 4) or discontinuation (n = 1). The MTD or RP2D were not reached by BLRM with EWOC. **Conclusions:** AG-881 was associated with a favorable safety profile at doses $<$ 100mg in pts with glioma and non-glioma solid tumors. No ALT/AST AEs Gr $>$ 2 were observed at 10mg and 50mg. These doses are being explored in an ongoing perioperative glioma study. Updated safety, PK/PD, and efficacy data will be presented. Clinical trial information: NCT02481154.

2003 Oral Abstract Session, Fri, 2:45 PM-5:45 PM

ALLELE: A consortium for prospective genomics and functional diagnostics to guide patient care and trial analysis in newly-diagnosed glioblastoma. *First Author: Mehdi Touat, Dana-Farber/Brigham and Women's Cancer Center, Harvard Medical School, Boston, MA*

Background: Multi-dimensional genomic analyses may improve outcome in glioblastoma (GB) but are not widely available as routine clinical care. ALLELE is an ABC^2-funded consortium to generate prospective clinical genomics and develop novel biomarkers for use in GB patients. **Methods:** Multicenter prospective study of tumor genotyping in newly diagnosed GB. Clinical (CLIA) genome-wide tumor whole exome sequencing (WES) and chromosomal microarray (CMA) were performed following surgery. Primary objective: to evaluate the feasibility of genotyping tumors in a time-frame to support real-time use in clinical trials. Comparisons with orthogonal genomic and functional methods were incorporated to inform best practices. **Results:** As of 1/30/18, 46 patients with GB enrolled among 5 sites. Median age was 60. WES and CMA were completed in 39 patients, with a median time between surgery and biomarker analysis completion of 51 days. Actionable findings, including activating BRAF and FGFR1 mutations were identified in 2 patients, and two tumors were reclassified as non-GB based on genomics. 26 patients with MGMT unmethylated GB were enrolled in INSIGhT, a companion randomized multi-arm trial comparing standard of care versus adjuvant CC-115, neratinib or abemaciclib in newly diagnosed GB (NCT02977780). Pre-defined biomarker groups (EGFR-, PI3K- and CDK-positive) will be evaluated for their ability to predict outcome in each arm. 10 patients received standard of care, and 3 patients enrolled in other clinical trials. In a subset of patients, exploratory functional biomarker assays were generated on live cells from freshly resected tumors and patient-derived GB cell line models were derived. Updated outcomes and results of exploratory biomarker analyses will be presented at the conference. Prospectively generated genomic data will be made publicly available. **Conclusions:** Molecular profiling with WES and CMA is feasible within a clinically acceptable time frame following surgery for patients with newly diagnosed GB. Genomic analyses conducted in a prospective manner can inform subsequent clinical trial analysis aiming at matching outcome with tumor genotyping.

2004 **Oral Abstract Session, Fri, 2:45 PM-5:45 PM**

Feasibility and benefit of molecularly-informed enrollment into early phase trials for patients with recurrent gliomas. *First Author: Capucine Baldini, Gustave Roussy, Villejuif, France*

Background: Recent reports showed that patients (pts) with recurrent glioma may be good candidates for early phase clinical trials (eaCTs), however clinical benefit is often limited to a small subset of pts in all-comers design trials. We aimed to evaluate whether selecting pts through tumor genotyping is associated with better outcome in this population. **Methods:** From 2008 to 2017, individual records of pts enrolled in eaCTs of cytotoxic therapies, small molecule inhibitors or immune checkpoint blockers were analyzed for clinical and histomolecular characteristics, toxicity, tumor response, and progression-free survival (PFS). The primary objective was to evaluate the feasibility and potential benefit of using tumor genotyping for guiding enrollment in eaCTs. Molecular screening methods included immunohistochemistry and PCR-based assays, array CGH, next-generation sequencing, and RNA sequencing. **Results:** Seventy pts were enrolled, of whom 41/70 (58.6%) patients were molecularly oriented. Therapeutic targets included FGFR mutations/fusions (n = 11), BRAF (7) and IDH (15) mutations, MDM2 amplification (1) and mismatch repair deficiency (7). In addition, 34 pts participated in the MOSCATO 01 and 02 precision medicine study (NCT01566019), which allowed the identification of potentially actionable targets in 12/34 (35%) pts, of whom 4/12 (33.3%) received a molecularly-informed therapy. Grade 3/4 adverse events were reported in 6/70 (8.6%) pts. In the subgroup of IDH1/2-wild type high-grade tumors, response rate and disease control rate were 16.7% (3/18) and 55.6% (10/18) respectively in pts who were molecularly oriented, versus 0% (0/14) and 31.5% (5/14) in molecularly-unselected pts. There was no statistically significant difference in median PFS between molecularly-oriented and -unselected pts (2.83 months [95% CI 1.3-4.6] vs. 1.54 months [1.05-2.85], *P*= 0.29). **Conclusions:** A subset of pts with recurrent glioma may benefit from incorporating tumor genotyping to guide their enrollment in eaCTs. Accelerating the use of prospective genomics could increase the percentage of pts who may benefit from this strategy.

2005 **Oral Abstract Session, Fri, 2:45 PM-5:45 PM**

Actionable targets involving FGF receptors in gliomas: Molecular specificities, spatial distribution, clinical outcome and radiological phenotype. *First Author: Anna Luisa Di Stefano, Foch Hospital, Suresnes, France*

Background: to characterize clinical, molecular and radiological features of diffuse gliomas with *FGFR3-TACC3* fusions or *FGFR1* mutations, which are both actionable with new oral anti-FGFR inhibitors. **Methods:** We screened for *FGFR3-TACC3* fusions 1112 gliomas (861 grade IV, 140 grade III and 111 grade II) by RT-PCR. We performed sequencing for hotspot *FGFR1* mutations (N546 and K656) in 73 midline gliomas (8 grade II, 10 grade III, 54 grade IV, affecting cerebellum, spinal cord, brainstem, thalamus and diencephalon) and 479 hemispheric gliomas (170 grade IV, 151 grade III, 157 grade II). **Results:** We identified 50 gliomas (all *IDH* wild-type) with *FGFR3-TACC3* fusion (45 grade IV, 2 grade III and 3 grade II). *FGFR3-TACC3* fusion was mutually exclusive with *EGFR* amplification (p = 0.000) and co-occured with *CDK4* and *MDM2* amplifications (p = 0.011 and p = 0.005). *FGFR3-TACC3* positive glioblastoma patients had a longer median overall survival (OS) (40.1 months versus 19.0; p = 0.006). Multivariate analysis showed that *FGFR3-TACC3* fusion is an independent predictor of better outcome for glioblastoma patients. Paired case-control analysis on pre-operative Magnetic Resonance Imaging MRI (24 *FGFR3-TACC3* positive cases and 48 controls) by the VASARI vocabulary and sparse canonical correlation showed that *FGFR3-TACC3* gene fusions have specific radiological features, are constantly unifocal and involve specifically cortico-subcortical regions. We identified recurrent *FGFR1* mutations in 13 out of 73 midline gliomas with diverse locations and in only one hemispheric glioma with corpus callosum involvement. *FGFR1* mutations occurred in both *K27M* mutated and *K27*wild-type and were constantly *IDH* wild-type. *FGFR1* mutations tended to be associated with younger age (p = 0.06) and ATRX loss (p = 0.05) and was an independent predictor of better outcome (median OS 45.0 months versus 13.8 months, p = 0.01). **Conclusions:** gliomas with *FGFR3-TACC3* gene fusions and *FGFR1* mutations represent two specific entities with distinct anatomical, clinical and molecular features . They should be recognized because both alterations are eligible for currently ongoing anti-FGFR clinical trials.

2006 **Oral Abstract Session, Fri, 2:45 PM-5:45 PM**

Phase II study of pembrolizumab or pembrolizumab plus bevacizumab for recurrent glioblastoma (rGBM) patients. *First Author: David A. Reardon, Dana-Farber Cancer Institute and Harvard Medical School, Boston, MA*

Background: Blockade of programmed-death 1 (PD-1) mediated immunosuppression has achieved meaningful benefit across many cancers. Vascular endothelial growth factor (VEGF), a highly upregulated proangiogenic growth factor in GBM tumors, can contribute to tumor-associated immunosuppression. We evaluated the safety and efficacy of pembrolizumab (P), a fully human IgG4 PD-1 blocking antibody, with and without bevacizumab (Bev) in rGBM patients. **Methods:** Bev-naïve patients at $1^{st}/2^{nd}$ recurrence requiring $\leq$ 4 mg dexamethasone/day were randomized to receive P (200 mg IV Q3W) with (Cohort A; n = 50) or without (Cohort B; n = 30) Bev (10 mg/kg IV Q2W). The primary endpoint, PFS-6 per RANO, was assessed independently per cohort relative to historical benchmarks. Archival tumor PD-L1 expression and inflammatory gene expression signature were explored as potential biomarkers. **Results:** Grade 2 or 3 treatment related adverse events (TRAEs) occurring in $\geq$10% patients included: Cohort A- hypertension (50%), fatigue (18%), headache (16%), infection (14%) and proteinuria (14%); Cohort B – headache (30%), and fatigue (17%). There were no grade 4 or 5 TRAEs. With a median follow-up of 25.3 months, PFS-6 was: Cohort A-26.0% (95% CI: 16.3, 41.5); Cohort B-6.7% (95% CI: 1.8, 25.4). Median OS was: Cohort A-8.8 mths (95% CI: 7.7,14.2); Cohort B- 10.3 mths (95% CI: 8.5, 12.5). As of 14Jan18, 10 patients remain alive (cohort A – 7; cohort B – 3) including 2 receiving study therapy (both cohort A). **Conclusions:** P is well tolerated +/- Bev but has limited monotherapy activity for rGBM. The anti-tumor activity of P+standard-dosed Bev was comparable to historical Bev monotherapy data. Clinical trial information: NCT02337491.

2007 **Oral Abstract Session, Fri, 2:45 PM-5:45 PM**

Phase II study of pembrolizumab in leptomeningeal carcinomatosis. *First Author: Priscilla Kaliopi Brastianos, Massachusetts General Hospital, Boston, MA*

Background: Approximately 5-8% of patients with cancer develop leptomeningeal carcinomatosis (LMD). Median survival of patients with LMD is approximately 4-6 weeks and there are no effective treatment options. We performed a phase II study of pembrolizumab in LMD from any solid tumor malignancy (NCT02886585). **Methods:** The primary endpoint is the rate of overall survival at 3 months (OS3). A Simon two-stage design was used to compare a null hypothesis OS3 of 18% against an alternative of 43%. Ten patients were to be enrolled in the first stage. If 2 or more patients were alive at 3 months, an additional 8 patients would be enrolled. If at least 6 patients among the total of 18 patients were alive at three months, then the treatment would be deemed promising in the cohort. Serial CSF, blood samples and tumor samples were collected to elucidate the genomic and transcriptional determinants of immunotherapy response in central nervous system (CNS) lesions. **Results:** A total of 18 patients were accrued (15 with breast cancer, 2 with lung cancer and 1 with gastric cancer). The median follow-up of patients still alive was 2.9 months (range: 2.2 to 6.3 months). The percentage of patients with one or more grade-3 or higher adverse events that were at least possibly related to treatment is 33.3%. At the time of the data retrieval, eight (8) patients (44%) were alive at three months after enrollment (OS3). Therefore, the study met its primary endpoint. Whole exome sequencing of tissue samples and cell-free DNA from CSF and blood, as well as single-cell RNA sequencing of CSF, were carried out to track the evolution of the tumor and the immune system in the CNS and identify biomarkers of response. Genetic and transcriptomic differences within the CSF were detected between the pre- and post-treatment samples and in patients that reached OS3 compared with those that did not. **Conclusions:** Pembrolizumab is well-tolerated and has activity in LMD. CSF provides an opportunity to monitor the clonal evolution of tumor and the immune microenvironment in LMD. Clinical trial information: NCT02886585.

2008 Oral Abstract Session, Fri, 2:45 PM-5:45 PM

Window-of-opportunity clinical trial of a PD-1 inhibitor in patients with recurrent glioblastoma. *First Author: John Frederick De Groot, The University of Texas MD Anderson Cancer Center, Department of Neuro-Oncology, Houston, TX*

Background: A Phase III study failed to demonstrate a therapeutic benefit of anti-PD-1 therapy in recurrent GBM. This study was initiated to ascertain tumor immune modulatory properties of pembrolizumab in these patients requiring surgery. The primary objectives were to evaluate immune effector function in resected GBM tissue after pembrolizumab treatment and to determine progression-free survival at 6 months (PFS6). **Methods:** In an open label, single-center, single-arm biomarker-driven Phase 2 trial, 15 patients with GBM, at first or second recurrence who required reoperation for tumor progression were enrolled (NCT02337686). Patients were treated with up to two doses of pembrolizumab prior to surgery and afterwards received pembrolizumab until disease progression or the development of unacceptable toxicities. Recurrent GBM patients receiving standard of care (SOC) were immunologically analyzed (n = 10) as a comparator. **Results:** 21 patients were screened. 15 were enrolled and received at least one dose of pembrolizumab. The most common adverse event was grade 1 or 2 fatigue in 40% of patients. There were no treatment-related deaths. The median follow-up time for all patients was 12 months (95% CI: 3-31). The longest ongoing duration of response exceeded 34 months in two patients (one IDH1 mutant, one wild-type). Median PFS was 7 months (95% CI: 4-16) and PFS6 was 53% (95% CI: 33%-86%). Median overall survival has not been reached (95% CI: 15 to not reached), with an estimated 1-year overall survival of 72% (95% CI: 52%–99.6%). Analysis with 35 immune markers by mass cytometry revealed that GBM tumors are poorly infiltrated with T cells but are enriched with distinct CD68+ populations. These CD68+ cells are less frequent in pembrolizumab-treated patients (n = 6) relative to those treated with SOC (n = 10; $P = 0.01$); however, GBM-infiltrating Tregs are more frequent in patients treated with pembrolizumab ($P = 0.02$). **Conclusions:** Although pembrolizumab was well tolerated, PFS6 data and immune analysis indicates that anti-PD-1 monotherapy is insufficient for a response in the majority of GBM patients, likely secondary to a marked scarcity of T cells within the tumor microenvironment and a preponderance of CD68+ cells. Clinical trial information: NCT02337686.

Durability of brain metastasis response and overall survival in patients with non-small cell lung cancer (NSCLC) treated with pembrolizumab. *First Author: Sarah B. Goldberg, Yale School of Medicine, New Haven, CT*

Background: Pembrolizumab can have significant and durable activity in patients (pts) with advanced NSCLC, however the activity in the central nervous system (CNS) and the long-term benefit in pts with active brain metastases (BrM) have not been well-described. **Methods:** This is a Phase II trial for pts with NSCLC or melanoma with at least 1 BrM between 5 and 20 mm that is asymptomatic and either untreated or progressing after prior local therapy. For NSCLC pts, cohort 1 is for PD-L1 positive and cohort 2 for PD-L1 negative or unevaluable pts. Pembrolizumab 10mg/kg is administered every 2 weeks. The primary endpoint of this trial is BrM response rate (RR), as determined by modified RECIST (mRECIST) in which brain lesions $\geq$ 5mm are considered measurable and up to 5 target lesions are allowed. **Results:** By this interim analysis, 67 pts with advanced NSCLC were screened, and 39 were eligible and treated with pembrolizumab: 34 in cohort 1 and 5 in cohort 2. 12 pts (30.8%) were treated as initial therapy for metastatic disease, 14 (35.9%) had 1 prior systemic therapy, and 13 (33.3%) had 2 or more prior lines of therapy. 10 of 34 pts in cohort 1 had a response in CNS, for a BrM RR of 29.4% (95% CI 15.1-47.5). 7 pts had discordance between CNS and systemic responses (4 with PD in brain and PR in body, and 3 with PR in brain and PD in body). Progression-free survival in the CNS among pts with a BrM response or stable disease was 10.7 months (95% CI 6.6-not reached). Median OS among all pts was 8.9 months (95% CI 6.6-29.7), with 31% of pts living at least 2 years (95% CI 19-51%). No pts in cohort 2 had a BrM response, but 2 of the 5 lived $>$ 1 year. Treatment was well-tolerated, with no neurologic adverse events (AEs) $>$ grade 1 considered related to treatment; the only grade $\geq$ 3 AE related to treatment in more than 5% of pts was grade 3 pneumonitis in 2 pts. **Conclusions:** Pembrolizumab can result in durable benefit and long-term survival in patients with untreated BrM from NSCLC, with almost a third of patients living more than 2 years after initiation of therapy. We have demonstrated that a PD-L1 inhibitor can have activity in the CNS and may be a safe and active treatment option for patients with small, asymptomatic BrM. Clinical trial information: NCT02085070.

2010 Poster Discussion Session; Displayed in Poster Session (Board #168), Sat, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Sat, 4:45 PM-6:00 PM

Risk of CNS adverse events (CNS-AEs) for patients with non-small cell lung cancer (NSCLC) and melanoma brain metastases (BM) treated with CNS radiation (CNS-RT) and immune checkpoint inhibitors (CPIs). *First Author: Michael Edward Devitt, University of Virginia, Charlottesville, VA*

Background: CPIs are widely used in the treatment of both metastatic melanoma and NSCLC. BM frequently occur and are treated with CNS-RT. Since both CNS-RT and CPIs can cause neuro-inflammation, we tested the hypothesis that concomitant treatment with CPIs and CNS-RT results in an increased risk of CNS-AEs. **Methods:** We identified patients with melanoma and NSCLC with BM treated with CNS-RT and seen at our institution between 2014 and 2016. Concomitant treatment with CPIs and CNS-RT was defined as administration of CPIs within 3 months before or after CNS-RT. CNS-AEs were defined as new or worsening edema on brain MRI without disease progression, new or worsening neurological deficit, or need to start or increase corticosteroids. A generalized linear model incorporated significant variables from a univariate analysis to model the incidence of CNS-AEs. Variables considered included the use of CPIs within 3 months of CNS-RT, cancer type, type of CNS-RT (gamma knife [GKRS] versus whole brain radiation therapy [WBRT]), number of metastases, and maximum metastasis size. **Results:** We identified 213 cases of CNS-RT (NSCLC 167 [78%], GKRS 147 [69%], WBRT 63 [30%], median 2 BM [1 to $>$ 20], median 17 mm max diameter [2 mm-74 mm]). Patients were 52% female with median age 61 (range 21-87), and ECOG 0-2 in 93% at time of CNS-RT. CNS-AEs occurred in 40 (19%) cases. Receipt of CPIs within 3 months of CNS-RT was the only factor associated with an increased risk of CNS-AEs (odds ratio 3.9, 95% CI 1.6-9.2, p-value 0.002). The rates of CNS-AEs were 11 of 28 (39%) in cases which received CPIs within 3 months of CNS-RT and 29 of 184 (16%) in cases which did not. The characteristics of the 11 cases with CPI exposure and CNS-AEs were: 73% underwent GKRS, 45% were NSCLC, 18% received CTLA4 alone, 55% PD-(L)1 alone, 27% combined CTLA4/PD-1, and 55% had a neuro deficit as part of their CNS-AE. **Conclusions:** This retrospective analysis demonstrates that the use of CPIs within 3 months of CNS-RT is associated with an increased risk of CNS-AEs. CNS-RT modality, cancer type, and metastasis size or number were not associated with an increased risk of CNS-AEs.

2011 Poster Discussion Session; Displayed in Poster Session (Board #169), Sat, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Sat, 4:45 PM-6:00 PM

Risk-adjusted survival for melanoma brain metastases in the era of checkpoint blockade immunotherapies: Results from a national cohort. *First Author: Bryan Iorgulescu, Brigham and Women's Hospital, Boston, MA*

Background: The recent successes of checkpoint blockade immunotherapy (CBI) and $BRAF^{V600}$-targeted therapy trials have generated exciting promise for revolutionizing the management of patients with advanced melanoma. However, because early clinical trials of CBIs and $BRAF^{V600}$-targeted therapy either excluded or included disproportionately fewer cases of melanoma brain metastases (MBM), the survival benefit of these novel therapies for MBM remains unknown. **Methods:** The characteristics, management, and overall survival (OS) outcomes of patients who presented with cutaneous MBMs during 2010-2015 were evaluated using the National Cancer Database, which comprises approximately 70% of all newly diagnosed cancers in the U.S. OS was analyzed with risk-adjusted Cox proportional hazards and compared by Kaplan-Meier techniques. **Results:** 2,753 (36%) of patients presenting with stage 4 melanoma had MBMs. MBM patients who presented after the 2011 FDA approvals for CBI and $BRAF^{V600}$-targeted therapy demonstrated a 91% relative increase in 4-yr OS to 14.1% (95CI: 12.2-16.1) from 7.4% pre-approval (95CI: 5.3-10.0, $p < 0.001$). In the post-approval era, the proportion of MBM patients that received CBI rose from 10.5% in 2011 to 34.0% in 2015 ($p < 0.001$). Initial CBI in MBM patients displayed a 2.4x improved median and 4-yr OS of 12.4 mos (95CI: 10.4-15.8; vs. 5.2 mos, 95CI: 4.7-5.9, $p < 0.001$) and 28.1% (95CI: 22.1-34.4; vs. 11.1%, 95CI: 9.3-13.1). These benefits were particularly pronounced in MBM patients without extracranial metastases, in which CBI demonstrated improved median and 4-yr OS of 56.4 mos (95CI: 25.0-not reached; vs. 7.7 mos, 95CI: 6.7-8.7, $p < 0.001$) and 51.5% (95CI: 38.9-62.8; vs. 16.9%, 95CI: 13.5-20.6) that persisted in MBMs that underwent resection or SRS. **Conclusions:** Using a large national cohort comprised of a "real-life" treatment population of MBMs, we demonstrate the dramatic improvements in OS associated with novel checkpoint blockade immunotherapies.

2012 Poster Discussion Session; Displayed in Poster Session (Board #170), Sat, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Sat, 4:45 PM-6:00 PM

A large, multicenter, retrospective study to identify a cutoff of MGMT methylation status by quantitative pyrosequencing approach in patients (PTS) with glioblastoma (GBM). *First Author: Giuseppe Lombardi, Department of Clinical and Experimental Oncology, Medical Oncology 1, Veneto Institute of Oncology, IOV-IRCCS, Padua, Italy*

Background: MGMT promoter methylation status representsan important prognostic factor for GBM PTS in terms of progression free survival (PFS) and overall survival (OS). Quantitative pyrosequencing approach is a valid alternative to methylation-specific PCR but a cut-off value in still unclear. We performed a large, multicenter, retrospective study to identify a real cut-off value to discriminate its impact on clinical outcome in terms of PFS and OS. **Methods:** Retrospectively, from italian neuro-oncology centers, we collected GBM PTS from 2005 to 2016 with assessment of MGMT promoter methylation by pyrosequencing approach evaluating CpG islands from 74 to 83. Other inclusion criteria were: confirmed histological diagnoses of GBM, ECOG PS $\geq$2, treatment with concomitant radiation therapy and temozolomide. Kaplan-Maier method was used to estimate the survival curves and ROC curve for defining cut-off value for PFS and OS. **Results:** 376 GBM PTS were enrolled;median age was 62 ys (25-86); ECOG PS was 0 in 129 PTS, 1 in 160 PTS, 2 in 87 PTS; 212 PTS (58%) had a complete resection. 67 PTS (18%) received a second surgery. Median PFS and OS was 8.6 and 14.3 months. The optimal cut-off value to identify a strong prognostic value of MGMT methylation status in terms of PFS and OS, was 26% (sensitivity 72%, specificity 61%, accuracy 71%) and 24% of methylation (sensitivity 72%, specificity 61%, accuracy 71%), respectively. On multivariate analyses, corrected for age, KPS, type of surgery and second surgery, the MGMT cut-off values remained significantly correlated to longer PFS (HR = 0.5, 95%CI 0.4-0.7) and OS (HR = 0.47, 95% CI 0.3-0.6). **Conclusions:** From this large, multicenter study, we identify, by pyrosequencing approach, a strong prognostic value of MGMT methylation, in terms of PFS and OS. This value could be used as stratification factor in prospective clinical trials.

Differential elevation of TERT activity and sensitivity to temozolomide by type of TERT mutation in MGMT promoter-methylated glioblastoma. *First Author: Michael Weller, Department of Neurology, University Hospital Zurich, Zurich, Switzerland*

Background: Benefit from temozolomide chemotherapy in glioblastoma is essentially limited to patients with tumors with O^6-methylguanine DNA methyltransferase (MGMT) promoter methylation. The impact of the MGMT status on chemosensitivity may be modulated by telomerase reverse transcriptase (TERT) promoter mutations which affect two regions of the TERT promoter, designated as C228T and C250T. **Methods:** TERT promoter mutation status and TERT activity were determined in a panel of glioma cell lines and correlated with sensitivity to irradiation or temozolomide. TERT status alterations were induced using sh-mediated gene TERT silencing or wildtype TERT overexpression. TERT mutation and MGMT promoter methylation status were also determined in a clinical patient cohort from the German Glioma Network. **Results:** C228T-mutant glioma cell lines (n = 8) express higher levels of TERT mRNA (mean 0.046 ± 0.012 vs 0.012 ± 0.004 arbitrary units, p = 0.049) and exhibit higher TERT catalytic activity (mean 122 ± 16 vs 53 ± 11 arbitrary units, p = 0.022) than C250T-mutant glioma cell lines (n = 5). C228T-mutant glioma cell lines are also more sensitive to irradiation (mean ED90 4.6 ± 0.7 versus 7.1 ± 0.8 Gy, p = 0.039) or temozolomide (mean EC50 101.6 ± 58.5 versus 295.2 ± 53.8 μM, p = 0.045) *in vitro*. Targeted alterations of TERT status result in profound changes in radiosensitivity and chemosensitivity: TERT gene silencing is protective whereas TERT overexpression sensitizes to either genotoxic treatment. Consistent with these preclinical observations, patients with C228T TERT mutation and MGMT promoter methylation appeared to derive more benefit from temozolomide chemoradiotherapy (median overall survival 26.5 months, 95% CI 20.3-32.7) than patients with the C250T mutation (median overall survival 16.2 months, 95% CI 8.5-23.8) or patients without TERT mutation (median overall survival 23.7 months, 95% CI 18.7-28.8). **Conclusions:** These data refine current models on how TERT and MGMT interact to determine outcome in human glioblastoma and illustrate how future targeted interventions focusing on TERT and MGMT may help to tailor pharmacotherapy of glioblastoma.

The natural course of hypermutator gliomas. *First Author: Carlos Kamiya-Matsuoka, The University of Texas MD Anderson Cancer Center, Department of Neuro-Oncology, Houston, TX*

Background: Hypermutator genotype (HMGen) is seen in glioblastoma (GB) and lower-grade gliomas. It may be induced by temozolomide (TMZ) and leads to TMZ resistance. We describe demographics, mutational features, treatments and outcomes of HMGen gliomas. **Methods:** Retrospective review at MD Anderson between 02/2006-02/2017 identified 309 gliomas with tissue analyzed by next-generation sequencing (T200-1, Oncomine, FoundationOne). HMGen was defined as tumor mutation burden (TMB-30) of 30 or more mutations (mut) per Mb, or displaying mut in mismatch repair (MMR) or DNA polymerase (Pol) genes. **Results:** 38 (12.3%) patients had HMGen. 25 (66%) were men. 19 (50%) had TMB-30, 10 (26%) had mut in Pol gene, 6 (16%) in MMR (1 had mut in both MLH and MSH6 genes), 1 had mut in both MMR and Pol genes and only 2 met all three criteria. GB (N = 26, 68%) was the most common tumor (N = 6, 23.1% IDH1-mut), followed by WHO grade III oligodendroglioma (N = 8, 21%), grade II astrocytoma (N = 3, 8%) and grade II oligodendroglioma (N = 1, 3%). HMGen was found as initial genotype in 17 (45%) cases, the rest after treatment with alkylating agents. Of those patients with de novo HMGen, Pol gene mut was most common (N = 9, 53%), followed by MMR mut (N = 4, 23.5%) and TMB-30 (N = 4, 23.5%). Of those 17, 15 (88%) were GB followed by WHO grade II gliomas: 1 oligodendroglioma with MMR mut (MSH6) and 1 astrocytoma with TMB-30. For post-treatment HMGen, the most common alterations was TMB-30. The mean cumulative TMZ dose at HMGen diagnosis for GB, WHO grade II/III astrocytoma and grade II/III oligodendroglioma was 16g, 24.6g/28g, and 41g/29.6g, respectively with a mean monthly dose of 1.5-1.8g. Only 1 patient received CCNU (0.4g). For de novo and post-treatment HMGen GB IDH1-wild-type, the OS and PFS from HMGen diagnosis was 19.6/15 and 23.7/3.9 months (m) respectively. The latency interval from histopathologic GB to HMGen was 17.5 m and the total OS was 43.6 m. Most of this subgroup (65%) are still alive with a time from initial diagnosis to last follow-up of 35.7 m. **Conclusions:** HMGen gliomas may occur spontaneously at initial diagnosis before treatment and may be associated with longer survival than historical controls. Further investigation is needed to determine whether HMGen can be predicted due to potential clinical implications.

2015 Poster Discussion Session; Displayed in Poster Session (Board #173), Sat, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Sat, 4:45 PM-6:00 PM

Phase 1b/2 study of pexidartinib (PEX) in combination with radiation therapy (XRT) and temozolomide (TMZ) in newly diagnosed glioblastoma. *First Author: Howard Colman, Hunstman Cancer Institute, Salt Lake City, UT*

Background: PEX is an oral small molecule inhibitor of KIT and CSF1 receptor expressed on microglia, blood vessels, and glioblastoma (GBM) tumor cells. PEX achieved good tissue exposure in a prior recurrent GBM study, and preclinical studies indicate PEX may sensitize GBM to standard of care (SOC) therapy through effects on both tumor and microenvironment. **Methods:** Phase Ib determined the recommended Phase II dose (RP2D) with SOC XRT/TMZ. Phase II primary endpoint was progression free survival (PFS); secondary endpoints included overall survival (OS) and safety. Patient entry criteria were designed to replicate the RTOG 0525 control arm, which was used as a historical control. **Results:** The identified RP2D was PEX 400mg BID 5 days/week during and 7 days/week after SOC XRT/TMZ. Of the total RP2D population, 42 were evaluable for comparison and demonstrated similar characteristics to the RTOG 0525 control arm. As of November 2017, mPFS from registration is 6.7 months in PEX patients (95% CI 4.2, 10.2) vs. 7.5 months in historical controls. Estimated mOS for PEX is 15.4 months (95% CI 12.3, 20.7) vs. 18.9 months in controls. PEX was well tolerated, with most common drug-related toxicities including neutropenia and increased ALT/AST. MGMT unmethylated patients comprised 60% of the patients, with estimated mOS of 13.8 months (95% CI 12.3, 20.7) vs. 68% and estimated mOS of 16.6 months in historical controls. MGMT methylated patients comprised 40%, and mOS not yet reached vs. 32% and estimated mOS of 23.5 months in historical controls. Tumors with high expression of monocyte/macrophage marker CD163 and macrophage stimulating factor CSF1 trended to worse overall survival. mOS was 13.8 months for tumors with high expression of CD163 vs. 19.2 in tumors with low expression (p = .323). mOS was 12.3 months in tumors with high CSF1 expression vs. 19.2 in tumors with low (p = .328). **Conclusions:** PEX can be safely combined with SOC XRT/TMZ in newly diagnosed GBM. Results suggest minimal PEX activity when added to XRT/TMZ in an unselected GBM population for improving PFS and OS compared to robust, well-matched historical controls. Further investigation in relevant biomarker subgroups is ongoing. Clinical trial information: NCT01790503.

Safety and preliminary efficacy data from a phase I study of an implantable low intensity pulsed ultrasound (LIPU) device for disrupting the blood-brain barrier (BBB) in patients treated by chemotherapy for recurrent glioblastoma (GBM). *First Author: Ahmed Idbaih, Inserm U 1127, CNRS UMR 7225, Sorbonne Universités, UPMC Univ Paris 06 UMR S 1127, Institut du Cerveau et de la Moelle épinière, ICM, Paris, France*

Background: The BBB limits the efficacy of many chemotherapies in GBM patients by blocking the passage of drugs to the brain. Two to four minutes of LIPU in combination with injection of micron-sized microbubbles can transiently disrupt the BBB to increase the passage of drugs such as carboplatin. **Methods:** This first-in-man, single arm, monocentric trial was performed at Hôpital Universitaire Pitié-Salpêtrière, Paris, France from 2014-2018. Recurrent GBM patients were implanted with (1) or (3) 1 MHz, 10-mm diameter cranial devices in burr holes during debulking surgery or during a dedicated procedure under local anesthesia. Ultrasound dose was escalated using a Simon titration design. The device was activated monthly to transiently disrupt the BBB before IV administration of carboplatin (AUC4-6). BBB disruption was visualized using MRI and patients were monitored clinically. **Results:** Twenty-seven patients were implanted with LIPU devices and 25 per-protocol were sonicated: 19 patients with (1) US emitter and six patients with (3) US emitters. In 85 ultrasound sessions, BBB disruption was visible on post-sonication T1w MRI for 72 sonications and was ultrasound dose dependent. Few transient and manageable severe related adverse events were observed: a partial seizure, two cases of transient edema (H1 and D15) and one transient facial palsy. No carboplatin-related neurotoxicity was observed. All patients treated with (1) emitter had tumor progression and 3/19 patients were alive. In this cohort, patients with no or poor BBB disruption (n = 8) had a median PFS of 13 weeks, and a median OS of 8.9 months. Patients with clear BBB disruption (n = 11) had a median PFS of 15 weeks, and a median OS of 13 months. **Conclusions:** LIPU was well tolerated and may increase the effectiveness of drug therapies in the brain. The sonication of larger volumes of brain in recurrent GBM will be investigated in a future trial and may further enhance the observed effectiveness of this treatment modality. Clinical trial information: NCT02253212. Clinical trial information: NCT02253212.

VXM01 phase I study in patients with progressive glioblastoma: Final results. *First Author: Wolfgang Wick, Neurology Clinic, DKFZ, DKTK, Heidelberg, Germany*

Background: VXM01 consists of an attenuated *Salmonella typhi* Ty21a carrying a plasmid encoding for vascular endothelial growth factor receptor (VEGFR)-2. The bacterium is a vector *via* the oral route of administration carrying the plasmid into the Peyer's plaques. The vaccine elicits a systemic T-cell response targeting VEGFR-2. This trial examined safety and tolerability, clinical and immunogenic response to VXM01 after at least four vaccinations [10^6 or 10^7 colony-forming units (CFU)] in patients with progressive glioblastoma who have failed at least radiochemotherapy with temozolomide. **Methods:** Patients with progressive operable glioblastoma were subjected to VXM01 in one oral administration each on day 1, 3, 5, and 7. In addition, VXM01 was allowed to be administered in 4-weekly single doses every 4 weeks during the tumor follow-up period after surgery. Follow-up was done by weekly safety laboratories and physical examinations in the treatment period and 12-weekly thereafter T-cell immunomonitoring in the peripheral blood, and brain tumor immunohistochemistry. **Results:** Fourteen patients have been treated with VXM01. Three out of them with additional nivolumab. Surgery has been performed in eight patients. Under VXM01 treatment 119 adverse events, mostly unrelated to VXM01, were observed after a median of 8 doses per patient. ELISpot analysis showed a detectable VEGFR-2 specific T cell response in 7 out 12 (58%) patients measured. In the observation period of up to 20 months 7 patients are alive, 5 out of them survived for more than one year, 2 patients are ongoing at month 10. In one patient there was an objective and durable T1 response. Survival seemed to be correlated with a higher CD8/Treg ratio in progressive and primary tumor, which further increased after VXM01 treatment. In patients with prolonged survival a decrease in intratumoral PD-L1 was observed arguing for combination of VXM01 with an anti-PD-L1 checkpoint inhibitor. **Conclusions:** VXM01 was safe and produces detectable specific peripheral immune responses as well as CD8/Treg ratio increase in post-vaccine tumor tissue. There was one patient with an objective response. As a next step, a combination study of VXM01 and anti-PD-L1 checkpoint inhibitor has been launched. Clinical trial information: NCT02718443.

2018 Poster Discussion Session; Displayed in Poster Session (Board #176), Sat, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Sat, 4:45 PM-6:00 PM

Phase I clinical trials evaluating olaparib in combination with radiotherapy (RT) and/or temozolomide (TMZ) in glioblastoma patients: Results of OPARATIC and PARADIGM phase I and early results of PARADIGM-2. *First Author: Anthony J. Chalmers, University of Glasgow, Glasgow, United Kingdom*

Background: The poly(ADP-ribose) polymerase (PARP) inhibitor olaparib (O) has radio and chemosensitizing properties in GBM models. Clinical development of PARP inhibitor combinations has been restricted by exacerbation of hematological toxicity and acute radiation toxicity. We studied pharmacokinetics (PK), safety and toxicity of O with RT and/or TMZ in three phase I studies. **Methods:** OPARATIC determined PK of O (AZ tablet formulation) in core and margins of recurrent GBM and maximum tolerated dose (MTD) of O with 42 day cycles of daily TMZ. PARADIGM determined recommended phase II dose (RP2D) of O with 40 Gy 15 fractions of radiotherapy in newly diagnosed patients aged $>$ 70. PARADIGM-2 comprises two phase I studies of O+RT (60 Gy 30#, MGMT unmethylated) or O+RT+TMZ (MGMT methylated) in newly diagnosed patients aged $<$ 70. **Results:** OPARATIC: 48 patients recruited; 27 underwent surgery, 36 receiving O/TMZ were evaluable. O detected in 71/75 tumor core specimens (27 patients); mean conc. 588nM (97-1374nM), and 27/28 tumor margin specimens (10 patients); mean conc. 500nM (97-1237 nM). Myelosuppression necessitated intermittent O dosing. MTD defined as O 150 mg (OD) days 1-3 weekly plus TMZ 75 mg/m2 daily. For 36 evaluable patients receiving 0/TMZ, progression-free survival at 6 months was 39%. PARADIGM: 16 patients (median age 72) treated in four O dose cohorts. One DLT (agitation grade 3) recorded (cohort 3, 100 mg BID). RP2D of O +40Gy 5# in elderly GBM was 200 mg BID daily. Median overall survival 10.3 months (80% CI: 6.3 – 11.7 months) at 12.9 months median follow up. PARADIGM-2: 29 patients screened, 14 commenced study treatment. Three MGMT unmethylated patients completed cohort 1 (50 mg QID) with no DLTs and 4 recruited to cohort 2 (100 mg QID) with no DLTs to date. Seven MGMT methylated patients recruited to cohort 1 (100 mg x1 per week); 1 DLT reported to date (low platelets). **Conclusions:** O penetrates core and margins of recurrent GBM. Combination with TMZ requires intermittent dosing but is safe and well tolerated. Combination with radiotherapy is extremely well tolerated and randomized phase II evaluation is underway. Clinical trial information: NCT01390571.

2019 Poster Discussion Session; Displayed in Poster Session (Board #177), Sat, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Sat, 4:45 PM-6:00 PM

CXCR4 blockade at the end of irradiation to improve local control of glioblastoma (GBM). *First Author: Reena Parada Thomas, Stanford University, Palo Alto, CA*

Background: Based on preclinical work identifying an important role for the CXCL12 (SDF1)/CXCR4 chemokine axis in reestablishing vascularity after irradiation of GBM, we launched a Phase I/II study assessing the impact of CXCR4 blockade with a continuous infusion of Plerixafor (AMD3100, Mozobil), an established CXCR4 small molecule antagonist, already in clinical use for bone marrow stem cell mobilization. **Methods:** Open label Phase I/II study for newly diagnosed adult GBM patients, ages 75 or younger, with KPS of at least 60 were administered a 4-week continuous intravenous infusion starting one week prior to the completion of standard irradiation. **Results:** 29 patients (median age: 60 years) were enrolled and completed the infusion course. The Phase I study established that 16.6 μg/kg/hr was well tolerated (no Gr III drug associated toxicity) with achievable Plerixafor serum values above the threshold level for CXCR4 blockade. A total of 19 patients underwent DSC-MRI for quantification of relative cerebral blood volume (rCBV) at their 1-month and 6-month follow up scans. Compared to a group of 11 contemporaneous patients treated with standard chemo-radiation, there was a significant reduction of mean rCBV within the 95% isodose radiation field at 1-month (0.76 vs 0.88, $p = 0.04$) and 6-months (0.67 vs 0.87, $p = 0.001$), as observed in our preclinical studies. In association with this, was an out of field (i.e., beyond the 95% isodose field or within leptomeninges) first recurrence rate of 58.8% compared to 10% in the control group ($p = 0.018$, Fisher exact test). The Kaplan-Meier estimated median overall survival in months was 20.7, 95% CI (17.3, NA) and was not correlated with surgical extent, age, or MGMT status. **Conclusions:** GBM recurrences using standard treatment are generally local in 80% of patients. The high out of field first recurrence rate in this series, in conjunction with a marked decrease in rCBV, is therefore extremely notable. When viewed with the favorable survival data, it suggests improved local control and enhancement of the therapeutic response to radiation. We therefore conclude that blockade of the SDF1/CXCR4 axis represents a novel, clinically impactful strategy worthy of further investigation in GBM.

2020 Poster Discussion Session; Displayed in Poster Session (Board #178), Sat, 1:15 PM-4:45 PM, Discussed in Poster Discussion Session, Sat, 4:45 PM-6:00 PM

Effect of dexamethasone in glioblastoma (GBM) patients on systemic and intratumoral T-cell responses induced by personalized neoantigen-targeting vaccine. *First Author: David A. Reardon, Dana-Farber Cancer Institute and Harvard Medical School, Boston, MA*

Background: The impact of individualized neoepitope vaccination targeting neoantigens arising from tumor-specific mutations for GBM, a low mutation burden tumor with an immunologically cold tumor microenvironment, as well as that of concurrently administered dexamethasone (dex), are unknown. **Methods:** Individualized vaccination of up to 20 synthetic, long neoepitope peptides with high predicted HLA binding affinity admixed with poly-ICLC, were administered subcutaneously using a prime-boost schedule after RT to newly diagnosed, MGMT unmethylated, at least partially resected, GBM patients without progression after radiation (RT) in our phase 1b study. **Results:** 9 of 10 screened patients had sufficient ($\geq$ 10) identified neoepitope peptides. 8 patients without progression after RT received vaccine consisting of a median of 12 peptides (range, 7-20) beginning a median of 18.6 wks (range 16.0-23.2) after surgery. Adverse events were limited to infrequent grade 1/2 local reactions and fatigue. Median PFS and OS were 7.5 mths (90% CI: 6.2, 9.7) and 16.8 mths (90% CI: 9.6, 21.3). Evaluation of neoepitope-specific immune responses and tumor immune infiltrate analyses were performed on five patients with pre- and post-vaccination samples. Three patients on dex for post-RT edema during vaccine had no immune responses and no change in tumor infiltrating effector cells. In contrast 2 patients not on dex had robust, de novo immune responses against multiple predicted personal neoantigens including polyfunctional neoantigen-specific CD4+ and CD8+ T cell responses that were enriched for memory and activated phenotypes as well as increased numbers of tumor-infiltrating CD4+ and CD8+ T cells. T cell receptor analysis from one patient identified identical clonotypes isolated from post-vaccination tumor tissue and peripheral blood including a clonotype specific for ARHGAP35, a neoantigen targeted by vaccination. **Conclusions:** Individualized, multi-neoepitope vaccines are feasible, safe and capable of generating systemic and intra-tumoral immune responses in GBM patients that appear to be abrogated by dex. Clinical trial information: NCT02287428.

2021 Poster Session (Board #179), Sat, 1:15 PM-4:45 PM

Long-term stroke risk of single-fraction photon-based stereotactic radiosurgery for meningioma. *First Author: Shearwood McClelland, Oregon Health and Science University, Portland, OR*

Background: A recent randomized study of fractionated radiation therapy (RT) examining 44 subtotally resected/recurrent benign meningioma patients revealed that at median follow-up of 17.1 years, the risk of stroke following proton-photon RT was 20.5%; the average stroke developed 5.6 years following RT completion (Sanford et al., 2017). This stroke risk is up to 10 times higher than the 2-6% rate expected for the general population of ages 40-79 (Mozaffarian et al., 2015). The stroke rate following single-fraction stereotactic radiosurgery (SRS) has not been previously studied in meningioma patients. **Methods:** A PubMed database search for relevant articles examining SRS for meningioma with minimum mean/median follow-up of six years was undertaken. Stroke rate was assessed either from direct description in manuscripts, or from extrapolating post-SRS complications from reported clinical examinations (i.e. hemiparesis/weakness, pituitary dysfunction following treatment of cavernous sinus lesions). Results were then culled to determine an overall stroke rate. **Results:** Fourteen studies met inclusion criteria; 1,431 patients received photon-based SRS for meningioma with a sufficient long-term follow-up. Median/mean follow-up ranged from 75-144 months. Operative resection prior to SRS occurred in 769/1377 patients (55.8%) for whom surgical history was reported. Twenty-four patients suffered a stroke following SRS, yielding a rate of 1.7%. **Conclusions:** The long-term stroke rate following single-fraction photon-based SRS for benign meningioma was 1.7%, more than twelve times lower than for fractionated proton-photon RT and comparable to that expected for the general population. The majority of patients underwent resection prior to SRS. These findings indicate that for patients with benign meningioma desiring to avoid the high stroke risk of fractionated proton-photon RT, SRS has a comparable stroke risk profile to observation. Such findings are pertinent for radiation oncology, neuro-oncology, and neurosurgery management of these patients.

2022 Poster Session (Board #180), Sat, 1:15 PM-4:45 PM

A unique MRI-based radiomic signature predicts hypermutated glioma genotype. *First Author: Islam Hassan, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Hypermutation is defined as the excessive accumulation of DNA mutation in cancer cells and is reported in several forms of cancer including low and high grade gliomas. Incidence of hypermutated genotype was associated with failure of DNA repair machinery such as mismatch repair (MMR) or disruption of DNA fidelity due to mutations in DNA polymerase genes (POLE and POLD).Hypermutated gliomas (mainly glioblastoma (GB)) are largely seen at recurrence with associated resistance to temozolomide therapy. Herein, we sought to identify an imaging-based signature for hypermutated gliomas using a radiomics-based approach. **Methods:** In this IRB-approved retrospective study, we analyzed a total of 101 patients with primary gliomas from the University of Texas MD Anderson Cancer Center. Next generation sequencing (NGS) platforms (T200 and Foundation 1) were used to determine the Mutation burden status in post-biopsy (stereotactic/excisional). Patients were dichotomized based on their mutation burden; 77 hypomutated ($<$ 30 mutations) and 24 hypermutated ($>$ = 30 mutations or $<$ 30 with MMR gene or POLE/POLD gene mutations). Radiomic analysis was performed on the conventional MR images (FLAIR and T1 post-contrast) obtained prior to tumor tissue surgical sampling; and a total of 2480 rotation-invariant radiomic features were extracted using: (i) the first-order histogram and (ii) grey level co-occurrence matrix. The Maximum Relevance Minimum Redundancy technique was used to select the most relevant radiomic features. ROC analysis and leave-one-out cross-validation (LOOCV) were used to assess the performance of the Support Vector Machine (SVM) classifier as and AUC, Sensitivity, Specificity, and p-value were obtained. **Results:** We found 100 radiomic features that can discriminate between hypermutated versus hypomutated gliomas, AUC 96.3% (CI: 90.2%-98.9%), Sensitivity 100%, Specificity 95%, p-value = 3.769e-6. **Conclusions:** Hypermutated gliomas has a unique radiomic quantitative signature that can be used to predict mutation burden regardless of tumor grade or histopathology.

2023 Poster Session (Board #181), Sat, 1:15 PM-4:45 PM

Updated results of the INTELLANCE 2/EORTC trial 1410 randomized phase II study on Depatux –M alone, Depatux-M in combination with temozolomide (TMZ) and either TMZ or lomustine (LOM) in recurrent EGFR amplified glioblastoma (NCT02343406). *First Author: Martin J. Van Den Bent, Erasmus MC Cancer Center, Rotterdam, Netherlands*

Background: Depatux-M is a tumor-specific antibody-drug-conjugate consisting of an antibody (ABT-806) bound to the toxin monomethylauristatin-F. In the primary analysis on EORTC 1410 we reported a trend (p = 0.06) towards improved overall survival (OS) in patients with EGFR-amplified (amp) recurrent glioblastoma treated with Depatux-M in combination with TMZ. **Methods:** Eligible were patients with centrally confirmed EGFRamp glioblastoma at 1st recurrence after TMZ chemo-irradiation, occurring $\geq$3 months after radiotherapy. Patients were randomized to either a) Depatux-M 1.0 mg/kg every 2 weeks intravenously, or b) the same treatment combined with TMZ 150-200 mg/m^2 day 1-5 every 4 weeks, or c) either LOM or TMZ (TMZ/LOM) depending on the time of relapse. Primary endpoint was OS. Pharmacokinetic (PK) sampling was done on day (d) 1 before and after dosing, d 4-7, d 1 course 2 before and after dosing, d 5-7 course 4, d 1 course 3, and then every 2 cycles. All available PK samples were used to calculate the Depatux-M average concentration during course 1 (CavgC1). The level of EGFRamp was determined using both qPCR, next generation sequencing and FISH. **Results:** An updated OS comparison of Depatux-M in combination with TMZ versus TMZ/LOM with longer follow-up, performed after 220 observed deaths using log-rank test and cox models stratified by stratification factors at randomization showed a HR of 0.68 (95%CI [0.48, 0.95]; p = 0.024) and 1-year OS rates of 40% versus 28%. In multivariate analysis including performance status, MGMT, surgery for the recurrence, time from last TMZ to relapse and lesion diameter, CavgC1 was a significant predictor for OS (HR 0.96, 95% CI [0.93, 0.98], p = 0.0013). In Depatux-M treated patients, EGFR status (high vs low level amplification) did not correlate with OS. **Conclusions:** This updated OS analysis of Depatux-M in combination with TMZ confirmed the OS improvement in EGFRamp recurrent glioblastoma. In Depatux-M treated patients, higher drug levels during course 1 were associated with improved OS but high levels of EGFR amplification at first diagnosis were not. Clinical trial information: NCT02343406.

2025 Poster Session (Board #183), Sat, 1:15 PM-4:45 PM

Depression and survival of glioma patients: A systematic review and meta-analysis. *First Author: Nayan Lamba, Harvard Medical School, Boston, MA*

Background: There is currently a lack of well-established meta-analyses examining the association between depression and patient survival in glioma patients. The aim of this meta-analysis was to study the effect of depression on glioma patients' survival. **Methods:** A meta-analysis was conducted according to the PRISMA guidelines. PubMed, Embase, and Cochrane databases were searched for studies that reported depression and survival among glioma patients through 11/06/2016. Both random-effects (RE) and fixed-effect (FE) models were used to compare survival outcomes in glioma patients with and without depression. **Results:** Out of 619 identified articles, six were selected for the meta-analysis. Using RE model, the various measures of survival outcomes displayed worsened outcomes for both high and low grade glioma patients with depression compared to those without depression, with an overall pooled risk ratio for survival of 0.67 (95%CI: 0.46, 0.99; I2 = 51.4%, P-heterogeneity = 0.06); an overall pooled standard mean difference for the overall survival time (in months) of -0.88 (95%CI: -1.89, 0.13; I2 = 87.1%, P-heterogeneity $<$ 0.01); and a pooled hazard ratio of death of 1.42 (95% CI: 1.00, 2.01; I2 = 0%, P-heterogeneity = 0.85). Using the FE model, results were similar except for overall survival time, where the shorter survival time in glioma patients with versus without depression reached statistical significance (-0.70; 95%CI: -0.86, -0.53). Among high-grade glioma patients, pre-operative depression diagnosis was associated with fewer months of survival compared to postoperative diagnosis, as shown under the FE model (P-interaction $<$ 0.01), but not under the RE model (P-interaction = 0.14). **Conclusions:** Among patients with either low or high-grade glioma, depression was associated with significantly worsened survival regardless of time of diagnosis.

2026 Poster Session (Board #184), Sat, 1:15 PM-4:45 PM

Association between treatment facility volume and mortality in patients with glioblastoma (GBM): A large national analysis. *First Author: Sonikpreet Aulakh, Mayo Clinic, Jacksonville, FL*

Background: Glioblastoma (GBM) is an aggressive primary malignancy of the brain, treated with surgical resection and chemo-radiotherapy, yet it has a dismal prognosis of 12-14 month overall survival (OS). Optimal outcomes require an experienced team providing multidisciplinary management. We explored the association of treatment facility volume and mortality in patients with GBM. **Methods:** We identified incident GBM (ICD-O-3 code: 9440/3) cases from the National Cancer Database (NCDB) (2004-2013) and utilized Cox-regression to determine the facility volume-outcome (volume = quartiles; Q) relationship, adjusting for year of diagnosis, demographic (sex, age, race, ethnicity), socio-economic (income, education, insurance type), geographic (area of residence, treatment facility location, travel distance) and co-morbidity factors (Charlson-Deyo score). **Results:** There were 114,467 patients (median age 60 years, range: 18-90) with GBM treated at 1207 facilities of which, 54.8% were men. Median annual facility volume was 5 patients/year (range: 0.1-136.4). The top 14 (1.2%) facilities treated $>$ 60 patients/year (10%). Median overall survival (OS) was 15 months There were significant differences (all $p < 0.001$) in patient characteristics by facility volume (Table). Unadjusted median OS by facility volume (months) was Q1: 29.1, Q2: 32.9, Q3: 36.4, Q4: 48.2 ($p < 0.0001$). Multivariate analysis showed facility volume to be independently associated with all-cause mortality (Reference Q4; Q3 HR: 1.30, 95% CI 1.28-1.33; Q2 HR: 1.36, 95% CI 1.36-1.43; Q1 HR: 1.58 95% CI 1.50-1.67). OS disparity by facility volume is persistent but not worsening in recent years (2010-2013 vs 2004-2005). **Conclusions:** In GBM, facility-volume independently affects OS of the patients. Attempts should be made to address modifiable factors and get patients access to high-volume centers earlier in the disease course.

Characteristic	Lower Quartile (Q1, Q2, Q3)	Higher Quartile (Q4)
Patients seen/year	$<$ 1-12.2	12.2-136.4
Academic centers	7.3%	48.9%
Median age (years)	63	58
Median travel distance to facility (miles)	7.2	14.7
Private Insurance	41.2%	50.4%
Medicare/Medicaid	51%	40.7%
Income > $46000	38.7%	43.6%

Angiotensinogen gene silencing to predict bevacizumab response in recurrent glioblastoma patients. *First Author: Thomas Urup, Rigshospitalet, Copenhagen, DK*

Background: Bevacizumab in combination with chemotherapy has shown activity in recurrent glioblastoma patients. Patients who achieve response to bevacizumab have improved survival as well as quality of life. Recently, we found that low gene expression of angiotensinogen (*AGT*) was a predictive factor for bevacizumab response in recurrent glioblastoma patients. Because promoter methylation of *AGT* has been associated with *AGT* gene silencing, we investigated if *AGT* promoter methylation in tumor tissue predicts response to bevacizumab combination therapy in recurrent glioblastoma patients. **Methods:** The study includes 82 recurrent glioblastoma patients treated with bevacizumab combination therapy whom were both RANO response and biomarker evaluable. DNA methylation of 7 CpG sites in the CEBPA binding site (~200 bp from TSS) of the *AGT* promoter was measured using pyrosequencing. *AGT* gene expression in tumor tissue was measured by NanoString analysis. For each CpG site, methylation levels were associated with angiotensinogen gene expression using Spearman correlations and to treatment response using Mann-Whitney U test and logistic regression analysis. **Results:** *Preliminary results on 58 of 82 patients analyzed: AGT* gene expression was inversely associated with *AGT* promoter methylation on CpG site 1 (P = 0.049) and borderline significant on CpG site 2 (P = 0.074). Compared to non-responding patients, responders expressed significantly higher methylation levels of CpG site 1 (P = 0.015), 2 (P = 0.013) and 3 (P = 0.045). DNA methylation levels at CpG site 4-7 were not associated with *AGT* gene expression or response. By univariate analysis, increased methylation of the *AGT* promoter region were predictive for bevacizumab response on CpG site 1 (2-fold increase: OR = 1.81; 95%CI: 1.02-3.23; P = 0.043) and on CpG site 2 (2-fold increase: OR = 2.08; 95%CI: 1.04-4.17; P = 0.040). **Conclusions:** Increased methylation of the *AGT* promoter regions is associated with *AGT* gene silencing and is predictive for bevacizumab response in recurrent glioblastoma patients. Updated results will be presented.

2028 Poster Session (Board #186), Sat, 1:15 PM-4:45 PM

Genomic landscape of pineoblastoma. *First Author: Bryan Kincheon Li, Hospital for Sick Children, Toronto, ON, Canada*

Background: Pineoblastoma (PB) is a rare but aggressive pediatric brain tumour arising from the pineal gland. Overall survival rates are estimated at 50-60%, with younger patients ($<$ 5 years old) faring much worse (15-40%) despite intensive treatment regimens. Although germline RB1 and DICER1 alterations have been reported in a small proportion of PB, the clinical significance of such alterations and the biology of sporadic cases remains unknown. **Methods:** We collected tumor tissue from 75 cases of PB diagnosed at their local centres from across five continents. We undertook global DNA methylation profiling and performed multiple orthogonal consensus clustering analyses to elucidate PB subgroups. Chromosomal copy number alterations were determined using Conumee then GISTIC 2.0. Mutational analysis was conducted by whole exome and RNA sequencing. Clinical data was analyzed with correlative statistical methods and outcomes were measured by Kaplan-Meier survival estimates. **Results:** We discovered that PBs comprise four molecular sub-types, designated groups 1 to 4, with characteristic copy number alterations and mutational patterns. These molecular sub-groups exhibit distinct clinical features and survival outcomes. While PB groups 1-3 arose in older children (median ages 5.2-12.6 years), group 4 PB was restricted to much younger children (median age 1.4 years). Group 4 PB exhibited the highest incidence of metastases (53%) and had the worst 5-year event-free survival (EFS) and overall survival (OS) at 7.7% and 16.7%, respectively. In contrast, group 2 patients had a 5-year EFS and OS of 100%, while groups 1 and 3 had intermediate outcomes (5-year EFS 36.1% and 53.3%, 5-year OS 68.1% and 53.3%, respectively). **Conclusions:** PBs divide into four groups, each with a distinct genetic and clinical profile. These findings will have important implications for precise patient stratification and form the foundation for preclinical studies of biology-informed therapies.

Contrast enhancement as a prognostic factor in IDH1/2 mutant glioma. *First Author: Bogdana Suchorska, Department of Neurosurgery LMU, Munich, Germany*

Background: Mutational status of the *IDH1/2* gene and co-deletion of on chromosome 1p/19q (co-del 1p/19q) is gaining further relevance for the evaluation of clinical outcome in lower grade glioma. Out of the established clinical and imaging parameters known to influence survival in these tumors, contrast enhancement (CE) has been reported to indicate poor outcome in the past. The present study aimed at re-assessing the value of clinical and imaging parameters in lower grade glioma within the framework of molecular markers using a machine learning approach (random survival forests, RSF) as well as conventional Cox regression modeling. **Methods:** 301 patients with grade II (n = 181) or grade III diffuse glioma (n = 120) were stratified according to their molecular profile (presence of *IDH1/2* mutation and/or co-deletion 1p/19q.) Preoperative magnetic resonance (MR) imaging was reviewed and volumetrical analyses of CE and T_2 volumes were performed. Multivariate cox models and RSF were trained on this data set using five-fold cross validation to assess the predictive value of pre-therapeutic molecular and imaging factors as well as age, Karnofsky performance status, surgical procedure and adjuvant therapy to predict the individual risk for each patient. As a measure of prediction accuracy, the concordance indices for Cox and RSF models were determined. **Results:** RSF modeling revealed presence of *IDH1/2* mutation, co-deletion 1p/19q and WHO II to be the most relevant factors for favorable outcome in lower grade glioma. In *IDH1/2* mutant tumors, both conventional Cox regression modeling and RSF analyses show that CE on initial MR imaging is a prognostic factor for survival independently of its magnitude in both co-deleted and non-co-deleted tumors ($p < 0.05$). In contrast, presence of CE on initial MRI is not associated with outcome in *IDH1/2* wildtype tumors. Likewise, the RSF model identified predictive influence of CE in the *IDH1/2* mutant tumors only. **Conclusions:** In patients with diffuse *IDH1/2* wildtype gliomas WHO grade II/III, CE is not associated with survival. In tumors with an *IDH1/2* mutation, presence of CE on initial MRI is linked to inferior survival.

2030 Poster Session (Board #188), Sat, 1:15 PM-4:45 PM

Meningioma: Association of mean and "hot spot" MIB1 with grade. *First Author: Christopher Dardis, Barrow Neurological Institute, Phoenix, AZ*

Background: The MIB1 labeling index is typically measured by counting cells in the region ('hot spot') with the highest proliferative activity. MIB1 is not currently one of the criteria used to classify meningioma as WHO Grade 1 or 2. Here we compare this 'hot spot' MIB1 ($MIB1_{hs}$) with the mean MIB1 ($MIB1_m$) of the whole sample. **Methods:** Both methods used computer-assisted quantitative analysis on images/optical fields at 400x magnification. $MIB1_{hs}$ was taken by counting a minimum of 1,000 cells in the most proliferative field of the tumor. $MIB1_m$ was estimated by taking the mean of 14x fields, from randomly selected regions of the tumor. This was done for meningiomas which underwent resection at our institution in 2009: 108x Grade 1, 32x Grade 2. **Results:** $MIB1_{hs}$ was more than double that of $MIB1_m$ (5.9% vs. 2.7%; two-sided t-test $p = 6\times10^{-9}$). The log of both measures was found to increase in a linear fashion, irrespective of grade. Using recursive partitioning, an optimal 'cutpoint' for MIB1 (in terms of Grade) was found to be 1.5% for both methods. As shown in the classification table, the methods were concordant in 100/140 (70%) cases. With these cutpoints, Fisher's exact test showed a stronger association with Grade for $MIB1_m$ vs. $MIB1_{hs}$ ($p = 0.04$ vs. $p = 0.0008$). **Conclusions:** For meningioma, $MIB1_m$ shows a significantly greater association with Grade than $MIB1_{hs}$. The method can be implemented with minimal additional burden to the practicing pathologist. The result appears to be of greater importance clinically. As MIB1 also increases in an exponential manner in breast cancer, schwannoma and low-grade glioma, we propose that this is a general property of the test.

$MIB1_{hs}$	$MIB1_m$	WHO Grade	
		1	2
< 1.5%	< 1.5%	59	28
	≥ 1.5 %	35	4
≥ 1.5%	≥ 1.5 %	13	0
	< 1.5 %	1	0

2031 Poster Session (Board #189), Sat, 1:15 PM-4:45 PM

Interrogating machine learning classifiers and dimensionality reduction techniques for radiomic prediction of glioma tumor grade. *First Author: Kareem Wahid, McGovern Medical School, Houston, TX*

Background: Radiomics derives quantitative features from medical images to reveal novel information about imaging phenotypes. Although significant research has been conducted on the application of machine learning algorithms to radiomic features for clinical prediction, much remains unknown about which models are best. Further, for models to be reproducible in the clinical setting, machine learning models should be explored using open-source tools and data. Herein, we assess the performance of various machine-learning classifier methods and dimensionality reduction techniques in predicting brain tumor grade with open-source tools and data. **Methods:** We utilized the publicly available 2017 BraTS Challenge magnetic resonance imaging dataset for lower-grade gliomas (n = 44) and glioblastomas (n = 191). Radiomic features were extracted using PyRadiomics, an open-source radiomics toolbox. A bootstrap approach was used to assess model predictive performance. **Results:** Logistic regression (area under curve [AUC] = 0.91) and factor analysis (AUC = 0.90) demonstrated the highest average performance among dimensionality reduction techniques and classifier methods, respectively. The highest overall performance was achieved by a support vector machine classifier coupled with factor analysis (AUC = 0.94). Variance analysis revealed that classifier method is the major contributor to performance variation (42%), followed by number of dimensions (15%) and dimensionality reduction technique (4%). **Conclusions:** This study demonstrated that the appropriate choice of classifier methods and dimensionality reduction techniques plays a significant role in machine learning model performance for prediction of glioma grade.

2032 Poster Session (Board #190), Sat, 1:15 PM-4:45 PM

Phase II trial of ponatinib in patients with bevacizumab-refractory glioblastoma. *First Author: Eudocia Quant Lee, Dana-Farber Cancer Institute, Boston, MA*

Background: Responses to bevacizumab in recurrent glioblastoma (GBM) are not durable. Plasma levels of basic fibroblast growth factor (bFGF) increase at the time of tumor progression. By concomitantly targeting vascular endothelial growth factor receptor (VEGFR), platelet derived growth factor receptor (PDGFR), and FGF receptor (FGFR) pathways, the multikinase inhibitor ponatinib may potentially help overcome some of the putative mechanisms of resistance and demonstrate antitumor effects. **Methods:** We performed a phase II trial of ponatinib in patients with bevacizumab-refractory GBM. Adult patients with KPS ≥ 60, measurable disease, normal organ and marrow function received ponatinib at 45 mg daily. No limit on the number of prior therapies but only one prior bevacizumab-containing regimen was allowed. Primary endpoint was 3-month progression free survival (PFS3). Based on a Simon optimal two-stage design, the trial was powered to discriminate between a 15% and 35% PFS3 rate, with an alpha error 0.10 and beta error 0.2. Plasma biomarkers of angiogenesis and inflammation were evaluated before and after treatment. **Results:** The study closed after the first stage. Fifteen patients enrolled, median age 62 [28-75], median KPS 80 [70-90], median number of prior relapses 2 [2-4]. PFS3 rate was 0, median OS was 98 days [95% CI 56, 257] and median PFS was 28 days [95% CI 27, 30]. No responses were seen, and 2 patients had SD (13%). Grade 3 adverse events possibly related to ponatinib included fatigue (n = 3), hypertension (2), lipase elevation (2), ALT elevation (1), AST elevation (1), GGT elevation (1), and lymphopenia (1). There were no grade 4 or 5 events attributable to treatment. Ponatinib treatment significantly increased plasma soluble (s)VEGFR1, sVEGFR2, sTIE2, VEGF, IFNγ, TNF-a, IL-6, IL-8, and IL-10 rapidly (at day 1) and persistently (until the end of treatment). **Conclusions:** Ponatinib was tolerated but associated with minimal activity in bevacizumab-refractory GBM patients. Circulating biomarker data indicate potent anti-VEGFR activity, and suggested that resistance to ponatinib may be related to inflammation. Clinical trial information: NCT02478164.

2033 Poster Session (Board #191), Sat, 1:15 PM-4:45 PM

Effect of therapeutic pressure on stability of EGFR amplification in glioblastoma. *First Author: Manmeet Singh Ahluwalia, Burkhardt Brain Tumor and Neuro-Oncology Center, Cleveland Clinic, Cleveland, OH*

Background: Depatuxizumab mafodotin (depatux-m, formerly ABT-414) is an EGFR-directed antibody-drug conjugate being developed for treatment of *EGFR*-amplified glioblastoma (GBM). As therapeutic pressure engenders tumor adaptations, it is important to understand the stability of biomarkers targeted by precision medicine approaches such as depatux-m. Therefore, we assessed *EGFR* amplification (amp) and expression in longitudinally-sampled GBMs from patients (pts) treated +/- depatux-m to explore biomarker stability. **Methods:** Formalin-fixed, paraffin embedded GBM tumor tissue was analyzed from 68 patients who underwent at least 2 surgeries; *EGFR* amp was detected by *in situ* hybridization (*e.g.*, FISH) or next-generation sequencing in all samples. Fifty-six pts did not receive depatux-m; among 12 pts who did, *EGFR* expression was also evaluated by RNA sequencing. **Results:** Of 56 pts who did not receive depatux-m, 31 (55%) had tumors harboring *EGFR* amp at 1st surgery (initial diagnosis); among those, *EGFR* amp was maintained at re-operation in 27 (87%), and not maintained in 4 (13%). None of the 25 cases without baseline *EGFR* amp acquired it at the 2nd surgery. Of 12 pts treated with depatux-m between surgeries, 9 cases harbored *EGFR* amp at baseline which was maintained in 4 (44%) at the 2nd surgery, all 4 of which had the highest levels of *EGFR* expression at baseline. Of the 3 cases without *EGFR* amp at baseline, none acquired amplification at the 2nd surgery, and all 3 had the lowest levels of *EGFR* expression at study start. **Conclusions:** The presence of *EGFR* amp in GBM tissue at baseline was maintained at 2nd surgery in 87% of pts who received treatment other than depatux-m, and in 44% following depatux-m exposure. Therefore, depatux-m exposure appears to reduce *EGFR* amp maintenance ($p = 0.0159$ by Fisher's exact test); accordingly, the therapeutic approach may influence EGFR status. In no case was *EGFR* amp acquired at recurrence, regardless of depatux-m therapy. Ongoing analyses of additional tumor samples will increase power and further examine concordance among *EGFR* amp assays.

2034 Poster Session (Board #192), Sat, 1:15 PM-4:45 PM

NKG2D chimeric antigen receptor-T cells to target GBM. *First Author: Hong-jiu Dai, Nanjing Kaedi Biotech Inc, Nanjing, China*

Background: GBM is the most common and the most lethal brain tumors with the 5-year survival rate of ~4% for patients over age 55. Recently people are exploring the potential of chimeric antigen receptor T (CAR-T) cell therapy in glioblastoma, yet the clinical outcome is limited. It's reported that NKG2DLs are wildly expressed in glioma stem-like cells, which supports NKG2D system might play an important role in GBM therapy. Here we used NKG2D as antigen binding domain to construct a second generation of CAR (KD-025) for GBM treatment. **Methods:** U251 cell line as well as GBM cancer patient samples were evaluated for NKG2DLs expression. The KD-025 CAR T cells showed antigen-specific stimulation by cytokine secretion and target cell lysis. U251 were used to establish in vivo subcutaneous and xenograft models in NSG mice. Mice received a single treatment of 10 million KD-025 CAR-T cells intravenously. The main organs of mice were examined by hematoxylin and eosin (HE) staining after different doses of KD-025 administration. **Results:** NKG2DLs were detected on U251 cells and most of screened glioma patient samples. The KD-025 expression was $>$ 50% on the surface of T cells confirmed by flow cytometry. Co-incubation of KD-025 CAR with U251 cell specifically upregulates TNFa, IFN-γ, IL-10 and IL-2 cytokines and strongly lysis tumor cells even at low E:T ratio (50-60% at 1:1, 70% at 10:1). Strikingly, KD-025 CAR demonstrate very potent anti-tumor activity in vivo. All the tumor cells are gone 14 days after single treatment of KD-025 CAR T cells. Regarding to T cell persistence, the CAR-T cells are barely detectable 24 days after injection, which is comparable with CD19 CAR in our experiments as well as published data. No obvious pathological changes were found in the tested organs. **Conclusions:** Our work with the KD-025 CAR contributes to the growing body of research committed to discovering a novel therapy for GBM. NKG2D ligands are highly expressed on human GBM samples. NKG2D based CAR T cells KD-025 potently respond to GBM and eliminate tumor in a xenograft mouse model with no obvious safety issue. The results support future clinical trial of KD-025 CAR in patients with GBM, where the need for effective treatment is great.

2035 Poster Session (Board #193), Sat, 1:15 PM-4:45 PM

A phase I/II clinical trial of autologous CMV-specific cytotoxic T cells (CMV-TC) for glioblastoma: Dose escalation results. *First Author: Marta Penas-Prado, The University of Texas MD Anderson Cancer Center, Department of Neuro-Oncology, Houston, TX*

Background: Cytomegalovirus (CMV) antigens are present in $>$ 90% of GBMs but not in normal brain, and can be targeted as a tumor-specific antigen. CMV-TC present in GBM tumor tissue have their effector function suppressed. Highly functional CMV pp65 specific T cells can be expanded *in vitro* from peripheral blood (PB) of GBM patients. We have established GMP-compliant conditions for *ex vivo* expansion of polyclonal CD8+ and CD4+ CMV-TC from GBM patients. **Methods:** We explored 4 dose levels of autologous CMV-TC (from 5×10^6 cells to 1×10^8 cells) with a 3+3 design. CMV-TC were given after 3 weeks of lymphodepleting dose-dense temozolomide (ddTMZ, 100 mg/m2 for 3 weeks). Treatment was repeated q 6 weeks for a total of 4 cycles. Patients ≥18 years of age with KPS ≥60, CMV seropositivity, receiving ≤ 2 mg of dexamethasone daily, and any number of relapses were eligible. Imaging response was evaluated by MRI q 6 weeks. *In vivo* persistence and expansion of adoptively-infused CMV-TC was determined by dextramer staining and multiparameter flow cytometry in serially-sampled PB. **Results:** 27 patients were screened, of whom 15 underwent leukapheresis. Twelve patients (3 at each level) completed cycle 1. Median age 51 (27-65), median KPS 90; 9 were at 1st and 3 at 2nd relapse. MGMT was methylated in 5, unmethylated in 3, indeterminate or unknown in 4. IDH status was wildtype in 7, mutated in 3, unknown in 2. Number of cycles received was 4 in 4 patients, 2 in 3, and 1 in 5. No dose limiting toxicities (DLTs) were observed at any level. Complete radiographic response was observed in 1 patient, partial response in 1 patient, stable disease in 5 patients, and progressive disease in 5. Repeated infusions of CMV-TC were associated with a significant increase in circulating CMV+ CD8+ T-cells. **Conclusions:** Adoptive infusion of CMV-TC after lymphodepleting therapy with ddTMZ was well tolerated with no DLTs or serious CMV-TC related adverse events. The final dose level is currently being enrolled. Thereafter efficacy will be evaluated in expansion cohorts in newly diagnosed and recurrent GBM. The expansion in recurrent GBM will include correlative studies in tumor tissue after administration of CMV-TC. Clinical trial information: NCT02661282.

2036 Poster Session (Board #194), Sat, 1:15 PM-4:45 PM

Phase I study of afatinib and radiotherapy (RT) with or without temozolomide (TMZ) in newly diagnosed glioblastoma (GB). *First Author: Frank Saran, The Royal Marsden NHS Foundation Trust, London, United Kingdom*

Background: GB is a malignant primary incurable CNS tumor with poor prognosis. RT + TMZ is standard treatment for newly diagnosed GB suitable for radical treatment. ErbB pathway dysregulation has a role in the pathogenesis of GB and EGFR activation contributes to RT resistance. The irreversible ErbB family blocker afatinib has a manageable safety profile and modest activity in recurrent GB. This Phase I study assessed the feasibility of first-line afatinib + RT ± TMZ in GB. **Methods:** This 3+3 dose-escalation study enrolled 36 pts with newly diagnosed GB. Treatment was stratified by *MGMT* promoter methylation status. Pts with promoter methylation received RT + TMZ + afatinib (20, 30, 40 mg/day) for 6 wks (RT period), then afatinib 40 mg/day + TMZ for up to 6 months before afatinib 40 mg/day until progression/undue AEs (maintenance period; Regimen M). As TMZ has limited benefit in pts with unmethylated *MGMT*, these pts received RT + afatinib then afatinib (Regimen U). Primary endpoint: MTD of afatinib + RT ± TMZ. Secondary endpoints: AEs, ORR, PK. **Results:** In regimen M, 20 pts (median [range] age: 52.5 [2566] yrs) were treated for median [range] 151 [62340] days (20 mg n = 7; 30 mg n = 6; 40 mg n = 7); of those evaluable for MTD, 1/6, 0/6 and 2/5 had dose-limiting toxicities (DLTs) in the RT period (2 grade [G] 4 thrombocytopenia and 1 G3 vomiting). MTD of afatinib + RT + TMZ was 30 mg/day. In regimen U, 16 pts (53.5 [3468] yrs) were treated for median [range] 168 [1397] days (20 mg n = 3; 40 mg n = 13); of those evaluable for MTD, 0/3 and 1/6 had DLTs (1 G3 diarrhea) in the RT period. MTD of afatinib + RT was 40 mg/day. Common treatment-related AEs (TRAEs) are shown in the Table. ORRs were 25% and 6% in regimens M and U, respectively. PK evaluation indicated that combination of afatinib with RT + TMZ had no influence on afatinib exposure. **Conclusions:** The MTD of afatinib + RT was 30 mg/day with TMZ and 40 mg/day without TMZ. The safety profile of afatinib + RT ± TMZ was as expected, based on the known profiles of the individual agents. *Common TRAEs* Clinical trial information: NCT00977431.

2037 Poster Session (Board #195), Sat, 1:15 PM-4:45 PM

Neurologic assessment in neuro-oncology (NANO) scale in a prospective phase II trial of anti-PD1 antibody, pembrolizumab with or without bevacizumab in patients with recurrent glioblastoma. *First Author: Lakshmi Nayak, Dana-Farber Cancer Institute, Boston, MA*

Background: The neurologic assessment in neuro-oncology (NANO) scale was developed as a standardized metric to objectively measure neurologic function in patients (pts) with brain tumors to complement radiographic assessment in defining overall outcome. The scale has been incorporated in various prospective studies to assess pts and to determine its utility. **Methods:** A multicenter, open label, phase II trial of pembrolizumab with and without bevacizumab in pts with recurrent glioblastoma (GBM) incorporated NANO scale as an exploratory endpoint. Neurologic examination by NANO was documented at baseline and each cycle until pts came off study. Statistical analyses including descriptive data analysis and generalized linear models were performed using R (version 3.4.3). **Results:** Eighty pts received treatment on study and underwent NANO evaluations. NANO compliance rate was 94%; of a total 388 expected NANO evaluations, 24 were missing. Of 80 pts, 7 missing NANO at baseline visit were excluded from analysis. Fifteen pts did not have end of treatment NANO evaluation. Of 73 pts, 35 (48%) had a normal neurologic examination at baseline by NANO. Two NANO domains (strength and language) accounted for the majority of variability in neurologic function over the course of study treatment. There was a significant correlation between NANO at each cycle and Karnofsky performance status score ($p = 0.02$). Nineteen pts were on dexamethasone at baseline; 42 required it during study. Corticosteroid requirement (OR = 1.9, $p < 0.001$) and an increase in corticosteroid dose (OR = 2.6, $p < 0.001$) were associated with higher risk of NANO progression (PD). Eighteen pts (25%) met NANO criteria for PD, including 2 without PD on MRI. Three pts (4%) had a neurologic response per NANO criteria associated with stability on MRI. **Conclusions:** Evaluation of neurologic function by NANO was feasible in a multicenter prospective study in GBM pts with a high compliance rate. NANO was able to objectively track neurologic function throughout the trial including preservation of baseline status in non-progressors. Clinical trial information: NCT02337491.

2038 Poster Session (Board #196), Sat, 1:15 PM-4:45 PM

How far have we really come? Trends in survival and mortality for gliomas between 1973 to 2014 from SEER. *First Author: Shehryar Rahim Sheikh, Cleveland Clinic Lerner College of Medicine of Case Western Reserve University, Cleveland, OH*

Background: Historical controls are often used as benchmarks for early stage, single arm trials of novel agents. We have investigated whether general or specific changes in the treatment of patients with gliomas drive meaningful changes in outcome and affect the validity of the use of historical control arms. Furthermore, we evaluated factors that impact on selection bias. **Methods:** We used data from the NCI SEER database and included 92,182 gliomas in our analysis. We identified 4 distinct epochs from 1973 to 2014 and compared survival curves between epochs using 2-year survival, median survival, and Cox-proportional hazards ratio (PHR) analysis. We also compared relative risk of mortality after diagnosis (RRM i.e. risk of death compared to age/sex matched controls) profiles between these periods. Gliomas were stratified by histological grade and age of diagnosis. **Results:** For low grade tumors, the most significant improvements occurred between the first (1973-1992) and second (1992-2000) epochs (PHR 0.4 and 0.6 for Grades I and II, $p < 0.001$), while for higher grade tumors it was in between the third (2000-2007) and fourth (2007-2014) epochs (PHR 0.8 for both Grades III and IV, $p < 0.001$) Since 2005, 2-year survival probability and median GBM survival have increased consistently (slope: 0.3 months/yr, R^2: 0.8, $p < 0.001$); no such trend was discernable in earlier data. RRM profiles for high grade gliomas demonstrate a characteristic pattern that varies with time from diagnosis. RRM rises sharply for the first 1.5 years after diagnosis, and then approaches baseline. **Conclusions:** The most meaningful improvements in survival measures coincide with the emergence of phase III evidence supporting combined treatment with temozolomide (TMZ) and radiation around 2005. Since at least 2005, there has been a trend of increasing baseline survival in GBM patients; commonly used survival estimates for historical controls may thus be inaccurate and future clinical trials should acknowledge this trend when setting expectations of the control arm. RRM varies as a function of time from glioma diagnosis which may provide a basis for selection bias; patients recruited for clinical trials should be comparable in respect to RRM.

2039 Poster Session (Board #197), Sat, 1:15 PM-4:45 PM

Comprehensive genomic profiling of brain tumors to provide targeted therapy options and diagnostic certainty for oligodendrogliomas. *First Author: Lee A. Albacker, Foundation Medicine, Cambridge, MA*

Background: Genomic profiling of gliomas is vital to ensure diagnostic accuracy, inform prognosis, and identify therapeutic options for primary and recurrent tumors. The integration of genomic biomarkers into brain tumor classification has advanced the development of molecularly stratified clinical trials and the need to characterize tumors by genomic signature. **Methods:** Comprehensive genomic profiling (CGP) was performed on FFPE material from 6304 consecutive cases of pediatric and adult brain tumors initially diagnosed by submitting institutions based on histology. We analyzed tumors via CGP in 395 cancer-associated genes (including *IDH1/2*) and for 1p/19q codeletion using a validated algorithm. **Results:** Of 6304 brain tumor samples, known *IDH* point mutations included 1182 *IDH1* R132, 50 *IDH2* R172, and 1 *IDH2* R140 variants. In the *IDH*-mutant cohort, 1p/19q codeletion was detected in 72% (260/363) of histologically defined oligodendrogliomas (ODGs), 21% (17/82) of oligoastrocytomas (OAs), 6% (22/360) of glioma (NOS, not otherwise specified), 4% (2/50) of gliosarcomas, 3% (26/859) of astrocytomas (NOS), and 1% (32/3200) of glioblastomas. ODG with 1p/19q loss were enriched for *TERT, CIC,* and *FUBP1* alterations, whereas 1p/19q intact tumors were enriched for *TP53* and *ATRX* alterations. Actionable alterations in ODG included 8% (29/363) with high tumor mutational burden (potential immunotherapy responsiveness) and 15% (56/363) with *PIK3CA* mutation. Analysis of OA (mixed glioma) revealed genomic subtypes similar to well-defined gliomas including ODGs (*IDH*-mutant, 1p/19q loss, *TERT*, *CIC*, *FUBP1*), diffuse astrocytomas (*IDH*-mutant, *TP53*, *ATRX*), and high-grade gliomas (*IDH*-wild-type, *EGFR*, *NF1*). **Conclusions:** Using co-occurring *IDH* mutation and 1p/19q codeletion as the diagnostic signature of ODG, we show that as many as 25% may be misclassified on morphologic criteria alone. OAs exhibit genomic features of defined glioma subtypes, suggesting CGP may provide diagnostic clarity in this setting. This study highlights how CGP can improve diagnostic accuracy and provide additional treatment options for patients.

2040 Poster Session (Board #198), Sat, 1:15 PM-4:45 PM

Concordance between RTOG and EORTC risk factors in low grade gliomas: Who will remain standing in the ring at bell's sound? *First Author: Enrico Franceschi, Department of Medical Oncology, Bellaria Hospital, Azienda USL - IRCCS Institute of Neurological Sciences, Bologna, Italy*

Background: Low grade gliomas (LGG) are a heterogeneous group of brain primary tumors. The EORTC and the RTOG criteria are the most valuable scores to evaluate risk factors and for treatment decision. However, there is no data about concordance between criteria. **Methods:** We conducted an analysis on LGG patients treated in our Institution from 1998 to 2015. The population was stratified by RTOG criteria and whenever feasible we assessed the risk using both RTOG and EORTC criteria. **Results:** Median follow up (mFU) was 78.6 months. We evaluated 204 patients with histologically diagnosed LGG. All the patients were stratified by RTOG criteria and a subgroup of 51 patients by both RTOG and EORTC criteria. The univariate analysis showed a statistically significant difference according to RTOG criteria (p = 0.01) for both OS and PFS. Low risk patients had a better OS compared to high risk group (211.0 vs 145.5 months, p = 0.01) and a longer PFS (60.0 vs 39.8 months, p = 0.005). The multivariate analysis confirmed that RTOG risk was an independent prognostic factor (p = 0,024). In the subgroup of 51 patients stratified by both RTOG and EORTC risk-factor criteria, the concordance was 54.9% (K = 0.113, p = 0.08). All the EORTC high risk patients (n = 25) were high risk also with RTOG criteria. Among the 26 EORTC low risk patients, only 3 (11.5%) were low risk with RTOG criteria, while 23 (88.5%) would have been deemed as high risk. In this population, after a FU or 91 months, no statistical difference regarding OS and PFS was documented applying either RTOG or EORTC criteria, probably due to the limited population. **Conclusions:** The concordance between RTOG and EORTC criteria is low, especially in the evaluation of low risk patients. So far, we cannot compare clinical trials adopting different risk criteria.

2041 Poster Session (Board #199), Sat, 1:15 PM-4:45 PM

Phase II trial of SurVaxM combined with standard therapy in patients with newly diagnosed glioblastoma. *First Author: Manmeet Singh Ahluwalia, Cleveland Clinic, Cleveland, OH*

Background: To determine 6-month progression-free survival (PFS-6), 12-month overall survival (OS-12) and immunologic response in newly diagnosed glioblastoma (nGBM) treated with concurrent temozolomide (TMZ) and radiation, followed by adjuvant TMZ and survivin-targeted immunization with SurVaxM (SVN53-67/M57-KLH). **Methods:** A single-arm, multi-center phase II trial was conducted in 63 evaluable patients with nGBM with HLA-A*02, -A*03, -A*11 and -A*24 haplotypes and Karnofsky performance status $\geq$70. Patients (Pts) underwent craniotomy with near-total resection (< 1 cm^3 residual contrast enhancement), followed by chemoradiation (Stupp) were eligible. Pts received 4 priming doses of SurVaxM (500 mcg) with Montanide and sargramostim (100 mcg) every 2 weeks, followed by adjuvant TMZ and maintenance SurVaxM every 12 weeks until progression. Immunogenicity of SurVaxM was assessed using expansion of survivin-specific CD8+ T-cells (dextramers) and survivin antibody (IgG) levels. **Results:** Interim analysis of the first 55 pts. Pts ranged in age from 20-82 yrs (median = 60), male:female = 32:23 with survivin tumor expression of 1-40% (median = 12%) by immunohistochemistry. PFS-6 was 96.3% (+2.8, -10.3)(n = 55) measured from diagnosis and 62.8% (+12.5, -16.2) (n = 43) from first immunization. OS-12 was 90.9% (+6.1, -16.5)(n = 33) from diagnosis and 70.8% (+14.1, -22.4)(n = 24) from first immunization. Median time to first immunization was 3.0 mo (1.9-4.0 mo). The regimen was generally well tolerated and immunization-related adverse events were mild with no serious adverse events attributable to SurVaxM. The drug was highly immunogenic and produced survivin-specific antibody (IgG) titers and CD8+ T-cells detectable by survivin dextramers. IDH-1, MGMT methylation status, HLA class I haplotype, survivin expression levels, and the relationship of these variables to survival will be presented. Outcomes will be compared to historical patients receiving Stupp regimen, and Stupp plus Optune. **Conclusions:** Standard therapy plus SurVaxM appears promising in nGBM compared to standard therapy alone. The use of SurVaxM is safe in nGBM. A randomized, prospective trial of SurVaxM in glioblastoma is planned. Clinical trial information: NCT02455557.

2042 Poster Session (Board #200), Sat, 1:15 PM-4:45 PM

Secondary prophylaxis with romiplostim for temozolomide-induced thrombocytopenia in newly diagnosed glioblastoma. *First Author: Emilie Le Rhun, University of Lille, U-1192, F-59000 Lille, France; Inserm, U-1192, F-59000 Lille, France; CHU Lille, General and Stereotaxic Neurosurgery service, F-59000 Lille, France; Oscar Lambret Center, Medical Oncology Department, F-59000 Lille, Lille, France*

Background: Thrombocytopenia is a major adverse event of temozolomide (TMZ) chemotherapy. It may lead to dose reduction/interruption or bleeding. Platum (NCT 02227576) was a phase II open label, multicenter single arm trial evaluating the thrombopoetin receptor agonist, romiplostim, for secondary prevention of TMZ-induced thrombocytopenia in patients with newly diagnosed glioblastoma. **Methods:** Patients diagnosed with CTCAE grade 3/4 thrombocytopenia during standard treatment of glioblastoma received weekly subcutaneous injections of romiplostim at a starting dose of 750 μg. Dose adjustments were based on weekly platelets counts. The study aimed at demonstrating that the percentage of thrombopenic patients treated with romiplostim able to complete 6 cycles of maintenance TMZ chemotherapy exceeded 10% (p0 = 0.10; pA = 0.35) (Gerber et al., 2007). Using type I error equal to 0.05 and 95% power, 31 patients had to be recruited. According to a Fleming's two step design, an interim analysis was planned after recruitment of 20 evaluable patients. Three scenarios were pre-defined: (1) $\leq$2 patients meeting the endpoint: termination for futility ($p < P0$), (2) $\geq$6 patients meeting the endpoint: termination for success ($p > P0$), (3) 3 to 5 patients meeting the endpoint: enrollment of 11 more evaluable patients. **Results:** 20 patients were enrolled in step 1 between July 2014 and December 2016. Median age was 61 (range: 33-73 years). Surgery included biopsy (n = 8), partial (n = 5), subtotal (n = 1) or gross total resection (n = 6). Isocitrate dehydrogenase 1^{R132H} mutations were noted in 2 cases. 12 patients enrolled in step 1 received the 6 planned maintenance TMZ cycles, corresponding to a success rate of 60% (95% confidence interval 36-81). Three of 8 patients discontinued TMZ because they did not respond to romiplostim, 3 for progression and 1 for clinical deterioration prior to completion of six cycles, 1 due to an adverse event. Romipostim was well tolerated. The trial was terminated early for success. **Conclusions:** Thrombopoetin receptor agonists such as romiplostin allow to assure adequate exposure to chemotherapy in glioblastoma patients experiencing early, severe chemotherapy-induced thrombocytopenia. Clinical trial information: NCT 02227576.

2043 Poster Session (Board #201), Sat, 1:15 PM-4:45 PM

Association of anticonvulsant prophylaxis in patients with primary and metastatic brain tumors and 1-year overall survival: A systematic review and meta-analysis. *First Author: Timothy J Brown, The University of Texas Southwestern Medical Center, Dallas, TX*

Background: Despite high-quality evidence suggesting anticonvulsant prophylaxis in primary and metastatic brain tumors does not improve seizure outcomes, debate persists on the use of anticonvulsants in these patients. Valproic acid use has attracted particular interest due to its histone deacetylase and CYP2C9 inhibitory action. We sought to determine if the body of the world's literature supports the use of anticonvulsant prophylaxis to improve survival in patients with primary or metastatic brain tumors. **Methods:** A systematic review of PubMed and EMBase was performed with MeSH headings to identify all studies of anticonvulsant prophylaxis in adult patients with primary or metastatic brain tumors. Data was extracted from the text of included studies or from survival curves. Statistics were performed using Cochrane ReviewManager software. Endpoints of interest were one-year overall survival. **Results:** Two-hundred seventy-six studies were reviewed. Eleven studies of 3767 patients with primary and metastatic brain tumors were included in the analysis of survival with any anticonvulsant, while ten studies of 3576 patients provided survival data with valproic acid. Compared to control, any anticonvulsant prophylaxis was associated with a relative risk (RR) of death of 0.88 [95% confidence interval 0.81-0.94, p = 0.0006]. Valproic acid compared to control was associated with RR of death at one year of 0.86 [95% CI 0.78-0.95, p = 0.003]. Eight studies of 3194 patients with glioblastoma associated a RR of death at one year of 0.86 [95%CI 0.75-0.99, p = 0.04] with any valproic acid prophylaxis compared to none. Two studies of 344 patients examined the effects of non-valproic acid anticonvulsant prophylaxis demonstrated no significant effect on the RR of death at one year, 0.90 [95%CI 0.79-1.03, p = 0.13], compared to control. **Conclusions:** In this meta-analysis of anticonvulsant prophylaxis in patients with primary and metastatic brain tumors, anticonvulsant prophylaxis was associated with a significant survival benefit at one year. This association appears to be driven primarily by valproic acid prophylaxis.

2044 Poster Session (Board #202), Sat, 1:15 PM-4:45 PM

Phase I factorial study of temozolomide plus memantine, mefloquine, and metformin as post-radiation adjuvant therapy for newly diagnosed glioblastoma. *First Author: Stefania Maraka, Neuro-Oncology Department, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Repurposing non-cancer drugs may represent a new source of novel therapies for glioblastoma (GBM). Memantine, mefloquine, and metformin have putative anticancer activity potentially relevant to gliomas. The aim of this phase I factorial study was to determine the maximum tolerated doses (MTD) of combinations of these agents with temozolomide (TMZ) for newly diagnosed GBM. **Methods:** Adults ($\geq$18 years of age) with newly diagnosed GBM who received chemoradiation with TMZ, with no progressive disease on post-treatment imaging, were eligible. The patients were sequentially enrolled to one of seven treatment arms (doublet, triplet, or quadruplet therapy with TMZ combined with mefloquine, memantine, and/or metformin). Dose-limiting toxicities (DLTs) were determined over the first 28 days of treatment, using a 3+3 study design. **Results:** Of 85 enrolled patients, 81 patients completed the MTD period. The final MTDs for doublet therapy arms (TMZ plus 1 drug) were memantine 20 mg twice a day (BID), mefloquine 250 mg 3 times/week, and metformin 850 mg BID. For triplet therapy arms, the MTDs were memantine 10 mg BID, mefloquine 250 mg 3 times/week, and metformin 850 mg BID. For quadruplet therapy, the MTDs were memantine 10 mg BID, mefloquine 250 mg 3 times/week, and metformin 500 mg BID. DLTs included dizziness related to memantine and gastrointestinal effects related to metformin. Lymphopenia was the most common adverse event (66%); fatigue was the second most common (65%). From study entry, median survival was 21 months; the 2-year survival rate was 43%. **Conclusions:** Memantine, mefloquine, and metformin can be safely combined with TMZ as treatment for newly diagnosed GBM. The MTDs determined by this study can be used for subsequent clinical trials.

2045 Poster Session (Board #203), Sat, 1:15 PM-4:45 PM

A randomized phase 2 trial of veliparib (V), radiotherapy (RT) and temozolomide (TMZ) in patients (pts) with unmethylated MGMT (uMGMT) glioblastoma (GBM): Feasibility and safety outcomes (the VERTU study). *First Author: Mustafa Khasraw, Royal North Shore Hospital/ University of Sydney, St Leonards, Australia*

Background: TMZ offers minimal benefit in uMGMT GBM pts. V is synergistic with both RT and TMZ in preclinical models, safe when combined with either RT or TMZ clinically but the triplet (V+RT+TMZ) is poorly tolerated. This study examines a novel approach to patients with uMGMT GBM. **Methods:** VERTU is a randomized Phase 2 trial comparing Arm A (experimental arm) = RT (60gy/30 fractions) + V (200mg BID) followed by TMZ (150-200mg/m^{2}D 1-5) + V (40mg bid, D 1-7) every 28 days for 6 cycles vs Arm B (Standard of care) = RT (60gy/30 fractions) + TMZ (75mg/m^2 daily) followed by TMZ (150-200mg/m^{2}D 1-5) every 28 days for 6 cycles in pts with newly diagnosed uMGMT GBM. The study aims to randomize 120 pts (2:1 to the experimental arm). The primary endpoint is 6 months Progression Free Survival (6PFS) with multiple secondary and tertiary endpoints. Evaluation of feasibility and safety was planned after completion of RT in the first 60 pts (Stage 1). Acceptable feasibility and safety criteria for study continuation was defined as ≥70% of pts on the experimental arm completing ≥70% of the planned treatment with ≤30% of pts having any ≥ Grade (G) 3 Adverse Events (AEs). (ANZCTR #ACTRN12615000407594) **Results:** 60 pts have been randomized in Stage 1 (Arm A = 39, Arm B = 21). Patient characteristics (age, gender, performance status, and extent of resection) were well matched. All 39 pts in the experimental arm completed at least 80% of the planned V treatment, receiving at least 70% of the full V dose and 80% of the planned RT dose. Eleven pts (28%) in the experimental arm experienced ≥ G3 AEs during concurrent treatment. The commonest severe AEs were seizures observed in 3pt in each arm, 7% in the experimental arm and 15% in the standard treatment arm followed by thrombocytopenia seen in 2 pts in each arm, 5% in the experimental arm and 10% in the standard arm. **Conclusions:** Stage 1 of VERTU satisfied the predefined feasibility and safety criteria and the study will continue until the accrual target (120pts) is reached (anticipated mid-2018). Efficacy endpoints will be analyzed and reported after completion of accrual. Clinical trial information: 12615000407594.

2046 Poster Session (Board #204), Sat, 1:15 PM-4:45 PM

Hypofractionnated stereotactic radiotherapy and anti-PDL1 durvalumab combination in recurrent glioblastoma: Results of the phase I part of the phase I/II STERIMGLI trial. *First Author: Damien Pouessel, Saint Louis Hospital, Paris, France*

Background: Glioblastoma (GBM) is the most aggressive primary brain tumor with inevitable local relapse and no standard treatment. Hypofractionated stereotactic radiotherapy (hFSRT) has shown signs of efficacy with tolerable safety with PFS ranging from 3.4 to 5 months, but needs improvement. Radiotherapy (RT) causes immunogenic tumor cell death but also induces PDL1 and PD1 expression on tumors and immune cells, potentially evoking resistance to RT. Pre-clinical studies combining hFSRT with an anti-PD-1 antibody in GBM have shown increased efficacy of the combination. Clinical studies also show encouraging results when checkpoint inhibitors have been combined with high dose RT. We hypothesized that combining the anti PD-L1 Durvalumab (Durva) with hFSRT will be an effective regimen for patients with recurrent GBM. We designed a phase I and a phase II clinical trials studying the combination of hFSRT with Durva for recurrent GBM≤35 mm diameter. Results of the phase I are presented. **Methods:** A standard 3+3 dose escalation design was used. Patients were treated by hFSRT 24 Gy, 8 Gy/fraction at 80% isodose, every other day, combined with Durva infusion 1500mg first dose (Level 1) or 750 mg (Level -1) delivered on the last hFSRT, day followed by 1500 mg Durva infusion every four weeks until relapse and for a maximum of 12 months. The schema was defined as safe if one patient or less among 6 presents a dose limiting toxicity (DLT). DLT period started on the first Durva infusion with radiotherapy until 4 weeks. Brain MRI were performed before RT and then every 8 weeks until relapse. **Results:** Among the 6 patients (3 methylated MGMT, 3 unmethylated MGMT) included at the level 1, all completed the hFSRT course, only one had a DLT which was an immune related grade 3 vestibular neuritis. No DLT related to hFSRT or the Durva combination was reported. No other serious adverse event (SAE), immune-related AE or AE of special interest was reported. **Conclusions:** Combining three 8 Gy fractions of hFSRT with 1500 mg Durvalumab on the 3rd fraction hFSRT and every 4 weeks for recurrent GBM is well tolerated justifying exploration of its efficacy in the phase II component of the study. Clinical trial information: NCT02866747.

2047 Poster Session (Board #205), Sat, 1:15 PM-4:45 PM

Updated results of REGOMA: A randomized, multicenter, controlled open-label phase II clinical trial evaluating regorafenib in relapsed glioblastoma (GBM) patients (PTS). *First Author: Giuseppe Lombardi, Department of Clinical and Experimental Oncology, Medical Oncology 1, Veneto Institute of Oncology, IOV-IRCCS, Padua, Italy*

Background: There is no established treatment regimen for recurrent GBM. GBMs have activation of multiple signaling pathways in the tumor microenvironment, including the receptor tyrosine kinases, VEGFR, FGFR, and PDGFR. REG, an oral multikinase inhibitor, inhibits these angiogenic kinases and the mutant oncogenic kinases KIT, RET, and B-RAF. **Methods:** We present, after the first analysis, the updated results of REGOMA trial. The primary aim of this trial was to assess REG activity in prolonging overall survival (OS) in PTS with relapsed GBM after surgery and Stupp regimen (α = 0.2, 1-sided; β = 0.2). Secondary objectives were PFS, disease control rate (DCR), safety, quality of life (QoL); exploratory objectives included analysis of metabolic tissue biomarkers as possible predictors of response. PTS with histologically confirmed GBM, ECOG PS 0-1, documented disease progression were randomized 1:1 to receive REG 160 mg/day (3 weeks on, 1 week off) or lomustine (LOM) 110 mg/m2 (every 6 weeks) until disease progression or unacceptable toxicity. Tumor response was evaluated by brain MRI every 8 weeks according to the RANO criteria. **Results:** 119 PTS were randomized (n = 59 REG; n = 60 LOM) and stratified for surgery at recurrence; baseline characteristics, including MGMT methylation status, were balanced. Median age was 57.3 yrs; 27 PTS (22.7%) had surgery at recurrence, 22% and 23.3% in REG and LOM arm. At the time of analysis (cut-off date: Dec 31, 2017), median follow up was 15.4 months(m), 99 PTS had died. Median OS was 7.4m (95% CI 5.8-12.0) for REG and 5.6m (95% CI 4.7-7.3) for LOM (HR = 0.50, 80%CI 0.38-0.65; p = 0.0007; 1-sided Log-rank test); 12m-OS rates were 38.9% and 15.0% for REG and LOM. 6m-PFS rates were 16.9% and 8.3% (HR = 0.65; 95% CI 0.45-0.95; p = 0.0223) for REG and LOM , DCR was 44.8% and 21.1% (p = 0.009) for REG and LOM. Grade ≥3 adverse events were reported in 56% and 40% for REG and LOM, no treatment-related deaths were reported. **Conclusions:** In this multicenter, randomized study, REG significantly improved OS, PFS and DCR in recurrent GBM PTS. REG treatment was feasible and well tolerated. QoL and biomarker analyses are ongoing. A phase 3 study will be planned. Clinical trial information: NCT02926222.

2048 Poster Session (Board #206), Sat, 1:15 PM-4:45 PM

Plasma cell-free DNA (cfDNA) concentration and radiographic tumor burden in patents with glioblastoma (GBM). *First Author: Stephen Joseph Bagley, Division of Hematology/Oncology, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA*

Background: Distinguishing between radiographic pseudoprogression and true tumor progression is a significant challenge in patients with GBM. A non-invasive means of assessing GBM disease activity is needed. Recent data has suggested that plasma cfDNA concentration may serve as a viable surrogate for tumor burden and disease activity in other solid tumors. We performed a pilot study to determine the feasibility of using plasma cfDNA concentration as a surrogate of radiographic tumor burden in patients with GBM. **Methods:** We collected blood in Streck cfDNA tubes from patients with radiographically suspected high grade glioma prior to planned surgical resection. Plasma was isolated using a 3 step centrifugation protocol. cfDNA was extracted from using a QIAamp Circulating Nucleic Acid Kit. cfDNA was stored at -20 degrees C and quantified the following day using an Invitrogen Qubit dsDNA kit. Tumor burden was defined as the sum of products of diameters (SPD) of the target enhancing lesions plus the SPD of the T2 FLAIR signal abnormality on preoperative magnetic resonance imaging (MRI). Correlation between cfDNA concentration and tumor burden was assessed using Spearman's correlation coefficient. **Results:** 10 preoperative patients were enrolled. Following surgery, 9 patients were diagnosed with GBM and 1 with diffuse midline glioma, H3K27M mutant. The median cfDNA concentration was 12.4 ng/mL (IQR 5.5-19.7, range 4.3 - 34.5). Median SPD of target enhancing lesions was 15.7 cm^2 (IQR 10.8-24, range 1.2 – 29.8), and median SPD of T2 FLAIR lesions was 35.7 cm^2 (IQR 21.6-43.5, range 12.7 – 81.8). There was a significant correlation between cfDNA concentration and the sum of the SPDs of the target enhancing lesions and T2 FLAIR lesions (Spearman's rho = 0.70, p = 0.025). **Conclusions:** In this small pilot study, we demonstrated a correlation between the preoperative plasma cfDNA concentration and radiographic tumor burden by MRI in patients with newly diagnosed high grade glioma. This preliminary finding suggests that cfDNA yield may serve as a viable surrogate for tumor burden in patients with GBM. A larger, longitudinal study of cfDNA quantification and its relationship to GBM disease status is ongoing at our institution.

2049 Poster Session (Board #207), Sat, 1:15 PM-4:45 PM

Preoperative and non-invasive prediction of chromosome arm 1p/19q codeletion in oligodendroglial tumors using MRI-based radiomics. *First Author: Jingwei Wei, Chinese Academy of Sciences, Beijing, China*

Background: Oligodendroglial tumor (OT) is a main subtype of gliomas, carrying poor prognosis. Fortunately, part of OT patients with chromosome 1p/19q codeletion show favorable response to chemo/radiotherapy and improved survival. Preoperative knowledge of 1p/19q codeletion could beyond doubt provide seasonable evidence for personalized treatment decision making. However, the 1p/19q co-deletion genotype is currently examined via invasive biopsy-based methods, which are highly risky causing neurologic deficit. Thus, it arouses an urgent need to develop a non-invasive approach for early prediction of 1p/19q codeletion. Hence, we used a new technique termed radiomics to perform the prediction on 1p/19q status using magnetic resonance imaging in this study. **Methods:** A cohort of 262 OT patients was collected from Beijing Tiantan Hospital and divided into training (n = 175) and validation (n = 87) datasets. We extracted 647 three-dimensional imaging features on T2-weithed images to describe the archetypal cancer phenotypes. Qualified features were selected by reproducibility and stability analysis. Random forest algorithm was finally adopted to perform the classification between 1p/19q codeletion and non-codeletion groups. Moreover, comparisons were explored between relevant clinical predictors and the proposed radiomics model. **Results:** The radiomics model demonstrated satisfactory performance on both the training and validation cohorts with areas under curve (AUCs) of 0.889 and 0.743, respectively. Among the top three most significant features, there were two first-order intensity features (Coif1_fos_kurtosis, ori_fos_skewness), and one textural feature (ori_glcm_cluster_shade). The radiomics model outperformed the clinical factor: heterogeneous intensity, the AUCs of which were 0.580 and 0.616. When combining the radiomics features and the clinical factor together, it turned out to be the best predictive result with AUCs of 0.891 and 0.739. **Conclusions:** Our study highlights that radiomics model can effectively identify the 1p/19q codeletion in OTs by a non-invasive manner, thereby offering preoperative evidence for the treatment regime planning.

2050 Poster Session (Board #208), Sat, 1:15 PM-4:45 PM

IDH-wild type low grade gliomas: An AINO (Italian Association of Neuro-Oncology) retrospective study. *First Author: Roberta Ruda, Department of Neuro-Oncology, University of Turin and City of Health and Science, Turin, Italy*

Background: Information regarding clinical characteristics and response to treatments of IDH-wild type grade II gliomas are still lacking. This national retrospective study aimed to investigate natural history, management, factors affecting response to treatments and outcome of a cohort of WHO grade II IDH-wild type glioma patients. **Methods:** We collected all clinical data of patients diagnosed with WHO grade II IDH-wild type glioma from 1999 to 2017 in six major Italian Institutions. IDH mutation was assessed by either immunohistochemistry or sequencing (in cases with negative immunohistochemistry). Exclusion criteria were the presence of minimal anaplastic foci or radiological features of HGGs. Kaplan-Meier curves and Cox-regression models were used for univariate and multivariate analysis. **Results:** Overall, 194 patients were collected and ultimately 122 met the inclusion criteria. Median age was 45 years. Non-enhancing tumors on MRI accounted for 74% while 26% had minimal/mild contrast enhancement. Surgery consisted in gross total resection in 29%, partial/subtotal in 45%, biopsy in 24%, and unknown in 2%. According to WHO 2007 astrocytomas were 44%, oligodendrogliomas 35%, and mixed gliomas 21%. MGMT methylation was available in 68% of patients and in 40% of them was methylated. Post-surgical management consisted in watch and wait in 42%, chemoradiation in 21%, chemotherapy alone in 21%, radiotherapy alone in 5%, radiotherapy followed by chemotherapy in 5%, and 6% unknown. Median time of follow-up was 31 months. Progressive disease was observed in 64% of patients. Median PFS was 24.0 months (1.2 – 147.0), and median OS was 45.3 months (1.0 – 225.6). Factors positively associated with PFS and OS in univariate analysis were younger age, absence of contrast enhancement, and gross total resection. Age and extent of surgery retained a statistically significant importance in multivariate analysis. **Conclusions:** WHO grade II IDH-wild type gliomas have worse outcome compared with IDH-mutant tumors. This is the first study that details clinical and radiological presentation of this rare subgroup of tumors and suggests that gross total resection is critical in improving survival.

2051 Poster Session (Board #209), Sat, 1:15 PM-4:45 PM

Non-invasive determination of the O^6-methylguanine-DNA-methyltransferase (*MGMT*) promoter methylation status in glioblastoma (GBM) using magnetic resonance imaging (MRI). *First Author: Saima Rathore, Center for Biomedical Image Computing and Analytics, Department of Radiology, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA*

Background: *MGMT* promoter methylation is associated with better prognosis and increased benefit from temozolomide in patients with GBM. The methylation status of the *MGMT* promoter is typically determined by tissue-based polymerase chain reaction assays, which can be limited by inadequate specimen or assay failures. We hypothesized that multivariate analysis of quantitative imaging (QI) features, extracted from multi-parametric MRI (mpMRI), could enable the non-invasive determination of *MGMT* promoter methylation status. **Methods:** We performed a retrospective cohort study of 111 GBM patients at the University of Pennsylvania whose tumors underwent *MGMT* methylation testing (pyrosequencing across 4 CpG sites in the *MGMT* promoter) and for whom pre-operative structural mpMRI data (T1, T1-Gd, T2, and T2 FLAIR) were available. For each enhancing and non-enhancing tumor sub-region and its peritumoral edema/invasion, we extracted a diverse set of QI features comprising volumetric, morphologic, and texture characteristics, histogram-based signal profiling, and spatial distribution patterns. These features were multivariately integrated via a support vector machine to construct a non-invasive marker of *MGMT* promoter methylation that was quantitatively evaluated using a 10-fold cross-validation (CV). **Results:** 40 patients (36%) were positive for *MGMT* promoter methylation and 71 (64%) were negative. The accuracy of the non-invasive *MGMT* methylation marker was 88.28% [Specificity = 97.0%, Sensitivity = 75.0%, Area under the curve (AUC) = 0.80]. The most predictive features were consistently selected across the 10-fold CV. **Conclusions:** Multivariate integrative analysis of QI features extracted from mpMRI yields an accurate, non-invasive marker of *MGMT* promoter methylation status in GBM. If validated in larger datasets, this marker may allow for early stratification of newly diagnosed GBM trial candidates by *MGMT* methylation status, non-invasive *MGMT* methylation testing in patients for whom tissue is inadequate, and potential monitoring of *MGMT* methylation status during treatment.

2052 Poster Session (Board #210), Sat, 1:15 PM-4:45 PM

Improved prognostic accuracy of alternative MGMT methylation status cutpoint: A single institution experience. *First Author: Jacob Easaw, Cross Cancer Institute, Edmonton, AB, Canada*

Background: We evaluated the clinical relevance of the current cutpoint used to define methylation status in patients (pts) with glioblastoma (GB) in comparison to a proposed alternative cutpoint (PAC) that was derived based on clinical outcomes of pts from Calgary, AB, Canada. **Methods:** We identified and reviewed all pts diagnosed with GB treated in our institution between2015 and 2016. We analyzed prognostic value, sensitivity and specificity of the current cutpoint (9%) and PAC (12.2%) for MGMT promoter methylation status. **Results:** We included 153 pts with a median age of 61.7 years (range; 29 – 86); 53% male. Maximal safe tumor resection was subtotal in 61 (39.0%) and gross-total in 75 (49%) of pts. A biopsy was performed in 17 cases (11.1%). Thirteen pts (8.5%) did not receive any postoperative treatment, 105 (68.8%) of pts received standard concurrent temozolomide (TMZ) with radiotherapy (RT) followed by monthly TMZ; and the rest received mostly RT alone +/- sequential TMZ. MGMT methylation status, extent of resection, age and KPS ($<$ vs $\geq$ 70) were included in multivariate analysis and only MGMT status and age were independently associated with median overall survival ($p < 0.001$ and $p < 0.003$, respectively) using either cutpoints. However, there was an improvement in accuracy using the PAC. **Conclusions:** In this cohort we found an alternative cutpoint with improved correlation with overall survival in patients with newly diagnosed GB. This finding warrant further evaluation as deeming a tumor as unmethylated implies not only a worse prognosis but may impact therapeutic options; i.e. clinical trial participation.

	Current MGMT cutpoint (9%)	Proposed alternative cutpoint (12.2 %)
Sensitivity	59	60
Specificity	63.2	67.6
Positive Predictive Value	35.4	38.2
Negative Predictive Value	81.8	83.5
Accuracy	62.1	65.7

2053 Poster Session (Board #211), Sat, 1:15 PM-4:45 PM

NRG BN002: Phase I study of checkpoint inhibitors anti-CTLA-4, anti-PD-1, the combination in patients with newly diagnosed glioblastoma. *First Author: Andrew E. Sloan, University Hospital Case Medical Center, Cleveland, OH*

Background: Glioblastoma (GBM) remains an incurable disease that is associated with impaired immunity. Recently, immune checkpoint inhibitors (ICIs) have demonstrated efficacy in several solid tumors including brain metastases. This study evaluated the safety of anti-CTLA-4 (Ipilimumab; IPI) and anti-PD-1 (Nivolumab; NIVO) ICIs alone or in combination in newly diagnosed GBM during adjuvant temozolomide (TMZ) treatment. **Methods:** This is a phase I study of IPI (3mg/kg), NIVO (3mg/kg), and the combination (1 mg/kg & 3 mg/kg respectively) followed by an expansion cohort for the combined treatment of adults with confirmed unifocal, supratentorial newly diagnosed GBM after gross or near total resection. Treatment with ICIs started after standard chemo-radiotherapy along with adjuvant TMZ; starting dosing of ICIs were at target with dose reduction planned for toxicity. The primary endpoint was the dose limiting toxicity (DLT) from the start of ICIs to 8 weeks after in each arm. A standard up-and-down design was used, with 6 evaluable patients enrolled at a given dose level. The dose level would be declared safe if no more than 1 of 6 had an DLT. **Results:** Thirty-two patients were enrolled at 9 institutions, 6 to each arm and 14 to the expansion cohort. One patient was not treated, yielding 31 analyzable. Median age was 54 years (range: 23-74), 68% were male and 84% were white. Overall, treatment was well tolerated with a 16% rate of Grade 4 events; the combination did not have an increased toxicity rate and there was no reported Grade 5 event. One DLT was seen in each single-agent arm; none in the combination arm. Median follow-up time was 7.1 months (range: 0.5-21.3) for all analyzable patients, at which time 10 had progressed (32%) and 8 had died (26%), 7 due to disease progression and 1 due to pulmonary embolism. For the 18 patients who had at least 1-year follow-up, 6 on each arm, 3 died within 1 year, 1 on each arm. **Conclusions:** IPI and NIVO are safe and tolerable with similar toxicity profiles noted with other cancers when given with adjuavant TMZ for newly diagnosed GBM. These results provide necessary safety data justifying the performance of a subsequent trial to test the efficacy of ICIs in this disease. Clinical trial information: NCT02311920.

2054 Poster Session (Board #212), Sat, 1:15 PM-4:45 PM

GEINO 1402: A phase Ib dose-escalation study followed by an extension phase to evaluate safety and efficacy of crizotonib in combination with temozolomide (TMZ) and radiotherapy (RT) in patients with newly diagnosed glioblastoma (GB): Results of the dose-escalation phase. *First Author: Maria Martinez Garcia, Hospital del Mar, Barcelona, Spain*

Background: Crizotinib is an ALK, ROS-1 and c-MET inhibitor with an interesting rationale to be tested in NDGB due to the role of MET signaling in gliomagenesis and stem cell maintenance and capability of midkine, a recently discovered ALK ligand, to promote resistance of glioma cells to anticancer therapies such as RT and TMZ. Primary objective of this trial was to determine maximum tolerated dose (MTD) and recommended phase 2 dose (RP2D) of crizotinib in combination with RT and TMZ. **Methods:** Eligible patients received crizotinib with standard RT and TMZ and afterwards continued crizotinib daily with sequential adjuvant TMZ. Additional treatment with crizotinib beyond 6 TMZ cycles was allowed at the discretion of physician. Crizotinib MTD was determined using a standard "3+3" dose escalation design. Dose-limiting toxicities were observed during the first 12 weeks of therapy. **Results:** 12 patients (median age: 53,5 (33-60 y)) were enrolled in 3 crizotinib cohorts (200 mg/QD, 250 mg/QD and 200 mg/BID). Most common related adverse events (all grades) were: nausea (66.7%), asthenia (58.3%), transaminitis (50%), neutropenia (50%), constipation (41.7%) and diarrhea (41.7%). Thirteen drug-related AEs $\geq$ G3 were reported, 5 neutropenia, 2 thrombopenia, 2 transaminitis, 1 asthenia, 1 lymphopenia, 1 constipation and 1 hypophosphatemia. 3 DLTs were observed (transaminitis G3, neutropenia G4 and constipation G3): 0/3 in cohort 1 (200 mg/QD); 1/6 in cohort 2 (250 mg/QD) and 2/3 in cohort 3 (200 mg/BID). Median follow-up of 18.3 m (months) (5.4-34.5) and 8 events, median PFS was 16.8 m (95% IC: 8,2-25,3). Three patients died and median OS has not been reached. OS at 6m was 92%, at 12m 80% and 60% at 24m. **Conclusions:** On the basis of observed DLTs, the safety profile and MTDs, a dose regimen of crizotinib 250 mg/QD in association to standard RT and TMZ has been selected for further investigation in the expansion phase. At this point, efficacy results, especially PFS, seem very encouraging. Funding for this study was provided by Pfizer, Inc, New York, USA Clinical trial information: NCT02270034.

2055 Poster Session (Board #213), Sat, 1:15 PM-4:45 PM

Correlation of immune infiltration of cytotoxic T cells and activated microglia in glioblastoma (GBM) post anti-PD1 therapy with response. *First Author: Andrew Silverman, Columbia University Medical Center, New York, NY*

Background: Glioblastoma (GBM) is an aggressive malignancy of the central nervous system with an abysmal prognosis. Recent advances in immunotherapy, including anti-programmed cell death-1 (anti-PD1), has shown potential to improve outcomes for some GBM patients. In this study, we evaluate the immune cell densities in post-treatment biopsies from patients treated with anti-PD1 for refractory GBM. We hypothesized that density of both cytotoxic T lymphocytes (CTLs) and activated microglia is higher within the tumor mircro-environment (TME) in patients who respond to anti-PD1. **Methods:** Formalin-Fixed, Paraffin-Embedded (FFPE) tumor samples from a preliminary cohort of five patients with GBM, 2 non-responders and 3 responders, were stained using quantitative multiplex Immunofluorescence (qmIF). Response was classified as decrease in tumor volume by $>$ 50% and/or survival for 6 months without growth of tumor by $>$ 25%. Stains were sequentially applied, using Opal multiplexing/qmIF for CD3 (T cells), CD8 (cytotoxic T lymphocytes (CTLs)), FOXP3 (regulatory T cells – Tregs), CD68 (microglia), HLA-DR (immune activation/tumor presentation), and SOX2 (tumor marker). Multispectral images (MSIs) were acquired using Vectra and analyzed using inForm software and R studio to evaluate density of immune phenotypes within the TME. **Results:** We find that post-treatment, the patents who responded to anti-PD1 have a significantly increased CTL/total cell density ($p = 0.0393$) and higher activated microglia CD68+HLA-DR+/total CD68 density ($p = 0.0208$), when compared to non-responders. Tregs were rarely seen in either subset of patients and had no significant correlation with response. **Conclusions:** Preliminary analysis demonstrates higher CTLs and activated microglia in the TME after treatment in patients with GBM who responded to anti-PD1 therapy. Analysis of a larger cohort of 17 patients with specimens at baseline, recurrence and post anti-PD1 is underway and will be presented at the meeting. This data would confirm that anti-PD1 can induce increased inflammation within the TME in GBM despite the blood brain barrier and suggest that further alteration of the immune TME may improve outcomes in GBM.

2056 Poster Session (Board #214), Sat, 1:15 PM-4:45 PM

Preliminary report of a multicenter, phase 2 study of bevacizumab in children and adults with neurofibromatosis 2 and progressive vestibular schwannomas: An NF Clinical Trials Consortium study. *First Author: Scott Randall Plotkin, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Profound hearing loss is common in patients with neurofibromatosis 2 (NF2) and vestibular schwannomas (VS). Bevacizumab treatment at 7.5 mg/kg every 3 weeks has been associated with hearing improvement and tumor shrinkage in 36% and 43% of patients, respectively. However, the optimal treatment dose and schedule are unknown. **Methods:** This multicenter, phase II, open-label study evaluated subjects ($\geq$6 years old) with NF2 and progressive VS. Subjects received bevacizumab 10 mg/kg every 2 weeks during induction therapy (6 months), and 5 mg/kg every 3 weeks during maintenance therapy (18 months). Hearing response was defined as a significant increase in word recognition score above baseline. Radiographic response was defined as $\geq$20% decrease in tumor volume from baseline. The primary endpoint was hearing response rate in the target ear at 6 months. **Results:** We enrolled 22 subjects (median age = 23 years). The overall hearing and radiographic response rates were 41% (9/22) and 23% (5/22), respectively. In an unplanned post-hoc analysis, the hearing and radiographic response rates were 14% (1/7) and 0% in pediatric subjects $\leq$21 years, as compared with 53% (8/15) and 33% (5/15) in adult subjects. Bevacizumab was well tolerated. Adverse events included hypertension, proteinuria, arthralgias, AST/bilirubin elevation, delayed wound healing, fatigue, and irregular menstruation. 11/13 women with elevated FSH underwent evaluation for premature ovarian insufficiency. All continued treatment with bevacizumab. **Conclusions:** Bevacizumab treatment at 10 mg/kg every 2 weeks is associated with hearing and radiographic response rates comparable to previous studies using lower doses. Pediatric subjects appear to benefit less than adults during bevacizumab treatment. Clinical trial information: NCT01767792.

2057 Poster Session (Board #215), Sat, 1:15 PM-4:45 PM

Prospective analysis of cancer stem cell drug response assay for glioblastoma patients. *First Author: Tulika Ranjan, Duke University Medical Center, Durham, NC*

Background: Over the past 20 years even with the aggressive standard of care (SoC) Stupp treatment protocol the prognosis of glioblastoma (GBM) has only minimally improved from 12 to 14 months. This is due in large part to the presence of chemo- and radiation-resistant GBM cancer stem cells (CSCs) that contribute to tumor propagation, maintenance, and treatment resistance. We are using ChemoID, a CLIA certified and CAP accredited drug response assay that identifies the most effective chemotherapy against CSCs and bulk of tumor cells from of a panel of potential treatments, offering great promise for individualized cancer management. A prospective study was conducted evaluating the use of the ChemoID drug response assay in glioblastoma patients. **Methods:** Fresh tissue samples were collected for drug sensitivity testing from 61 glioblastoma patients enrolled in IRB approved protocol. Patients were prospectively monitored for tumor response, time to recurrence, progression-free survival (PFS), and overall survival (OS). Odds Ratio (OR) associations of 12-month recurrence, PFS, and OS outcomes were estimated for CSCs, bulk tumor and combined assay responses to treatment; sensitivities/specificities, areas under the curve (AUC) were examined. **Results:** The data suggests that ChemoID guided treatment significantly enhanced tumor response. For every 5% increase in ex-vivo cell kill of CSCs by assay-guided chemotherapy, 12-month patient response (non-recurrence $_{of}$ cancer) increased 2-fold, OR = 2.2 (p = 0.01). Bulk of tumor assay was found not statistically significant. Median recurrence time was 20 months for patients with a positive ($>$ 40% cell kill) CSCs test versus only 3 months with a negative CSCs test, whereas median recurrence time was 13 months versus 4 months for patients with a positive ($>$ 55% cell kill) bulk test versus negative. Similar favorable results for the CSC test were observed for PFS and OS outcomes. **Conclusions:** The ChemoID CSCs drug response assay has the potential to increase the accuracy of bulk tumor assays to help guide individualized chemotherapy choices. Glioblastoma cancer recurrence may occur quickly if the CSC test has a low ex-vivo cell kill rate, even if the bulk tumor test cell kill rate is high.

2058 Poster Session (Board #216), Sat, 1:15 PM-4:45 PM

Phase 2 trial of SL-701 in relapsed/refractory (r/r) glioblastoma (GBM): Correlation of immune response with longer-term survival. *First Author: David M. Peereboom, Cleveland Clinic, Cleveland, OH*

Background: SL-701 is a novel immunotherapy comprised of synthetic peptides designed to elicit an anti-tumor immune response against GBM targets: interleukin-13 receptor alpha-2, EphrinA2 and Survivin. Updated Phase 2 data are reported. **Methods:** Patients with r/r GBM HLA-A2+, bevacizumab (bev)-naive and KPS $>$ 60, enrolled. Stage 1: SL-701 with adjuvants GM-CSF and imiquimod dosed biweekly for 6 months, then q28 days. Stage 2: SL-701 with adjuvant poly-ICLC dosed biweekly with bev (10 mg/kg) for 6 months, then q28 days. Primary objectives: safety, tolerability, investigator assessed objective response rate (ORR, RANO criteria) and 12-month OS rate (OS-12). SL-701-specific CD8+ T-cell frequency was assessed by flow cytometry. PBMCs were isolated by density gradient and stimulated for 4h with SL-701 peptides (1mg/ml/peptide) before intracellular staining with live/dead, CD3, CD4, CD8, IFNγ, TNFα, IL-2, and PD-1. **Results:** As of 2/7/18, 74 bev-naive patients received median of 8.5 SL-701 doses. Most frequent treatment-related adverse events (TRAEs) were fatigue (22%) and injection site reaction (18%). Grade 3 TRAE was fatigue (3%); no other grade 3 TRAEs. In Stage 1, 1 partial response (PR) (duration: 78 wks) and 15 stable disease (SD) (median 16 wks; range: 1.3–99) seen in 46 patients. In Stage 2, 2 complete responses (CR) (duration: 30, 46 wks), 4 PRs (median 31 wks; range 12–47) and 19 SDs (median 14 wks; range 0.1-41) seen in 28 patients. OS-12: 43% (median 11.7 mos) in Stage 2 and 37% (median 11 mos) in Stage 1. 5 patients receive SL-701 on compassionate use basis. Preliminary flow cytometry analysis of subset of Stage 2 patients: 5/6 responders (CR, PR or SD of $\geq$6 mos) had SL-701-specific T cell responses, with 1 CR patient at wk 16 generating $>$ 6% SL-701-specific CD8+ T cells by wk 58. **Conclusions:** SL-701 with immunostimulants, alone and in combination with bev, was well-tolerated and demonstrated anti-tumor activity including multiple major responses. There is also a preliminarily promising survival tail in r/r GBM patients who received SL-701 with bev Further analyses ongoing; updated data to be presented. Clinical trial information: NCT02078648.

2059 Poster Session (Board #217), Sat, 1:15 PM-4:45 PM

Integrated clinical experience with ONC201 in H3 K27M glioma. *First Author: Andrew S. Chi, Massachusetts General Hospital Cancer Center and Harvard Medical School, Boston, MA*

Background: ONC201 is a DRD2 antagonist in Phase II trials for cancers that exhibit dysregulation of the dopamine pathway. We previously reported an objective response in the first recurrent H3 K27M midline glioma patient who received ONC201 and that H3 K27M gliomas exhibit enhanced sensitivity to the compound *in vitro*. Here, we report the clinical experience with ONC201 to date in adult and pediatric H3 K27M glioma. **Methods:** As of February 1, 2018, 14 patients with H3 K27M glioma have received single agent ONC201 and had at least one post-treatment MRI. This includes 9 adult patients (8 glioblastoma, 1 diffuse midline glioma) and 5 pediatric patients (3 DIPG, 2 other diffuse midline gliomas). All patients had recurrent disease, except for 2 DIPG patients who had completed radiotherapy. Seven patients were enrolled on a clinical trial and seven were enrolled on compassionate use protocols. ONC201 was orally administered at 625 mg to adult patients and scaled based on body weight for pediatric patients. All but one patient were dosed once a week. **Results:** Six out of the 14 patients remain on therapy with a median follow up of 5.4 months (range: 2.9-22.6) with durable radiographic and/or clinical stability or improvement. This includes the first responder who has now been on treatment for 22 months with a 96% overall regression. All 6 patients who experienced benefit had 1-2 prior lines of therapy, whereas 5 patients who had at least 3 prior lines of therapy did not experience benefit. Among the five patients with thalamic glioma, two experienced complete regressions of their thalamic lesions while another underwent a 30% regression. One patient with previously-irradiated DIPG that exhibited a 300nM IC50 ex vivo has experienced improvements in hemiparesis and other disease-related symptoms. Another previously-irradiated DIPG patient has experienced improvements in her facial palsy and other disease-related symptoms, along with a 40% regression. **Conclusions:** Preliminary clinical data indicates ONC201 induces durable radiographic regressions and clinical benefit in a subset of patients with H3 K27M glioma. The clinical activity of ONC201 in pediatric and adult H3 K27M gliomas is being evaluated in ongoing clinical trials. Clinical trial information: NCT03295396, NCT02525692, NCT03416530.

2060 Poster Session (Board #218), Sat, 1:15 PM-4:45 PM

Community socioeconomic status to identify higher-risk patients with malignant glioma. *First Author: Aaron Stephen Bower, Wake Forest School of Medicine, Winston-Salem, NC*

Background: Patients living in rural areas face barriers to accessing optimal, guideline driven care including proximity to tertiary centers and lower socioeconomic status. We sought to examine the impact of geographic and economic variables on clinical outcomes in a cohort of primary malignant glioma patients. **Methods:** A retrospective cohort study of patients newly diagnosed with WHO grade 3-4 glioma between 1999 – 2017 was performed. Relevant clinical and demographic data including marital status, employment, insurance, race, ethnicity, primary physician, and treatment factors were collected. Median household income was obtained from the US Census Bureau, linked to each patient by home zip code, and used to estimate patients residing in advantaged (above median state income, MSI) and disadvantaged (below MSI) communities. Median overall survival (OS) was assessed by Kaplan-Meier method. **Results:** Of the 310 patients identified, 27% resided in high MSI communities (n = 85). Age, sex, WHO grade, radiation and chemotherapy received did not differ by MSI status (all p $>$ 0.19). Patients from high MSI communities were more likely to have undergone any resection compared to biopsy (80% vs 68%, p = 0.04). Median OS was 3.1 months longer for patients from high MSI (22.1 months vs 19.0, Hazard Ratio [HR] 0.81, 95% CI 0.61-1.09, p = 0.16). This survival difference was observed for grade 4 (HR 0.75, 0.54-1.04, p = 0.09) and not grade 3 gliomas (HR 0.97, 0.52-0.82, p = 0.92). When stratified by MSI status, men from high MSI communities showed a trend towards survival advantage (HR 0.71, 0.46-1.08, p = 0.10); this was not observed for women (HR 0.86, 0.51-1.45, p = 0.57). **Conclusions:** Male patients with glioblastoma residing in economically disadvantaged communities in NC experience worse outcomes than similar patients from advantaged areas. Further efforts to understand the patient-specific, community, and socioeconomic barriers are warranted.

Characteristic	Hazard Ratio (95% CI)	P-Value
High vs Low MSI	0.77 (0.57 – 1.03)	0.08
WHO Grade 4 vs 3	2.85 (2.01 – 4.03)	$<$ 0.001
Age (by decade)	1.41 (1.26 – 1.57)	$<$ 0.001
Era of Treatment (Pre- vs Post-Temozolomide)	1.28 (0.96 – 1.70)	0.09

2061 Poster Session (Board #219), Sat, 1:15 PM-4:45 PM

Dianhydrogalactitol in bevacizumab-refractory GBM: Further analysis of a phase 1-2 trial. *First Author: Kent C. Shih, Sarah Cannon Research Institute/ Tennessee Oncology, Nashville, TN*

Background: Dianhydrogalactitol (VAL-083) is a first-in-class DNA-targeting agent with anticancer activity established in prior NCI-sponsored trials. We have previously reported results of DLM-10-001 (NCT01478178), a multicenter Phase 1-2 trial of VAL-083 in bevacizumab refractory GBM (BEV-rGBM), with median overall survival (mOS) of 8.35mo from BEV failure and an observed dose response. Here, we report further analysis of OS in DLM-10-001 from the start of treatment for patients (pts) receiving a clinically active dose of VAL-083 compared to pts receiving an inactive dose of the agent and two derived controls of historical and recent electronic medical records (EMR) data. **Methods:** 45 BEV-rGBM pts were enrolled across 10 cohorts at doses ranging from 1.5mg/m^2 to 50mg/m^2. Pts received VAL-083 IV on days 1, 2, 3 of a 21-day cycle. MTD was established at 40mg/m^2/day. A clinically active dose of VAL-083 was determined at or below MTD based on PK data and *in vitro* studies against GBM cell-lines included pts from 20, 30 & 40 mg/m^2 dose cohorts. OS in DLM-10-001 was calculated from the 1st dose of VAL-083. DLM-10-001 trial data are also compared to historical publications of BEV-rGBM, and recent EMR for BEV-rGBM pts receiving salvage therapy with TMZ, CCNU or carboplatin. mOS and hazard ratios (HR) were estimated by Kaplan-Meier and nominal p-values to compare survival curves by log-rank test (MedCalc Software v18). **Results:** OS for BEV-rGBM pts treated with a clinically active dose of VAL-083 (mOS = 7.9mo, 95% CI = 3.1-9.6mo) was superior to OS for pts receiving an inactive dose of VAL-083 (mOS = 2.9, HR = 0.341, p = 0.003); historical publications (mOS = 2.8mo, HR = 0.362, p = 0.0005); and EMR data (mOS = 2.9mo, HR = 0.399, p = .011). There was no statistical difference between the control groups. Pts receiving a clinically active dose of VAL-083 demonstrated an OS benefit compared to an aggregate of the controls (mOS = 2.9mo, HR = 0.395, p = .0003). **Conclusions:** The results suggest a statistically significant and meaningful OS benefit for BEV-rGBM pts treated with a clinically active dose of VAL-083. While small sample size and retrospective nature of the analyses is limiting, the results warrant further exploration via a randomized trial. Clinical trial information: NCT01478178.

2062 Poster Session (Board #220), Sat, 1:15 PM-4:45 PM

Neurological death in patients with EGFR-mutant non-small cell lung cancer. *First Author: Matthew Ramotar, Radiation Medicine Program, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Patients with EGFR mutant non-small cell lung cancer (EGFRmNSCLC) have a high incidence of brain metastases (BM). We sought to determine the rate of neurologic death in EGFRmNSCLC patients diagnosed with brain metastases. **Methods:** A single-institution prospectively managed database identified 204 patients with EGFRmNSCLC treated for brain metastases between 2000 and 2016. We estimated actuarial survival rates using the Kaplan-Meier method. The incidence of neurologic death (ND) was determined using a competing risks analysis. ND was correlated to clinical and treatment variables using Fisher's exact test. Survival was calculated from the date of BM diagnosis. We defined neurologic death as death due to brain metastases or leptomeningeal disease **Results:** Fifty-six percent of patients had BM at the time of initial diagnosis. The initial BM treatment was up front stereotactic radiosurgery (SRS), whole brain radiation therapy (WBRT), or tyrosine-kinase inhibitor (TKI) alone in 22, 60, and 18 percent of patients, respectively. Two-year rates of OS in these subgroups were 64%, 38%, and 50%, respectively (p = 0.016). The 5-year rate of neurologic death was 38%. Thirty-four percent died of non-neurologic causes, 8% died of unknown causes, and the remaining patients were alive at last follow-up. Median survival (MS) was 19 months; MS in patients who died of non-neurologic causes and neurologic causes was 23, and 15 months, respectively. Of age, staging, BM at diagnosis, history of TKI therapy, initial treatment of BM, staging at diagnosis, and leptomeningeal disease at diagnosis (LMD), only LMD was significantly associated with ND (p = 0.047). **Conclusions:** Neurologic death due to EGFRmNSCLC BM was more common in our cohort than has been previously reported, highlighting the need for dedicated studies focused on the best management of BM in this population.

2063 Poster Session (Board #221), Sat, 1:15 PM-4:45 PM

Impact of prior systemic therapy on lymphocytic infiltration in surgically resected breast cancer brain metastases. *First Author: Andrew Bacotti, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Tumor infiltrating lymphocytes (TILs) have been positively correlated with response to systemic therapy and for triple negative and HER2+ subtypes and clinical outcomes in early breast cancer (BC) (Denkert C et al., Lancet Oncol 2018). Less is known about TILs in metastatic sites (Cimino-Mathews A et al., Hum Pathol 2016; Ogiya R et al., Cancer Sci 2016), particularly brain (BM), where unique immune regulation governs stromal composition (Duchnowska R et al., Breast Can Res 2016; Harter PN et al., Oncotarget 2015). Reactive glial cells actively participate in cytokine-mediated T cell stimulation (Fitzgerald DP et al., Clin Exp Met 2008). The impact of prior medical therapy (chemotherapy, endocrine therapy, and HER2-targeted therapy) on the presence of TILs and gliosis in human BCBMs has not been previously reported. **Methods:** In order to determine the impact of prior medical therapy on the presence of TILs and other histopathologic variables, we examined prior treatment data for 133 patients who underwent craniotomy for resection of BMs from the electronic medical record. We examined the relationship between prior systemic therapy exposure and the histologic features of gliosis, necrosis, hemorrhage, and lymphocyte infiltration (LI) assessed by hematoxylin and eosin stain in BCBMs resected at subsequent craniotomy in uni- and multivariate analyses (Prince G et al. Proc ASCO 2017, abstract 2072). **Results:** Complete treatment data were available for 122 patients. 36 of 114 patients (31.6%) who had received prior systemic treatment had BCBM LI while BCBM LI was observed in 6 of 8 patients (75%) who had not received systemic treatment {significant by Fisher's exact test p = 0.02}. There were no statistically significant relationships between prior systemic therapy and the three other histologic variables examined. **Conclusions:** This observation suggests that systemic therapy may interfere with the immune response to BCBMs. This motivates clinical investigation of strategies to enhance LI for therapeutic benefit to improve outcomes for patients with BCBMs. Analysis of these tissue samples to address the potential significance of the pattern of LI as well as relevant biomarkers is ongoing.

2064 Poster Session (Board #222), Sat, 1:15 PM-4:45 PM

Outcomes of lung cancer patients with leptomeningeal metastases in the targeted therapy era. *First Author: Kathryn Sara Nevel, Memorial Sloan Kettering Cancer Center - Fellowship (GME Office), New York, NY, US*

Background: Recent improvements in detection and molecular characterization of leptomeningeal metastasis from lung cancer (LC-LM) coupled with cerebrospinal fluid (CSF)-penetrating targeted therapies have substantially altered the management of this disease. In this new era, outcomes of patients harboring LC-LM are not well defined. This study identifies molecular and clinical characteristics of LC-LM and correlates these with clinical outcome. **Methods:** We retrospectively reviewed charts of 171 patients diagnosed with LC-LM between June 2009 and June 2017 at Memorial Sloan Kettering Cancer Center. Presence of targetable mutations (TM) in the primary tumor and CSF was determined by MSKCC IMPACT. Extent of radiographic involvement was scored by number of gadolinium-enhancing sites in eight locations. CSF studies included cytopathology, quantification of circulating tumor cells (CTCs), and cell free DNA (cfDNA) analysis. Kaplan-Meier survival curves were compared by log-rank analyses. **Results:** Median overall survival (OS) after LC-LM diagnosis (dx) was 125 days; 80/171 patients harbored a TM. At one year, 29% of patients with a TM were alive versus 12% of those without. Treatment of LC-LM with targeted therapies (TTx) was associated with improved OS (0 TTx = 70 days, 1 TTx = 109 days, 2+ TTx = 507 days; $p < 0.0001$). A subset of 93/171 patients underwent MRI brain, spine and CSF studies within 30 days of LM dx. Extent of radiographic involvement correlated with OS: 0-2 sites of disease OS = 113 days, 3+ sites OS = 75 days; p = 0.015. CTCs were analyzed in 15/171 patients. Fewer than 50 CTCs/3 mL correlated with OS of 377 days, versus OS 66 days for $>$ 50 CTCs/3mL. cfDNA was extracted from 20/171 patients. cfDNA concentration correlated with outcome; cfDNA < 0.025 ng/μl = OS of 231 days, vs cfDNA > 0.025 ng/μl OS of 60 days p = 0.022. **Conclusions:** In this largest study of LC-LM, presence of a TM and treatment with TTx were associated with improved OS. Extent of radiographic involvement at dx was also a prognostic indicator. These findings support complete molecular characterization and CNS staging for clinical management, prognostication and clinical trial stratification of LC-LM.

2065 Poster Session (Board #223), Sat, 1:15 PM-4:45 PM

Impact of apolipoprotein E (APOE) genotype on neurocognitive function (NCF) in patients with brain metastasis (BM): An analysis of NRG Oncology's RTOG 0614. *First Author: Jeffrey Scott Wefel, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Whole brain radiotherapy (WBRT) is a common treatment for BM and is associated with decline in NCF. The APOE e4 allele is associated with increased risk of Alzheimer's disease, and NCF decline after chemotherapy for non-CNS cancer, treatment for primary brain tumor, and in irradiated mouse models. APOE carrier status has not been evaluated as a risk factor for impaired NCF in patients with BM before and after WBRT. **Methods:** RTOG 0614 treated adult patients with BM with 37.5 Gy of WBRT (+/- memantine), performed NCF testing (HVLT-R, TMT, COWA) at baseline, 8, 16, 24, and 52 weeks, and included an optional blood draw for APOE analysis. APOE alleles were evaluated by real-time PCR based SNP analysis using TaqMan genotyping. NCF test results were compared at baseline and over time with mixed effects models adjusted for baseline score, treatment arm, time, and interaction between time and APOE carrier status. A cause-specific Cox model for time to NCF failure was performed to assess the effects of treatment arm (memantine versus placebo) and APOE carrier status (e4 versus no e4). **Results:** APOE results were available for 45% (n = 227/508) of patients. No pretreatment differences were detected between patients with APOE available versus not available. APOE e4 carrier status was evenly distributed between treatment arms (e4 positive = 29.5%). NCF test results did not differ by APOE e4 carrier status at baseline, but e4 carriers were less often white and had started WBRT at study entry more often. Mixed effects modeling showed that patients without an APOE e4 allele had better memory after WBRT compared to patients with an APOE e4 allele (HVLT-R Total Recall [estimate = 2.44, p = 0.026], Delayed Recognition [estimate = 1.15, p = 0.024]). For time to NCF failure, treatment arm was significant (HR = 0.715, 95% CI: 0.513-0.998, p = 0.0487) in favor of memantine; however, APOE e4 status was not (HR = 0.865, 95% CI: 0.606-1.233, p = 0.422). **Conclusions:** Patients with an APOE e4 allele exhibited worse memory function after treatment with WBRT (+/- memantine), but no difference in time to NCF failure. APOE carrier status was not associated with NCF in patients with BM prior to WBRT. Clinical trial information: NCT00566852.

2066 Poster Session (Board #224), Sat, 1:15 PM-4:45 PM

Incidence of treatment effect and characteristic MRI findings in immunotherapy-treated melanoma patients with brain metastases receiving stereotactic radiosurgery. *First Author: Justin Lin Sovich, University of Michigan, Ann Arbor, MI*

Background: Melanoma brain metastasis (MBM) treated with stereotactic radiosurgery or stereotactic body radiation therapy (SRS/SBRT) and immunotherapy may have higher rates of treatment-related injury including radiation necrosis, which can be difficult to differentiate from disease progression. Little is known about characteristic radiographic findings to guide decision-making. **Methods:** We identified all patients (pts) with MBM from the University of Michigan from 2012-2017 who were treated with SRS/SBRT. Pts receiving immunotherapy were compared to those who had not. Overall incidence of treatment-effect (TE) (pathologically confirmed or inferred by $>$ 6 mos stable imaging) were calculated. We reviewed MRIs in pts with TE for conventional metrics including enhancement, T2 hyperintensity, and apparent diffusion coefficient (ADC) and perfusion parameters including calculated blood volume (rBV), blood flow (rBF), time to maximum (tMAX), and leakage (K2). **Results:** 104 pts received SRS/SBRT and immunotherapy and 29 pts had not. Among the immunotherapy group, 16 had TE (6 pathologically confirmed, 10 by serial imaging) (15.4%). Of the 29 who did not receive immunotherapy, one had TE (pathologically confirmed) (3.45%). The observed risk difference was 12.0% (95% CI 2.4% to 21.6%). We reviewed MR findings for 18 lesions in 15 pts with TE, all of which had enhancement with T2 hyperintensity. Reliable ADC values were calculated for 14 lesions, averaging 112.8 (range 72 to 192). Perfusion imaging was available for 9 lesions, with average rBV 1.63 (range 0.63 to 3.6), rBF 23.86 (9 to 55.4), tMAX 5.71 (0.99 to 27), and K2 -266.78 (-111to -636). **Conclusions:** SRS/SBRT and immunotherapy resulted in higher absolute risk of treatment-related changes. MRI findings were consistent with existing data on radiation necrosis in glioblastoma multiforme which could help guide decision making in MBM. Comparative analysis on tumor progression in this population is ongoing and will be presented.

2067 Poster Session (Board #225), Sat, 1:15 PM-4:45 PM

Mutational complexity increases in lung adenocarcinoma (LADC) with the development of brain metastasis (BM). *First Author: Matthew K Stein, Department of Hematology-Oncology, West Cancer Center/University of Tennessee Health Science Center, Memphis, TN*

Background: Up to 40% of LADC patients (pts) develop BM but little is known about the inciting molecular events. **Methods:** We compared mutational profiles of LADC BM pts with primary (P) LADC submitted to Caris Life Sciences from 2015-2017. Testing included next-generation sequencing (NGS) of 592 cancer-related genes, PD-L1 IHC and tumor mutational burden (TMB). NGS aberrations were test-defined as pathogenic (PATH), variants of undetermined significance or unclassified mutations (VUS). TMB was defined as: high (H; $\geq$17 mutations/megabase), intermediate (I; 7-16) and low (L; 0-6). **Results:** 145 BM (57% female (f)) and 1145 P (58% f) cases were identified; BM median age was 64 (range 31-86) vs. 70 (25-90) in P pts. BM had 55 PATHs (38% pts) in *KRAS*, 34 *STK11* (23%), 17 *EGFR* (12%), 5 *BRAF* (3%); 3 were *MET*-amplified (2%), 3 *ALK* (2%) and 1 *ROS1*-rearranged (1%). Compared to P, more BM pts harbored *STK11* PATHs (23% vs. 11%, P $<$ 0.0001); no other difference in PATHs was observed. 143 BM and 1102 P pts had TMB data. BM cases were more-frequently TMB-H compared to P (39% (N = 56) vs. 12% (132), P $<$ 0.0001) and less likely to be TMB-L (8% (12) vs. 33% (366), P $<$ 0.0001). 131 (92%) BM pts were TMB-I or H. Of 142 BM and 1060 P with PD-L1 testing, incidence of $\geq$1% (46% BM vs. 49% P) and $\geq$50% (24% vs. 23%) cases were similar. 327 VUS in 28 receptor tyrosine kinases (RTK) were observed in 117 BM (median 1 (0-12)) vs. 1648 VUS in 807 P pts (median 1 (0-13); 79% vs. 70%, P = 0.007). RTK VUS more frequently observed in BM included: 51 *EPHA3* VUS (17% pts vs. 8%. P = 0.0002), 25 *EPHA5* (15% vs. 8%, P = 0.004), 26 *NTRK3* (14% vs. 6%, P = 0.0002), 22 *EPHB1* (13% vs. 6%, P = 0.0001) and 17 *PDGFRA* (12% vs. 5%, P = 0.0001). No significant difference was observed between BM specimen site and *EGFR*, *KRAS*, TMB and PD-L1 status. **Conclusions:** While classic LADC biomarkers including PD-L1, *EGFR* and *KRAS* were similar between BM and P cases, nearly 40% BM pts were TMB-H ($\geq$25% more than P) and $>$ 90% either TMB-I or H, indicating an increased mutational complexity in BM development, suggesting immune checkpoint inhibitor use. In addition to *STK11* PATHs, RTK VUSs including *NTRK3*, *EPHA3*, *EPHA5* and *EPHB1* were more-frequently mutated and warrant further evaluation as biomarkers or targets in BM.

2068 Poster Session (Board #226), Sat, 1:15 PM-4:45 PM

Discovery of a predictive protein biomarker for leptomeningeal disease after craniotomy and radiation. *First Author: Michael Henry Soike, Wake Forest Baptist Medical Center, Winston-Salem, NC*

Background: Leptomeningeal disease (LMD) is a common but morbid disease progression after craniotomy for resection of brain metastases (BrM). LMD has been observed most commonly with breast cancer BrM, but the cellular mechanisms facilitating LMD have not been elucidated. We sought to identify a protein associated with a higher risk of developing LMD. **Methods:** At our institution, patients (2005-2016) who had craniotomy for BrM followed by adjuvant radiation therapy were eligible for this IRB approved study. Frozen BrM samples were reduced with trypsin digestion, pelleted by centrifugation, and analyzed by liquid chromatography–mass spectrometry. Mass spectra were searched with Sequest HT algorithm in Proteome Discoverer v2.1 (Thermo Scientific). Patient outcomes were obtained from the medical record and overall survival (OS) and time-to-event were calculated with Kaplan-Meier and Competing Risk. To identify proteins of interest, we used empirical Bayes based linear models (limma) and the Benjamini–Hochberg false discovery rate analysis (FDR). Univariate (UVA) and multivariate (MVA) analyzed patient characteristics and proteins associated with LMD. **Results:** Proteomic expression data for 39 patients were included. The median OS was 13 months. Eleven (28%) developed LMD. 6407 proteins were analyzed. After FDR, only collagen type 1 alpha 1 chain (COL1A1) and collagen type I alpha 2 chain (COL1A2) were associated with a higher risk of LMD (FDR 0.045 and 0.089, respectively). On UVA and MVA analysis, COL1A2 was associated with a statistically significant higher risk of LMD (Table). **Conclusions:** COL1A2, a component of type I collagen, is associated with a higher risk of LMD development, even when accounting for breast histology. COL1A2 may be a protein of interest in the mechanism facilitating LMD progression.

UVA and MVA for proteins of interest developing in LMD progression.

Variable	UVA Hazard Ratio (confidence interval)	MVA Coefficient and p-value
Previous systemic therapy	7.8 (1.6-38)	1.24 p = 0.15
Smoking at diagnosis	0.4 (0.1-1.3)	
Age	1.0 (0.9-1.0)	
Gender	0.3 (0.1-1.5)	
Breast vs other histology	4.4 (1.5-12.8)	0.08 p = 0.89
COL1A1	1.3 (1.2-1.4)	-0.002 p = 0.98
COL1A2	1.3 (1.1-1.4)	0.20 p = 0.03

2069 **Poster Session (Board #227), Sat, 1:15 PM-4:45 PM**

MRI texture features and outcomes to immune checkpoint inhibitors in melanoma brain metastases. *First Author: Ankush Bhatia, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Brain metastases (BM) in patients (pts) with melanoma historically portend a dismal prognosis, but immune checkpoint inhibitors (ICI) are associated with durable responses in a subset of pts. There are no validated imaging biomarkers associated with outcomes in pts with melanoma BM receiving ICI. We hypothesized that texture analysis of contrast T1-weighted magnetic resonance images (MRI) could identify "higher order" features associated with progression-free (PFS) and overall survival (OS). **Methods:** Between 2010 and 2017, we retrospectively reviewed pts with measurable ($>$ 1.0cm) melanoma BM on MRI who received ICI with or without concurrent radiation therapy (RT). Volume-of-interests were drawn around up to 5 BM per pt, and Haralick textures (n = 5), and Gabor edge features (n = 4) at angles (0°, 30°, 45°, 90°) and a bandwidth (γ = 2) were extracted for each lesion. Progression for BM was determined using RANO-BM; pts who died without repeat MRI were considered to have progressed. OS was calculated from date of ICI receipt. Cox regression was performed for each texture feature. **Results:** 88 pts with 196 total BM were identified. Median age was 63.5 (19-91), ECOG (0-54%, 1-34%, 2-3 12%), 38% had elevated LDH, and 42% had prior systemic treatment. ICI was CTLA-4 monotherapy in 77%, PD-1 monotherapy in 9%, and PD-1 + CTLA-4 in 14%. 79% received concurrent RT (38% focal, 62% whole brain). Median OS was 5.4 months (0.3-80.9). Increased energy (HR = 1.04, 95%CI 1.01-1.07, p = 0.02) was associated with a poorer progression-free (PFS) and OS (HR = 1.04, 1.00-1.07, p = 0.03). Increased entropy was associated with an improved PFS (HR = 0.82, 0.69-097 p = 0.02) and OS (HR = 0.84, 0.72-.99, p = 0.03). Both features remained significantly associated with OS (Energy HR = 1.15, 1.03-1.20, p = 0.02; Entropy HR = 0.84, 0.71-0.98, p = 0.03) after adjusting for receipt of RT and ICI (PD-1 vs. CTLA-4 vs. PD-1+ CTLA-4). **Conclusions:** In the first ever analysis of higher order MRI features in pts with melanoma BM receiving ICI, Haralick texture features are associated with both PFS and OS. Further research is required to determine whether these features are independently associated with OS in a multivariate analysis.

2070 **Poster Session (Board #228), Sat, 1:15 PM-4:45 PM**

Timing, presentation, and patterns of failure of leptomeningeal disease after surgical resection and radiosurgery for brain metastases: A multi-institutional analysis. *First Author: Roshan Sudhir Prabhu, Levine Cancer Institute and Southeast Radiation Oncology Group, Charlotte, NC*

Background: Postoperative (post-op) radiosurgery (SRS) has been proposed as a standard of care based on 2 phase III trials, but has been associated with up to 30% risk of leptomeningeal disease (LMD). The specifics of timing, presentation, and patterns of LMD failure have not been well described. **Methods:** The records of patients (pts) with brain metastases (BM), of which 1 was resected and treated with post-op or pre-op SRS, and who subsequently developed LMD were combined from 7 tertiary care centers. Pts with classically radiosensitive tumors or prior or planned whole brain radiotherapy were excluded. LMD pattern was categorized as either nodular or linear ("sugarcoating"). **Results:** The study cohort consisted of 147 pts. The most common primary sites were lung (40%), breast (24%), and melanoma (16%), and most pts received post-op SRS (94%). Pts with breast primary were enriched for HER-2 positivity (60%). The majority of resected BM (82%) extended to within 5 mm of the pial surface. Median time from initial SRS to 1st LMD was 5.6 months (interquartile range [IQR] 3.2 – 11). The majority of LMD events were nodular (60%), of which 64% were within 5 cm of the surgical corridor. The median number of nodules was 2 (IQR 1 – 4), with a median distance of 2.5 cm from the surgical corridor (IQR 1.1 – 5.2). Most pts (60%) were symptomatic at time of LMD diagnosis, of which the most common symptoms were headache (58%), cranial nerve deficit (28%), and dizziness/balance issues (24%). Of the pts who received LMD treatment and had follow-up imaging (n = 101), 50% experienced 2nd LMD at a median of 5.5 months after 1st LMD (IQR 2.8 – 9.4). Of these, 68% were symptomatic at the time of 2nd LMD diagnosis, 58% had nodular LMD with a median of 1 nodule (IQR 1-3), and 70% underwent salvage therapy. **Conclusions:** LMD failure is an increasingly recognized event after surgery and SRS for BM. Pts who experience LMD are enriched in HER-2 positive disease and superficial location of the resected BM. Nodular LMD is the predominant pattern of LMD failure in this pt population, with most LMD events being symptomatic. 2nd LMD is common after initial salvage therapy and also has a predominantly nodular pattern.

TPS2071 **Poster Session (Board #229a), Sat, 1:15 PM-4:45 PM**

A randomized, multicenter phase 2 study of DSP-7888 dosing emulsion in combination with bevacizumab (Bev) versus Bev alone in patients with recurrent or progressive glioblastoma. *First Author: John Frederick De Groot, The University of Texas MD Anderson Cancer Center, Department of Neuro-Oncology, Houston, TX*

Background: Glioblastoma (GBM) is the most frequently diagnosed high-grade glioma with an incidence of 3-4/100,000 in the US. Although treatments have improved, median survival remains 15–18 months for newly diagnosed patients. DSP-7888 is an investigational peptide cancer vaccine comprised of peptides derived from the Wilms' Tumor 1 (WT1) protein, with immunomodulating and antineoplastic activities. DSP-7888 may induce a WT1-specific cytotoxic T-lymphocytes against WT1-expressing tumor cells in HLA-A*02:01+, HLA-A*02:06+, and HLA-A*24:02+. DSP-7888 may induce a helper T-lymphocyte–mediated immune response against WT1-expressing tumor cells. **Methods:** This phase 2, active-controlled, multicenter, open-label randomized study (NCT03149003; WIZARD201G) is randomizing patients with recurrent or progressive GBM 1:1 to treatment with DSP-7888 + Bev or Bev alone. A screening phase of $\leq$28 d determines eligibility. DSP-7888 is administered intradermally at 10.5mg every 7 d ($\pm$1 d) for 5 doses (induction phase), then every 14 d ($\pm$3 d) for 6–15 doses (consolidation phase), then every 28 d ($\pm$7 d) for each additional dose (maintenance phase). Bev is administered every 14$\pm$3 d IV at 10mg/kg. The primary endpoint is overall survival. Secondary endpoints include progression-free survival, response rate, and 12-month survival. Safety will be evaluated based on adverse events (AEs) recorded at each visit, physical examinations, and laboratory test results. The severity of AEs or abnormal laboratory results will be based on the CTCAE V4.03. About 200 patients will be enrolled. The study has 2 parts. In part 1, 3 patients are to receive DSP-7888 + Bev in a single-arm manner. If no patients experience a dose limiting toxicity (DLT), the study proceeds to part 2. If $\geq$1 patient experiences DLT, 3 more patients will be treated in the same manner. If $\geq$1 patient again experiences a DLT, the dose is reduced to 3.5mg. In part 2, new patients are randomized to one of the 2 treatment arms. Treatment continues in the absence of clear progression, clinical neurologic deterioration, or until 150 deaths have occurred. Study funding: Boston Biomedical, Inc. Clinical trial information: NCT03149003.

TPS2073 **Poster Session (Board #230a), Sat, 1:15 PM-4:45 PM**

A phase II, open label, single arm study of nivolumab for recurrent or progressive IDH mutant gliomas with prior exposure to alkylating agents. *First Author: Laura Donovan, Columbia University Medical Center, New York, NY*

Background: Gliomas are the most common malignant primary brain tumors in adults. Mutations in Isocitrate dehydrogenonase 1 (IDH1) or IDH2 genes are associated with longer survival. These mutations are found in over 70% of WHO Grade II and III astrocytomas and are now required for the diagnosis of oligodendroglioma. Upfront standard of care treatment for high grade gliomas includes a combination of radiation with alkylating agents including temozolomide or procarbazine and lomustine. Unfortunately, independent of initial grade or IDH mutation status, recurrence after first line therapy is nearly universal. Currently, there is no standard of care therapy for recurrent disease. Trials of PD1 and PD-L1 inhibitors in recurrent high grade gliomas and IDH inhibitors in IDH mutant gliomas have been disappointing. Multiple studies in other solid tumors have shown that high mutational burden is associated with response to immune checkpoint inhibitors. In comparison to other cancers, gliomas have a low mutational burden. However, there is evidence suggesting that IDH mutant gliomas are more prone to develop a hypermutated phenotype after exposure to alkylating agents. This subgroup of patients may be more likely to benefit from treatment with nivolumab, an anti-PD1 agent. **Methods:** Design This is a Phase 2, open label, single arm study. We will enroll 37 evaluable subjects. The primary endpoint is ORR based on RANO criteria. Secondary endpoints are PFS, OS, and duration of response. Exploratory endpoints include evaluation of mutational burden, 2HG spectroscopy, spatial profiling of PD-1/PD-L1 interaction and NANO scale. Eligibility Adult patients with recurrent or progressive IDH mutant high-grade gliomas who have received prior treatment with alkylating agents with no prior bevacizumab or other immune checkpoint inhibitors. Treatment All subjects will be treated with nivolumab 240mg IV every 2 weeks for 8 cycles. Beginning with cycle 9, nivolumab 480mg IV will be administered every 4 weeks until completion of the study.

TPS2074 **Poster Session (Board #230b), Sat, 1:15 PM-4:45 PM**

Phase I/II study of laser interstitial thermotherapy (LITT) combined with checkpoint inhibitor for recurrent glioblastoma (rGBM). *First Author: Andrew E. Sloan, University Hospital Case Medical Center, Cleveland, OH*

Background: Glioblastoma (GBM) has a survival of only 3-5 months at recurrence.. Salvage chemotherapy has been largely ineffective with PFS-6 rates of 10-15%. Bevacizumab's impact on OS is modest at best.· Thus, there is a pressing need for minimally invasive, approaches to debulk rGBM such as laser interstitial thermotherapy (LITT). **Methods:** Rationale for treating rGBM with LITT: Laser interstitial thermotherapy (LITT) is a minimally invasive technique for ablating tumors percutaneously using thermal radiation which has demonstrated efficacy in several non CNS tumors. Subsequent studies reproduced the efficacy of LITT for glioma demonstrating that survival was consistently related to tumor volume and a minimal dose threshold. This suggested the possibility of an *abscopal effect* mediated by unmasking of tumor antigens by LITT as has been previously demonstrated for ionizing radiation (radiotherapy). Rationale for Immunotherapy for rGBM: GBM patients are known to have elevated levels of immunosuppressive cells such as T_{reg}, M2 macrophages and MDSC, both in the tumor as well as in the systemic circulation. *Rationale:* Immunotherapy targeting co-inhibitory checkpoints such as CTLA-4 and PD-1 have proven highly effective for some solid tumors. The first trial targeting CTLA + PD-1 in rGBM demonstrated evidence of safety. Interestingly, targeting PD-1 concurrent with RT appeared to be synergistic and was effective in preclinical models. However, patients with rGBM have typically received maximum tolerated radiotherapy and are thus not candidates for additional RT off trial. We hypothesize that thermal radiation delivered using LITT technology interferes with tumor microenvironment, minimizing immunosuppression and re-introducing tumor neoantigens. The primary objective of this phase II trial is to estimate radiological response to LITT + pembrolizumab and compare this to that observed for LITT alone. Each patient will undergo a stereotactic biopsy followed by 200 mg pembrolizumab at various times before or after LITT. Secondary endpoints include a putative serum biomarker for GBM. Here we present the concept and the outcomes of the first patients in the study. Clinical trial information: NCT 03277638.

2500 Oral Abstract Session, Fri, 2:45 PM-5:45 PM

Single agent activity of ZW25, a HER2-targeted bispecific antibody, in heavily pretreated HER2-expressing cancers. *First Author: Funda Meric-Bernstam, Department of Investigational Cancer Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: ZW25, a novel Azymetric bispecific antibody, targets HER2 domains ECD2 and ECD4, resulting in multiple differentiated mechanisms of action including increased tumor cell binding, blockade of ligand-dependent and independent growth, and improved receptor internalization and down-regulation relative to trastuzumab (T). *In vivo* studies demonstrate anti-tumor activity in HER2-low to high expressing models. This Phase 1 study evaluated ZW25 single agent safety and anti-tumor activity. **Methods:** Part 1 (P1) evaluated ZW25 5, 10 and 15 mg/kg weekly and 20 mg/kg biweekly using a 3+3 design to identify a recommended dose (RD) for further study. Part 2 (P2) is ongoing and evaluating safety and efficacy in separate expansion cohorts, including HER2-high (IHC 3+ or 2+/FISH+) breast (BC), gastric/esophageal (GE), and other cancers. Pts had to have progressive disease after standard of care, including HER2-targeted agents. Adverse events (AE), PK, and response per RECIST 1.1 (every 8 wks in pts with measurable disease) were assessed. **Results:** 33 pts have been treated in P1 and P2: 17 BC, 11 GE and 5 other cancers. HER2-high BC pts had prior T and T-DM1 (100%), pertuzumab (82%) and lapatinib (53%), with a median of 6 HER2-targeted regimens for metastatic disease. All GE pts had received prior T, with a median of 4 systemic tx. Safety and anti-tumor activity were similar across dose levels with no DLTs. The RD for Part 2 was 10 mg/kg weekly or 20 mg/kg biweekly. The most common AEs were diarrhea and infusion reaction, all Gr 1 or 2, with no tx-related discontinuations. Time on study is 14-348 days with 9 pts still active. 23 pts are response evaluable, with 3 pts not yet restaged. **Conclusions:** ZW25 has been well tolerated with promising single agent anti-tumor activity in pts with heavily pretreated HER2-expressing cancers that have progressed after standard of care, including multiple HER2-targeted regimens. These data support the therapeutic potential of ZW25 and suggest that its unique MOA may overcome mechanisms of resistance to other HER2-targeted agents. Clinical trial information: NCT02892123.

Trastuzumab deruxtecan (DS-8201a) in subjects with HER2-expressing solid tumors: Long-term results of a large phase 1 study with multiple expansion cohorts. *First Author: Hiroji Iwata, Aichi Cancer Center, Nagoya, Japan*

Background: DS-8201a is a HER2-targeted antibody drug conjugate with novel topoisomerase I inhibitor payload and linker technology. **Methods:** This ongoing phase 1 study (NCT02564900) enrolls subjects (sbj) with HER2+ breast cancer (BC) post T-DM1, HER2+ gastric cancer (GC) post trastuzumab, HER2 low BC (IHC 1+ or 2+, ISH-), and other HER2-expressing solid tumors (IHC ≥1+). **Results:** [Results will be updated for presentation at meeting] From Sep 2015–Dec 2017, 212 sbj received ≥1 dose of DS-8201a; 200 at 5.4 or 6.4 mg/kg. Median (mdn) age was 59 y with mdn of 4 prior regimens. At data cutoff, 121/200 (60.5%) sbj remain on treatment (tx). Mdn duration of tx was 10.3 mo (range 0.7+, 21.2+ mo). Overall, RECIST-confirmed overall response rate (ORR) in the evaluable sbj was 81/160 (50.6%) with the highest ORR in HER2+ BC (64.2%). Mdn duration of response was not reached (NR, range 0.03+, 15.2+ mo). 155/181 (85.6%) of sbj with ≥1 postbaseline scan (ps) experienced tumor shrinkage (92.3% of them at 1st ps at 6 weeks). Major reasons for tx discontinuation were progressive disease (PD; 50/200; 25.0%) and adverse event (AE; 18/200; 9.0%); 93/200 (46.5%) experienced a grade ≥3 AE. Common AEs included nausea 73.5% (3.5% grade ≥3), decreased appetite 59.5% (4.5% grade ≥3) and vomiting 39.5% (1.5% grade ≥3). Two grade 5 cases of interstitial lung disease were reported. **Conclusions:** DS-8201a shows antitumor activity in multiple tumor types with high ORR and durable responses in heavily pre-treated sbj. Clinical trial information: NCT02564900.

*Sbj who received 5.4 or 6.4 mg/kg with 2 ps (N=141), or PD prior to 2nd ps (N=19), excluding 40 sbj too early to evaluate. Two low-HER2 GC sbj are not included in the Table; 1 had a confirmed response.

2502 Oral Abstract Session, Fri, 2:45 PM-5:45 PM

A multi-histology basket trial of ado-trastuzumab emtansine in patients with *HER2* amplified cancers. *First Author: Bob T. Li, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Human epidermal growth factor receptor 2 (*HER2*, *ERBB2*) amplification occurs in 2-5% of non-breast non-gastric cancers. Ado-trastuzumab emtansine is a HER2 targeted antibody drug conjugate that may have activity against a variety of cancers driven by *HER2* amplification. **Methods:** Patients with *HER2* amplified cancers were enrolled into a multi-histology basket trial of ado-trastuzumab emtansine, treated at 3.6mg/kg IV every 3 weeks. The primary endpoint was overall response rate (ORR) using RECIST v1.1 or PERCIST. A Simon two stage optimal design was applied to each histology cohort with type I error rate under 2.7%, power of 89%, H0 10%, H1 40%. Other endpoints include duration of response (DOR), progression-free survival (PFS) and toxicity. *HER2* amplification was identified by next generation sequencing (NGS), and tumors with adequate tissue were subsequently tested by fluorescence in situ hybridization (FISH) and immunohistochemistry (IHC). **Results:** 58 patients were treated across 8 cohorts of advanced lung, endometrial, salivary gland, biliary tract, ovarian, bladder, colorectal and other cancers. The median age was 63 (range 34-90 years), 72% were female. The median lines of prior systemic therapy was 2 (range 1-7). ORR was 26% (14/53 confirmed, 95% CI 15-40%), including 50% (3/6) for lung cancers, 22% (4/18, 2 CR) for endometrial cancers, 100% (5/5, 3 CR) for salivary cancers, 17% (1/6) for biliary cancers, 17% (1/6) for ovarian cancers, not including partial responses awaiting confirmation. Median DOR was 6 months (range 2-22+), median PFS was 3 months (95% CI 2-6). There was 1 (2%) grade 3 febrile neutropenia, but no treatment related deaths. The degree of *HER2* amplification (NGS fold change 1.7 to 27.9) did not predict response. *HER2* amplification by NGS correlated well with HER2/CEP17≥2 by FISH (40/41 tested) or IHC3+ (31/40 tested), and tumor shrinkage was seen in 2 patients who were tested IHC negative. **Conclusions:** Ado-trastuzumab emtansine showed efficacy in patients with *HER2* amplified lung, endometrial, salivary gland, biliary tract and ovarian cancers as identified by NGS. This study has met its primary endpoint. Further development is warranted. Clinical trial information: NCT02675829.

2503 Oral Abstract Session, Fri, 2:45 PM-5:45 PM

Molecular analysis for therapy choice (MATCH) arm W: Phase II study of AZD4547 in patients with tumors with aberrations in the FGFR pathway. *First Author: Young Kwang Chae, Northwestern University, Chicago, IL*

Background: MATCH is a histology-agnostic signal finding trial targeting pathways in cancer. AZD4547 is a selective inhibitor of the fibroblast growth factor receptor (FGFR) 1-3 kinases. **Methods:** Patients (Pts) were screened by NGS for *FGFR* aberrations including amplification (≥7x), mutation, and fusion. 70/5558 (1.3%) of pts who underwent successful NGS evaluation were assigned to arm W. 52/689 (7.5%) of total pts enrolled in all treatment arms were in arm W (July 2016 to June 2017). 50 pts received treatment with AZD4547 80mg PO twice a day until progression of disease (PD) or drug intolerance. **Results:** 39/50 (78%) were female, 45/50 (90%) were Caucasian with a median age of 62 years (range: 22-80). 25/50 pts (50%) had received more than three prior lines of treatment. The most common histologies were breast (n = 16), urothelial (n = 7), and endometrial cancer (n = 4). Pts were divided into three groups: amplification (Amp) (n = 21), single nucleotide variant (SNV) (n = 20), or fusion (n = 9). Best confirmed response for the three groups are shown in the table below. Of 41 evaluable pts, the objective response rate was 5% (all partial response, PR), 51% stable disease (SD), and 44% PD. All pts with PR had tumors harboring FGFR fusions; one with urothelial transitional cell carcinoma (FGFR3-TACC3 F17T8) and the other with squamous cell carcinoma of cervix (FGFR3-TACC3 F17T11). Six cases [2 PR and 4 SD (2 SNV, 1 Amp, 1 fusion)] out of 41 achieved a duration of response greater than 24 weeks (disease control rate, 15%). The 6-month progression-free survival rate is 17% (90% CI: 8.6-34%): Amp 15% (90% CI: 4-58%), SNV 8% (90% CI: 2-38%), and fusion 42% (90% CI: 19-94%). Of 49 pts evaluable for adverse events (AEs), 39 experienced any AEs (80%) with 19 having grade 3/4 AEs (49%). Common AEs were fatigue, anorexia, dry mouth, nausea/vomiting, diarrhea, constipation, oral mucositis, anemia and liver function tests abnormality. **Conclusions:** AZD4547 demonstrated modest activity across various solid tumors with aberrations in FGFR pathway with acceptable toxicities. Further trials are warranted in tumors harboring FGFR fusions. Clinical trial information: NCT02465060.

Biomarker-driven access to crizotinib in ALK, MET, or ROS1 positive (+) malignancies in adults and children: The French National AcSé Program. *First Author: Gilles Vassal, Gustave Roussy, Villejuif, France*

Background: Crizotinib (czb) is registered for the treatment of patients (pts) with ALK+ or ROS1+ lung cancer. Czb targets (ALK, MET, ROS1) are also altered (translocation [tlc], amplification [amp], mutation [mut]) in a wide range of malignancies (malg.) in adults and children. To generate high evidenced-based knowledge and to prevent off-label use, the French National Cancer Institute (INCa) launched the AcSé Program: equal access to tumor molecular diagnosis along with an exploratory phase II trial, to allow for a nationwide safe and controlled access to czb outside its indication. **Methods:** Biomarker identification was proposed to pts ≥ 1 year old (yo) with an advanced disease among more than 15 malg. known to harbor a czb target alteration. If not eligible for any other trial, pts may enter one of the 22 cohorts defined by the type of tumor and target. Tumor response was evaluated every 2 months (mo) using RECIST criteria v1.1. The primary endpoint is the objective response rate (ORR) at 2 mo [complete + partial response]. A two-stage Simon design is applied to each cohort. **Results:** From 08/2013 to 12/2017, 12836 pts from 186 centers have entered the biomarker program. Alterations found in pts were: ALK tlc, mut, amp in 14/2053, 8/306, 10/1846; MET amp (> 6 copies/diploid genome) in 392/7847 [250/4127 NSCLC, 60/1232 glioblastomas, 28/939 colon, 33/546 esogastric, 7/635 ovarian, 3/82 kidney cancers]; MET mut in 98/2697; ROS1 tlc in 80/4625 [NSCLC, cholangiocarcinoma, inflammatory myofibroblastic tumor (IMT)]. Clinical trial information: NCT02034981. Overall, 235 pts (median age, 58 yo [1–92]) received czb (adult 250 mg bid; child 280 mg/m^2 bid). **Conclusions:** Czb displayed a wide antitumor activity in several MET, ALK and ROS1+ malg. Equal and safe access across France to molecular testing and targeted therapies outside their approved indication is feasible.

Positive cohorts	Pts analyzed	CR/PR	ORR % [IC95%]
ALCL ALK tlc	22	12	54 [34-75]
NSCLC MET amp	25	6	24 [7-40]

MET mut	27	6	22 [7-38]
Esogastric MET amp	8	3	37 [10-74]
IMT ALK tlc / ROS1 tlc	7	1	28 [5-70]

2505 **Oral Abstract Session, Fri, 2:45 PM-5:45 PM**

First-in-human phase 1 study of the PARP/tankyrase inhibitor 2X-121 (E7449) as monotherapy in patients with advanced solid tumors and validation of a novel drug response predictor (DRP) mRNA biomarker. *First Author: Elizabeth Ruth Plummer, Northern Centre for Cancer Care, Newcastle-upon-Tyne, United Kingdom*

Background: A phase I study was done to establish the safety, MTD and anti-tumour efficacy of the novel PARP 1/2 and Tankyrase 1/2 inhibitor, 2X-121 (E7449). A novel tumor agnostic molecular biomarker, 2X-121 DRP, was developed to identify responders and non-responders. **Methods:** Patients (pts) with advanced solid tumors were eligible. 2X-121 was administered orally, once daily (QD), continuously. Archival tumor samples were obtained from consenting patients. Following completion of the study the 2X-121 DRP was applied in a blinded manner following a pre-specified analysis plan. This biomarker is based on expression of 414 genes predictive of response to 2X-121. **Results:** 41 pts were treated at 6 dose levels: 50, 100, 200, 400, 800 and 600 mg QD. Tumor types were pancreatic (n = 13), ovarian (n = 5), breast (4), lung (n = 4), colorectal (n = 4) and other (n = 11). Fatigue is the dose limiting toxicity. The MTD is 600 mg QD. The most frequently reported (> 30% of pts) TEAEs were fatigue, chromaturia, decreased appetite, nausea, diarrhea, constipation, and vomiting. No significant hematological toxicity and no Gr4 or 5 AEs were reported. Two pts had partial response (PR, both ovarian cancer), 13 pts had stable disease (SD), with 8 of these > 24 weeks; 7/8 were pancreatic cancer pts. Sustained PARP inhibition of ~90% is seen at doses over 600mg QD in PBMCs. The 2X-121 DRP was applied to 13 patients from which adequate biopsy material was available evaluating the 414 gene signature. Patients with PR and durable SD were correctly identified. It divided patients in two groups, sensitive (N = 6) or resistant (N = 7) to 2X-121. The median time to progression was 296 and 155 days, respectively (HR = 0.29, P = 0.14). Overall survival (OS) differed between the two groups, with a median survival in excess of 800 days and 208 days, respectively (HR = 0.26, P = 0.07). **Conclusions:** 2X-121 was generally well tolerated at the MTD of 600 mg QD, with evidence of antitumor activity. The 2X-121 DRP predicted the responders irrespective of BRCA mutation status. Clinical trial information: NCT01618136.

2506 **Oral Abstract Session, Fri, 2:45 PM-5:45 PM**

First-in-human phase 1 study of TAK-931, an oral cell division cycle 7 (CDC7) inhibitor, in patients (pts) with advanced solid tumors. *First Author: Toshio Shimizu, Department of Experimental Therapeutics, National Cancer Center Hospital, Tokyo, Japan*

Background: TAK-931 is an oral selective inhibitor of CDC7, a protein kinase with key roles in DNA replication and DNA damage response. TAK-931 has demonstrated potent antitumor activity in various preclinical models. **Methods:** We evaluated safety, dose limiting toxicity (DLT), maximum tolerated dose (MTD), and preliminary antitumor activity of TAK-931 in pts with advanced solid tumors. Four schedules are being tested, and we report data from Schedule A: TAK-931 QD for 14 days on/7 days off in 21-day cycles. A Bayesian logistic regression model with overdose control was used to guide dose escalation and MTD estimation. **Results:** As of 14-Nov-2017, 25 Japanese pts (60% male; median age 59 [range 42–75] years) were treated with TAK-931 30 mg (n = 3), 40 mg (n = 3), 60 mg (n = 3), and 50 mg (n = 16: 7 pts in dose escalation, 9 pts in expansion). Pts received a median of 3 cycles (range 1–12). Most common any-grade adverse events (AEs) were nausea (n = 15), neutropenia (n = 12), decreased white blood cells (WBCs) (n = 8), decreased appetite, vomiting, and diarrhea (each n = 7). Most common grade ≥3 AEs were neutropenia (n = 11), decreased WBCs (n = 3), leukopenia, and decreased appetite (each n = 2). DLTs (grade 4 neutropenia) were observed in 2 of 3 pts at 60 mg; 50 mg was considered the MTD. Preliminary pharmacokinetics (PK) showed increased systemic exposure of TAK-931 in a dose proportional manner between 30 and 60 mg, with minimal accumulation and mean terminal elimination half-life of 5.4 hours (15% CV). Dose-dependent inhibition of pMCM2, a direct substrate of CDC7, was observed in skin biopsies from most pts treated with TAK-931, which correlated well with drug exposure (R^2= 0.6598). Partial responses were observed in pts with duodenal, esophageal, and cervical cancers (1 pt each) as well as prolonged stable disease of ~6 months in a bladder cancer pt and ~9 months in a pancreatic cancer pt. **Conclusions:** TAK-931 demonstrated an acceptable safety profile with early signs of clinical antitumor activity. Isolated neutropenia was the DLT with the tested schedule. Strong pharmacodynamic (PD) effects and PK-PD correlation provide clinical evidence of target engagement of TAK-931 in pts. Clinical trial information: NCT02699749.

2507 **Oral Abstract Session, Fri, 2:45 PM-5:45 PM**

Phase I dose escalation study of the first-in-class selective PTEFb inhibitor BAY 1251152 in patients with advanced cancer: Novel target validation and early evidence of clinical activity. *First Author: Jennifer Robinson Diamond, University of Colorado, Aurora, CO*

Background: PTEFb/CDK9 mediated transcription of short-lived anti-apoptotic survival proteins and oncogenes like MYC and MCL-1 plays a critical role in a variety of cancers. We present findings from a phase I study of BAY 1251152 in pts with solid tumors and aggressive NHL. **Methods:** Patients with advanced or metastatic solid tumors or aggressive NHL and refractory to available therapies were eligible. BAY 1251152 was administered once weekly as a 30-minute IV infusion on Days 1, 8 and 15 of a 21-day cycle. Tumor response was assessed according to RECIST v1.1 and the revised Cheson criteria (2007). **Results:** A total of 31 pts were enrolled and evaluable for safety, including subjects with breast cancer (n = 6), pancreatic adenocarcionoma (5), ovarian cancer (4), and colorectal cancer (3). No DLTs were reported in the first 3 cohorts (5 mg, 10 mg and 15 mg). There was one DLT in the 22.5 mg cohort (grade 4 [G4] neutropenia), which was then expanded to 6 pts without subsequent DLTs. At 30 mg, neutropenia became the most prominent AE, with one G3 febrile neutropenia and two G4 neutropenia's reported as DLTs in 9 evaluable pts. Three additional pts were enrolled in the 22.5 mg cohort, with one DLT (G3 neutropenia) but no other G3 or G4 drug-related AEs. The 30 mg dose was deemed the MTD. There were 4 deaths on study, none of which was attributed to study drug. Pharmacodynamic biomarker analysis showed significant dose-dependent reduction of MYC, PCNA, and MCL-1 RNA. PK was generally linear over the dose range. Antitumor activity consisted of stable disease (SD) in 9 subjects and durable SD in 3 pts: one relapsed pancreatic adenocarcinoma pt treated for 15 cycles, one double-hit DLBCL (GCB subtype, 2 prior lines) pt was treated > 22 cycles with a 40% reduction in tumor size and complete metabolic response, and a salivary gland carcinoma pt treated for > 24 cycles with a 21% reduction in tumor size; the latter 2 pts remain on treatment. **Conclusions:** PTEFb inhibitor BAY 1251152 had a manageable safety profile, apparent dose-proportional PK, on-target pharmacodynamic activity and signs of antitumor activity. Clinical trial information: NCT02635672.

2508 Oral Abstract Session, Fri, 2:45 PM-5:45 PM

A first-in-human phase 1 dose-escalation trial of the oral HIF-2a inhibitor PT2977 in patients with advanced solid tumors. *First Author: Kyriakos P. Papadopoulos, START, San Antonio, TX*

Background: Hypoxia-inducible factor (HIF)-2α is a transcription factor that plays a central role in the hypoxic response pathway in tumors. HIF-2α heterodimerizes with HIF-1β and binds to hypoxic response elements in target genes. The first-in-class HIF-2α inhibitor, PT2385, demonstrated clinical activity in patients (pts) with clear cell renal cell carcinoma (ccRCC). PT2977 is a novel, orally administered selective small molecule HIF-2α inhibitor with improved potency compared to PT2385. PT2977 inhibited expression of HIF-2α target genes in tumor cells and induced regression in mouse xenograft models. **Methods:** Pts with advanced solid tumors who had received at least 1 prior therapy were treated with PT2977 once daily (QD) in a Phase 1 dose-escalation trial to determine the recommended Phase 2 dose (RP2D) and evaluate safety, pharmacokinetics (PK) and pharmacodynamics (PD). Plasma PK were measured on days 1 and 15 and PD weekly. **Results:** 29 pts were treated at doses of 20 - 160 mg QD in the dose-escalation. As of January 15, 2018, no treatment-related dose-limiting toxicities have been observed. The most common all-grade AEs have been anemia (35%), fatigue (24%), edema (17%), headache (17%), and nausea (17%). Anemia (11%) was the most common Grade 3 AE; there have been no Grade 4 events. Exposure increased with dose along with dose-dependent reductions in erythropoietin (PD marker) consistent with the pharmacology of PT2977. At the RP2D of 120 mg, PT2977 was rapidly absorbed (T_{max} = 3.1 h) with a C_{max} of 1.83 mg/mL, a C_{min} of 0.71 mg/mL, and a $T_{1/2}$ of 20 h. A pt with SDHB mutant paraganglioma has had stable disease (SD) $>$ 25 weeks with sustained decrease in normetanephrine levels. Of 6 pts with ccRCC treated at 120 mg or 160 mg, there was one PR and 4 SD with tumor reductions from 8%-26%. **Conclusions:** PT2977 is well tolerated and has a favorable safety and PK/PD profile. Early evidence of clinical activity shows promise for HIF2a inhibition in the treatment of ccRCC. PT2977 is currently under evaluation in an expansion cohort of 50 pts with previously treated advanced ccRCC at a dose of 120 mg QD. Clinical trial information: NCT02974738.

2509 Poster Discussion Session; Displayed in Poster Session (Board #335), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 3:00 PM-4:15 PM

Preliminary results of a first-in-human, first-in-class phase I study of MTL-CEBPA, a small activating RNA (saRNA) targeting the transcription factor C/EBP-α in patients with advanced liver cancer. *First Author: Debashis Sarker, King's College London, London, United Kingdom*

Background: MTL-CEBPA is a liposomal formulation of saRNA targeting the transcription factor C/EBP-α, which acts as a master regulator of liver homeostasis and multiple oncogenic processes including cell cycle control, proliferation and angiogenesis and inhibits hepatocellular cancer (HCC) tumor growth in preclinical models. MTL-CEBPA is the first saRNA and the first drug targeting C/EBP-α entering clinical trials. **Methods:** Patients (pts) with advanced HCC (Child-Pugh A/B) or secondary liver cancer, were enrolled in a 3+3 dose escalation study. MTL-CEBPA is administered as a 1-hr IV infusion on Day 1, 8 and 15 of a 28 day cycle. The primary endpoint was safety and the secondary endpoints included PK, liver function improvement and anti-tumor activity. Correlative studies include C/EBP-α mRNA levels in PBMCs and tumor tissue, evaluation of C/EBP-α downstream target genes (e.g.TGFβ) and distal target engagement in WBCs (e.g.IL-6, NF-κB). **Results:** 19 participants have been treated across 5 dose levels (28-130 mg/m^2): 13M/6F, median age 67 yrs (range 27 - 80), ECOG PS 0/1: 9/10. Tumour types include HCC (13), colorectal (4) and fibrolamellar (2). The most common treatment-related AEs (all grades/grade 3) include fatigue (9/1), diarrhoea (5/0), AST increase (5/1), low platelets (2/1) hyperbilirubinaemia (5/1) and hypophosphataemia (4/1). Maximum tolerated dose has not yet been reached. Serum PK analysis shows a terminal half life of $>$ 24 hrs, with dose proportional C_{max} and AUC. Analysis of WBCs showed a significant increase of C/EBP-α expression during treatment providing evidence of target engagement. Of 10 evaluable pts with HCC, 4 pts have had SD$\geq$ 4months, with one patient having an ongoing PR for 18 months associated with 73% decrease in tumour volume and reduction in IL-6, NF-κB and IFN-γ. **Conclusions:** Once weekly MTL-CEBPA therapy was well tolerated, shows promising PD and initial clinical response in patients with advanced HCC. Updated results for the dose escalation will be presented. Clinical trial information: NCT02716012.

2510 Poster Discussion Session; Displayed in Poster Session (Board #336), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 3:00 PM-4:15 PM

Results of the first-in-human study of ABBV-075 (mivebresib), a pan-inhibitor of bromodomain (BD) and extra terminal (BET) proteins, in patients (pts) with relapsed/refractory (R/R) solid tumors. *First Author: Sarina Anne Piha-Paul, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: BDs are protein domains that bind to acetylated histone tails, leading to upregulation of target genes driving oncogenesis. Inhibition of the BET family prevents assembly of the macromolecular complex and its transcriptional response. ABBV-075 is a pan-BET inhibitor that induces death in cell lines and tumor growth inhibition in xenograft models. This first-in-human, phase 1, two-part study (NCT02391480) assessed the safety and pharmacokinetics of ABBV-075 in pts with advanced tumors. Results from the dose escalation part in pts with solid tumors are reported. **Methods:** The dose escalation part of this open-label study enrolled adult pts with R/R solid tumors in a 3+3 fashion. Endpoints included maximum tolerated dose, recommended phase 2 dose (RP2D) at different ABBV-075 dosing schedules (daily, Monday/Wednesday/Friday [MWF], or 4 days on/3 off [4/7]), safety and preliminary efficacy. **Results:** As of Dec 2017, 72 pts with solid tumors enrolled in the dose escalation cohort. Most common tumors were: uveal/choroidal melanoma (n = 10); breast (n = 8); pancreatic (n = 6); head and neck (n = 5); and prostate (n = 3). Median age was 61.5 years (range 23–83); median treatment duration was 7.6 weeks (range 0.9–39.6). In total, 23, 27, and 22 pts entered the daily, MWF and 4/7 schedules. Overall, 71 pts (98.6%) reported ≥1 treatment-emergent adverse events (TEAEs); thrombocytopenia (56.9%), dysgeusia (48.6%), fatigue (43.1%) and nausea (34.7%) were most common. Grade 3/4 TEAEs were reported in 52 pts (72.2%); thrombocytopenia (30.6%) and anemia (15.3%) were most common; 11 pts died (none considered study drug related). Dose-limiting toxicities included thrombocytopenia, fatigue, aspartate aminotransferase elevation, gastrointestinal bleed and hypertension. The RP2D is 1.5 mg for the daily schedule, 2.5 mg for 4/7 and 3 mg for MWF. Of 65 evaluable pts, 25 pts (38.5%) had stable disease and 40 pts (61.5%) had progressive disease. Median progression-free survival was 1.8 months (95% CI: 1.8, 1.9). **Conclusions:** ABBV-075 has a tolerable safety profile and led to stable disease in some pts with malignant solid tumors. Clinical trial information: NCT02391480.

Ph 1 study of MRG-106, an inhibitor of miR-155, in CTCL. *First Author: Francine M. Foss, Yale Cancer Center, Woodbridge, CT*

Background: MRG-106 is an inhibitor of miR-155, a microRNA with a strong link to CTCL pathogenesis. The goals of this FIH study are to evaluate the safety, tolerability, PK, and efficacy of MRG-106 in mycosis fungoides (MF) patients (pts). **Methods:** This Ph 1 trial evaluated MRG-106 given via intralesional injection (75 mg/dose), subcutaneous or IV rapid bolus injection, or 2-hour IV infusion (300, 600 or 900 mg/dose). Pts must have MF stage I-III with plaques and/or tumors and could remain on concurrent stable CTCL therapy. Pts received 6 doses (SC/IV) in the first 26 days of the study followed by weekly or bi-weekly doses. Safety was monitored by physical exams, clinical lab tests, and reported adverse events (AEs). Efficacy was assessed by CAILS and by the modified Severity Weighted Assessment Tool (mSWAT). The effect of MRG-106 on quality of life was assessed by Skindex-29. **Results:** 36 subjects (20M/16F, median age 63 yrs) have been on study for up to 17 months (as of 25Jan2018). No serious AEs have been attributed to MRG-106. Most common AEs in ≥ 15% of subjects were: fatigue, neutropenia, injection site pain, nausea, pruritus, and headache. Two AEs were deemed DLTs: Gr3 worsening pruritus and Gr 3 tumor flare. MTD has not yet been reached. In the SC/IV cohorts, 26/29 evaluable subjects had improvement in mSWAT score. Skin improvements were observed as early as the first assessment (Day 17). Best improvements were after ≥ 1 month. All 8 pts (across all doses with SC or IV infusion) who achieved ≥ 50% reduction in mSWAT and received $>$ 2 treatment cycles, maintained response for ≥ 4 months. 4/5 pts treated at the 300 mg IV infusion dose had ≥ 50% mSWAT improvement. The overall skin response in pts who received MRG-106 as monotherapy or MRG-106 with concurrent stable therapy were not significantly different. Reductions in Skindex-29 total score correlated to reductions in mSWAT score during the treatment phase. **Conclusions:** These preliminary results suggest that MRG-106 is well-tolerated, has clinical activity, and has potential to impact MF quality of life. These encouraging data support the continued investigation of MRG-106 in this population. The study is expanded to enroll pts with other hematologic malignancies in which miR-155 is elevated and relevant, including CLL, DLBCL, ATLL. Clinical trial information: NCT02580552.

Single agent activity of U3-1402, a HER3-targeting antibody-drug conjugate, in breast cancer patients: Phase 1 dose escalation study. *First Author: Takahiro Kogawa, Department of Breast and Medical Oncology, National Cancer Center Hospital East, Chiba, Japan*

Background: U3-1402 is a human epidermal growth factor receptor 3 (HER3)-targeting antibody-drug conjugate (ADC) of high drug-to-antibody-ratio (DAR: 7 to 8) with a novel linker and topoisomerase I inhibitor payload. HER3 is overexpressed in a variety of cancers, including breast, lung, colorectal, ovarian, prostate and urothelial cancer. This ongoing, Phase 1/2 study (NCT02980341) of U3-1402 in HER3-expressing metastatic breast cancer (MBC) is divided into three parts: dose escalation (Part 1), dose finding (Part 2), and dose expansion (Part 3). **Methods:** In Part 1 of the ongoing study, the dose of U3-1402 was escalated based on dose-limiting toxicity data, guided by the modified Continuous Reassessment Method (mCRM). U3-1402 was administered via intravenous (IV) infusion in 21-day cycles. The primary objectives are to determine safety and tolerability of U3-1402, the maximum tolerated dose (MTD), and the recommended dose for Phase 2. AEs, PK, ORR per RECIST v1.1, and durability of responses were assessed. Efficacy-evaluable patients (pts) received at least one dose of U3-1402 and had pre- and post-treatment tumor assessments. **Results:** As of December 28, 2017, 21-evaluable pts (female, median age 59 years, ECOG 0-1, and $\geq$ 2 previous treatment regimens) have received U3-1402 at dose levels between 1.6 mg/kg to 8.0 mg/kg. Reversible Grade 3/4 thrombocytopenia, and Grade 3/4 liver enzyme increase as dose-limiting toxicities were observed in 4 (19%) and 2 (9.5%) pts respectively. The most common treatment-related adverse events were nausea (71.4%), vomiting (47.6%), and decreased appetite (47.6%). ORR was 33% and DCR (CR+PR+SD) was 95%. Three pts (14%) discontinued due to PD and 1 pt discontinued due to Grade 2 pneumonitis. Seventeen pts (80%) remain on treatment, including 6 pts (28%) who have remained on treatment for more than 6 months. HER3 IHC has been evaluated in 294 breast cancer pts, 87 (30%) showed high levels of HER3 expression. **Conclusions:** In a preliminary analysis of 21 pts, U3-1402 exhibits antitumor activity in previously treated HER3 expressing MBC pts and treatment is associated with a manageable safety profile. Clinical trial information: NCT02980341.

A phase 1 study of the next-generation ALK/ROS1/TRK inhibitor ropotrectinib (TPX-0005) in patients with advanced *ALK/ROS1/NTRK+* cancers (TRIDENT-1). *First Author: Alexander E. Drilon, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Pts with *ALK*/*ROS1*/*NTRK* fusion-positive cancers can develop on-target TKI resistance [e.g. solvent front mutations (SFMs)] and/or central nervous system (CNS) relapse. Ropotrectinib is a potent next-generation *ALK/ROS1/TRK* TKI designed to inhibit SFMs in addition to most clinically relevant resistance mutations. **Methods:** Phase I eligible pts had *ALK*, *ROS1*, or *NTRK1-3* fusion-positive advanced solid tumors and were TKI-naïve or TKI pre-treated. Pts with treated/untreated asymptomatic brain mets were allowed. Dose escalation followed a 3+3 design. **Results:** As of Jan 2, 2018, 65 pts (28 *ALK+,* 29 *ROS1+,* and 8 *NTRK+*) received at least 1 dose of ropotrectinib. The most common tumor was NSCLC (83%). The median # of prior chemo- or immune-therapy was 1 (range 0-9). Many pts were TKI pre-treated (86% of *ALK+* had $\geq$ 2 prior TKIs, 66% of *ROS1+* and 50% of *NTRK+* had $\geq$ 1 prior TKIs). 23 pts (35%) had baseline CNS metastases, including 52% with untreated CNS disease. Pts were treated over 5 dose levels/schedules (40–240 mg QD & 160 mg BID). The majority of AEs were G1-2. Treatment-related AEs ($>$ 10% of pts) included: dysgeusia (38%), dizziness (35%), paresthesia (24%), nausea (12%), anemia, constipation, fatigue, and oral numbness (11% each). DLTs occurred in 2 NSCLC pts: G3 dizziness at 240 mg QD (resolved with dose reduction) and G3 dyspnea/hypoxia at 160 mg BID (resolved with drug discontinuation). The MTD has not been reached. Dose escalation is ongoing. Confirmed partial responses (cPR, RECISTv1.1, n = 8) were observed in TKI-naïve or TKI pre-treated ROS1+/NTRK+ pts at all dose levels. These include pts with acquired SFM+ tumors (1 entrectinib-refractory NTRK3 G623E+, 1 crizotinib-refractory ROS1 G2032R+ pt with untreated CNS mets). The median duration on study of cPRs was 6.7 mos (range 2.6-9.9+ mos), and 88% (7/8) of responses are ongoing. Of the 16 ALK+ pts completed 2 cycles of ropo, 4 had confirmed SD (4 cycles) as best response at data cutoff. **Conclusions:** Ropotrectinib was well-tolerated and exhibited both intra- and extra-cranial clinical activity in TKI-refractory *ROS1+* and *NTRK+* pts with SFM-containing tumors. Clinical trial information: NCT03093116.

First-in-human study of DS-6051b in patients (pts) with advanced solid tumors (AST) conducted in the US. *First Author: Kyriakos P. Papadopoulos, South Texas Accelerated Research Therapeutics, San Antonio, TX*

Background: DS-6051b is an oral, small molecule receptor tyrosine kinase inhibitor with high affinity for ROS1 and NTRK kinases. Preclinical studies demonstrated activity against tumors harboring ROS1 or NTRK fusion genes. We report results from the dose escalation (ESC) and food effects (FE) portion of a phase 1/1b study of DS-6051b with follow-up through October 2017. **Methods:** Pts aged $\geq$18 y with ASTs harboring ROS1 and NTRK mutations/fusion genes or with neuroendocrine tumors (NET) or with tumor-induced pain (TIP), regardless of ROS1/NTRK status, were eligible. Pts with ROS1 non-small cell lung cancer (NSCLC) progressing on crizotinib (CRZ) or $>$ 1 ROS1 inhibitor were included. Primary objectives: determine the maximum tolerated dose (MTD), assess safety/tolerability (ESC) and determine FE on the pharmacokinetics (PK) of a single 400-mg daily (QD) DS-6051b dose with/without food. PK and antitumor activity were also assessed. A design of accelerated titration followed by modified continuous reassessment method and escalation with overdose control was used (50–1200 mg QD or 400 mg twice daily). Tumor assessments were every 3 cycles by RECIST 1.1. **Results:** In ESC, 35 pts (n = 14 NET; n = 9 TIP; n = 2 NET/TIP; n = 10 AST with ROS1/NTRK [n = 1 NTRK fusion; n = 9 ROS1 fusion including 7 NSCLC with prior CRZ]) enrolled, with 31 tumor evaluable. Dose-limiting toxicities (grade [G] 3 increased transaminases) occurred in 2 pts (1200 mg QD dose); 800 mg QD was the MTD. TEAEs G $\geq$3 occurred in 69% (overall) and 31% (drug-related) and all serious TEAEs in 20% (overall) and 9% (drug-related) of pts. Most common TEAEs were gastrointestinal disorders (89%); the majority (71%) G1/2. Peak concentration (C_{max}) and AUC increases were generally dose-proportional. Of 6 tumor evaluable NSCLC ROS1 pts with prior CRZ, 2 had partial response (PR) and 2 had stable disease (SD). Two other pts (n = 1 NTRK fusion thyroid cancer; n = 1 NET) had PR. Prolonged SD (6.9–27.2 months) was observed in 4 (40%) of 10 tumor-evaluable NET pts. In FE (n = 11), food intake had a modest PK effect: C_{max} and AUC increased by 30-45%. **Conclusions:** DS-6051b was well tolerated up to 800 mg QD. The observed efficacy signal in targeted populations warrants further evaluation. Clinical trial information: NCT02279433.

A phase I study of AL101, a pan-NOTCH inhibitor, in patients (pts) with locally advanced or metastatic solid tumors. *First Author: Anthony B. El-Khoueiry, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: Notch signaling can be deregulated in human cancer. AL101 (formerly BMS-906024), a gamma secretase inhibitor that potently inhibits all Notch receptors, was evaluated. The primary objective was safety and tolerability of multiple IV doses of AL101 and to establish a RP2D. **Methods:** Pts with advanced tumors refractory to standard therapies were included. Primary and secondary endpoints included safety, pharmacokinetics (PK), pharmacodynamics (PD), and anti-tumor activity. Cohorts were administered escalating doses of AL101 IV weekly (QW) or q 2 weeks (Q2W) using a 3+3 design, with expansion at the MTD in TNBC, NSCLC, and selected other tumors with reported Notch activation. The DLT period was 4 weeks (4 doses QW or 2 doses Q2W). PD markers of Notch activity, including HES1 mRNA, were evaluated in serial whole blood. **Results:** As of 1Feb2018, preliminary data are available on 94 pts dosed at 0.3 mg to 8.4 mg QW, and 4 mg to 6 mg Q2W. The MTD for QW was 4 mg with 0 DLTs in 7 evaluable pts; DLTs occurred at 8.4 mg QW (Gr 3 infusion reaction, Gr 3 vomiting, Gr 5 liver failure) and 6 mg in de-escalation (Gr 3 vomiting/lipase elevation, Gr 3 diarrhea [n = 3]). The MTD for Q2W was 6 mg, with 1 DLT in 6 evaluable pts (Gr 3 diarrhea). In escalation/expansion at the QW MTD (n = 43), Gr 3 or higher related AEs were: hypophosphatemia (42%), diarrhea (16%), hypokalemia (7%), and anaphylaxis, anemia, AST increase, nausea, pruritus, and vomiting (2% each). There were dose related increases in exposures over 0.3 to 8.4 mg, and the mean plasma half-life following 4 doses QW was 67 - 148 hours, supporting QW dosing. Dose related reduction of HES1 mRNA was seen with $>$ 80% peak inhibition and $>$ 50% inhibition sustained over several days at QW doses of 4 mg and higher. Objective responses were seen in 4 pts (RECIST v1.1): gastroesophageal junction adenocarcinoma (n = 1, 1 cCR ongoing $>$ 1 y), desmoid tumor (n = 3, 2 cPR, ongoing $>$ 1 y, $>$ 3 y), adenoid cystic carcinoma (n = 2, 1 cPR with PD at 8 m). SD was best response in 9 pts (9.6%). **Conclusions:** AL101 at the RP2D was generally well-tolerated and demonstrated sustained Notch inhibition as well as clinical activity across different tumor types. Future trials will evaluate AL101 in tumors with Notch activating mutations. Clinical trial information: NCT01292655.

2516 Poster Discussion Session; Displayed in Poster Session (Board #342), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 3:00 PM-4:15 PM

Phase I trial of z-endoxifen with estrogen receptor imaging in adults with advanced hormone receptor–positive solid tumors including desmoid and gynecologic tumors. *First Author: Naoko Takebe, NCI/ NIH, Elkridge, MD*

Background: Differential response to tamoxifen observed in patients (pts) with hormone receptor-positive cancer may be due to variations in tamoxifen metabolism from CYP2D6 genetic polymorphisms that limit exposure to the active metabolite, z-endoxifen (Z). We conducted a phase 1 clinical trial (3+3 design) with estrogen receptor imaging to determine the safety, MTD, and pharmacokinetics (PK) of oral Z. **Methods:** Adults with refractory gynecologic tumors, hormone-positive breast or other solid tumors, or desmoid tumors were eligible with ECOG performance status of 0-2 and adequate organ functions. Z was administered at 20, 40, 60, 100, 140, 200, 280, and 360 mg q day on a 28-day cycle. Estrogen receptor imaging with 16 alpha-[^{18}F]-fluoro-17 beta-estradiol (FES)-PET was performed before dosing and, if positive, repeated during C1W1. **Results:** Median age of the 40 pts enrolled was 60 (range 21-80 yr) and 90% were female. MTD was not reached up to the targeted maximum dose of 360 mg/day. Of the 38 pts evaluable for response, 2 (fallopian tube and breast) had partial responses and 9 had 6+ cycles of stable disease. Pts stayed on study for 1-47+ cycles (average, 6 cycles; median, 2.5 cycles); two pts remain on treatment. Grade 3/4 adverse events occurring in ≥5% of pts were hypertension (13%), hyponatremia (8%), hypophosphatemia (8%), neutropenia (8%), dehydration (5%), and elevated ALT (5%). Mean Z plasma levels increased linearly with administered dose. Increases were seen in mean D1 C_{max} (68.6 to 1309 ng/mL) and $AUC_{0\text{-}24}$ (1084 to 20546 ng/mL•hr) between doses of 20 and 360 mg/day. The elimination $t_{1/2}$ was 30.6-55.9 hr, based on the AUC accumulation ratio of 2.4-3.9 over the 28-day dosing period. FES-PET from 9 pts with FES-positive lesions demonstrated a 2%-76% reduction in average FES standard uptake values following 2-5 days of Z. **Conclusions:** We established a targeted maximum dose of 360 mg/day Z and evidence of antitumor activity was observed. Oral Z administration produces Z plasma exposures well above those obtained after therapeutic doses of tamoxifen. Clinical Trial Information: NCT01273168. Supported in part by NCI Contracts CM52206 and HHSN261200800001E. Clinical trial information: 01273168.

2517 Poster Discussion Session; Displayed in Poster Session (Board #343), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 3:00 PM-4:15 PM

First-in-human, first-in-class phase 1a study of BXQ-350 for solid tumors and gliomas. *First Author: Olivier Rixe, University of New Mexico Cancer Center, Albuquerque, NM*

Background: BXQ-350 is a novel agent composed of the multifunctional, lysosomal activator protein Saposin C and phosphatidylserine. BXQ-350 demonstrated antitumor effects *in vitro* and *in vivo*, particularly in glioma and pancreatic cancer models. **Methods:** A phase 1a dose-escalation trial (NCT02859857; Phase 1b ongoing) was conducted in refractory solid tumors/high-grade glioma (HGG) patients (Pt) by administering escalating IV BXQ-350 doses of 0.7, 1.1, 1.4, 1.8, or 2.4 mg/kg on days 1-5, 8, 10, 12, 15, 22 (cycle 1) and at 28-day cycles thereafter. Response was assessed at day 113 by RECIST or RANO. **Results:** 17 Pt (age 24-67) with a median 7 (range, 2-12) prior systemic therapies completed a median 2 (range, 1-6) cycles without DLTs or treatment-related serious adverse events (AEs). Moderately severe related AEs occurred in 3 (100%), 1 (33%), 1 (33%), and 2 (25%) Pt at 1.1, 1.4, 1.8, and 2.4 mg/kg cohort doses, respectively. The most common treatment-related AEs was transient fatigue ($n = 4$, 23.5%). At 2.4 mg/kg, 1 Pt had moderate blood pressure elevation. Best response in 7 Pt completing to day 113 was 1 PR (appendiceal carcinoma) at 2.4 mg/kg, and 6 SD (1 HGG Pt at 0.7 mg/kg had stable disease >12+ months, and 6 had improved day 113 RANO/RECIST). BXQ-350 pharmacokinetics was dose proportional with half-life and Cmax, consistent with preclinical data. **Conclusions:** BXQ-350 showed clinical activity in heavily pre-treated patients with advanced solid and brain tumors. BXQ-350 has a tolerable safety profile with no significant DLT at the highest planned dose, supporting continued monotherapy dose expansion at 2.4 mg/kg. Clinical trial information: NCT 02859857.

A phase Ia/Ib trial of the DNA-PK inhibitor M3814 in combination with radiotherapy (RT) in patients (pts) with advanced solid tumors: Dose-escalation results. *First Author: Baukelien Van Triest, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: DNA-dependent protein kinase (DNA-PK), regulates one of the major pathways responsible for repair of DNA double-strand breaks. The combination of RT and DNA-PK inhibition (DNA-PKi) has been shown to be synergistic in preclinical studies. The purpose of this phase I trial is to explore the safety, tolerability, pharmacokinetic (PK) profile, and clinical activity of M3814 administered together with RT (Arm A) and chemo-RT (CRT; Arm B). Results for Arm A are reported. **Methods:** Pts with tumors or metastases in the head and neck region or thorax in need of palliative RT (30 Gy in 10 factions) are enrolled in the dose escalation part Ia of Arm A to receive M3814, starting dose 100 mg. Dose escalation is aided by a Bayesian logistic regression model. Dose-limiting toxicity (DLT) is evaluated up to 3 weeks after RT. Rich PK sampling is taken during treatment. Tumor evaluation is performed every 6 weeks up to 6 months and every third month thereafter. **Results:** 16 pts had been enrolled, 100 mg (N = 7), 200 mg (3) and 400 mg (6). The most frequent adverse events (AEs) were fatigue (n = 12), nausea (8), constipation, decreased appetite, dysphagia, mucosal inflammation/stomatitis (6), vomiting (5), back pain, chest pain, diarrhea, radiation skin injury, and weight decreased (4). All pts completed treatment (> 80% of specified dose) and no pts discontinued due to DLTs. Four DLTs were reported: grade 3 mucositis lasting > 7 days in 3 pts (100 and 400 mg) and odynophagia in one pt (400 mg). All pts with DLTs recovered without sequelae. One fatal suspected unexpected serious AE considered as radiation pneumonitis occurred. Preliminary efficacy: in field response: one pt had pCR, 4 PR, 7 SD, and 3 have not yet been evaluated one pt was not evaluable. PK was like an earlier first-in-man study, including high inter-subject variability. **Conclusions:** M3814 is well tolerated at doses of 100 and 200 mg QD as part of a palliative treatment combination with RT. Since 2 DLTs were seen at 400 mg QD, the therapeutic window will be further evaluated based on toxicity profile and PD data. Currently, M3814 300 mg QD is being explored. Updated safety and efficacy data will be presented Clinical trial information: NCT02516813.

2519 Poster Discussion Session; Displayed in Poster Session (Board #345), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 3:00 PM-4:15 PM

First-in-human phase I study of JPH203, L-type amino acids transporter 1 inhibitor, in patients with advanced solid tumors. *First Author: Naohiro Okano, Department of Medical Oncology, Kyorin University Faculty of Medicine, Tokyo, Japan*

Background: The uptake of amino acids is essential for cancer growth. The L-type amino acid transporter 1 (LAT1) is overexpressed in various cancers, and the LAT1-mediated uptake of plasma-free amino acids (PFAA) plays a critical role in cancer growth. JPH203 is a novel, selective LAT1 inhibitor. **Methods:** A first-in-human phase I study of JPH203 was designed to determine the safety, maximum-tolerated dose (MTD), and recommended phase II dose (RP2D) of JPH203. This study evaluated the anti-tumor effects, progression-free survival, pharmacokinetics (PK), and pharmacodynamics (PD) of JPH203 and analyzed PFAA levels. JPH203 was administered intravenously for seven days, at planned doses ranging from 12–110 mg/m^2, followed by a 21-day rest, in patients with advanced solid tumors that were refractory to standard therapies. Before treatment, we confirmed the safety of a single dose of JPH203. Dose-limiting toxicity was evaluated during the first cycle, using a 3+3 design. **Results:** Seventeen patients were enrolled. One patient discontinued JPH203 after a single dose because of tumor progression. Grade 3 liver dysfunction occurred in one of six patients who received 60 mg/m^2 and the first patient received 85 mg/m^2. Although we determined that the MTD was 60 mg/m^2, the PK/PD profile and anti-tumor effects supported an RP2D of 25 mg/m^2. Common treatment-related adverse events were increased ALT/AST, malaise, nausea, hypertension, and grade 1 or grade 2 fevers. A partial response was achieved in a patient with biliary tract cancer (BTC) who continued JPH203 for two years without disease progression. Disease control was observed in three of five patients with BTC, and in two of six with colorectal cancer. LAT1 substrates, PFAA and branched-chain amino acids (BCAA), were higher in patients with BTC than in those with other cancers. All patients with disease control had a body mass index (BMI) greater than the median BMI of 20.5 kg/m^2. Furthermore, BCAA levels were associated with BMI. **Conclusions:** At the RP2D of 25 mg/m^2, JPH203 was well tolerated and showed promising results against BTC. This phase I study also suggests that BMI and BCAA might predict the efficacy of targeted cancer chemotherapy. Clinical trial information: UMIN000016546.

First-in-class phase I study evaluating MP0250, a VEGF and HGF neutralizing DARPIN molecule, in patients with advanced solid tumors. *First Author: Analia Azaro, Vall d'Hebron University Hospital, Barcelona, Spain*

Background: The VEGF/VEGFR and HGF/c-MET pathways are key mediators of the growth of solid tumours. MP0250 is a first-in-class, tri-specific DARPin compound neutralizing VEGF-A and HGF as well as binding to human serum albumin to increase plasma half-life and potentially enhance tumour penetration. **Methods:** Patients with advanced solid tumours were enrolled in a 3+3 dose escalation part (cohorts 1-5) and then in a single-arm dose expansion part (cohorts 6-7) (NCT02194426). The primary objectives were to evaluate safety, tolerability, the recommended biological dose, the maximum tolerated dose (MTD), the dose-limiting toxicities (DLTs) and the pharmacokinetics of MP0250. The secondary objective was to characterize the immunogenicity of MP0250. **Results:** From August 2014 until January 2018, 45 patients were enrolled in 7 different cohorts: cohort 1 to 5 (3 hr infusion, q2w): 0.5 mg/kg; 1.5 mg/kg; 4 mg/kg; 8 mg/kg, and 12 mg/kg; dose expansion cohorts: cohort 6 (1 hr infusion, q2w): 8 mg/kg and cohort 7 (1 hr infusion, q3w): 12 mg/kg. Patients were heavily pre-treated with a median of 3.6 lines of previous treatment (1-13). Median number of MP0250 infusions were 6.5 (1-31). Most common any-grade TEAEs were: hypertension 67% (grade 3: 37%), proteinuria 49% (grade 3: 4.4%), diarrhoea 36% (grade 3: 2.2 %), nausea 36% and fatigue 31% (grade 3: 2.2%). Two out of 5 patients in the 12 mg/kg q2w had a DLT (hypertension, nephrotic syndrome, GI bleeding). Additional DLTs (1 patient per cohort) occurred at 4 mg/kg q2w (left ventricular failure), 8 mg/kg q2w (creatinine and urea increase and thrombocytopenia), 8 mg/kg 1 hr infusion q2w (nephrotic syndrome) and 12 mg/kg q3w (nephrotic syndrome). Based on these data, the MTD for MP0250 was determined to be 8 mg/kg q2w or 12 mg/kg q3w. Two patients achieved a partial response, 44 % of patients were on MP0250 treatment for 3 months, 9 % for 6 months and 1 patient for over 1 year. **Conclusions:** In this FIH study, MP0250 was well tolerated with most AEs being consistent with profound inhibition of the VEGF pathway. Signs of single agent antitumour activity were observed and MP0250 is being further developed in lung cancer and multiple myeloma. Clinical trial information: NCT02194426.

2521 Poster Session (Board #347), Mon, 8:00 AM-11:30 AM

Can VEGFA and ICAM1 polymorphisms predict response to bevacizumab? *First Author: Apostolos Papachristos, Laboratory of Pharmacokinetics, Department of Pharmacy, School of Health Sciences, University of Patras, Rio-Patras, Greece*

Background: Most targeted treatments are associated with biomarkers, predictive of drug response. Although bevacizumab is widely used, there are still no available biomarkers. Given the need of individualized treatment approaches and the high cost of Bevacizumab, it is necessary to find biological predictors of response. The present study investigated the role of selected single nucleotide polymorphisms (SNPs) in *VEGFA* (Vascular Endothelial Growth Factor) and *ICAM1* (Intracellular Adhesion Molecule 1) genes as response biomarkers. **Methods:** 46 patients with metastatic colorectal cancer (mCRC) treated with Bevacizumab and chemotherapy (fluoropyrimidines/oxaliplatin or irinotecan) as first-line treatment were enrolled. Selected *VEGFA* (rs2010963, 1570360, rs699947) and *ICAM1* (rs5498, rs1799969) SNPs were detected using PCR-based Sanger sequencing (KAPABIOSYSTEMS, MA, USA). Statistical analysis was done using ANOVA and Kaplan-Meier Survival Analysis on SPSS software. Ethical committee of University Hospital of Patras approved study. **Results:** 61% of patients were males and 39% females, mean age was 64.5 years (31-86). *ICAM1* genotype analysis was available in 27 patients. For rs699947 (A > C), the % genotype frequencies were 29.8% AA, 23.4% A C , and 46.8% CC, while the rs1570360 (A > G) ones were determined to be equal to 10.6% AA, 23,4% A G , and 66% GG. For rs2010963 (C > G), 12.7% CC, 27.7% CG , and 59.6% GG were obtained. In the case of ICAM1, rs5498 AA, rs5498 AG and rs5498 GG were present with % frequencies of 37%, 37% and 26% , respectively. For rs1799969 (G > A) , 85% GG, and 15% AG. Mean Progression Free Survival (PFS) and Overall Survival (OS) were 14 and 44 months, respectively. PFS was significantly longer in rs699947 AA (27.1 months, p = 0.039) and rs5498 GG (27.8 months, p = 0.018) carriers. Moreover, OS was significantly increased in rs2010963 GC carriers (59.5 months, p = 0.03). **Conclusions:** Our findings suggest that rs699947, rs5498, and rs2010963 serve as candidate response biomarkers. All three might be able to stratify patients, who may gain a long-term benefit towards the optimization of Bevacizumab therapy and achieving better-informed therapeutic outcomes.

2522 Poster Session (Board #348), Mon, 8:00 AM-11:30 AM

A phase I dose escalation study of hPV19, a novel humanized monoclonal antibody against vascular endothelial growth factor (VEGF), in patients with advanced solid tumors refractory to standard therapy. *First Author: Dongmei Ji, Department of Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: hPV19 is a novel inhibitory mAb against VEGF with unique binding site different from that of Bevacizumab. This phase 1 study aimed to determine its dose-limiting toxicity (DLT), maximum tolerated dose (MTD), safety and pharmacokinetics (PK) in patients with advanced solid tumors. **Methods:** This is a first-in-human study with a 3+3 design. Eligible patients received hPV19 on day 1 and were observed for DLTs for 21 days. Subsequent treatment was every 14 days until disease progression or toxicity. DLTs were defined as occurrence of grade 3 or above non-hematological or grade 4 hematological toxicities. Response was evaluated at week 8 and then every 8 weeks using RECIST criteria. Extension enrollment (n = 5) was planned at dose levels 2.5 mg/kg and 6 mg/kg. **Results:** From 08/23/2016 to 01/25/2018, 24 patients were enrolled (22 for toxicity study) to 6 dose levels: 0.3 mg/kg (n = 3), 1 mg/kg (n = 3), 2.5 mg/kg (n = 8), 4mg/kg (n = 3), 6mg/kg (n = 4) and 10mg/kg (n = 3, not included in PK or response assessment). The median age was 46.5 years old (range 29-70). No DLTs have been observed and MTD has not been reached. Common grade 3 toxicities were hypertension 22.7%, proteinuria 9%, and LFT abnormalities 9%. Common grade 1 or 2 toxicities were hypertension 13.6%, proteinuria 59%, epistaxis 22.7%, dysphonia 18.2%, LFT abnormality 59%, renal abnormality 27.3%, anemia 22.7%, leukopenia 18.2% and thrombocytopenia 18.2%. A linear AUC dose response with elimination mean serum half-life ($t_{1/2}$) of 66.88-156.09h (2.78-6.50 days) and C_{max} of 4.06 to 132.01μg/ml were observed between doses 0.3 mg/kg to 6 mg/kg. Low titres of anti-hPV19 antibody were detected in 3 patients at 0.3 mg/kg (n = 1) and 1 mg/kg (n = 2). Six patients (27.2%) had clinical response, including 1 PR (breast ca, 2.5mg/kg), and 5 SDs (colon ca x2, renal ca x2 and breast ca x1, at all dose levels). The median duration of response was 27 weeks (range 17-57 weeks). **Conclusions:** hPV19 is safe and tolerable with promising durable single agent activity in refractory solid tumors. The dose selected for phase Ib /phase II is 4 mg/kg every 2 weeks or 6 mg/kg every 3 weeks. Clinical trial information: CTR20160585.

2523 Poster Session (Board #349), Mon, 8:00 AM-11:30 AM

PK/PD properties of BI 836880, a vascular endothelial growth factor (VEGF)/angiopoietin-2 (Ang-2)-blocking nanobody, in patients (pts) with advanced/metastatic solid tumors. *First Author: Christophe Le Tourneau, Institut Curie, Paris, France*

Background: BI 836880 (q3w or qw, iv) was evaluated in two first-in-human, Phase I trials in pts with advanced/metastatic solid tumors. We report exploratory PK/PD analysis of these studies to support dose selection for further clinical development of BI 836880. **Methods:** PK/PD analysis used evaluable data from 23 pts treated over ≥1 cycle (14 q3w; 9 qw [pt accrual ongoing in the qw schedule to confirm the maximum tolerated dose]). Analytes were systemic BI 836880, free VEGF, free Ang-2 and total Ang-2. Levels of BI 836880 in plasma were analyzed using a LC-MS/MS method, via monitoring a unique peptide of BI 836880 (lower limit of quantification [LLOQ] 0.5 mg/L). Total and free systemic Ang-2 were analyzed using ELISAs (LLOQ 0.1 and 0.08 ng equivalents [ngeq]/mL). Free systemic VEGF was analyzed using ECLIA with LLOQ 2.7 pgeq/mL. Development of an assay for total VEGF is ongoing. DCE-MRI data, as PD markers, were evaluated in 8 pts. **Results:** BI 836880 plasma kinetics appeared dose-proportional over 40–1000 mg q3w and 40–180 mg qw, with accumulation ratios between 1 and 2.The geometric mean half-life of BI 836880 in the q3w schedule over all dose groups was 8.2 days (cycle 1; n = 12), 9.9 days (cycle 2; n = 7) and 14.3 days (cycle 4; n = 4). Required trough values (20 mg/L; predicted based on preclinical experiments) were achieved at doses ≥720 mg q3w.Predose free VEGF levels were 0.022 to 0.669 ngeq/mL. Predose free Ang-2 levels were 0.72 to > 15 ngeq/mL. Individual pt PK/PD profiles showed that free VEGF was below LLOQ at the lowest dose; free Ang-2 was blocked dose-dependently and was below LLOQ at doses ≥360 mg q3w or 120 mg qw. Both analytes remained below LLOQ at these doses even before the next treatment cycle. Total Ang-2 (the majority bound to BI 836880) increased 100- to 1000-fold above predose levels and for some samples to the upper LOQ (1000 ngeq/mL). K_{trans} (capillary permeability) decreases ≥20% were observed in 5/7 pts at the 720 mg q3w dose, including 3 with K_{trans} reduction > 40%. **Conclusions:** PK/PD analysis supported BI 836880 720 mg q3w as the biologically relevant dose. DCE-MRI analysis confirmed anti-angiogenic activity in the tumor at this dose. Clinical trial information: NCT02674152; NCT02689505.

2524 Poster Session (Board #350), Mon, 8:00 AM-11:30 AM

Evaluation of fixed-dose regimens of seribantumab in patients with solid tumors. *First Author: Bambang Adiwijaya, Merrimack Pharmaceuticals, Inc., Cambridge, MA*

Background: Seribantumab (MM-121) is an anti-ErbB3 human monoclonal antibody being tested as an anti-cancer therapy for patients with high expression of heregulin mRNA in NSCLC (SHERLOC study, 3g every 3 weeks [Q3W]+docetaxel) and in and in HR+/ HER2- metastatic breast cancer (mBC) (SHERBOC study, 3g every 2 weeks [Q2W]+fulvestrant). Here we aimed to evaluate seribantumab dose regimens based on PK and safety. **Methods:** Pharmacokinetics (PK) and safety were evaluated for fixed and weight-based dose: in NSCLC, 3 g Q3W vs. 20 mg/kg Q2W; in mBC, 3 g Q2W vs. 40 mg/kg loading dose, followed by 20 mg/kg QW. PK was quantified using nonlinear mixed effect with the following covariates: sex, race, age, weight, dose, study, and hepatic functions. Adverse events (AEs) were evaluated for associations to PK and weight: Grade 1+ and 3+ diarrhea, fatigue, hypokalemia, hypomagnesemia, nausea, pulmonary embolism, rash, stomatitis, and vomiting. **Results:** Seribantumab PK from 499 patients in 7 previous trials identified associations with sex and weight. Fixed and weight-based doses showed similar variability. With higher weight, weight-based dose resulted in higher exposure (average concentration [Cavg] and maximum concentration [Cmax]), and fixed dose resulted in lower exposure. Steady-state Cmax were higher with 3 g than with 20 mg/kg; these values were comparable to Cmax with 40 mg/kg. Steady-state Cavg were equal to or higher for fixed dose than comparable weight-based dose. All doses tested had minimum concentrations (Cmin) higher than the nonclinical target concentration of 100 mg/L. Among AEs evaluated, significant associations with seribantumab exposure were observed for G1+ diarrhea, fatigue, nausea, rash, and stomatitis. Weight-based dose showed higher AE rates with increasing weight. Fixed dose is predicted to reduce AE rates in high-weight patients and to increase AE rates in low-weight patients, with the latter rates still lower than those in patients with high weight dosed by weight. **Conclusions:** The recommended dose of seribantumab is 3 g Q3W+docetaxel in NSCLC and 3 g Q2W+fulvestrant in mBC. The fixed dose of seribantumab allows acceptable concentrations and safety profiles and potentially reduces drug waste and dosing errors.

2525 Poster Session (Board #351), Mon, 8:00 AM-11:30 AM

Pharmacokinetics of Hu5F9-G4, a first-in-class anti-CD47 antibody, in patients with solid tumors and lymphomas. *First Author: Balaji Agoram, Forty Seven, Inc., Menlo Park, CA*

Background: Hu5F9-G4 is a humanized monoclonal antibody targeting CD47, a "don't eat me" signal on cancer cells, that stimulates tumor cell phagocytosis and activates an anti-tumor T-cell response. The objectives of this analysis were to characterize the pharmacokinetics (PK) and anti-drug antibody (ADA) incidence of Hu5F9-G4 after single and multiple doses in patients with solid tumors and lymphomas. **Methods:** Data from a first-in-human Phase 1 study in 58 patients with advanced solid tumors and lymphomas (NCT02216409) were used for this analysis. Multiple intravenous (IV) doses in the range 0.1 – 30 mg/kg were given at once or twice weekly frequencies. Serum samples were collected in all subjects at various timepoints after first and subsequent doses. PK data were analyzed by a noncompartmental approach using the PKNCA package in R; population modelling analysis was done with NONMEM software. Presence of ADA was analyzed using a 3-tiered - screening, confirmatory, titre - approach. **Results:** At doses of 0.1 – 10mg/kg increases in maximum serum concentration (C_{max}) and area under concentration curve (AUC) of Hu5F9-G4 were greater than dose-proportional indicating nonlinearity in PK. The PK parameters were consistent with the presence of a CD47 antigen sink, which was saturated at doses ≥ 10 mg/kg. Above this dose level, increases in C_{max} and AUC were dose proportional and the half-life of the antibody was ~14 days – typical of human IgG4. Simulations with the model predicted that a maintenance dosing regimen of 30 mg/kg every other week from cycle 2 onwards would result in serum concentrations ≥200 μg/mL, a level where full CD47 receptor occupancy on blood cells was observed in this study and where preclinical efficacy has also been previously reported. ADA were confirmed in 2 subjects (3.4%) in this study but had no observable impact on the PK parameters. **Conclusions:** Hu5F9-G4 has PK properties typical of antibodies directed towards cell-surface receptors. Hu5F9-G4 exhibits nonlinear PK, typical of a receptor-targeted antibody, with doses ≥10 mg/kg saturating the antigen sink. The PK profile of Hu5F9-G4 is suitable for every other week maintenance dosing in solid tumor and lymphoma patients in Phase 2.

2526 Poster Session (Board #352), Mon, 8:00 AM-11:30 AM

A phase I study to evaluate safety, tolerability, pharmacokinetics and activity of oraxol in patients (pts) with advanced malignancies. *First Author: Wen Wee Ma, Mayo Clinic, Rochester, MN*

Background: Oraxol is an oral formulation of paclitaxel (PTX) co-administered with the potent, selective, poorly absorbed, P-glycoprotein inhibitor HM30181A (HM) that enhances the absorption of PTX. PK modelling of prior data showed fixed dose administration was feasible. The objectives were to determine the MTD and PK of Oraxol administered as a fixed dose for up to 5 consecutive days. **Methods:** Eligible pts had advanced solid tumors, ECOG PS ≤ 1 and adequate organ function. The dose escalation utilized the standard 3+3 design (Part 1) and then expanded to enroll additional pts at the MTD (Part 2). The treatment consisted of sequential administration of HM oral 15 mg then PTX oral 270 mg daily while fasting. Dose escalation was achieved by increasing the number of dosing days per week (2 to 5 days per week x 3 weeks then 1-week rest, per 4-week cycle). Pts were monitored for dose limiting toxicity (DLT) during the first cycle for dose escalation/de-escalation decisions. Adverse events (AEs) were assessed per CTCAE v4.03 and response by RECIST v1.1. **Results:** A total of 34 pts received treatment and were AEs evaluable. Twenty-one of 24 pts in Part 1 were DLT evaluable and 1 DLT (febrile neutropenia) occurred at the 5-day dose level. Ten additional patients were treated at the 5-day dose level in Part 2. The most common (≥30%) treatment-related AEs (TRAEs) were nausea, diarrhea, anorexia and vomiting. Serious TRAEs included febrile neutropenia, pneumonia and dehydration. Pre-medication with steroids/anti-histamines was not required and hypersensitivity reactions were not observed. Partial responses occurred in 2 pts at the 5-day dose level (salivary gland, ovarian cancers). The median Tmax was 1 to 2 hrs. PTX exposure (Cmax and AUC) was comparable following 2-5 days of treatment; with a Day 1 C_{max} ranging from 147 to 246 ng/mL and $AUC_{0\text{-}8hr}$ ranging from 369 to 800 ng*hr/mL. Plasma levels of HM/metabolite were minimal. **Conclusions:** The MTD was not reached and the highest planned dose level (HM 15 mg/PTX 270 mg x 5-day) was selected for expansion. Sequential oral administration of HM and PTX achieved clinically efficacious PTX level and showed evidence of anti-tumor activity. Clinical trial information: NCT01967043.

2527 Poster Session (Board #353), Mon, 8:00 AM-11:30 AM

A phase I clinical trial of hepatic arterial infusion of oxaliplatin and oral capecitabine, with or without systemic bevacizumab, for patients with advanced cancer and liver involvement. *First Author: Elena Fountzilas, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Hepatic arterial infusion (HAI) of chemotherapy is a treatment option for patients (pts) with cancer metastatic to the liver. We investigated HAI oxaliplatin combined with capecitabine +/- bevacizumab, in advanced cancer with liver involvement. **Methods:** Pts received HAI oxaliplatin (140 mg/m^2) and escalating doses of capecitabine (500, 750, and 1000 mg/m^2), with (Arm A) or without (Arm B) bevacizumab (10 mg/kg IV). A 3+3 dose design was used, followed by an expansion phase. **Results:** From 9/2009 to 2/2014, 61 pts (34 men, 27 women) were enrolled (Arm A = 44; Arm B = 17). Pts were treated in Arm B if they had contraindications to bevacizumab (n = 13) or if there was no spot available in Arm A (n = 4). The median age was 60 yrs (range, 20-88). The most common cancers were colorectal (22 pts), liver (13), pancreas (7), breast (4), and biliary tract (4). The median number of prior therapies was 3 (range, 1-12); 32 (53%) pts had previously oxaliplatin. Grade 3 diarrhea was the only DLT and occurred in 2 pts receiving 1000 mg/m^2 capecitabine. Thus, the MTD was HAI oxaliplatin 140 mg/m^2, capecitabine 750 mg/m^2, and bevacizumab 10 mg/kg. Common toxicities were anemia, thrombocytopenia, neutropenia, hypomagnesemia, and nausea/vomiting. Outcomes are shown in Table. Eleven (18%) pts remained on treatment for ≥6 months, including 4 (6.6%) pts who remained on treatment for ≥1 year. **Conclusions:** HAI oxaliplatin combined with capecitabine +/- bevacizumab was well-tolerated and was associated with favorable outcomes in selected pts. Clinical trial information: NCT01213238.

2528 Poster Session (Board #354), Mon, 8:00 AM-11:30 AM

Plinabulin (Plin), a small molecule with anti-cancer activity and a novel mechanism of action (MoA) in docetaxel (Tax)-induced neutropenia: Phase (φ) 2 results from a head-to-head comparison with Pegfilgrastim (Peg). *First Author: Douglas W. Blayney, Stanford Cancer Institute, Stanford, CA*

Background: Plin has clinical anticancer activity in combination with Tax (Mohanlal ASCO-SITC 2017,18). Plin prevented Tax-induced neutropenia in a post-hoc analysis of a φ 2 trial (Blayney ASH 2016). Plin is being studied in the prevention of chemotherapy(chemo)-induced neutropenia (CIN) induced by Tax/ adriamycin/ cyclophosphamide in BC, by gemcitabine/ abraxane in PC, by carboplatin/ pemetrexed/ pembrolizumab in NSCLC , and irinotecan in CRC. We report final results of the φ 2 portion of a prospective φ 2/3 trial of Plin for CIN compared with Peg (NCT03102606; Study BPI-2358-105). The 105 study is designed to demonstrate non-inferiority (NI) of Plin vs Peg for duration of severe neutropenia (DSN) in φ 3. **Methods:** Patients (Pts; n = 55) with lung cancer (NSCLC) were randomized to Tax 75 mg/ m2 day (D)1, and either Peg 6 mg D2 or Plin 5, 10, or 20 mg/ m2 D1. Plin was dosed on the same day of (30 min after) chemo. Absolute Neutrophil Count (ANC) was collected D1,2,3,6,7,8,9,10,15 and 21. Primary endpoints were DSN and grade (Gr) 4 neutropenia to establish recommended phase 3 dose (RP3D). The NI margin for DSN is 0.65 D. Hypertension (HT) was evaluated by semi-continuous BP measurement on D1. **Results:** DSN for Peg was 0.51 D and for Plin 0.54 D. Gr 3 HT was transient and not different among all groups ($p < 0.18$). Bone Pain occurred in 33% of pts with Peg and 11% with 20 mg/ m2 Plin. Clinical trial information: NCT03102606. **Conclusions:** Plin 20 mg/ m2, given 30 min after chemo is well tolerated, has less bone pain, and has similar myeloprotective effect vs Peg. Its post chemo recovery curve is shallower, broader and later than Peg, with median ANC staying within normal range, suggesting a different MoA to prevent CIN. Plin 20 mg/m2 is the RP3D based upon its protection against Gr 4 neutropenia and safety profile.

			Median ANC (cell count x10E9/L)*							
	Dose	Pts	D1	D6	D7	D8	D9	D10	D15	Gr 4 CIN %
Peg	6 mg	14	9.43	4.65	5.82	12.1	15.7	16.7	11.4	14
Plin	20 mg/m^2	14	7.39	4.25	3.57	2.69	2.25	2.41	3.97	14
Plin	10 mg/m^2	13	7.93	4.13	1.91	1.76	1.94	2.30	4.69	23
Plin	5 mg/m^2	14	7.63	3.57	1.73	1.33	1.42	1.95	3.21	21

* Normal range of ANC: 1.8 to 7.7 X 10^9 cells/L

2529 Poster Session (Board #355), Mon, 8:00 AM-11:30 AM

Phase 1/2a study of BAL101553, a novel tumor checkpoint controller (TCC), administered as 48-hour infusion in adult patients with advanced solid tumors. *First Author: Markus Joerger, Cantonal Hospital St. Gallen, St. Gallen, Switzerland*

Background: BAL101553 is the prodrug of BAL27862, a small molecule TCC that binds microtubules and promotes tumor cell death by activation of the spindle assembly checkpoint. In a study of BAL101553 administered as a 2-h infusion on Days 1, 8 and 15 of a 28-day cycle (NCT01397929, Lopez et al. JCO 34, 2016; 2525), vascular toxicities were observed and appeared to be C_{max} related. Nonclinical models indicate that the antiproliferative effects of BAL27862 are AUC driven; this trial was intended to determine whether prolonged infusion reduces C_{max}-related toxicity and increases the AUC at the recommended phase 2 dose (RP2D) (NCT02895360, Joerger et al. JCO 2017; TPS2602). **Methods:** Patients with advanced solid tumors received 48-h infusions of BAL101553 using an elastomeric pump on Days 1, 8 and 15 of consecutive 28-day cycles using a 3+3 dose-escalation design to determine the maximum-tolerated dose (MTD). During Cycle 2, patients received BAL101553 orally QD (Days 15–21) instead of IV in order to assess oral bioavailability. Adverse events (AEs) were assessed by CTCAEv4.03 grade (G); tumor response by RECIST 1.1 every two cycles; pharmacokinetics were assessed during the first two cycles. **Results:** Phase 1 enrollment was completed with 20 patients (7M/13F; median age 60 years; median 3 prior chemotherapies) receiving IV BAL101553 at doses of 30, 45, 70 or 90 mg/m^2. Dose-limiting toxicities included transient G3 hypotension at 70 mg/m^2 and reversible G3 hyponatremia, G3 neutropenia, G2 hallucinations and ataxia at 90 mg/m^2. There were no relevant vascular toxicities. Of 16 evaluable patients, one had a confirmed partial response (ovarian cancer) and one had stable disease for 6 months (endometrial cancer). BAL27862 exposures (AUC) were near dose-proportional. At 70 mg/m^2, the BAL27862 Cycle 1/Day 1 C_{max} was 144 ng/mL and AUC was 8580 ng.h/mL. Oral bioavailability was estimated to be > 80%. **Conclusions:** The MTD/RP2D of BAL101553 48-h infusion was 70 mg/m^2. At this dose the AUC/C_{max} ratio was ~4× higher compared to the 2-h infusion regimen at the RP2D of 30 mg/m^2. There were indications of potential clinical benefits in patients with ovarian and endometrial cancers. Clinical trial information: NCT02895360.

2530 Poster Session (Board #356), Mon, 8:00 AM-11:30 AM

Phase 1/2a study of once daily oral BAL101553, a novel tumor checkpoint controller (TCC), in adult patients with advanced solid tumors. *First Author: Juanita Suzanne Lopez, The Royal Marsden Hospital and The Institute of Cancer Research, Sutton, United Kingdom*

Background: BAL101553 is the prodrug of BAL27862, a small molecule TCC that binds microtubules and promotes tumor cell death by activation of the spindle assembly checkpoint. In a study of BAL101553 administered as 2-h infusions on Days 1, 8 and 15 of a 28-day cycle (NCT01397929, Lopez et al. JCO 34, 2016; abstr 2525), vascular toxicities (troponin increases/ ECG changes suggestive of microvascular myocardial injury and hypertension) were observed and appeared to be C_{max} related. Nonclinical models indicate that the antiproliferative effects of BAL27862 are AUC driven; this trial was designed to determine whether oral once-daily (QD) administration of BAL101553 reduces C_{max}-related toxicity and increases the AUC at the Recommended Phase 2 Dose (RP2D) (NCT02490800, Kristeleit et al. JCO 35, 2017; abstr 2532). **Methods:** Adult patients with advanced solid tumors received QD oral BAL101553 (28-day cycles) in a 3+3 dose-escalation design to determine the maximum tolerated dose (MTD). Adverse events (AEs) were assessed by CTCAEv4.03 grade (G); tumor response by RECIST 1.1 every 2 cycles; pharmacokinetics on Day 1 of Cycles 1 and 2. **Results:** Phase 1 enrollment completed with 26 patients (10M/16F; median age 62 y; median 3 prior chemotherapies) receiving oral BAL101553 at doses of 2–30 mg QD. BAL101553 was generally well tolerated at doses ≤16 mg, with one G3 event of increased alkaline phosphatase not considered clinically significant and G1/G2 events that did not show organ-specific patterns. Dose-limiting toxicities were seen at doses ≥20 mg: G3–4 hyponatremia, G3 hypokalemia and G2 hallucinations (all reversible). Of 19 efficacy-evaluable, 7 patients treated for ≥4 cycles (range 4-10) had stable disease (5/10 at ≥16 mg). BAL27862 exposure (AUC) was dose-related, almost dose-proportional. C_{max} levels were below those seen with 2-h infusions at the RP2D and there were no effects on blood pressure. At 16 mg, the BAL27862 Cycle 1/Day 1 C_{max} was 120 ng/mL and the estimated weekly exposure was 8400 ng.h/mL. **Conclusions:** The MTD of daily oral BAL101553 was 16 mg. At this dose, the weekly AUC is ~2-fold higher than that achieved at the RP2D for the weekly 2-h infusion. Vascular side effects were absent. Clinical trial information: NCT02490800.

2531 Poster Session (Board #357), Mon, 8:00 AM-11:30 AM

Investigation of profile-related evidence determining individualized cancer therapy (I-PREDICT) in heavily pre-treated patients: A role for combinatorial precision cancer therapy. *First Author: Jason K. Sicklick, Department of Surgery, University of California San Diego, San Diego, CA*

Background: With the increasing availability of large gene panels and cognate agents, we hypothesized that offering individualized combination therapies to patients with refractory cancers would improve outcomes. **Methods:** I-PREDICT (NCT02534675) is a prospective navigation trial (two centers: UC San Diego and Avera Cancer Institute). Comprehensive genomic profiling (CGP, Foundation Medicine; 315 genes), and, if possible, PD-(L)1 immunohistochemistry, tumor mutational burden and circulating tumor DNA were performed. A molecular tumor board discussed results immediately upon receipt, and emphasized use of customized, matched targeted/ immunotherapy combinations. Final decisions were the treating physician's choice. **Results:** Overall, 149 patients with advanced cancers were enrolled: 83 (55.7%) have been treated [73 matched (49.0%); 10 unmatched (16.7%)]. Diverse malignancies including gastrointestinal, hepatobiliary, gynecologic, and brain were represented. Median number of prior therapies = 2; median (range) of genomic alterations per patient = 4 (1-20). Each tumor had a unique genomic profile. The median (range) number of agents given was 2 (1-5), dosed individually on an N-of-1 basis. There were no drug-related deaths. We classified the patients based upon their treatment regimens' molecular Matching Score [number of genomic alterations matched/total number of characterized DNA alterations (> 50%: "high," n = 28; ≤50%: "low," n = 55 (includes unmatched (score = 0))]. High vs low Matching Scores independently correlated with better outcomes: SD≥ 6 months/PR/CR, 50% versus 22% (P = 0.03); median PFS (6.5 vs 3.1 months; P = 0.0004); median OS (not reached vs 10.2 months; P = 0.04) (all multivariate). **Conclusions:** The use of customized, multi-drug combinations targeting > 50% of identified genomic alterations recommended by timely molecular tumor boards and based on CGP was safe and associated with improvements in all outcome parameters. These findings underscore the feasibility and the importance of designing precision oncology trials that emphasize tailored combinations rather than monotherapies. Clinical trial information: NCT02534675.

2532 Poster Session (Board #358), Mon, 8:00 AM-11:30 AM

Palbociclib (P) in patients (Pts) with pancreatic cancer (PC) and gallbladder or bile duct cancer (GBC) with *CDKN2A* alterations: Results from the Targeted Agent and Profiling Utilization Registry (TAPUR) study. *First Author: Tareq Al Baghdadi, Michigan Cancer Research Consortium, Ypsilanti, MI*

Background: The TAPUR Study is a phase II multi-basket study that evaluates the anti-tumor activity of commercially available targeted agents in pts with advanced cancers with genomic alterations known to be drug targets. Results in two cohorts of PC and GBC pts each with *CDKN2A* loss or mutation treated with P are reported. **Methods:** Simon's optimal two stage design was used to test the null hypothesis of 15% response rate versus the alternative of 35%. Power and alpha were set at 85% and 10%, respectively. Response was assessed per RECIST v1.1. This design requires 10 pts in stage 1 and if < 2 pts have objective response (OR) or stable disease (SD) at 16-weeks (wks), the cohort is closed. Secondary endpoints are progression-free survival (PFS), overall survival (OS) and safety. Genomic testing was performed using commercially available tests selected by clinical sites. Treatment was determined according to protocol matching rules based on pre-defined genomic inclusion criteria. **Results:** Twelve pts were enrolled in the PC cohort from July 2016 to April 2017, but 2 were subsequently found to be ineligible due to minor deviations from inclusion criteria. Ten pts were enrolled in the GBC cohort from August 2016 to November 2017. All pts are included in the data analysis for demographics, safety, PFS and OS (Table 1). No ORs or SD at 16 wks were observed in the PC or GBC pts and both cohorts were therefore closed. The most common toxicity from P was thrombocytopenia. **Conclusions:** Monotherapy with P does not have clinical activity in PC or GBC pts with *CDKN2A* loss or mutation. Toxicity is similar to previous experience with P. These pts should be offered other treatments, including clinical trials. Clinical trial information: NCT02693535.

Baseline demographics, clinical characteristics and outcomes by cohort.

	Palbociclib targeting *CDKN2A*	
Tumor Type	PC (N = 12)	GBC (N = 10)
Median age, yrs (range)	62 (52, 70)	63 (54, 81)
Male%	67	50

2533 Poster Session (Board #359), Mon, 8:00 AM-11:30 AM

Enrolling patients in clinical trials: Advice from close family and friends. *First Author: François Eisinger, Institut Paoli-Calmettes, Marseille, France*

Background: Clinical research is a major aspect of drug development and requires patient participation. Family and friends are known to play a role in medical decision-making, the extent of which depends on factors such as timing (onset or end of the disease), type of disease, the legal situation (e.g., patients under guardianship, or minor), and cultural aspects. The role of the close circle in inciting patients to enroll in clinical trials therefore warrants further study. **Methods:** The French nationwide observational survey, EDIFICE 6, was conducted online from 26 June-28 July 2017 on a core sample of 12 046 individuals (age, 18-69 years). Representativeness was ensured by quota sampling on age, gender, profession, and stratification by geographical area and type of urban district. Multivariate stepwise logistic regression analysis was conducted to identify factors likely to incite close relatives of cancer patients to urge them to enroll in a clinical trial. The present analysis included 11 307 individuals with no history of cancer and focused on the question "If a person you are close to had cancer and was invited to take part in a clinical trial, would you encourage them to participate?" **Results:** Most respondents declared they would very likely (22%) or likely (61%) encourage someone close to enroll in a clinical trial. Of the 21 significant explanatory factors affecting this opinion, two were predominant: believing that clinical research leads to important advances (OR = 2.75; 95% CI [2.33-3.24], $p < 0{,}001$) and that progress is made rapidly (OR = 2.18; 95% CI [1.95-2.43], $p < 0{,}001$). Other factors related to the "advice-giver" were also significant though less so: male gender (OR = 1.29), being married (OR = 1.20), not being socially vulnerable (OR = 1.17), former smoker (OR = 1.16), and having short-term perspectives (OR = 0.96). **Conclusions:** A large proportion (83%) of close family and friends of cancer patients were seen to encourage them to take part in clinical trials. Greater awareness and a clear understanding of the numerous benefits of clinical research would likely further increase the number of individuals who are in favor of clinical trials.

2534 Poster Session (Board #360), Mon, 8:00 AM-11:30 AM

AUCtox: A new method to evaluate the safety of anticancer drugs. *First Author: Vincent Launay-Vacher, Pitié-Salpêtrière Hospital, Paris, France*

Background: The evaluation of anticancer drugs safety currently relies on the NCI-CTCAE classification. Most often in clinical trials, attention is focused on severe adverse events (AE) *i.e.* grade 3 or more. However, AE of lower grades can have a significant deleterious impact, especially when recurrent or permanent. We aimed at defining a new method to better describe the impact of treatment on quality of life (QoL). **Methods:** The oncology patient monitoring program OptiSoins prospectively records treatment, number of cycles, and toxicities (NCI-CTCAE). Patients with castration-resistant metastatic prostate cancer treated with either docetaxel (DOC) or cabazitaxel (CABA) were identified in the database. For each patient, toxicities and their grade reported in medical records were plotted against time under treatment, to calculate the area under the curve of toxicities (AUCtox) that takes into account both the intensity and duration of toxicities, and the number of events. AUCtox was calculated for any toxicity reported at least once. The association with QoL, evaluated by EQ-5D-3L was determined. **Results:** In total, 146 patients were evaluable [DOC 85 (58%), CABA 61 (42%)]. Median age was 70.5 years (Q1-Q3: 64.7; 76.0). Median follow-up was 4.0 months. Patients underwent a median number of 6 cycles, with a median number of 15.0 evaluations (monitoring calls). At least one grade $\geq$3 AE was reported by 45.2% of patients, most frequently fatigue (20.6%) and pain (12.3%). A negative impact on global health status, assessed by the VAS of EQ-5D-3L, was identified for 3 AEs based on grade alone vs. 8 when considering AUCtox. **Conclusions:** Current evaluation of toxicity, based on grade alone, underestimates the impact of anticancer drugs on QoL. Our method, using AUCtox, can better detect this impact, allowing a more patient-oriented evaluation of drug safety.

Adverse events significantly associated with a negative impact on VAS, univariate analysis ($p \leq 0.05$).

Type of AE	AUCtox	≥Grade 3
Alopecia	+	-
Anorexia	+	+
Dyspnea	+	+
Fatigue/Asthenia	+	+
Tearing/Watering eye	+	-

2535 Poster Session (Board #361), Mon, 8:00 AM-11:30 AM

Trends in oncology trials termination due to toxicity over a period of 16 years. *First Author: Laura Vidal, Syneos Health, Barcelona, Spain*

Background: Pre-clinical studies may not fully determine the safety profile of an investigational agent resulting in the need to terminate studies due to safety concerns. Additionally, the development of effective new anti-cancer agents may undermine the risk-benefit ratio. We sought to determine the number of oncology studies indicated as terminated for safety reasons over the past 16 year period. **Methods:** Oncology and hematology trials listed as terminated due to safety or adverse event, between January 1 2002 and December 31 2017, and sponsored by biopharmaceutical industry were identified on the Citeline® Trialtrove database. Two periods were compared, prior to 2010 and from 2010. **Results:** 380 oncology trials were listed as terminated due to safety or adverse effects; 184 phase I and I/II, 147 phase II and II/III and 48 phase III and IV. 233 trials were terminated due to safety during 2002 – 2009 and 147 during 2010 - 2017. Considering the total number of trials terminated for all reasons, 10% of all terminations were due to safety reasons; 11% versus 9% in the early versus late 8 year period, respectively. For phases and period of time, 44% vs 57% phase I and I/II, 42% vs. 32% phase II, and 13% vs 10% phase III studies were terminated due to safety during 2002 – 2009 and 2010-2017 respectively. For trials performed in the elderly population, 33 trials (31 for $>$ 65 years old and 2 for $>$ 70 years old) were terminated for all reasons during the sixteen-year period: 21 trials terminated during 2002 – 2009 and 12 during 2010-2017. Of all 33 studies, 3 (9%) terminated due to safety (2 trials for $>$ 70 years old). Despite small numbers, the percentage is similar to safety terminations in all trials - nonage specific. **Conclusions:** The percentage of trials terminated due to safety has decreased very slightly. When examined as a proportion of trials by phase, the overall trend toward improvement seems to be result for decrease in late phase study terminations, indicating toxicity profile is better characterized at earlier stages. Although few studies focus on elderly cancer patients, there appears to be no increased risk for discontinuation due to safety reasons in this population.

2536 Poster Session (Board #362), Mon, 8:00 AM-11:30 AM

Systematic review of pediatric oncology phase I trials: Toxicity and outcomes in the era of targeted therapies. *First Author: Julia Wanda Cohen, Pediatric Oncology Branch, Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: Historically, objective response rates (ORR) (CR/CRi + PR) in pediatric phase I oncology trials have been $< 10\%$. With an increased emphasis on targeted treatment approaches, safety profiles and response rates may have changed. We analyzed outcomes of recent phase I pediatric oncology trials. **Methods:** Peer-reviewed phase I pediatric oncology trials published from 2012 through 2017 were identified through a PubMed search. Selection criteria included a pediatric population (median age ≤ 25 years), diagnosis of cancer (including CNS tumors), and a clear dose-escalation schema. Each publication was evaluated for therapy type (cytotoxic versus targeted, combination vs. single agent), trial design, patient characteristics, toxicity, and response. **Results:** Of 242 publications identified, 89 articles met the inclusion criteria. 46 (52%) incorporated targeted therapies. Total enrollment was 2187 patients; median age at enrollment/trial was 10 years (range 3-25 years). 1990 patients (91%) were evaluable for toxicity, of whom 256 (12.9%) experienced dose-limiting toxicity (DLT) with 3 study-related deaths (0.15%). Of 1708 patients evaluable for response in 78 trials, 287 (16.8%) demonstrated a response (188 CR, 15 CRi, 84 PR). 31 (40%) of trials had no objective responses. Sixteen trials (21%) had an ORR $\geq 25\%$ (leukemia trials = 9, solid tumor trials = 7), of which 8 were combination cytotoxic trials and 8 were targeted trials, the majority enrolling patients with the relevant target (e.g. CD19-directed therapy for CD19+ disease). Comparison between the 46 targeted trials and the 43 cytotoxic trials demonstrated similar pooled rates of DLT (11.1% vs. 15.4%) and ORR (16.9% vs. 16.7%). **Conclusions:** Our systematic review of recent pediatric oncology phase I trials demonstrated a higher pooled ORR than rates previously reported without increased toxicity. A subset of trials with substantially higher ORR included combination cytotoxic trials and targeted trials with target specific enrollment, supporting earlier introduction of combinatorial approaches and inclusion of pediatric patients with the relevant target in early phase targeted trials.

2537 Poster Session (Board #363), Mon, 8:00 AM-11:30 AM

A randomized Bayesian phase 1 design combining an MPS-1 inhibitor with paclitaxel: A strategy to improve determination of the incremental toxicity of a novel compound over a known backbone therapy. *First Author: Florence Atrafi, Erasmus MC Cancer Institute, Rotterdam, Netherlands*

Background: Here we present a study combining BAY1217389 (BAY), a potent MPS-1 kinase inhibitor with a backbone chemotherapy paclitaxel. Since we expected overlapping toxicities we sought to improve determination of the maximal tolerated dose (MTD) using a randomized phase 1 design with Bayesian dose modeling. We hypothesized that this approach may determine the MTD of BAY more accurately by limiting the effect of variability of dose limiting toxicities (DLTs) related to paclitaxel. **Methods:** Patients ($\geq$18 years) were randomized to receive oral BAY with intravenous paclitaxel (experimental arm) or paclitaxel monotherapy (standard arm) in cycle 1. Dose escalation was guided by Bayesian modeling targeting a DLT-rate in the experimental arm of 10% over DLT-rate in the standard arm. PK profiles were determined for both BAY and paclitaxel. Simulations were performed to estimate MTD for several scenarios. **Results:** We were able to establish an MTD of 65 mg BAY using 50 patients in the dose-escalation part. As expected the main DLTs were hematologic toxicity. Grade ≥ 3 neutropenia was predominantly observed in the experimental arm and was related to higher BAY AUC0-12 on D8 ($p<0.001$) and not to paclitaxel AUC0-24 ($p>0.1$). To determine whether the randomization adds value to the study design we ran simulations comparing our randomized strategy using variable toxicity rate (5, 10, 20, 40%) for paclitaxel monotherapy with the 3+3 design. These data showed that the randomized design outperformed the 3+3 design. The 3+3 design underestimated the MTD as dose escalation was terminated more frequently at first dose for higher paclitaxel toxicity rate. **Conclusions:** Randomized Bayesian phase 1 dose escalation design was feasible with BAY plus paclitaxel. A major advantage of this design is the precise determination of an exposure-toxicity relation for the experimental drug. Moreover, simulations support our hypothesis that the randomized design was able to determine the MTD accurately regardless of variable toxicity rate for paclitaxel. This approach may improve dose determination in phase I combination trials. Clinical trial information: NCT02366949.

2538 Poster Session (Board #364), Mon, 8:00 AM-11:30 AM

Successes and challenges faced by tissue collection during trials by oncology translational sciences. *First Author: Martine P Roudier, Oncology Translational Science, IMED Biotech Unit, AstraZeneca, Cambridge, United Kingdom*

Background: Knowledge of the success rates in obtaining baseline and on treatment tumour biopsies with sufficient evaluable tumour tissue is valuable in guiding strategies for evaluation of PD biomarker analysis in future clinical trials. **Methods:** We present a 12 month translational experience collecting patient paired-biopsies for pharmacodynamic (PD) biomarker evaluation in a multi-centre, multi-trial context. We analysed - 152 specimens, 72 pairs, for tumour content success rate and pair biopsy success rate in 8 investigational clinical trials. The tumour content was defined as successful when the biopsy contained greater than 100 tumour cells. All biopsies were formalin fixed paraffin embedded at the clinical sites and blocks or unstained slides were sent to a central pathologist for evaluation of tumour content and relevant PD biomarkers. **Results:** Tumour organ sites were per pair: bone (n = 14), lung (n = 16), prostate (n = 11), liver (n = 11), and no organ site (n = 20). Tissue size was an average of 17.25 mm^2 (range: 2-88 mm^2). Tumour content in skin biopsies was 42.7% (range 0-80%) and yielded the best tumour content sampling as compared to deep organ biopsies: bone:2.2% (range 0-20%); prostate: 20.3% (range 0-80%), liver: 27% (0.1-60%; lung: 28.1 % (0-60), no indication of organ site: 42.6% (range 1-90%). There was no correlation between tissue size and tumour content (r = - 0.083). Tumour content success rate was globally 40%. **Conclusions:** In summary, paired biopsies were 40% successful in sampling patient tumour. However 30% of them were evaluated without indication of primary or metastatic tumour status or initial tumour histopathology diagnosis. Processes to link meta-data collection (organ site or pathology report) with biopsies are in progress as well as encouragement to bone scan guiding when bone metastasis biopsies are necessary.

2539 Poster Session (Board #365), Mon, 8:00 AM-11:30 AM

Prospective assessment of tumor biopsies as part of clinical trials: Patients' (pts) perspectives. *First Author: Sunu Lazar Cyriac, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Despite the increased inclusion of mandatory biopsies for clinical trials, there are scant data related to the perceptions and acceptability by pts. This study assessed the pre and post biopsy perceptions among gynecological cancer pts. **Methods:** A prospective study was conducted at Princess Margaret Hospital for pts with gynecological cancers. The study was approved by local ethics committee and enrolled pts planned for core tumors biopsies as part of clinical trials. A questionnaire was completed by pts prior to and 1 week post biopsy. The questionnaire assessed the Hospital Anxiety and Depression Scale (HADS), pts' perceptions and experience. **Results:** 42 women completed the questionnaire at both time points. Median age was 63 years. Sites of biopsies were peritoneal nodules in 45%, liver in 24%, superficial lymphnodes (LN) in 17%, retroperitoneal LN in 7% and abdominal wall in 7%. 88% were Ultrasound guided, 8% was CT, and 4% as blind procedure. A risk threshold of less than 2% was considered acceptable for major complications, major bleeding or infection by 71%, 60% and 55% of pts, respectively. While 50% (21/42) of the pts reported that the biopsy didn't impact their care, but helps research; only less than 10% felt it would impact their care. 71% (30/42) of the pts would allow their specimen to be used for future research. Most pts (98%) were agreeable for genetic testing of their specimen and wanted to be informed of significant findings. Table 1 shows the HADS result. The baseline score was normal in 81%. 91% (38/42) felt that the side effects and risks of biopsy were adequately explained before the procedure. One week after the biopsy, only 1 pt had major pain. 91% (38/42) of pts did not feel any embarrassment during the procedure. The majority of pts (91% [38/42]) were agreeable for a repeat biopsy for research. Table 1 **Conclusions:** Core biopsies for correlative studies for research purpose are well accepted and tolerated by patients. Patients were well informed and importantly willing to undergo further biopsies in the future if necessary. This is critical with the growing integration of biopsies in clinical trial design.

HADS (Anxiety)(n = 42)	Pre Biopsy	1 week post Biopsy
Normal	34	39
Borderline abnormal	2	1
Abnormal	6	2

2540 Poster Session (Board #366), Mon, 8:00 AM-11:30 AM

Accelerated vs. regular approval: Lessons learned from U.S. FDA oncology approvals. *First Author: Ihid Carneiro Leao, U.S. Food and Drug Administration, Silver Spring, MD*

Background: This work categorizes the justifications for accelerated and regular approvals (AA and RA) of oncology products granted by U.S. FDA, based on endpoints other than overall survival (OS) that supported RA and pathways for AA conversion to RA. **Methods:** We reviewed FDA databases for approved oncology products for specific indications from January 2006 to November 2017. For each product and its indication, we reviewed the trial that supported its approval with respect to study population, trial design, endpoints, magnitude of the treatment effect and benefit-risk assessment. **Results:** Two hundred twenty-six new indications were granted, 159 (70%) received RA and 67 (30%) AA. OS was the primary endpoint supporting 40% of RAs. Non-OS endpoints that supported RA (60%, n = 95) included PFS (n = 51), response and response rate (n = 34), TTP (n = 4), DFS (n = 2), RFS (n = 2) and EFS (n = 2). The disease settings where non-OS endpoints were used included advanced breast cancer, multiple myeloma, chronic lymphocytic leukemia, acute lymphoblastic leukemia, advanced solid tumors such as thyroid, renal cancer, NSCLC and rare cancers. Of the 67 indications granted under AA, response including hematologic response endpoints and pathological complete response was the basis for most of AA (88%, n = 59). Eight approvals were based on a time to event endpoint (12%; PFS, n = 7 and DFS, n = 1). We identified two pathways for AA to RA conversion based on 33 out of 67 AAs converted: (1) longer follow-up of the same trial that supported the AA demonstrating the sustained treatment effect (18%) and (2) additional confirmatory trial with primary endpoint that represented clinical benefit in the intended indication (82%). **Conclusions:** Our results provide clarity of FDA oncology approvals and useful information to stakeholders for efficient development of oncologic products.

2541 Poster Session (Board #367), Mon, 8:00 AM-11:30 AM

A phase I molecular adaptive clinical study to evaluate safety and tolerability of BPM31510-IV in advanced solid tumors: Final study results. *First Author: Niven R. Narain, BERG, LLC, Framingham, MA*

Background: BPM31510-IV is an Ubidecarenone (CoQ10) containing IV nanodispersion targeting metabolic machinery in cancer, shifting bioenergetics from lactate dependency towards mitochondrial OxPhos and reversing the Warburg effect. This study evaluated the safety & tolerability of BPM 31510-IV alone or in combination with chemotherapy. The study design included PD sampling for multi-omic analysis to identify predictive markers of clinical benefit and patient stratification. **Methods:** Eligible patients were relapsed/refractory to standard therapy. The monotherapy arm received IV BPM 31510 for 6 d in continuous infusion in 28-d cycles, and combination arms (gemcitabine, 5-FU or docetaxel) were primed for 3 wks with BPM31510 prior to chemotherapy regimen followed by weekly dosing in a 6 wk cycle. Endpoints were safety, pharmacokinetics (PK) and pharmacodynamics (PD). Tumor response was evaluated at cycle 1 and then after every 2 cycles. **Results:** A total of 98 pts were enrolled. Thirty of 66 evaluable pts (45%) achieved stable Disease, for $\geq$ 2 cycles and 16/66 (24%) maintained a minimum of SD for $\geq$ 4 cycles. 99% patients receiving $\geq$ 1 treatments with BPM31510 experienced a TEAE. The most frequently experienced TEAEs were asymptomatic elevated APTT in 80% of pts, INR increased in 74%, PTT prolonged 64%, Anemia in 41%, fatigue in 24% and both AST increase & platelet decrease in 16% of pts. Molecular predictors of coagulation-related events prior to and 24h after 1st treatment with IP were identified. Biomarker candidates correlating with favorable clinical response & safety identified were independent of tumor type and prior therapy, suggesting a broad anti-tumor effect. Novel multi-omic panels with potential to stratify response before and 24h post treatment with AUC $>$ 0.85 were identified. **Conclusions:** BPM31510-IV is well tolerated as monotherapy and in combination with several standard chemotherapeutic agents. Molecular signatures with predictive potential of the safety and clinical response have been identified that will guide Phase 2/3 clinical development. Clinical trial information: NCT01957735.

2542 Poster Session (Board #368), Mon, 8:00 AM-11:30 AM

Adverse events (AEs) in early phase cancer clinical trials. *First Author: Grace Mishkin, National Cancer Institute, Rockville, MD*

Background: AE reporting is required in the conduct of clinical trials for patient safety and to understand the toxicities from treatment interventions. This analysis used a uniquely comprehensive dataset of AEs from early-phase NCI trials to describe overall clinician-reported AE frequency and prevalence, as well as changes in frequency and prevalence over time. **Methods:** Data were used from early phase trials using NCI-sponsored agents with complete AE reporting. Patients ages 25+ with at least one AE were included. These AEs were collected for treatment courses started 2000-2016 and standardized to CTCAE v4.0. R was used for analysis. **Results:** Over this 17-year period complete AE reporting was available for 1,594 early phase clinical trials representing a wide range of disease areas and agents. There were 1,417,529 total AEs reported for 59,023 patients. There are 790 CTCAE terms, but the 15 most frequently reported AEs represented 48% of all AEs reported (Table 1). Grade 3 AEs represented 13.1% of the AEs for 2000-2003, but decreased to 9.9% for 2012-2016. **Conclusions:** These initial results from an extensive AE database show a small number of AE terms represent most AEs reported. The proportion of AEs which were grade 3 decreased over time, potentially due to changes in agents and improvements in supportive care. As more trials which include patient reporting of AEs are completed, joint analysis could lead to more comprehensive understanding of the tolerability of lower grade AEs. Analysis by agent class, patient age, and disease is ongoing.

15 most commonly reported ctcae terms.

CTCAE Term	# AEs	% AEs (n = 1433896)	# Patients	% Patients (n = 59802)

2543 Poster Session (Board #369), Mon, 8:00 AM-11:30 AM

Violations of the proportional hazards assumption in randomized phase III oncology clinical trials. *First Author: Rifaquat Rahman, Harvard Radiation Oncology Program, Boston, MA*

Background: The hazard ratio is the most common measure of treatment effect in oncology trials, but many trials commonly violate the underlying Cox proportional hazards assumption. We aimed to evaluate the prevalence of non-proportionality of hazards in phase III oncology clinical trials. **Methods:** We performed a PubMed search for randomized phase III trials in breast cancer, lung cancer, prostate cancer and colorectal cancer published in high-impact journals between 2014 and 2016. To be included, studies were required to report on a cancer-directed intervention and provide Kaplan-Meier (KM) curves of a time-to-event outcome. We generated individual patient data for time-to-event outcomes for overall survival (OS) and non-survival endpoints. We reanalyzed trials with our reconstructed individual patient data and evaluated for evidence of violation of the proportional hazards assumption with the Grambsch-Therneau test with a p-value threshold of $<$ 0.1. **Results:** We identified 157 publications with 115 KM curves of overall survival (OS) and 139 KM curves of a non-survival time-to-event outcome. There was evidence of non-proportionality of hazards in a total of 62 (24%) time-to-event outcomes including 20 of 115 (18%) OS KM curves and 42 of 139 (30%) non-survival KM curves. Immunotherapy (50%) and endocrine/hormonal therapy (50%) trials had the highest prevalence of KM curves with evidence of non-proportional hazards, and this was less common in KM curves of targeted therapy (25%), radiation therapy (19%), and chemotherapy (15%) trials. **Conclusions:** A notable proportion of time-to-event outcomes reported in oncology clinical trials demonstrates evidence of violating the assumption of proportional hazards. Non-survival time-to-event outcomes were more likely to show evidence of non-proportionality of hazards. Consideration of violation of the proportional hazards assumption is warranted in designing clinical trials.

2544 Poster Session (Board #370), Mon, 8:00 AM-11:30 AM

FACTS: Factors affecting combination trial success. *First Author: Channing Judith Paller, Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD*

Background: Experimental therapeutic oncology agents are often combined in an effort to circumvent tumor resistance to individual agents; most combination trials, however, fail to demonstrate sufficient safety and efficacy to advance to a later phase. The FACTS study collected survey data on phase 1 combination therapies to: 1) assess rates of advancement and regulatory approval, 2) identify factors associated with these rates, and 3) assess the degree that phase 1 trials were concordant with Clinical Trial Design Task Force (CTD-TF) Guidelines. **Methods:** A 13-question survey collected data on phase 1 trial design, predefined expectations and criteria to assess success, biomarker information, and questions about the trials' results and progress. Online surveys (N = 289, July-Dec. 2017) were emailed to PIs of early-phase NCI and/or industry trials; 263 emails (91%) were received and 114 surveys completed (43%). Two independent coders validated 10% of survey responses (N = 12) against manuscript publications (intercoder Reliability = 99%). **Results:** Phase 1 results indicated further investigation was warranted for 39.8% of combinations (95% CI: 30.8%, 48.8%). 24.9% of combination trials (95% CI: 15.3%, 34.4%) progressed to phase 2 or further. 18.7% (95% CI: 5.90%, 31.4%) progressed to phase 3 or FDA approval. 12.4% (95% CI: 0.00%, 25.5%) achieved regulatory approval. Trial results where "clinical promise was observed" in phase 1 of the combination study were associated with higher rates of progression past each milestone toward regulatory approval (cumulative OR = 11.9; p = 0.0002). The phase 1 study designs were concordant with CTD-TF Guidelines for 79.6% of the combinations (95% CI: 72.2%, 87.1%); most discordances occurred where no plausible pharmacokinetic or pharmacodynamic interactions were expected. **Conclusions:** "Clinical promise" of a combination may predict progress toward regulatory approval. Although concordance between study designs of phase 1 trials of combination therapies and CTD-TF Guidelines was relatively high, raising more awareness of the best study design to use when no plausible pharmacokinetic or pharmacodynamic interactions are expected may be beneficial.

2545 Poster Session (Board #371), Mon, 8:00 AM-11:30 AM

The rate of tumor growth during treatment accurately predicts the FDA gold standard of overall survival [OS] in a broad range of malignancies. *First Author: Julia Wilkerson, Columbia University Medical Center, New York, NY*

Background: Novel clinical trial endpoints that predict overall survival (OS) are needed to streamline anticancer drug development. **Methods:** We used a novel mathematical approach to estimate simultaneously occurring exponential rates of tumor growth [*g*] and regression [*d*] using data stored for $>$ 10,000 patients [pts] enrolled in clinical trials. Data were provided by investigators, pharmaceutical companies, or were downloaded from Project Data Sphere [PDS], a publicly available data sharing warehouse; and included imaging measurements and serum tumor markers [eg. PSA, CA19-9 and M-spikes]. Pts with multiple myeloma, prostate, pancreas, colorectal, breast, renal, and neuroendocrine (NET) cancers undergoing cytotoxic, targeted, or immune therapies were included in this analysis. **Results:** In 85-90% of pts enrolled in a clinical trial, *g* and *d* could be estimated with p-values for fits $<$ 0.1 in all and $<$ 0.001 in the majority. Greater than 95% of the data fit the exponential equations, with 14 other equations describing models of tumor growth from the literature unable to fit $>$ 5% of the data. Regression (*d*) rates are 3-4x faster than growth (*g*) but do not correlate with OS. *g* can estimate doubling time (dt), and is highly predictive of progression free survival (PFS) and OS even when analyzing combined data from disparate studies. Straightforward modeling shows *g* can distinguish whether an experimental therapy is associated with OS gain in as few as 30 pts. Estimated median *g* values ranged from $0.0057d^{-1}$ (dt 0.3y) for pancreatic adenocarcinoma to $0.00046d^{-1}$ (dt 4.1yr) for NETs on therapy. **Conclusions:** Estimates of *g* accurately predict OS in a broad range of cancers and *g* should be considered a valuable surrogate in assessing trial outcomes. *g* can be compared easily across settings and allows large clinical trials to serve as benchmarks for estimating efficacy of experimental therapy. Development of this valuable assessment tool has been made possible by the sharing of clinical trial data by pharmaceutical companies directly or through PDS. Housing both the data and soon the benchmark analyses in PDS will offer investigators new strategies for clinical trial assessment.

2546 Poster Session (Board #372), Mon, 8:00 AM-11:30 AM

Phase 1 dose escalation of XMT-1522, a novel HER2-targeting antibody-drug conjugate (ADC), in patients (pts) with HER2-expressing breast, lung and gastric tumors. *First Author: Erika Paige Hamilton, Sarah Cannon Research Institute and Tennessee Oncology, PLLC, Nashville, TN*

Background: XMT-1522 is comprised of 10-15 molecules of the payload AF-HPA, an auristatin-derivative with two-step intra-tumor metabolism intended to optimize therapeutic index, conjugated to a novel anti-HER2 monoclonal antibody via the Dolaflexin ADC platform. **Methods:** In this ongoing Phase 1 study, pts with advanced HER2-expressing (IHC $\geq$1+) breast cancer (BC), gastric cancer (GC) and non-small cell lung cancer (NSCLC) progressing on standard therapy or for whom no standard therapy exists are treated with XMT-1522 administered intravenously every 3 weeks. Dose escalation uses a 3+3 design with a modified Fibonacci escalation and a 3 week dose limiting toxicity (DLT) evaluation period. Primary objectives in dose escalation are safety and tolerability and determination of maximum tolerated dose (MTD) and recommended Phase 2 dose (RP2D). (ClinicalTrials.gov NCT02952729) **Results:** As of February 1, 2018 19 pts have completed the DLT evaluation period across 6 dose levels (2 to 21.3 mg/m^2). There have been no DLTs nor serious adverse events (SAEs) attributed to study drug. Treatment-related adverse events (TRAEs) have been Grade 1 or 2; the most common TRAEs included increased liver enzymes, fatigue, nausea, vomiting, headache, and anorexia. 18 patients have had post-treatment restaging scans. Disease control rate (DCR) was 5/6 (83%) for patients dosed at 16 or 21.3 mg/m^2 with 1 PR and 4 SD. The ongoing PR occurred at first assessment in a pt with HER2-positive BC previously treated with ado-trastuzumab emtansine. Two SD were seen in HER2-positive BC pts (ongoing 13+ and 12+ wks duration) and SD was seen in two GC pts (12 weeks and ongoing 6+ weeks duration). DCR in patients treated at doses less than 16 mg/m^2 was 3/12 (25%) with 3 SD (duration 23, 13 and 9 wks). The systemic exposure of total payload showed approximately dose-proportional increase. Plasma concentration of free drug payload and its active metabolite were low. **Conclusions:** XMT-1522 has been well-tolerated up to the 21.3 mg/m^2 dose level with early signs of anti-tumor activity. Neither MTD nor RP2D has been identified. Dose escalation continues in pts with advanced HER2-expressing BC, GC and NSCLC. Clinical trial information: NCT02952729.

2547 Poster Session (Board #373), Mon, 8:00 AM-11:30 AM

A phase 1b study of the safety, pharmacokinetics, and preliminary antitumor activity of citarinostat (ACY-241) in combination with paclitaxel (Pac) in patients (pts) with advanced solid tumors (AST). *First Author: Michael S. Gordon, HonorHealth, Scottsdale, AZ*

Background: Citarinostat is an oral, selective histone deacetylase 6 inhibitor that inhibits growth of solid tumor cell lines and exhibits potent synergy with Pac in preclinical studies. We conducted a phase 1b dose-escalation study evaluating the safety and preliminary antitumor activity of citarinostat plus Pac in pts with AST. **Methods:** Pts with AST, including those who progressed on prior taxane therapy, were enrolled in a 3+3 escalation study. Cohorts: 1) 180 mg, 2) 360 mg, or 3) 480 mg oral citarinostat d1-21, all plus 80 mg/m^2 Pac d1, 8, 15 in a 28-day cycle. If no maximum tolerated dose (MTD) was identified, an additional cohort was allowed. Primary endpoints: dose limiting toxicity (DLT), MTD, and citarinostat recommended phase 2 dose (RP2D). Key secondary endpoints: safety, efficacy, and pharmacokinetics (PK). **Results:** Of 20 pts enrolled (cohort 1 = 3 pts, cohort 2 = 5 pts, cohort 3 = 6 pts, additional 360 mg cohort = 6 pts), 15 had prior taxane therapy. No DLTs were observed; MTD was not identified. Citarinostat RP2D was established at 360 mg/day. At 480 mg, a higher incidence and severity of neutropenia were observed (1 grade 4; 1 grade 3; 1 grade 2) vs 360 mg (1 grade 1). Common ($\geq$ 25%) treatment-emergent adverse events (TEAEs): anemia (50%), alopecia (40%), hypomagnesemia (40%), decreased appetite (35%), fatigue (35%), diarrhea (30%), nausea (30%), leucopenia (25%), dehydration (25%), and vomiting (25%). Peripheral neuropathy was observed in 30% of pts (15% grade 3; 8 Pac-related events, 1 Pac/citarinostat-related). Twelve serious TEAEs were reported in 8 patients. No deaths were observed under treatment. Citarinostat did not modify the overall safety profile of Pac. Two pts had confirmed partial response (PR); of 14 pts with stable disease, 2 had unconfirmed PR. In preliminary PK analysis, citarinostat exposure increased in a dose-proportional manner from 180 mg to 360 mg; however, a decrease in exposure was observed after dosing at 480 mg **Conclusions:** Citarinostat plus Pac showed acceptable safety in heavily pretreated pts without any unexpected toxicities. Further investigations of efficacy are needed. Clinical trial information: NCT02551185.

2548 Poster Session (Board #374), Mon, 8:00 AM-11:30 AM

NCI9782: A phase 1 study of talazoparib in combination with carboplatin and paclitaxel in patients with advanced solid tumors. *First Author: Anita Ahmed Turk, University of Wisconsin Carbone Cancer Center, Madison, WI*

Background: Poly(ADP-ribose) polymerase (PARP) enzymes are involved in DNA repair and activated by DNA strand breaks. DNA damage from carboplatin is associated with activation of PARP. Preclinical data indicate that PARP inhibition and trapping potentiates the anti-tumor effect of platinum chemotherapy. Talazoparib (T) is an oral, selective PARP inhibitor. This phase I study combines T with carboplatin (C) and paclitaxel (P). **Methods:** Two dosing schedules are being investigated. C is administered on day 1 and P on days 1, 8, and 15 of a 21-day cycle. T (100-1000mcg) is dosed once daily for days 1-7 (schedule A) or days 1-3 (schedule B) starting on day 1. Dose escalation is by 3+3 design. Key eligibility criteria include age 18+ with a solid incurable malignancy. Patients (pts) must have tumor type that is expected to respond to C + P or have BRCA germline or somatic mutation and adequate organ function. After 4-6 cycles of combination therapy, pts may continue the combination, change to C and intermittent T without P or change to T alone with continuous dosing. Each schedule will have a 6 pt dose expansion at the MTD. The starting dose for schedule B is the MTD from schedule A. **Results:** Schedule A results are reported: 23 pts (median age 55 yrs [range 37-70]) have been enrolled. Primary malignancies include breast (9), ovarian (3), SCC of skin/oropharynx (4), pancreatic (1), and other (5). 10 pts have known gBRCA1/2 mutations. Dose level 3 (T 350mcg with C AUC 6 + P 80mg/m^2) exceeded the MTD with 2 of 3 pts experiencing hematologic dose limiting toxicities (DLTs). Expansion of dose level 2 (T 250mcg with C AUC 6 + P 80mg/m^2) confirmed this level as the MTD. Most common adverse events included neutropenia (grade 3-4: 73.9%), anemia (grade 3-4: 39.1%), and thrombocytopenia (grade 3-4: 30.4%). Pts were on study a median of 15 weeks (range 1-98+). Of 17 pts with measurable disease, 9 (52.9%) had PR and 5 (29.4%) had SD. 35% of patients changed to T alone after combination chemotherapy. PBMC analysis for RAD51 foci, dH2AX, and PAR levels will be reported. **Conclusions:** The schedule A MTD and RP2D is T 250 mcg with C AUC 6 and P 80mg/m^2. This combination was tolerated with prolonged responses seen at lower dose T in combination with C+P. Clinical trial information: NCT02317874.

2549 Poster Session (Board #375), Mon, 8:00 AM-11:30 AM

Phase I trial of the triplet M6620 (formerly VX970) + veliparib + cisplatin in patients with advanced solid tumors. *First Author: Geraldine Helen O'Sullivan Coyne, Early Clinical Trials Development Program, DCTD, National Cancer Institute at the National Institutes of Health, Bethesda, MD*

Background: Ataxia-telangiectasia-related (ATR) protein kinase is central to the repair of damaged DNA through the homologous recombination (HR) pathway, activating phosphorylation cascades that culminate in cell cycle arrest to allow time for DNA damage repair (DDR). M6620 is an ATR inhibitor with antitumor activity across a range of cell lines. Veliparib (ABT-888), an oral poly (ADP-ribose) polymerase (PARP) 1/2 inhibitor, plays a pivotal role in DDR response through the base excision repair pathway, with clinical evidence of antitumor activity in combination with cisplatin in *BRCA* mutation carriers. As DNA damage and antitumor activity of platinum results from DNA cross-links that stall replication forks and halt transcription, this trial evaluates if veliparib together with M6620 impair DNA repair by inducing a "*BRCA* null"-like phenotype that potentiates the antitumor activity of cisplatin. **Methods:** Open label phase I trial of the M6620+veliparib+cisplatin combination; 3+3 design, 21-day cycle: cisplatin 40mg/m^2 intravenously (IV) Day 1 [Day 8 added from dose level (DL)3]; M6620 (M) IV Days 2+9; Veliparib (V) orally twice daily Days 1-3 and 8-10. Prior platinum, PARPi therapy permitted. Response: RECIST 1.1. **Results:** 23 patients(pts) enrolled, 22pts evaluable for response. 3/22pts confirmed partial responses (PR) lasting $>$ 4cycles (range 4-15): 1pt with *BRCA*-wildtype ovarian cancer (DL3), 1pt with esophageal cancer/biallelic loss of ATM (DL4); 1pt with NSCL cancer/ATM mutation (DL5); all remain on study. 12/22pts have stable disease: median time on study 5 cycles (range 3-10). DL3+4 expanded for dose limiting toxicity: grade 4 hypophosphatemia and thrombocytopenia respectively (1pt, 4%). Other adverse events: grade 3 thrombocytopenia (6pts, 27%), leucopenia (5pts, 22%), lymphopenia (4pts, 18%). Maximally tolerated dose (MTD) not reached for the combination, currently enrolling DL7: V 200mg, M 210mg/m2. **Conclusions:** combination is safe and shows antitumor activity in HR-compromised tumors. Planned biomarker assessment at MTD includes γH2AX, RAD51, pNbs1, and pATR in tumor biopsies and circulating tumor cells using a validated, quantitative immunofluorescence assay. Clinical trial information: NCT02723864.

2550 Poster Session (Board #376), Mon, 8:00 AM-11:30 AM

Phase ib/2a study of PLX51107, a small molecule BET inhibitor, in subjects with advanced hematological malignancies and solid tumors. *First Author: Amita Patnaik, South Texas Accelerated Research Therapeutics, San Antonio, TX*

Background: PLX51107 is an orally active small molecule inhibitor that exhibits low nanomolar potency in blocking interactions mediated by the four BET family proteins and a unique pharmacokinetic (PK) profile. **Methods:** We conducted a first-in-man 3+3 dose escalation study of PLX51107 in adult patients with relapsed or refractory solid tumors (lymphomas included) and AML to determine the recommended phase II dose (RP2D) (NCT02683395). Secondary endpoints included safety, efficacy, pharmacokinetics (PK), and pharmacodynamics (PD). Enrollment through Cohort 7 (160 mg QD) is ongoing as of January 2018. **Results:** 36 subjects with advanced solid tumors (median age 60.5 years) received PLX51107 in escalating doses from 20mg to 160mg QD and 60mg BID. Uveal Melanoma (n = 11) was the most common tumor type followed by sarcoma (n = 6), and NSCLC, Breast and CRPC (n = 2 each). Most common toxicities in $\geq$ 15% of pts: fatigue (33%), vomiting (25%), diarrhea (25%), nausea (19%), bilirubin increase (17%), and INR increase (17%). Most were grade (G) 1-2. There were 3 treatment-related serious AEs (1 each of G3 nausea, G2 vomiting, and G2 kidney injury). Subjects with extensive hepatic metastases ($>$ approx. 50% of the liver) demonstrated higher exposure and more AEs. Dose limiting toxicity (DLT) was observed at 20mg (1 G3 thrombocytopenia), 120mg QD (1 G3 nausea) and 160mg QD (1 G2 kidney injury). PK was dose proportional with t1/2 $<$ 2.5hr. Sixty mg BID dosing yielded same AUC as 120mg QD. RNA-seq analyses of peripheral blood mononuclear cells showed a dose-dependent induction of HEXIM1/WDR47 and reduction of CCR1/CCR2 gene expression within 3 hours of dosing. Eight pts achieved stable disease by RECIST (2 uveal melanoma, 3 sarcoma, 1 CRPC, 1 NSCLC), ranging from 4-14 months, and one subject with uveal melanoma demonstrated stable disease for 14 months. **Conclusions:** PLX51107 continues to enroll in dose escalation; patients with extensive hepatic metastasis are excluded going forward. Based on preclinical toxicology data, the expected Maximum Tolerated Dose will be in the 200-300 mg range. The BID dosing schedule will not move forward due to no increase in exposure observed. Clinical trial information: NCT02683395.

2551 Poster Session (Board #377), Mon, 8:00 AM-11:30 AM

Phase I trial of lurbinectedin (PM1183) in Japanese patients with advanced tumors: Results of the dose escalation part. *First Author: Shunji Takahashi, Cancer Institute Hospital of JFCR, Tokyo, Japan*

Background: PM1183 (lurbinectedin, Zepsyre) is a new anticancer agent that inhibits activated transcription, induces DNA double-strand breaks leading to apoptosis and modulates tumor microenvironment. The recommended dose (RD) in non-Japanese patients (pts) is 3.2 mg/m^2 on Day 1 every three weeks (q3wk), with reversible myelosuppression as dose-limiting toxicity (DLT). **Methods:** Japanese pts with solid tumors (excluding CRC or CNS primary tumors), adequate organ function and ECOG PS 0-2 were treated at 3 different dose levels (DLs), 1.5 mg/m^2, 2.5 mg/m^2 and 3.2 mg/m^2, using a 3+3 design. **Results:** Fifteen pts (10 female / 5 male) were treated and evaluated for safety and efficacy. Median age was 52 years (38-65), albumin 4 mg/dL (3.5-4.6) with 2 median previous lines (1-3). Tumors were, among others, biliopancreatic (3), esophageal (2), endometrial (2) and breast (1). 2 out of 4 pts on DL3 (3.2 mg/m^2) had a DLT consisting of a grade (G) 4 neutropenia and a G3 neutropenia lasting $>$ 7 days. Eight pts were treated at the RD established on 2.5 mg/m^2, with G2 neutropenia leading to dose reduction and dose delay in 1 pt each. Main adverse events at the RD were hematological with 1 pt (12.5%) presenting G3 neutropenia. Other G3/4 toxicities included a non-drug related G4 hypokalemia (12.5%). Non-hematological toxicities were exclusively G1/2, including G2 ALT increase (50%), AST increase (25%), anorexia (25%), nausea (25%), fatigue (12.5%) and dyspnea (12.5%). At RD, 1 pt (12.5%) with metastatic breast cancer achieved a durable partial response and 3 pts (37.5%) had confirmed stable disease. PK at RD (n= 6 pts) showed a similar behavior to non-Japanese pts, with a mean (standard deviation) total body clearance (CL) of 10.5 (4.5) L/h, half-life of 50.7 (18.1) h and volume of distribution at steady-state of 375.5 (172.0) L. **Conclusions:** The RD of PM1183 in Japanese pts is 2.5 mg/m^2 q3wk, with mild toxicity. Main DLTs were hematological. Hints of activity were observed in breast cancer. Japanese pts showed a similar CL to non-Japanese pts, but with a 26.5% lower distribution volume. A new cohort is exploring PM1183 3.2 mg/m^2 (non-Japanese RD) in Japanese pts receiving G-CSF support. Clinical trial information: NCT02210364.

2552 Poster Session (Board #378), Mon, 8:00 AM-11:30 AM

Abrogation of resistance against bevacizumab (Bev) by mitochondrial inhibition: A phase 0 randomized trial of Bev plus ME344 or placebo in early HER2-negative breast cancer (HERNEBC). *First Author: Miguel Quintela-Fandino, CNIO - Spanish National Cancer Research Center, Madrid, Spain*

Background: Our preclinical data show that one mechanism of acquired resistance to anti-angiogenic therapy involves hypoxia correction, measured by decreased SUV (↓ SUV) on FDG-PET followed by mitochondrial up-regulation. ME344 is a potent inhibitor of mitochondrial respiration. The aims of this study were to assess 1) the fraction of HERNEBC patients that show ↓SUV in response to single dose Bev and 2) if adding ME344 to Bev inhibits cell proliferation as determined by Ki67% decrease, a surrogate marker of efficacy in neoadjuvant breast cancer. **Methods:** Treatment-naïve HERNEBC patients (T > 1 cm, any N, M0) received 15 mg/kg Bev on d0 and were then randomized 1:1 to ME344 10 mg/kg IV d8, 15 and 21 (arm A) or placebo (arm B) followed by physician's choice of definitive therapy. FDG-PET was performed on d0 and d7 and tumor biopsy on day 0 and 28. The primary endpoint was Ki67% relative reduction from d0 to 28. A 40 patient sample size was powered to detect a 30% relative difference in Ki67% between arm A and B (alpha 0.05, beta 0.2). Threshold for hypoxia correction by PET was 10% ↓ SUV. A predefined interim analysis was planned when 20 patients had completed treatment. **Results:** 19 patients were randomized (arm A/B: 7/7 LumA, 2/2 LumB, 1/0 TNBC). Baseline characteristics: Ki67 by IHC: mean 10.3% (1%-48%), age: mean 56 (44-75), T (8 T1, 10 T2, 1 T3), N (14 N0, 5 N1) and G (4 G1, 12 G2, 3 G3) were balanced between arms. 31% of patients experienced ↓SUV > 10%. Mean absolute (relative) Ki67 decreases were 5.13 (29%) and 1.2 (9%) in arms A and B (P = 0.06). Patients with ↓ SUV > 10% experienced an absolute average Ki67 decrease of 16.6 vs. 2.3 in arms A and B (P = 0.19). Two G3 adverse events (high blood pressure) were reported (1 per arm) and deemed related to Bev. **Conclusions:** ME344 results in significant Ki67 reduction compared to placebo in HERNEBC patients exposed to single-dose Bev. This effect may be greater in those patients with Bev induced hypoxia correction. These clinical results are consistent with preclinical data suggesting that ME-344 can reverse resistance to anti-angiogenic therapy and warrant further studies to assess clinical efficacy of the combination. Clinical trial information: NCT02806817.

LBA2553 Poster Session (Board #379), Mon, 8:00 AM-11:30 AM

Precision medicine: Clinical outcomes including long-term survival according to the pathway targeted and treatment period: The IMPACT study. *First Author: Apostolia Maria Tsimberidou, The University of Texas MD Anderson Cancer Center, Houston, TX*

The full, final text of this abstract will be available at abstracts.asco.org at 7:30 a.m. ET on Saturday, June 2, 2018, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2018, issue of the *Journal of Clinical Oncology*. On-site at the Meeting, this abstract will be printed in the Monday edition of *ASCO Daily News*.

2554 Poster Session (Board #380), Mon, 8:00 AM-11:30 AM

A phase 1/2 study of relacorilant + nab-paclitaxel (nab-pac) in patients (pts) with solid tumors: The dose-finding phase. *First Author: Pamela N. Munster, University of California, San Francisco, San Francisco, CA*

Background: Glucocorticoid receptor (GR) expression has been linked with chemotherapy resistance. Nonclinical and clinical studies have suggested that a GR antagonist (GRA) can enhance the efficacy of chemotherapy. Relacorilant (formerly CORT125134), a potent selective GRA, is being evaluated in solid tumors in combination with nab-pac. **Methods:** This ongoing phase 1/2 study is evaluating the tolerability, anticancer activity, and Phase 2 dose of relacorilant + nab-pac. Nab-pac is administered weekly for 3 of 4 weeks of a 28-day cycle. The study includes assessment of 2 relacorilant dosing schedules: continuous (CON) daily dosing and intermittent (INT) dosing (the day before, of, and after nab-pac). Pts ≥18 y old with advanced solid tumors, up to 3 prior lines of therapy in the advanced setting, ECOG status 0-1, and adequate renal, hepatic, and marrow function are included. Prior treatment with nab-pac is allowed. **Results:** As of Jan 1, 2018, 25 pts were enrolled; 17 had prior taxane. In CON dosing, 16 pts received 100 mg relacorilant/80 mg/m^2 nab-pac and 1 received 100 mg relacorilant/60 mg/m^2 nab-pac. In INT dosing, 4 pts received 200 mg relacorilant/150 mg/m^2 nab-pac and 4 received 150 mg relacorilant/100 mg/m^2 nab-pac. Grade ≥3 AEs included neutropenia (40%), anemia (12%), pneumonia (8%), mucosal inflammation (8%), and leukopenia (8%). Dose-limiting toxicity included neutropenia; GCSF support was added to regimens subsequently. Among pts treated to date, 1 unconfirmed CR (ovarian CA), 2 confirmed PRs (pancreatic CA, vulvar CA), and 5 SDs (2 ovarian CA, 2 pancreatic CA, 1 carcinoid) were observed. Pancreatic CA pt with confirmed PR has remained on study 48 weeks, despite having progressed within 14 weeks on earlier gemcitabine/nab-pac. For the 6 pts with available tissue, all had GR IHC results with ≥50% staining (range 50%-100%); 4/6 pts were responders; all 4 had ≥60% GR staining. **Conclusions:** An efficacy signal has been observed in pts with pancreatic and gynecologic CA previously treated with taxane. Neutropenia is manageable with GCSF support and dose modification. Expansions are planned, including pancreatic and ovarian CA cohorts. Clinical trial information: NCT02762981.

2555 Poster Session (Board #381), Mon, 8:00 AM-11:30 AM

Real world results of liquid biopsy in stage 3/4 solid tumors and potential "clinical actionability." *First Author: Rebecca Christian Arend, University of Alabama at Birmingham, Birmingham, AL*

Background: Next-generation sequencing (NGS) of plasma circulating cell-free DNA (cfDNA) and cfRNA, also known as a "liquid biopsy", is a minimally invasive technique available in the clinic. Here we report initial liquid biopsy results from stage 3 and 4 solid tumors using the Circulogene Theranostics Personalized Gene Profile (CGP, 50-gene panel) on cfDNA and cfRNA. **Methods:** DNA mutations detected and, where available, PD-L1 expression, ALK, and ROS1 fusions in RNA were retrospectively compiled from CGP ordered at two centers. To be considered clinically actionable and commercially available (CA), the biomarker had to have demonstrated clinical efficacy in human cancer prospective trials using the biomarker and commercially available drug that can target that biomarker. To be considered a clinical trial possibility (CT), one of the biomarkers was required to have a drug in clinical development using the biomarker for the patient's cancer type and disease stage listing on clinicaltrials.gov during the time period that CGP was ordered. **Results:** One hundred forty-five patients (median age 66 years, range 25-95; 35 men and 110 women) underwent CGP testing between November 2015 and October 2017. The majority of cancer types were ovarian, breast, pancreatic, uterine, and prostate. Most common DNA mutations recorded were TP53, PTEN, PI3KCA, SMAD4, and BRAF. There was a median of 2 mutations/patient (range 0-11), with a 0.69% sample failure rate. Overall, 36 cases had no detectable mutations (24.8%). There were six samples with PD-L1 results, and one was positive (16.7%), in the range of expected PD-L1 positivity across solid tumors. In addition to the 36 mutation negative cases, 19 cases had no potential match for CA or CT (e.g. APC, GNAS, SMAD4 mutations). Thus, 89 (61.4%) of cases had the potential for CA and/or CT drug identified by liquid biopsy. CGP is priced at approximately $600 per sample comparable to current reimbursement rate. **Conclusions:** In this real world experience, despite the low plasma sample input, there was a 0.69% sample failure rate, suggesting CGP *in situ* enrichment is robust. More experience with this assay and linkage with clinical outcomes is warranted.

2556 Poster Session (Board #382), Mon, 8:00 AM-11:30 AM

A phase Ib study of ADI-PEG 20 plus pembrolizumab in advanced solid cancers. *First Author: Kwang-Yu Chang, National Institute of Cancer Research, National Health Research Institutes, Tainan, Taiwan*

Background: Arginine deprivation with pegylated arginine deiminase (ADI-PEG 20) has been shown to upregulate tumor programmed death-ligand 1 (PD-L1) expression and T cell infiltration. Current phase Ib study is to explore the feasibility of combining ADI-PEG 20 with pembrolizumab in patients with advanced solid tumors. **Methods:** Eligibility criteria included treatment-failure patients with measurable lesions. Pre-treatment tumor biopsy was required. In the "3 + 3" designed dose-escalation part, patients were enrolled to receive ADI-PEG 20 36 mg/m^2 at day 1, 8 and 15, and pembrolizumab (1 mg/kg or 200 mg) at day 1, every 3 weeks to determine the maximum tolerated dose (MTD) of pembrolizumab for expansion cohort study. In the expansion cohort part, patients with platinum-failed HNSCC would receive both ADI-PEG 20 and pembrolizumab (at MTD) from day 1; while patients in translation cohort who were required to have $<$ 50% PD-L1 expressing tumors would receive 3 doses of weekly ADI-PEG 20 and a post-ADI-PEG 20 biopsy before the start of combination treatment. The primary endpoint was safety and tolerability. Secondary endpoints included progression-free survival, overall survival, response rate, and the changes of tumorous PD-L1 expression and T-cell infiltration after treatment with ADI-PEG 20 with and without pembrolizumab. **Results:** The recruitment of dose-escalation cohorts was completed between July 2017-January 2018. There was only one dose-limiting toxicity, grade 3 hepatitis, observed in a patient in 1 mg/kg dose level; while none in the 200 mg dose level. Among them, two (22.2%) had partial response (PR) and four (44.4%) had stable disease. The two PRs were in thymus cancer and nasopharyngeal carcinoma, with both having 100% tumor baseline PD-L1 expression. The most common grade 3/4 adverse event (AE) was neutropenia, which occurred in seven patients. For serious AEs, two had neutropenic fever lasting less than one week in the third week, and one had tumor bleeding because of tumor progression in the eighth week. The expansion cohorts are enrolling. **Conclusions:** Co-administration of ADI-PEG 20 and pembrolizumab is feasible. The major toxicity is neutropenia which is transient and manageable. Responses were observed with the regimen. Clinical trial information: NCT03254732.

2557 Poster Session (Board #383), Mon, 8:00 AM-11:30 AM

Phase 1 study of ANDES-1537: A novel antisense oligonucleotide against non-coding mitochondrial DNA in advanced solid tumors. *First Author: Mallika Sachdev Dhawan, University of California San Francisco, San Francisco, CA*

Background: New non-coding RNAs, which appear to be involved in cell proliferation in animal cells, have been discovered by L.Burzio and co-workers. Andes-1537 is a short single stranded phosphorothioate-deoxyoligonucleotide which binds by base pairing to one of these newly discovered non-coding RNAs, named Antisense non-coding mitochondrial RNA (ASncmtRNA). The resulting RNA-DNA hybrid is then hydrolyzed by two cellular RNases: RNase H and DICER resulting in microRNAs. In vitro experiments with cells have shown Andes-1537 affects cancer cells by: a) inducing apoptosis by lowering the expression of anti-apoptotic proteins such as survivin b) decreasing proliferative signaling through inhibition of the expression of proteins such as cyclin D1 and cyclin B1, and c) inhibition of tissue invasion/metastatic proteins such as n-cadherin, B-catenin and metastasis inducing factors. **Methods:** The safety, tolerability, maximum tolerated dose (MTD), pharmacokinetic (PK) characteristics and efficacy of Andes -1537 was assessed in a phase 1 study. Patients with all solid tumors were enrolled in 5 cohorts at 100 mg subcutaneous (SC), 200 mg SC, 400 mg SC, 600 mg SC and 800 mg SC twice weekly. **Results:** 22 patients (14 M: 8F) with heavily pretreated solid tumors were enrolled in 5 cohorts. Two dose-limiting toxicities occurred at the 800 mg dose level both of which were injection site reactions: one precluding full cycle 1 dose delivery, and one involving grade 3 skin necrosis due to vascular occlusion and inflammation. No other grade 3/4 toxicities were seen. Grade 2 toxicities including injection site reactions and erythema. The MTD has been determined to be 600 mg SC twice weekly. Two patients (one with pancreatic cancer and one with cholangiocarcinoma) had stable disease on scans beyond six months. No partial or complete responses were seen with Andes 1537. PK data reveals a linear PK profile. **Conclusions:** Andes-1537 is a well-tolerated drug with a novel mechanism. It was determined to be tolerable at 600 mg SC twice weekly. An efficacy signal in pancreatic cancer and cholangiocarcinoma was seen at 200 mg dose level and thus dose expansion is under consideration. Clinical trial information: NCT02508441.

2558 Poster Session (Board #384), Mon, 8:00 AM-11:30 AM

Characterization of *KEAP1-NRF2* genomic alterations across diverse tumor types: Co-occurring alterations, survival outcomes, and implications for targeting cancer metabolism. *First Author: Shiraj Sen, The University of Texas Southwestern Medical School, Dallas, TX*

Background: CRISPR–Cas9-based genetic screening and metabolomic analyses have revealed that *KEAP1-NRF2*-mutated cancers depend on increased glutaminolysis and are vulnerable to glutaminase inhibition. However, alterations in *KEAP1-NRF2* have yet to be clinically characterized. **Methods:** We analyzed clinical and next gen sequencing data from pts treated at MD Anderson Cancer Center and performed bioinformatic analyses of alteration frequency using TCGA data on cBio Portal to characterize *KEAP1-NRF2* alterations and used Kaplan-Meier analysis to identify associations with overall survival (OS). **Results:** Among 189 pts with *KEAP1* or *NRF2* alterations (alts) at MDACC (97 with each, 5 with both), median age was 65 yrs (range: 18-89), 52% were females, 80% Caucasian, 11% Hispanic, and 5% African-American. *KEAP1-NRF2* alts were most common in NSCLC (19%), cholangiocarcinoma (8%), breast (7%), and renal cell CA (7%). Mean number of co-occurring alts was 8 (range:0-73). We identified 69 unique alts in *KEAP*1, most commonly Q619del (11%) and V369A (9%), and 68 unique alts in *NRF2*, most commonly E79Q (6%) and G31A (6%). Median OS in the entire cohort was 966 days. Of the 1505 co-alts identified with *KEAP1*, most common were *TP53* (57%), *ARID1A/B/2* (55%), *PI3K*-encoding genes (37%), and *NOTCH1* (29%). Of the 817 unique co-alts identified with *NRF2* alts, most common were *TP53* (52%), *PI3K*-encoding genes (36%), *ARID 1A/B/2* (25%), and *BRCA1/2* (19%). Co-alts in *TP53,* SWI/SNF complex, mTOR pathway, and NOTCH pathway genes did not impact survival. In TCGA, *KEAP1-NRF2* alts were most common in NSCLC (26%), uterine (15%), breast (10%), and cholangiocarcinoma (9%). *KEAP1-NRF2* alts were associated with decreased survival in lung adenocarcinoma (LUAD), 49 vs 33 months, log rank p = 0.02. **Conclusions:** KEAP1-NRF2 alts are prevalent across diverse tumor types and associated with decreased survival in LUAD. They most frequently co-occur with alts in TP53, SWI/SNF complex, and mTOR pathway genes but these co-occurring alts did not impact survival in our cohort. A Basket trial of Glutaminase Inhibitor (BeGIN) CB839 in patients with *KEAP1/NRF2* aberrant tumors is planned.

2559 Poster Session (Board #385), Mon, 8:00 AM-11:30 AM

Identification of predictive and pharmacodynamic biomarkers associated with the first-in-class selective axl inhibitor bemcentinib across multiple phase II clinical trials. *First Author: Robert J Holt, BerGenBio ASA, Bergen, Norway*

Background: AXL expression is strongly associated with immunosuppression and therapy resistance in a wide range of cancers. Bemcentinib is a first-in-class, orally bioavailable, selective AXL TKI which is being evaluated in solid tumours and myeloid malignancies in multiple Ph II clinical trials. Evidence of immune activation and reversal of therapy resistance upon treatment with bemcentinib has been observed in vivo as well as pts treated across the clinical programme. Here we report results of the accompanying biomarker research that utilises both liquid and tissue biopsies for gene expression, immunohistochemistry (IHC) and protein based analysis. **Methods:** Plasma protein biomarker levels were measured using the DiscoveryMap v3.3 panel (Myriad RBM) in a selection of pts pre-dose and at C2D1 across six clinical trials. Axl expression was measured in FFPE tissue samples together with an evaluation of distinct immune cell populations collected using multiplex IHC. Gene expression analysis was carried out by TaqMan qPCR. **Results:** Predictive and PD plasma biomarkers were identified in response to bemcentinib monotherapy in AML/MDS (NCT02488408), combination with pembrolizumab in NSCLC (NCT03184571), TNBC (NCT03184558) and melanoma (NCT02872259) as well as in NSCLC in combination with erlotinib (NCT02424617) and docetaxel (NCT02922777). Identified biomarkers include soluble AXL (sAXL) and other AXL regulated targets including angiogenin. A pharmacodynamic response of sAXL levels was observed after 1 cycle of treatment with bemcentinib which corresponded with the subset of pts that benefitted from treatment. Several biomarkers associated with treatment using bemcentinib + pembrolizumab across multiple different disease indications were also identified. AXL was detected by IHC in pt tumour tissue as well tumour associated immune cells. **Conclusions:** Results indicate the presence of predictive biomarkers which may be suitable for development into companion diagnostics to predict response to bemcentinib treatment. These biomarkers also confirm that bemcentinib has selective 'on-target' activity in a clinical setting.

2560 Poster Session (Board #386), Mon, 8:00 AM-11:30 AM

Interim results from a phase 1 trial of SL-801, a novel XPO-1 inhibitor, in patients with advanced solid tumors. *First Author: Judy Sing-Zan Wang, Florida Cancer Specialists and Research Institute, Sarasota, FL*

Background: SL-801 is a novel, oral, small molecule reversible inhibitor of Exportin-1 (XPO-1), a critical nuclear export protein overexpressed in many cancers. SL-801 has demonstrated potent in vitro and in vivo anti-tumor activity against a broad range of hematologic and solid cancers. SL-801's reversible inhibition of XPO-1 may translate to selective activity and potential safety benefits. Interim results from the dose-escalation study are reported. **Methods:** STML-801-0115 is a first-in-human, multicenter Phase 1 3x3 dose escalation study in patients with localized unresectable, or metastatic solid tumors resistant to or relapsed following standard therapy. Objectives are to evaluate safety and tolerability, identify maximum tolerated dose (MTD) or optimal dose/regimen for further evaluation, and assess pharmacokinetics and preliminary anti-tumor activity. SL-801 is orally administered on days 1-4 and 8-11 of a 21-day cycle. Starting dose was 5 mg and is currently 55 mg (escalation ongoing). **Results:** As of 1/6/18, 31 pretreated patients (range: 1-11 prior therapies; 71% ≥3rd line) received SL-801 (16 females, median age 63 years [range: 39-76]). No dose limiting toxicity (DLT) has been identified, and a MTD has not been reached. Median follow-up is 1.4 months (range: 0.2-8.5). Dose-dependent increases in C_{max} and AUC have been observed. The most frequent treatment-related grade 1-2 adverse events (TRAEs) were nausea (45%), vomiting (32%), diarrhea (19%), fatigue (26%) and decreased appetite (19%). Grade 3 TRAEs included nausea (n = 3; 40, 45, 50 mg), vomiting (n = 1; 45 mg), diarrhea (n = 2; 10, 50 mg), acute renal injury (n = 1; 30 mg), and neutropenia (n = 1; 10 mg). There were no grade 4 or 5 TRAEs. Nine patients had stable disease (SD) for 3-12+ cycles. Five patients, with GE junction, colon, neuroendocrine, basal cell, and breast cancer, had SD ≥4 months. Radiographic tumor shrinkage > 10% was noted in 3 patients. **Conclusions:** SL-801 appears to be well tolerated in advanced solid tumor patients, and 29% of patients achieved SD as best reponse. Enrollment and dose escalation continue in an effort to identify an optimal dose and regimen. Clinical trial information: NCT02667873.

2561 Poster Session (Board #387), Mon, 8:00 AM-11:30 AM

Phase I study of defactinib combined with pembrolizumab and gemcitabine in patients with advanced cancer. *First Author: Andrea Wang-Gillam, Washington University School of Medicine in St. Louis, St. Louis, MO*

Background: Focal adhesion kinase (FAK) is consistently hyperactivated in multiple tumor types including pancreatic ductal adenocarcinoma (PDAC). Our preclinical work showed that FAK and PD-1 inhibitors elicit significant tumor regression, and a maximal response is achieved by combining FAK and PD-1 inhibitors with gemcitabine, suggesting the need for a cytotoxic agent to bolster antigen presentation (Jiang H et al, Nature Medicine 2016). **Methods:** Eligible patients are being treated according to the dose escalation schema (Table 1). A 3+3 design is being used. The study has an expansion portion for PDAC patients at the recommended phase 2 dose (RP2D). The primary endpoint is to determine the RP2D. Secondary endpoints include safety, toxicity, objective response rate, progression-free survival and overall survival. The exploratory endpoints include developing a molecular and immune profile for treatment response. **Results:** The dose escalation cohort has been completed with a total of 20 patients with refractory solid tumors. The common treatment-related adverse events included nausea (50%), vomiting (40%), diarrhea (35%), anorexia (30%), fever (25%), and myalgia (25%). No DLTs were observed, therefore the Level 5 dose was deemed to be the RP2D. Among the 15 patients evaluable for treatment response, 1 (7%) partial response, 8 (53%) stable disease and 6 (40%) disease progression were observed. The median time on treatment was 132 days for all evaluable patients, and 127 days in the 8 PDAC patients with the longest time on treatment being 290 days. Partial response was seen in a patient with PDAC who progressed on gemcitabine and nab-paclitaxel. Paired biopsies in PDAC patients showed increased proliferating CD8+ T cells and decreased macrophages with treatment. **Conclusions:** The combination regimen is well tolerated. Dose Level 5 is the RP2D dose. The expansion cohort (PDAC only) is ongoing. Efficacy and correlative data is forthcoming. Clinical trial information: 02546531.

Dose escalation schema.

Dose Level	Defactinib D1-21 (BID)	Pembrolizumab D1	Gemcitabine D1, 8
Level 1 (starting dose)	200 mg	200 mg	-
Level 2	400 mg	200 mg	-
Level 3	400 mg	200 mg	500 mg/m^2
Level 4	400 mg	200 mg	750 mg/m^2
Level 5	400 mg	200 mg	1,000 mg/m^2

2562 Poster Session (Board #388), Mon, 8:00 AM-11:30 AM

Phase I clinical trial of the glutaminase inhibitor CB-839 plus capecitabine in patients with advanced solid tumors. *First Author: Jennifer Rachel Eads, University Hospitals Seidman Cancer Center, Case Comprehensive Cancer Center, Case Western Reserve University, Cleveland, OH*

Background: Colorectal cancers (CRCs) harboring a PIK3CA mutation demonstrate glutamine dependency in both *in vitro* and *in vivo* models, including those known to be fluoropyrimidine (FP) resistant. CB-839 (CB) is an oral inhibitor of glutaminase, a key enzyme in glutamine metabolism. Preclinical studies further show that the combination of CB and a FP is superior to either as a single agent, and can overcome FP resistance. We conducted a phase I trial to assess the maximum tolerated dose and dose limiting toxicities (DLTs) of CB when given with capecitabine (C). **Methods:** Patients with advanced solid tumors and disease progression on standard treatment, or for whom C is an acceptable treatment option, were enrolled. A standard 3+3 design was used to assess escalating doses of CB (400-800 mg) and C (750-1000 mg/m^2) in four dose levels. CB was given orally twice daily continuously and C was given orally twice daily on days 14/21 of a 21 day treatment cycle. DLT period was 21 days. Restaging CT scans were obtained every 9 weeks with response assessment per RECIST. Adverse events were assessed per CTCv4. **Results:** 16 patients were enrolled: 38% male, 94% white, 6% African American, median age 69.5 years (43-80), mean number of cycles 7.3 (1-11). Seven patients were treated at the final dose level (CB 800 mg and C 1000 mg/m^2) and no DLTs were observed. Grade 3 adverse events included elevated ALT (n = 1), elevated AST (n = 1), anorexia (n = 1), decreased lymphocytes (n = 1), palmar-plantar erythrodysesthesia (n = 3), diarrhea (n = 1) and vomiting (n = 1). Grade 4 AEs included decreased lymphocytes (n = 1). Ten patients achieved stable disease as their best response, 9 being FP resistant. Associated median progression free survival (PFS) was 16.5 weeks among all patients (n = 16) and 29.5 weeks in PIK3CA mutant CRC patients (n = 6). At this time 2 patients remain on treatment at 31 and 3 weeks. **Conclusions:** CB 800 mg may be safely administered with C 1000 mg/m^2 with minimal toxicity. While no RECIST response was observed, several patients with prior FP resistance experienced prolonged PFS, particularly patients with PIK3CA mutant CRC. The phase II portion of this study in patients with PIK3CA mutant CRC is pending. NCT02861300, 2P50CA150964-06A1 Clinical trial information: NCT02861300.

2563 Poster Session (Board #389), Mon, 8:00 AM-11:30 AM

The utility of genomics and functional imaging to predict Sunitinib PK and PD: The Predict SU study. *First Author: Michael Michael, Division of Cancer Medicine, Peter MacCallum Cancer Centre, Melbourne, Australia*

Background: Current dosing of Sunitinib (Su) is associated with marked variability in pharmacokinetics (PK) & pharmacodynamics (PD). Despite its hepatic metabolism, genotyping & phenotyping of ABCB1 & CYP3A4 have inconsistently accounted for this variability. This study has evaluated the utility of extensive excretory/metabolic/PD pharmacogenomics (PG) combined with ^{99m}Tc-MIBI hepatic nuclear imaging (HNI, to phenotype ABCB1 biliary excretory function), to predict Su PK/PD. **Methods:** Patients (pts) had advanced renal cell carcinoma (RCC) or GIST, treated with Su, 50mg daily for 4 weeks, q6 weekly. Pts had blood analyzed by Affymetrix DMET™ Plus Array and additional PD SNPs were genotyped. For HNI, pts were given IV 800MBq ^{99m}Tc-MIBI, the imaging data was analysed for hepatic extraction/excretion parameters (Clearance [CL], Deconvolutional excretion half-life [$DeT_{1/2}$], hepatic extraction fraction [HEF]). Pts were restaged after 2 cycles (12 weeks). Blood were taken for Su parent (SuP) and metabolite (SU12662-SuM) analysis in cycles 1 & 2, days 1, 14 and 28. PK parameters derived by non-compartmental analysis. Statistical associations were evaluated between (i) HNI parameters and (2) PGs, with Su PK, toxicity, response and progression-free survival (PFS). **Results:** 15 pts analysed (10 RCC, 5 GIST). (1) PK predictors: HEF with SuP and SuM cycle 1 $logAUC_{0\text{-}14days}$ ($P < 0.05$) and $DeT_{1/2}$ with SuP cycle 1 $logAUC_{0\text{-}28days}$ ($P < 0.02$) (2) Diarrhea ≥Grade 1 (N = 4): HEF ($P = 0.03$), and gene variants VEGFR3 ($P < 0.0004$) and SCL7A8, ABCC3 ($P < 0.05$), (3) ≥Grade 3 Adverse events (N = 2): variants in ABCC4, SLC7A7 ($P < 0.05$). (4) Disease control rate: N = 7 (54%): HNF1A (79A > C) ($P = 0.4$), variants in SCLO5A1, SLC7A5, ABCG1, ABCC4, ABCB4, ($P < 0.05$). (4) PFS: SuP cycle 1 $logAUC_{0\text{-}14days}$ ($P < 0.03$), HNF1A (79A > C) ($P < 0.03$), PDGFRα (-1171C > G) ($P < 0.04$), ABCC4, ABCC1, SULT1C2, SLC01A2, CYP2D6, ($P < 0.02$). Multiparameter models were generated for the prediction of (i) SuP $logAUC_{0\text{-}14days}$ incorporating HEF + TNFα (-857C > T) ($P = 0.02$) and (ii) SuM $AUC_{0\text{-}14days}$ with VEGFR3 (150A > G) + $DeT_{1/2}$ ($P = 0.009$). **Conclusions:** Hepatic functional imaging with extensive pharmacogenomics were associated with Su PK and PD, potentially enabling individualized dosing Clinical trial information: ACTRN12610000897066.

2564 Poster Session (Board #390), Mon, 8:00 AM-11:30 AM

Pharmacokinetic (PK) and exposure-response (ER) analysis of pertuzumab (P) in patients (pts) with HER2-positive metastatic gastroesophageal junction and gastric cancer (mGEJC/GC). *First Author: Whitney Paige Kirschbrown, Genentech Inc., South San Francisco, CA*

Background: The phase 2a, dose-finding JOSHUA study reported increased P clearance (CL; 37% lower P steady-state C_{min} [$C_{min,ss}$]) in pts with HER2+ mGEJC/GC vs metastatic breast cancer (MBC). Based on these data, 840 mg q3w was selected for testing in the phase 3 JACOB study (NCT01774786) to achieve similar P concentrations (conc) to BC studies with the 840 mg then 420 mg q3w P dose. In JACOB, while there was evidence of treatment activity, addition of P to trastuzumab (H) and chemotherapy (CT) in 1st-line therapy did not significantly improve overall survival (OS) vs placebo (Pla)+H+CT (hazard ratio: 0.84 [95% CI 0.71–1.00], median OS 17.5 vs 14.2 months), in pts with HER2+ mGEJC/GC. Here we report the PK and ER analysis of P in JACOB. **Methods:** PK samples were collected at Cycles 1–4, 6, and 8 (predose); Cycles 1, 2, 4 and 8 (postdose); and at follow-up. P+H peak and trough conc were summarized by descriptive statistics and % pts with a $C_{min,ss} \geq 20$ μg/mL (target conc) tabulated. PK exposure was compared across geographic regions. The Kaplan-Meier method and a log-rank test were used to assess OS across C_{min} quartiles. PK drug-drug interactions (DDIs) were assessed using serum C_{min} geometric mean ratios. **Results:** Pts with ≥1 dose of P or H and ≥1 PK sample were included (P: n = 374 [P+H+CT]; H: n = 372 [P+H+CT] and 375 [Pla+H+CT]). Mean $C_{min,ss}$ Cycle 6 for P was 114±51.8 μg/mL, 99.3% of pts had $C_{min,ss}$ for P ≥20 μg/mL. There were no differences in OS across Cycle 1 and Cycle 6 (s-s) P C_{min} quartiles (Q1: 0.075–30.6, Q2: 30.6–39.8, Q3: 39.8–51.9, Q4: 51.9–318; n = 349, P = 0.52 and Q1: 0.075–77.1, Q2: 77.1–110, Q3: 110–145, Q4: 145–450; n = 274, P = 0.78, respectively). Mean $C_{min,ss}$ was comparable across geographic regions. No apparent DDIs were observed for CT on P $C_{min,ss}$, or P on H. Two of 349 (0.6%) evaluable pts tested positive for anti-drug antibodies to P; there was no impact on P PK. **Conclusions:** In JACOB, the 840 mg q3w P dose achieved target $C_{min,ss}$ in > 99% pts with HER2+ mGEJC/GC. ER analysis showed no correlation between P trough conc and OS. PK data were consistent with prior GC (P: 840 mg) and BC (P: 840 mg/420 mg) studies and higher P CL in HER2+ mGEJC/GC vs other tumor types. Clinical trial information: NCT01774786.

2565 Poster Session (Board #391), Mon, 8:00 AM-11:30 AM

Validation of a new model for estimating glomerular filtration rate in patients with cancer. *First Author: Edward Williams, Cancer Research UK Cambridge Institute, Cambridge, United Kingdom*

Background: Estimation of glomerular filtration rate (GFR) is essential for carboplatin chemotherapy dosing. However, the most accurate method to estimate GFR in patients with cancer is unknown. Using data from 2471 patients with cancer, we developed a new model that improves estimation of GFR (eGFR) and carboplatin dose calculations when compared to BSA adjusted CKD-EPI, the next most accurate model for determination of eGFR in patients with cancer. [1] Here we present a multi-centre validation study of this work. **Methods:** Data on age, sex, height, weight, serum creatinine, and results for GFR from ^{51}Cr-EDTA excretion measurements (^{51}Cr-EDTA GFR) were obtained from Caucasian patients aged 18 years or older with histologically confirmed cancer diagnoses from one Swedish and six UK centres. We validated the new multivariate linear model for GFR using statistical analysis. ^{51}Cr-EDTA GFR was compared with the estimated GFR (eGFR) from seven published models and the new model using root-mean-squared-error (RMSE) and median residuals. A comparison of carboplatin dosing accuracy based on an absolute percentage error more than 20% (APE > 20%) was undertaken. **Results:** Data from 3869 patients were obtained. In a pooled analysis, the new model improved the eGFR accuracy (RMSE 16.58ml/min (95% CI 16.21 to 16.95)) compared with all other published models. Body surface area (BSA) adjusted CKD-EPI remained the second most accurate model for eGFR (RMSE 17.58ml/min (95% CI 17.20 to17.99)). The new model was also the least biased model (Residual Median 0.33 (95% CI -9.56 to 10.69)). Importantly, the new model reduced the fraction of patients with a carboplatin dose APE > 20% (16.93% compared with 19.07% for the next best model). The new model was the most accurate model for patients with seminoma (n = 642), ovarian cancer (n = 553), and bladder cancer (n = 253). A further 2000-2500 patients will be included before completion of the study. **Conclusions:** In a very large multicentre data set of patients with cancer, we confirm that our new model improves eGFR and carboplatin dose calculations when compared with commonly used, published models. [1] Janowitz T and Williams EH *et al.*, J Clin Oncol. 2017 Aug 20;35(24):2798-2805. doi: 10.1200/JCO.2017.72.7578

Selection of the recommended phase 2 dose (RP2D) for M7824 (MSB0011359C), a bifunctional fusion protein targeting TGF-β and PD-L1. *First Author: Yulia Vugmeyster, EMD Serono, Inc., Billerica, MA*

Background: The transforming growth factor β (TGF-β) pathway plays an important role in tumor immune escape and may enhance the response to PD-L1 monoclonal antibodies (mAb). M7824 is an innovative first-in-class bifunctional fusion protein composed of a human IgG1 mAb against PD-L1 fused with 2 extracellular domains of TGF-β receptor II (a TGF-β "trap") and has shown promising antitumor activity and manageable safety in phase 1 trials, including as 2L treatment for NSCLC. **Methods:** A population PK model for M7824 was developed based on serum concentration data from 350 pts from 2 clinical trials of M7824 in multiple solid tumor types. Simulations were performed using the model to explore exposure variability for various dosing regimens. Exposure-response analysis was performed for 500 and 1200 mg biweekly (q2w) 2L NSCLC cohorts (combined) using logistic regression for the investigator-assessed overall response rate (ORR) and Kaplan-Meier analyses for progression-free survival (PFS). **Results:** Simulations of AUC and C_{min} showed that variability in exposure was slightly higher for weight-based dosing compared with flat dosing, supporting the use of a flat-dose approach for M7824. Preliminary univariate analyses relating M7824 exposure (AUC and C_{min} after a single dose) to ORR in 500 and 1200 mg 2L NSCLC cohorts did not show a conclusive relationship. However, there was a trend for pts in the lowest exposure quartile (Q1, comprised of pts in 500 mg cohort only) to have a lower ORR (10% for AUC Q1; 5% for C_{min} Q1) than those in the higher exposure quartiles (25-30% and 20-40% ORR for AUC and C_{min} Q2-Q4, respectively). Results of Kaplan-Meier analysis of PFS by exposure quartiles were in line with the exposure-ORR analyses, supporting 1200 mg q2w as the RP2D. At the C_{min} associated with the RP2D, nearly complete target occupancy for PD-L1 (PBMC) and TGF-β trapping (plasma) was achieved. Moreover, these C_{min} values were associated with 95% tumor-growth inhibition in mouse models. **Conclusions:** Based on the integrated analysis and modeling data available to date, a flat dose of 1200 mg q2w is the RP2D for M7824.

2567 Poster Session (Board #393), Mon, 8:00 AM-11:30 AM

TAK-659 in combination with NKTR-214 and anti-PD-1 therapy leads to complete and sustained tumor regression and immune memory in pre-clinical syngeneic models. *First Author: Jie Yu, Takeda Pharmaceuticals, Cambridge, MA*

Background: TAK-659 is a highly potent, reversible inhibitor of spleen tyrosine kinase (SYK) and fms related tyrosine kinase 3 (FLT3) that is being tested in combination with nivolumab in patients with advanced solid tumors (NCT02834247). NKTR-214, a CD-122-biased agonist that targets the IL-2 pathway, provides sustained signaling through the heterodimeric IL-2 receptor pathway (IL-2Rβγ) to preferentially activate and expand NK and effector CD8+ T cells over T-regulatory cells in the tumor microenvironment, and is currently in multiple Phase I and II clinical trials in combination with checkpoint inhibitors (NCT02983045, NCT03138889). Treatment with TAK-659 in pre-clinical models resulted in a decrease in MDSCs and B220+ B-cells suggesting an immunomodulatory response, and the combination with anti-PD-1 therapy in pre-clinical *in vivo* models resulted in increased anti-tumor activity and durable complete responses. NKTR-214 monotherapy increases newly proliferative CD8+ T cells in tumors, increases cell surface PD-1 on immune cells and PD-L1 on tumor cells, and the combination with anti-PD-1 therapy shows marked efficacy in mouse syngeneic models. **Methods:** Here we explored the pre-clinical combination of TAK-659 with NKTR-214 in the presence or absence of anti-PD-1 therapy in multiple syngeneic tumor models. **Results:** TAK-659 in combination with NKTR-214 with or without anti-PD-1 therapy resulted in significant anti-tumor activity and durable complete tumor regressions. In the CT-26 murine colon cancer model, the TAK-659 + NKTR-214 or the triple combination with anti-PD-1 therapy resulted in 9 out of 10 mice having a maintained complete response (CR) 55 days post the end of treatment, versus 1 CR for TAK-659 or anti-PD-1 single agents, and none for NKTR-214 single agent. Complete responders, left untreated and re-challenged with another inoculation of tumor cells, did not form tumors, suggesting a potential immune memory. **Conclusions:** NKTR-214, TAK-659 and anti-PD-1 therapy bring together complementary non-overlapping mechanisms that create a promising potential therapy, supporting the rationale for examining the clinical combination.

2568 Poster Session (Board #394), Mon, 8:00 AM-11:30 AM

Unexpected pharmacokinetics of evofosfamide observed in phase III MAESTRO study. *First Author: Jack P. Higgins, Molecular Templates, Inc., Austin, TX*

Background: Evofosfamide (Evo) is a prodrug of Br-IPM that is preferentially activated under hypoxic conditions. Hypoxia in locally advanced unresectable pancreatic ductal adenocarcinoma (PDAC) is associated with disease progression and poor prognosis. **Methods:** Gemcitabine (Gem) was evaluated with or without Evo in a randomized phase II (Ph 2) trial (N = 214) in US patients with advanced PDAC (NCT01144455). Two doses of Evo (240 mg/m2 or 340 mg/m2) were tested with 340 mg/m2 showing a significant improvement in ORR and PFS.MAESTRO was an international, randomized, double-blind, placebo-controlled phase III (Ph 3) trial (N = 693) of Evo + Gem versus Placebo (Pbo) + Gem in patients with locally advanced unresectable or metastatic PDAC (NCT01746979) using the same Ph2 schedule and 340 mg/m2 Evo dose. **Results:** Median OS in the Ph 3 study was 8.7 mo with Evo + Gem vs 7.6 mo with Pbo + Gem; HR = 0.84 (p = 0.059). Median PFS was 5.5 mo with Evo + Gem vs 3.7 mo with Pbo + Gem; HR = 0.77 (p = 0.004). The outcomes observed in the Ph 3 study (340 mg/m2 dose) were similar to the 240 mg/m2 dose Ph 2 outcomes (median OS = 8.7 mo; median PFS = 5.6 mo). Notably, a new ethanol-based formulation to improve drug product solubility was introduced after the Ph 2 study and before the start of the Ph 3 study. **Conclusions:** : Comparison of the Evo PK profile from the Ph 3 and Ph 2 studies suggest the formulation change may have substantially reduced Evo serum exposure (Table 1). This reduction in Evo exposure could explain why the efficacy seen in the Ph 2 study at the 340 mg/m2 dose were not replicated in the Ph 3 study. Evo is currently being tested at higher doses with the new formulation (ethanol-based) in an attempt to replicate the PK seen with the previous formulation at 340 mg/m2. Clinical trial information: NCT01746979.

Evo PK Comparison: Ph 2 (old formulation) and Ph 3 (new formulation).

	Ph 2 Evo + Gem						Ph 3 Evo + Gem

2569 Poster Session (Board #395), Mon, 8:00 AM-11:30 AM

An open-label, randomized cross-over bioavailability and extension study of oral paclitaxel and HM30181 compared with weekly intravenous (IV) paclitaxel in patients with advanced solid tumours. *First Author: Christopher G. C. A. Jackson, Southern District Health Board, Dunedin, New Zealand*

Background: Paclitaxel has poor oral bioavailability due to active excretion by p-glycoprotein (Pgp) on intestinal epithelial cells. An oral formulation would reduce IV access, avoid allergic reaction to cremophor, forego steroid premedication, reduce day stay, and improve convenience. With a lower Cmax, oral therapy may have toxicity advantages. Oraxol (Athenex, USA) is a combination of HM30181, a novel, orally active, potent and specific inhibitor of Pgp with low systemic exposure and oral paclitaxel. We report the results of the first scheduled interim analysis of a bio-equivalence study of Oraxol compared to IV paclitaxel, and the results of an extension study with repeat PK sampling after 4 weeks administration. **Methods:** We conducted a randomized crossover study at 3 sites in New Zealand. HM30181 15mg plus paclitaxel 205mg/m^2 was given PO on days 1-3 and compared to a single dose of IV paclitaxel (80 mg/m^2) in patients (pts) with advanced solid tumours. PK blood samples were taken d1-9 for PO paclitaxel and d1-5 for IV paclitaxel. Pts who completed were permitted to enroll on an extension study of Oraxol 205mg/m^2 d1-3 q1w with repeat PK sampling at week 4. **Results:** Paclitaxel PK was compared from the first 6 pts in the bioequivalence study, to 10 pts that were enrolled in the extension study. There was one treatment related SAE (tachycardia) which resolved. Treatment related toxicities were mostly GI and haematological, and manageable. One pt remains on study > 1 year without neuropathy. Clinical trial information: ACTRN12615000894594. **Conclusions:** Oraxol 615mg/m^2 PO d1-3 achieved paclitaxel AUC comparable to IV paclitaxel 80mg/m^2. This schedule of Oraxol is within predicted range needed to demonstrate bioequivalence. 4-week PK results show PK profile is not altered with repeated dosing. A phase 3 study in patients with metastatic breast cancer is ongoing.

	Paclitaxel 80mg/m^2 IV (n = 6) Mean (SD)	Oraxol, Baseline (n = 6) Mean (SD)	Oraxol Week 4 (n = 10) Mean (SD)

2570 Poster Session (Board #396), Mon, 8:00 AM-11:30 AM

Gene expression and cytokine modulation in a first in human (FIH) study of a pan BET inhibitor ABBV-075 in solid tumors. *First Author: Bert H. O'Neil, Indiana University School of Medicine, Indianapolis, IN*

Background: ABBV-075 is an oral small molecule inhibitor of the BET family of bromodomain-containing proteins that function as regulators controlling many transcriptional programs required for cancer pathogenesis. ABBV-075 is currently being evaluated in a FIH study in advanced solid tumors (M14-546). Using a 3+3 dose escalation design, a total of 72 solid tumor patients were treated across 3 dosing schedules. Dose-limiting toxicities were thrombocytopenia, fatigue, aspartate aminotransferase elevation, gastrointestinal bleed, and hypertension in the dose escalation phase. **Methods:** In this report, pharmacokinetic (PK) and pharmacodynamic (PD) data are presented for 40 subjects. PD effect was measured in surrogate tissue (whole blood and serum), which was collected prior to therapy and at various time points post-dosing. Gene expression was evaluated by branched DNA assay. Soluble cytokines were analyzed by immunoassay (Myriad RBM's InflammationMAP®). **Results:** The observed T_{max} occurred at 2-4 hours post dosing, C_{max} and AUC_{inf} increased dose-proportionally within the dose-range studies, mean $t_{1/2}$: 13 - 32 hours. Exposure (C_{max}) at day 8 correlated with decrease in platelet count on day 15 compared to baseline counts (Pearson correlation: -0.46, p = 0.032). HEXIM1 and DCXR gene expression increased, CD93 gene expression decreased at 6 hours post treatment. CD93 and DCXR demonstrated dose-dependent modulation. Statistically significant correlation was observed between gene modulation at 6 hours and drug exposure at day 8 (Pearson correlation: HEXIM1 = 0.435, CD93 = 0.375, DCXR = 0.541). Soluble BDNF expression demonstrated a dose and time-dependent decrease at cycle 2 and 3 compared to baseline ($p < 0.0001$). **Conclusions:** We demonstrated target engagement in surrogate tissue via modulation of gene and soluble cytokine expression, both of which were dose dependent. Strong correlation was observed between drug exposure and gene expression modulation as well as thrombocytopenia, after ABBV-075 treatment. Correlation of these PD effects with adverse events and clinical response, are currently under investigation. Clinical trial information: NCT02391480.

2571 Poster Session (Board #397), Mon, 8:00 AM-11:30 AM

Therapeutic drug monitoring (TDM) of tyrosine kinase inhibitors (TKI) in routine practice in an oncology service. preliminary results. *First Author: Manuel Sureda, Plataforma de Oncologia, Hospital Quironsalud Torrevieja. Catedra Oncologia Multidisciplinar-UCAM, Torrevieja, Spain*

Background: TKIs show a high pharmacokinetic variability. So, fixed dosing could result in inadequate exposure with decreased efficacy or increased toxicity. TDM allows individualized posology to improve efficacy and avoid adverse events. We report the preliminary experience with TDM of TKIs in routine clinical practice, the observed variability in exposure and subsequent dose changes. **Methods:** Patients treated with erlotinib, imatinib, lapatinib, sorafenib or pazopanib between 2010 and 2017 were included. Initial dose administered was as described in the data sheet for each drug. TDM was performed in basis of the Cmin described in the literature. Individual data were obtained from medical records and analyzed with the statistical package SPSS v.20. The study was approved by the Clinical Research Ethics Committee. Informed consent was obtained. **Results:** 61 patients were evaluable. TDM shown that 51% of patients had an initial inadequate exposure with standard doses and given the possibility of a tailored subsequent correction. Table 1 shows the average doses in first and last cycle of TDM. **Conclusions:** TDM significantly improved exposure levels of TKIs, increasing its effectiveness and safety in routine clinical practice. Further studies are warranted.

2572 Poster Session (Board #398), Mon, 8:00 AM-11:30 AM

Impact of curcumin with and without (+/-) piperine on tamoxifen exposure. *First Author: Gerardus Hussaarts, Department of Medical Oncology, Erasmus MC Cancer Institute, Rotterdam, Netherlands*

Background: Tamoxifen is extensively used as endocrine therapy for breast cancer. It is a prodrug that is primarily metabolized by CYP2D6 and CYP3A4, particular into endoxifen. In daily practice, the herb curcumin is widely used among patients (pts) because of its presumed anti-tumor effects. Preclinical studies show effects of curcumin on phase I and II drug metabolism, leading to altered plasma levels. We hypothesized that curcumin increases endoxifen exposure by affecting phase II metabolism. Therefore, we performed a randomized, 3-phase, cross-over study to compare tamoxifen exposure in breast cancer pts +/- curcumin, and with the addition of the bioenhancer piperine. **Methods:** Pharmacokinetic sampling (PK) was performed in 15 pts at the 28^{th}, 56^{th} and 84^{th} day of the trial. In the 28 days prior to PK, tamoxifen (20 mg qd) was either given alone, or combined with curcumin (1,200 mg TID), or with curcumin + piperine (10mg TID) in this order or *vice versa*. Genotyping was performed to determine CYP2D6 and CYP3A4 phenotypes. Primary endpoint was difference in geometric means for $AUC_{0\text{-}24h}$. A linear mixed model was used to analyze log-transformed area under the curve (AUC). For multiple testing a Bonferroni correction was applied. **Results:** Tamoxifen $AUC_{0\text{-}24h}$ decreased with 7.3 % (95% CI: -0.5,-13.6%; p = .04) with curcumin and 13.0% (95% CI: -5.6,-19.9%; p = .002) with curcumin and piperine, compared to tamoxifen alone. Endoxifen $AUC_{0\text{-}24h}$ decreased with 8.9% (95% CI: -0.9,-16.3%; p = .029) and 13.5% (95% CI: -2.8,-23.0%; p = .015), respectively. *CYP2D6*-screening resulted in 6 intermediate metabolizers (IM), and 6 extensive metabolizers (EM). Interestingly, for pts with a EM phenotype, effects of curcumin with piperine on drug exposure ($AUC_{0\text{-}24h}$) seem to be higher than for IM phenotype pts (a decrease of 21.8% *vs* 4.8% for tamoxifen, and 22.6% *vs* 10.2% for endoxifen, respectively). No severe toxicity resulting from co-treatment was observed. **Conclusions:** In contrast to our hypothesis, the exposure of tamoxifen and endoxifen significantly decreased by concomitant use of curcumin +/- piperine. Although limited effects in most pts, co-treatment with these herbs could drop endoxifen levels below the threshold for efficacy, especially for EM phenotype pts. Clinical trial information: NTR6149.

2573 Poster Session (Board #399), Mon, 8:00 AM-11:30 AM

The clinical relevance of multiple DPYD polymorphisms on patients candidate for fluoropyrimidine based-chemotherapy: A case-control study in a Northern Italy Cancer Centre. *First Author: Francesco Iachetta, Medical Oncology Unit, Clinical Cancer Center, AUSL-IRCCS Reggio Emilia, Reggio Emilia, Italy*

Background: Deleterious polymorphisms in gene-encoding DPD (DPYD) may result in the severe reduction of DPD enzymatic activity that causes life-threatening toxicities when the standard dose of fluorouracil is used. DPYD*2A (IVS14+1G > A) is the most common single-nucleotide polymorphism (SNP) associated with critical DPD deficiency. To enhance prevention of fluoropyrimidine toxicity, we assessed the potential clinical impact of additional DPYD polymorphisms. **Methods:** In 2011, we began screening DPYD*2A in patients candidate for fluoropyrimidine based-chemotherapy. We planned a case-control study with all cases of DPYD*2A wild type who developed CTC-NCI-V.3 toxicity ≥ G3 and with a cohort of patients who did not present severe toxicities (ratio 1:1.5). The two groups were matched for tumour site, staging (I-III vs IV) and patient's age. Then we tested the additional SNPs (c.2846A > T, c.1679T > G, c.2194G > A) using Real Time PCR. **Results:** From 2011 to 2016 we screened 1,827 patients for DPD deficiency, of those 31 subjects (1.7%) showed DPYD*2A SNP. Complete clinical information was available only for 668 patients and of those, 146 (21.9%) developed severe toxicities (Case group). A control group was instead established with 220 patients who experienced no or mild toxicities. Fifty-three patients carried a variant in one of the additional SNPs: 35 subjects (66%) fell into the Case group and 18 (34%) into the Control group (OR 3.53, 95% IC 1.91-6.53. p < 0.0001). c.2194G > A was the most frequent SNP (12.5%, 46 of 366 pts) and showed a correlation with hematologic toxicity. In particular, neutropenia was observed in 50% of the patients carrying c.2194G > A (23 out of 46) vs 21% of patients c.2194 WT (67 out of 320) (OR = 3.75 95%IC 1.98-7.10; p < 0001). We confirmed that c.2826A > T (1.37%, 5 of 366 pts) was related to various toxicity (p = 0.0097) and c.1679T > G (0.55%, 2 of 366 pts) showed only gastrointestinal toxicity (p = 0.0027). **Conclusions:** Our data suggested that additional DPYD polymorphisms could enhance prevention of fluoropyrimidine toxicity. c.2194G > A is the most frequent polymorphism and it resulted associated with neutropenia.

2574 Poster Session (Board #400), Mon, 8:00 AM-11:30 AM

Clinical pharmacology assessment of PF-06647020 (PF-7020), an antibody-drug conjugate (ADC) targeting protein tyrosine kinase 7 (PTK7), in adult patients (pts) with advanced solid tumors. *First Author: Dawei Xuan, Pfizer Early Oncology Development & Clinical Research, La Jolla, CA*

Background: PF-7020, an ADC composed of humanized monoclonal antibody (Ab) against PTK7, auristatin payload, and valine-citrulline linker, is being investigated in the ongoing first in human Phase 1 study in pts with advanced solid tumors resistant to standard therapy. We present preliminary results of clinical pharmacology assessments of PF-7020, including pharmacokinetic (PK) analyses, and exploratory exposure-response analyses for efficacy and safety endpoints. **Methods:** Non-compartmental PK analyses were conducted on data from dose escalation and expansion studies of once every 3 weeks dosing (Q3W). A semi-mechanistic model that integrates ADC, total Ab (TAb), and unconjugated payload (PL) was built to characterize PK. We explored the relationship between objective response rate (ORR, current 27%) in ovarian cancer pts (OVCA) and PF-7020 exposure ($C_{min,C1D21}$) with logistic regression modeling. A semi-mechanistic PK-pharmacodynamic (PD) model was built to explore the relationship between PL concentrations and absolute neutrophil counts (ANC). **Results:** As of Oct 24, 2017, 112 pts were treated with PF-7020 at doses of 0.2 – 3.7 mg/kg Q3W. PK exposure increased in a dose related manner, with a terminal half-life for PF-7020 of approximately 3 days at 2.8 mg/kg. Integrated PK model suggests that deconjugation and proteolytic degradation of ADC played major roles in elimination of PF-7020, and PL formation. A significant correlation was identified between ADC $C_{min,C1D21}$ and OVCA ORR based on univariate analysis ($P < 0.05$); ORR increased with higher $C_{min,C1D21}$, suggesting pts with lower exposures may benefit from increase in dose/dosing intensity. PK/PD analysis suggests higher PL concentrations were associated with lower ANC. **Conclusions:** The PK exposure increased in a dose related manner, with a terminal half-life for PF-7020 of approximately 3 days at 2.8 mg/kg. Increase in PK exposure correlated with better clinical response in OVCA pts. The PL exposure appeared to correlate with ANC profiles. The preliminary PK/PD analyses support evaluating PF-07020 under once every 2 weeks dosing (Q2W) in the ongoing study.

2575 Poster Session (Board #401), Mon, 8:00 AM-11:30 AM

The NantOmics Pharmacogenomics Test: An integrative panomic approach to pharmacogenomics screening. *First Author: Camille Schwartz, NantOmics, Santa Cruz, CA*

Background: Numerous oncology drugs have pharmacogenomics warnings on their FDA labels, yet pharmacogenomics screening is not routinely applied in clinical practice. Pharmacogenomics testing is used to reduce the chance of drug-induced toxicities, improve patient outcomes, and reduce treatment costs by tailoring therapies to the patient's genotype. Here we present the NantOmics Pharmacogenomics test, which screens for pharmacogenomics variants related to 19 gene-drug pairs with CPIC guidelines and FDA label indications. **Methods:** Pharmacogenomics screening was performed on whole genome and whole exome sequencing data of FFPE tumors and matched normals from 1,879 oncology patients. Patients were screened using a panel of 31 germline markers in 11 genes linked to toxicities from 14 cancer therapies. The test has been validated on 10 cell lines from the CDC GeT-RM, on a set of synthetic data, as well as on a cohort of patients previously genotyped by an independent CLIA-validated PCR-based panel. **Results:** Of the 1879 patients screened, 96.4% contained a variant with a pharmacogenomics recommendation. Furthermore, 6.8% of patients had genomic variants associated with severe or life-threatening drug toxicities. For all alleles in our clinical panel, we observed similar allele frequencies to those reported in the ExAC database. In all validation studies, we were able to demonstrate that the test detects each variant in our panel, and correctly determines patient genotype in all studied cases. **Conclusions:** The NantOmics pharmacogenomics test is able to accurately detect pharmacogenomic variants in oncology patients. Observed allele frequencies correspond well to known population frequencies, and validation studies demonstrated that the test detects each variant in our panel, and correctly determines patient genotype in all studied cases. Given the high percentage of patients with potentially treatment-altering genomic variants, these results underscore the need for more routine pharmacogenomics screening in the oncological setting.

2576 Poster Session (Board #402), Mon, 8:00 AM-11:30 AM

Dihydropyrimidine dehydrogenase gene (*DPYD*) polymorphism among pts with 5-FU/capecitabine (CAP)-related adverse events (AEs): Experience of 2 decades. *First Author: Nauman S Siddiqui, Tufts Medical Center, Boston, MA*

Background: *DPYD* gene encodes *DPD*, the rate-limiting enzyme responsible for catabolism of 5-FU and is responsible for > 85% of 5-FU elimination. Deficiency of *DPD* due to *DPYD* polymorphism gives rise to severe 5-FU AEs from reduced catabolism. This pharmacogenetic '*DPD syndrome*' manifests typically as severe or fatal diarrhea, mucositis/stomatitis, myelosuppression and even rare toxicities, such as hepatitis, encephalopathy and acute cardiac ischemia following first or second dose of 5-FU. The most compelling reason to introduce routine *DPD* testing is to avoid severe AEs in pts who receive 5-FU/CAP. *DPYD* mutations are found in 50% of severe 5-FU toxicity cases. **Methods:** We analyzed all pts who were tested for *DPD* deficiency after excessive toxicities from 5-FU/CAP, treated for GI cancers. *DPD* activity was evaluated by PBMC radioassay, genotyping of *DPYD*, or 2-^{13}C uracil breath test after an informed consent. Demographics of pts, grades of toxicity, chemotherapy (dose, route) and outcomes were analyzed. **Results:** A total of 52 pts with *DPD* deficiency were identified [age range: 35 - 79 yrs; M:F = 1.3:1; Ethnicities: Caucasian (≥ 60%), African-American, unknown, Asian]. Most commonly used regimens in decreasing order were infusion 5-FU, CAP and bolus. Excessive AEs included mucositis (70%), diarrhea (40%), cytopenias (40%), nausea/vomiting (30%), HFS or skin rashes (20%), neurotoxicity (12%) and cardiotoxicity (5%). 11/12 pts had low *DPD* activity (range:0.064 – 0.18nmol/min/mg). *DPYD* genotyping showed: IVS14 + 1 G > A (c.1905+1 G > A, rs3918290) 38%, D949V (c.2846A > T, rs67376798) 21%, C29R (rs1801265) 4%, and Y186C (rs115232898, c.557 A > G) 2%. UraBT confirmed *DPD* deficiency in 2 pts: DOB_{50} of 49.4% and 52.5%. Re-challenge with CAP in 5 pts resulted in atypical or similar AE. 6 pts received vistogard; 5 recovered. 3 pts died due to AEs. **Conclusions:** *DPYD genotyping* (+ *TYMS*) may identify ≥ 50% of pts, who are at greatest risk of AEs. At present, no formal recommendations regarding testing for *DPYD* exist except warning on FDA website and prescription inserts. Our data mandates the need for prospective studies to develop guidelines in pts receiving 5-FU/CAP.

2577 Poster Session (Board #403), Mon, 8:00 AM-11:30 AM

Pharmacokinetics/pharmacodynamics (PK/PD) of ivosidenib in patients with IDH1-mutant advanced solid tumors from a phase 1 study. *First Author: Bin Fan, Agios Pharmaceuticals, Inc., Cambridge, MA*

Background: Mutant isocitrate dehydrogenase 1 (mIDH1) produces the oncometabolite D-2-hydroxyglutarate (2-HG). Ivosidenib (IVO; AG-120) is a targeted mIDH1 inhibitor under evaluation in an ongoing phase 1 study (NCT02073994) in mIDH1 advanced solid tumors including cholangiocarcinoma (CC), chondrosarcoma (CS), and glioma. We explored the PK profile of IVO, the relationship between IVO exposure and 2-HG inhibition, and the effect of intrinsic/extrinsic patient factors on IVO exposure. **Methods:** IVO was administered orally once (QD) or twice (BID) daily in continuous 28-day cycles. As of May 12, 2017, 168 patients (pts) had received IVO 100 mg BID to 1200 mg QD in dose escalation (8 dose levels, n = 60) and 500 mg QD in expansion (n = 108). IVO was assessed in plasma and 2-HG in plasma and tumor biopsies using LC-MS/MS assays. **Results:** After single and multiple doses, IVO showed good oral exposure, was rapidly absorbed, and plasma levels declined bi-exponentially after peaking, with a mean terminal half-life of 40–102 h after a single dose. IVO exposure and half-life were lower in pts with glioma than with CC/CS. IVO exposure increased less than dose proportionally. Steady state (SS) was reached within 14 days, with moderate accumulation (1.5- to 1.7-fold for AUC at 500 mg QD) across all tumors. No intrinsic patient factors were identified that affected IVO exposure. Mild/moderate renal impairment, mild hepatic impairment, and concomitant administration of weak CYP3A4 inhibitors/inducers had no effect on IVO clearance at SS. After multiple doses in pts with CC/CS, plasma 2-HG was reduced by up to 98% to levels seen in healthy subjects. Maximal plasma 2-HG reduction occurred at 500 mg QD in most pts, with no additional inhibition at higher doses. Tumor 2-HG showed a substantial reduction and positive correlation with plasma 2-HG. There was no significant pretreatment elevation of plasma 2-HG in glioma pts. **Conclusions:** IVO demonstrated good oral exposure and a long half-life, enabling oral QD dosing, and robust, persistent 2-HG inhibition in pts with mIDH1 CC/CS. IVO 500 mg QD is appropriate for these pts irrespective of intrinsic patient factors or concomitant weak CYP3A4 inhibitors/inducers. Clinical trial information: NCT02073994.

2578 Poster Session (Board #404), Mon, 8:00 AM-11:30 AM

A multicenter study of the Bruton's tyrosine kinase (BTK) inhibitor ibrutinib plus durvalumab in patients with relapsed/refractory (R/R) solid tumors. *First Author: David S. Hong, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Ibrutinib (ibr), a first-in-class, once-daily inhibitor of BTK, is approved in the US for the treatment of various B-cell malignancies. In solid tumors, ibr may inhibit EGFR, HER2, mast cell function, and alter Th1/Th2 polarity. Preclinical data suggest benefit with PD-L1 inhibitors for pancreatic adenocarcinoma (PC), non–small cell lung cancer (NSCLC), HER2+ breast cancer (BC), and triple neg BC (TNBC). These mechanisms may act synergistically. This study assessed the safety and efficacy of ibr plus durvalumab, a PD-L1–targeting antibody, in patients (pts) with R/R solid tumors. **Methods:** This open-label, multicenter, ph 1b/2 trial enrolled pts with R/R stage III/IV PC, BC (HER2+, TNBC), or NSCLC (adenocarcinoma, squamous). Pts must have failed ≥1 (PC, NSCLC) or ≥2 (BC) prior systemic therapy lines. Ph 1b (6+3 dose de-escalation design) determined the recommended ph 2 dose (RP2D). PD-L1 expression was assessed retrospectively. **Results:** In ph 1b, 560 mg ibr PO daily and 10 mg/kg durvalumab IV every 2 wk was identified as the RP2D. Of 124 pts enrolled, 122 pts were treated at the RP2D (PC n = 49; BC n = 45; NSCLC n = 28). Median age was 60.5 y; 94% had stage IV disease; median prior radiation/cancer therapies was 4 (range: 1–20); 5 NSCLC pts, but no PC or BC pts, had tumors with high PD-L1 expression. Response rates in evaluable pts were 3% for BC (1 complete response in a TNBC pt; duration of response [DOR]: 23 mo), 2% for PC (1 partial response; DOR: 10 mo), and 0% for NSCLC. Median progression-free survival was 2 mo in each cohort; median overall survival was 4, 4, and 8 mo in the PC, BC, and NSCLC cohorts, respectively. No clinically meaningful differences in the safety profile were observed across tumor types, except differences due to tumor type, location, and prior therapies. Gr ≥3 treatment-emergent adverse events in ≥5% of pts were hyponatremia (10%), dyspnea (7%), maculopapular rash (7%), pneumonia (7%), anemia (6%), and diarrhea (6%). **Conclusions:** The combination of 560 mg ibr daily and 10 mg/kg durvalumab every 2 wk had an acceptable safety profile, but limited activity in the solid tumors studied, which may be due in part to heavy pretreatment and low PD-L1 expression. Clinical trial information: NCT02401048.

2579 Poster Session (Board #405), Mon, 8:00 AM-11:30 AM

A phase 1b dose-escalation study of prexasertib, a checkpoint kinase 1 (CHK1) inhibitor, in combination with cisplatin in patients with advanced cancer. *First Author: Manish R. Patel, Florida Cancer Specialists/Sarah Cannon Research Institute, Sarasota, FL*

Background: CHK1 is a key kinase for DNA replication and repair. Prexasertib, a CHK1 inhibitor, enhanced the nonclinical activity of cisplatin and is predicted to potentiate the clinical activity of DNA-damaging agents like cisplatin. **Methods:** This Phase 1b study in patients (pts) with advanced cancer assessed escalating doses of prexasertib with 75 mg/m^2 cisplatin by IV infusion every 21 days, and had 3 parts: Part A, prexasertib (20 - 70 mg/m^2)/cisplatin given on Day 1; Part A2, prexasertib (40 - 105 mg/m^2)/cisplatin on Day 1 with prophylactic G-CSF starting on Day 2; Part A3, cisplatin on Day 1 and prexasertib (40 - 90 mg/m^2) on Day 2. Safety, dose-limiting toxicities (DLTs), maximum tolerated dose (MTD), preliminary efficacy, and prexasertib pharmacokinetics (PK) are reported. **Results:** 57 pts were enrolled (Part A: n = 14; A2: n = 24; A3: n = 19). Study treatment-related common adverse events (AEs) were leukopenia/neutropenia (68%; G4 49%), thrombocytopenia (63%; G4 33%), anemia (46%), nausea (44%), fatigue (32%), and vomiting (23%). 4 pts (7%) experienced febrile neutropenia (2 each in Parts A and A2). The nature of AEs was comparable between Parts. All DLTs were either febrile neutropenia or neutropenia > 5 days. The MTD for Parts A, A2, and A3 were 40, 90, and 80 mg/m^2, respectively. The prexasertib PK profile was consistent with the prexasertib monotherapy PK profile across all doses/schedules. In Part A, 3 pts (21%) achieved a partial response (PR: anal squamous cell carcinoma [SCC]; HNSCC; small cell lung cancer [SCLC]), and 2 pts (14%) had stable disease (SD). In Part A2, 12 pts (50%) had SD but no PR/CR. In Part A3, 1 pt (5%) achieved a CR (cholangiocarcinoma) and 2 pts (11%) achieved a PR (SCLC; follicular dendritic cell sarcoma) for a CR/PR rate of 16%; 7 pts (37%) had SD. Of the 6 pts with a CR/PR, 3 pts (at prexasertib doses: 45-90 mg/m^2) had previously received prior platinum. None had an objective response to the prior platinum. **Conclusions:** Prexasertib and cisplatin demonstrated acceptable safety and PK and preliminary evidence of anticancer activity. A dose of 80 mg/m^2 prexasertib given 24 h after cisplatin was selected for further study in the ongoing dose expansion. Clinical trial information: NCT02124148.

2580 Poster Session (Board #406), Mon, 8:00 AM-11:30 AM

Vorolanib (CM082) in Chinese patients with advanced solid tumor: A phase 1, open-label, dose escalation study. *First Author: Yan Song, National Cancer Center/Cancer Hospital,Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Vorolanib (CM082) is a potent and selective inhibitor of VEGFR and PDGFR, which is well tolerated from 20 to 400 mg without G3/4 treatment-related AEs (TRAEs) in patients in US. Here we present a phase I dose escalation study that assessed vorolanib in Chinese patients with advanced solid tumor. **Methods:** Patients with advanced solid tumors were enrolled to receive escalating dose of vorolanib once daily from 50 mg to 300 mg following the 3+3 design. Primary endpoints included evaluation of safety, pharmacokinetics, and maximum-tolerated dose (MTD) determination. **Results:** 19 patients were enrolled and treated, including 12 RCC. Most patients (n = 18) have received at least one prior systemic treatments, in which 10 have been treated with VEGFR TKIs. No DLT was seen, the MTD was not achieved. The most common TRAEs were leukopenia (9/19), fatigue (9/19), diarrhea (8/19), neutropenia (8/19), and hypertension (8/19). G3 or higher events were seen in 7 patients across 100 to 250 mg dose cohort. PK analysis was shown in table 1. Partial response was seen in 1 RCC patients in the 200 mg cohort, and 11 stable disease were seen in all dose cohorts. **Conclusions:** Vorolanib has an acceptable safety profile and showed preliminary activities in RCC. An expansion of RCC-enriched cohort is ongoing. Clinical trial information: NCT01863485.

2581 Poster Session (Board #407), Mon, 8:00 AM-11:30 AM

Clinical pharmacokinetics/pharmacodynamics (PK/PD) of ivosidenib in patients with IDH1-mutant advanced hematologic malignancies from a phase 1 study. *First Author: David Dai, Agios Pharmaceuticals, Inc., Cambridge, MA*

Background: Mutant isocitrate dehydrogenase 1 (mIDH1) produces the oncometabolite D-2-hydroxyglutarate (2-HG). Ivosidenib (IVO) is a selective mIDH1 inhibitor under evaluation in patients with mIDH1 hematologic malignancies. This translational analysis explored the PK profile of IVO, the relationship between IVO exposure and 2-HG suppression, and the impact of intrinsic/extrinsic patient factors on IVO exposure from the phase 1 monotherapy study (NCT02074839). **Methods:** IVO was administered orally once (QD) or twice (BID) daily in continuous 28-day cycles. As of May 12, 2017, 258 patients had received IVO at doses ranging from 100 mg BID to 1200 mg QD in dose escalation (n = 78) and at 500 mg QD (n = 180) in dose expansion. IVO levels were assessed in plasma and 2-HG levels in plasma/bone marrow using LC-MS/MS methods. **Results:** After single and multiple doses, IVO was readily absorbed (median T_{max} 3 h). After peaking, IVO concentrations declined in a bi-exponential manner, with a mean terminal half-life of 72–138 h after a single dose. Dose-exposure nonlinearity of IVO from 300 to 1200 mg QD suggests doubling of the dose would result in a ~30% increase in AUC. Steady state (SS) was reached within 14 days. Moderate accumulation was observed after 500 mg QD, with mean AUC and C_{max} accumulation ratios of 1.9- and 1.46-fold. IVO clearance was not altered by intrinsic patient factors. Concomitant administration of weak CYP3A4 inhibitors/inducers did not affect IVO clearance, though moderate/strong CYP3A4 inhibitors decreased IVO clearance and increased IVO SS exposure ($AUC_{0\text{-}24hr}$ by ~56%; C_{max} by ~47%). Plasma 2-HG reduction reached a plateau within 14 days of dosing after multiple doses of 500 mg QD, and was reduced by ≥90% over the range of IVO SS AUC in patients with newly diagnosed and relapsed/refractory AML, regardless of IDH1-R132 mutation type. **Conclusions:** IVO demonstrated a long half-life suitable for QD dosing, moderate accumulation, and robust 2-HG inhibition in patients with mIDH1 myeloid malignancies. Intrinsic/extrinsic patient factors, including concomitant moderate/strong CYP3A4 inhibitors, did not significantly alter IVO exposure. Clinical trial information: NCT02074839.

2582 Poster Session (Board #408), Mon, 8:00 AM-11:30 AM

BAX-BAK heterodimer as a pharmacodynamic biomarker of on-target drug action of Mcl-1 inhibitors to evaluate in-vivo effectiveness. *First Author: Apurva K. Srivastava, Clinical Pharmacodynamics Biomarker Program, Frederick National Laboratories for Cancer Research, Frederick, MD*

Background: Clinical development of promising small molecule Mcl-1 inhibitors is underway. The Mcl-1 inhibitors act by disrupting complexes of Mcl-1 with pro-apoptotic proteins such as BAK/BIM/Noxa, leading to formation of oligomers of BAK and BAX at the mitochondrial membrane and activation of an apoptosis cascade. Therefore, measurement of BAX-BAK heterodimers on the mitochondrial membrane is considered an on-target pharmacodynamic (PD) biomarker for this class of drugs. We describe use of the BAX-BAK assay to screen and prioritize small molecule Mcl-1 inhibitors (Taekyu et al, FEBS Let 2017) for on-target activity and in vivo potency in relevant cancer models. **Methods:** The BAX-BAK heterodimer immunoassay was developed on the Luminex platform using monoclonal antibodies specific to active BAX and BAK proteins. Single-dose PD and PK of each Mcl-1 inhibitor was evaluated at 100-mg/kg (IP) in nude mice bearing AMO-1 (myeloma) or NCI-H929 xenografts. Tumors quadrants were collected at 4, 8, 12, 18 and 24 hours after dosing, mitochondrial (mito.) fractions prepared, and biomarkers measured as described previously (Srivastava et al, Clin Can Res 2016). **Results:** The sandwich oassay provided a reliable, quantitative measurement of BAX-BAK levels in mito. fractions from both in-vitro (AMO-1, MOLP-8, MOLT-4, NCI-H929) and in-vivo xenograft (AMO-1, NCI-H929) models. The PD study showed a wide range of BAX-BAK activation, with the most potent compounds causing a 10-20 fold increase in peak BAX-BAK levels between 4-18 hours after dosing. Compounds that produced the highest levels of BAX-BAK also produced the highest cleaved caspase-3 levels and were associated with the highest tumor drug concentrations. The PD biomarker strategy, in conjunction with PK, prioritized select compounds for further development. **Conclusions:** We describe the application of a BAX-BAK heterodimer assay to effectively identify potent Mcl-1 inhibitors with early proof of on-target activity in tumor tissue. The PD biomarker could provide a benchmark assay to compare and contrast potency and mechanism-of-action of Mcl-1 inhibitors in clinical studies. Funded by NCI Contract No HHSN261200800001E.

2583 Poster Session (Board #409), Mon, 8:00 AM-11:30 AM

Phase 1/2 precision medicine study of the next-generation BRAF inhibitor PLX8394. *First Author: Filip Janku, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: First-generation BRAF inhibitors (BRAFi) show high response rates and prolonged survival in some *$BRAF^{V600}$*-mutant cancers; however, paradoxical activation of the RAF/MEK/ERK pathway promotes resistance and development of skin malignancies. PLX8394 is a next-generation, orally available small-molecule BRAFi that does not induce the RAF/MEK/ERK paradoxical activation and blocks signaling from both monomeric $BRAF^{V600}$ and dimeric $BRAF^{non\text{-}V600}$ protein. **Methods:** This is a phase 1/2 study of PLX8394 and cobicistat (cstat,150mg), a CYP3A4 inhibitor used to enhance PLX8394 exposure, to determine the safety, tolerability in subjects with refractory solid tumors (phase 1) and RECIST response rate in $BRAF^{V600}$ and dimer-dependent, RAS-independent $BRAF^{non\text{-}V600}$ mutant patients (phase 2). A hot-melt extrusion (HME) formulation of PLX8394 was used for this study. Results are reported as of January 8, 2018. Results: Phase 1: The RP2D was 900mg BID + cstat (Proc AACR-NCI-EORTC 2017, abst B176). A single DLT of reversible grade (G) 3 transaminitis occurred in a subject treated with PLX8394 900mg BID + cstat. Cstat co-administration resulted in a 2-3-fold increase in PLX8394 systemic exposure. Of 13 evaluable $BRAF^{V600}$-mutated subjects, 3 (23%) achieved partial responses [colorectal cancer (42%), glioma (65%); both BRAFi naïve, and ovarian cancer (62%) previously treated with 3 lines of BRAF/MEKi]. Phase 2: Of 18 patients enrolled, 13 had $BRAF^{V600}$ mutation [melanoma (n = 5), colorectal (n = 4), glioblastoma (n = 2), thyroid (n = 2)] and 5 $BRAF^{non\text{-}V600}$ mutation [pancreatic (n = 2), and prostate, thyroid, and colorectal (each n = 1)]. No prior MAPK pathway inhibitors were permitted for non-melanoma subjects. G≥3 AEs included G3 transaminitis and hyperbilirubinemia in one patient. Of 10 evaluable patients, 3 (30%, all with $BRAF^{V600}$ mutations) had stable disease (+7%, -10%, -14%, respectively). Efficacy and exploratory biomarker analysis including transcriptome and ctDNA analysis is on-going. **Conclusions:** PLX8394 + cstat has been well tolerated and shows promising activity in refractory solid tumors with BRAF mutations. This work was sponsored by Plexxikon Inc. Clinical trial information: NCT02428712.

2584 Poster Session (Board #410), Mon, 8:00 AM-11:30 AM

Precision oncology: Results of a phase I study of M2698, a p70S6K/AKT targeted agent in patients with advanced cancer and tumor PI3K/AKT/mTOR (PAM) pathway abnormalities. *First Author: Apostolia Maria Tsimberidou, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: M2698 is a potent and selective dual inhibitor of p70S6K and AKT1/3 in the PAM pathway. M2698 has the advantages of being an oral, brain penetrant, PAM pathway inhibitor, which can mitigate the effects of the AKT feedback loop, a potential escape mechanism in tumors resistant to standard therapies. **Methods:** Patients (pts) with advanced cancer received once-daily oral M2698 (15–380 mg; 9 dose levels) in 21-day cycles. The 3+3 dose escalation [DE] design was followed by an expansion phase (240 mg/day) in a pt population enriched with tumors that have PAM molecular alterations (PAM+). PAM+ profiles, potential resistance markers (RM), including *EGFR*, *KRAS* and *Akt2*, safety and efficacy were investigated (cut-off Nov 2017). **Results:** From 12/2013 to 3/2017, of 66 pts screened, 50 received M2698 (DE [n = 40] and expansion [n = 10]); 18 men, 32 women, 78% were < 65 years old. Of these 50 pts, 44 were PAM+ (37 without RM, 7 with RM). M2698 was well tolerated. Adverse events were transient. The maximum tolerated dose was not reached at the maximum dose tested. Efficacy outcomes are shown in the table. In addition, 5 pts in the PAM+ without RM subgroup had tumor control > 6 months (mo; range, 6.9–15.2 mo), whereas no pts in the PAM+ with RM subgroup had such prolonged tumor control. Clinical trial information: NCT01971515. PFS, progression free survival; SD, stable disease. **Conclusions:** M2698 was well tolerated. PAM+ pts without RM were more likely to have sustained tumor control. Molecular characterization of tumor resistance signals may help identify patients who are likely to benefit from M2698.

	All pts (n = 50)	PAM+ pts (n = 44)	PAM+ pts with RM (n = 7)	PAM+ pts without RM (n = 37)

A phase 1 study of NOX66 in combination with carboplatin in patients with end stage solid tumours. *First Author: Paul L. de Souza, University of Western Sydney School of Medicine, Liverpool, Australia*

Background: NOX66 is under development as an enhancer of chemotherapy and radiotherapy across multiple tumour types. The primary mechanism of action of idronoxil (the active ingredient of NOX66) stems from its selective binding to ENOX2 - a tumour-specific NADH oxidase - inhibiting Sphingosine kinase activity within tumour cells and leading to inhibition of the PI3K/Akt pathway and induction of apoptosis. Here we report the results of the first-in-human study of NOX66 as monotherapy and in combination with carboplatin (carbo). **Methods:** 19 patients with metastatic end stage solid tumours were recruited to one of two dose cohorts, NOX66 400mg, and 800mg respectively. Following a monotherapy run in period (NOX66 administered PR, Day 1-14 followed by a 7 day break) patients received 6 cycles of combination therapy - NOX66 administered on Day 1-7 and intravenous carbo on Day 2 of a 28-day schedule. Carbo was administered at AUC4 for 3 cycles, followed by AUC6 for 3 cycles. Recruitment is complete, with last patient last visit scheduled for May 2018. **Results:** 16 patients have completed study treatment. Radiologic assessment of disease state is shown in the table below (Progressive Disease – PD; Stable Disease – SD; Partial Response – PR). 4 SAEs (including 3 deaths) were reported, none were considered related to NOX66. One Adverse Event (Grade 2 anaemia, NOX66 800mg + carbo AUC4) considered possibly related to NOX66 has been reported. **Conclusions:** NOX66 is well tolerated as a monotherapy and in combination with carboplatin at AUC = 4 or AUC = 6. Efficacy signals from this study warrant further investigation of NOX66 as a chemo-sensitizing agent. Clinical trial information: NCT02941523.

NOX66 Dose	400mg	800mg
Enrolled	8	11
Completed 3 cycles carbo (AUC4)	8	10
Evaluable	4 (All SD)	9 (1PR; 7SD; 1PD)
Completed 6 cycles carbo (AUC4; AUC6)	6	5
Evaluable	2 (1SD; 1PD)	3 (2SD; 1PD)
Ongoing	0	3

2586 Poster Session (Board #412), Mon, 8:00 AM-11:30 AM

A phase I study of LXH254 in patients (pts) with advanced solid tumors harboring MAPK pathway alterations. *First Author: Filip Janku, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: CRAF is a key mediator of oncogenic mitogen-activated protein kinase (MAPK) pathway reactivation following MEK or BRAF inhibition. LXH254 is a BRAF and CRAF inhibitor with antitumor activity in MAPK-driven tumor models. This Phase I dose-finding study of LXH254 in pts with advanced solid tumors harboring MAPK pathway alterations is evaluating safety/tolerability and preliminary antitumor activity (NCT02607813). **Methods:** Primary objective: characterize the safety/tolerability of single-agent LXH254 and identify a recommended dose (RD)/schedule for future study. Secondary objectives: characterize antitumor activity (per RECIST 1.1) and PK. Dose escalation was guided by a Bayesian model-based approach. Eligible pts had advanced, pretreated solid tumors with MAPK pathway alterations. **Results:** At data cut-off 4 Dec 2017, 75 pts were enrolled in 9 dose cohorts: 100 (n = 4), 200 (n = 4), 300 (n = 5), 400 (n = 6), 800 (n = 12), 1200 mg QD (n = 12), and 200 (n = 7), 400 (n = 12), 600 mg BID (n = 13). Pts (ECOG PS 0/1, 41% male, median age 57 yrs) had lung (n = 16), colorectal (n = 14), ovarian (n = 12), melanoma (n = 12), or other (n = 21) cancers. Median duration of exposure was 7.7 wks; 59/75 (79%) pts discontinued treatment, due to disease progression (49 pts [65%]), physician/pt decision (5 pts [7%]), death (3 pts [4%]), or AE (2 pts [3%]). Three DLTs were reported: platelet count decrease (Gr 4, 1 pt 1200 mg QD), pruritus and maculopapular rash (both Gr 3, 1 pt 600 mg BID). The most common (> 15%) drug-related, any-Gr AEs were rash (dermatitis acneiform/rash/maculopapular rash, 53%), fatigue (20%), and nausea (20%). Gr ≥3 drug-related AEs occurred in 16% of pts, most frequently rash, myalgia, and increased lipase (2 [3%] pts each). Plasma peak drug concentration (C_{max}) and exposure (AUC) after QD/BID oral doses increased approximately dose-proportionally. There were two confirmed partial responses (with > 50% tumor size reduction) in pts with *KRAS*-mut and *BRAF*-mut cancers; stable disease was reported in 25/75 (33%) pts. **Conclusions:** Oral LXH254 was well tolerated, all AEs were manageable, and preliminary antitumor activity was observed. The study is ongoing to establish a RD/schedule, and further establish antitumor activity. Clinical trial information: NCT02607813.

2587 Poster Session (Board #413), Mon, 8:00 AM-11:30 AM

Safety, tolerability, and antitumor activity of once-daily Wee-1 inhibitor AZD1775. *First Author: Naoko Takebe, NCI/ NIH, Elkridge, MD*

Background: Wee1 tyrosine kinase promotes G2 cell cycle arrest following DNA damage via inactivating phosphorylation of cyclin-dependent kinase 1. We are conducting a phase I study of the oral Wee1 inhibitor AZD1775 in patients (pts) with advanced solid tumors, examining twice daily (Arm A) and once daily (Arm B) schedules. Results for Arm A have been reported previously, and partial responses (PR) were observed in 2 pts with *BRCA* mutations. Here, we present results for Arm B. **Methods:** AZD1775 was given orally once daily (QD) for 5 days during weeks 1 and 2 of a 21-day cycle (Arm B) or twice daily (BID) for 5 doses during weeks 1 and 2 (Arm A). Primary objectives were to determine safety, tolerability, and pharmacokinetics (PK). Secondary objectives were to assess pharmacodynamic (PD) biomarkers of DNA damage in tumor tissue and circulating tumor cells and evaluation of antitumor activity. Dose-limiting toxicity was evaluated during cycle 1, and response was defined by CT using RECIST 1.1. **Results:** Thirty-four pts have enrolled on Arm B; of the 28 assessable for response, 4 (14%) had a PR (3 ovarian, 1 endometrial) and 18 (64%) experienced stable disease (mean: 7.22 cycles). Of the 9 Arm B pts with confirmed *BRCA* mutations, 2 had a PR (22%; ovarian) and 6 had SD (67%; mean: 7.17 cycles). The maximum tolerated dose (MTD) for Arm B was 300 mg; dose-limiting toxicities were grade (gr.) 4 myelosuppression and gr. 3 fatigue. The type, rate, and severity of commonly observed gr. 3/4 toxicities were similar between Arms A and B, including (Arm A [%]; Arm B [%]): anemia (28%; 24%), lymphopenia (20%; 35%), neutropenia (16%; 15%), and thrombocytopenia (12%; 12%), and fatigue (0%, 12%). Preliminary PK data indicate improved AZD1775 exposure (AUC and C_{max}) for Arm B vs. Arm A MTD cohorts. **Conclusions:** Once-daily AZD1775 is well tolerated, with toxicities comparable to twice-daily AZD1775. Plasma drug exposure was higher for the QD vs. BID MTD cohort. AZD1775 antitumor activity was observed in pts with and without known *BRCA* mutations. Accrual to Arm B is ongoing, as is PD analysis. Future whole-exome sequencing analyses may uncover additional predictive biomarkers. Clinical trial NCT01748825. Supported in part by NCI Contract HHSN261200800001E. Clinical trial information: 01748825.

2588 Poster Session (Board #414), Mon, 8:00 AM-11:30 AM

Dose finding study of varlitinib ± trastuzumab with carboplatin/paclitaxel in advanced solid tumors. *First Author: Matilda Lee, National University Health System, Singapore, Singapore*

Background: Varlitinib (V) is a reversible inhibitor of HER1/HER2/HER4. This is a phase 1b dose confirmation study to determine safety and early efficacy signals of V ± T combined with weekly P 80mg/m^2 and C AUC = 2 (NCT02396108). **Methods:** Eligible patients had metastatic solid tumors. A 3+3 dose de-escalation study design was used and pharmacokinetic (PK) analyses of V and P were done. **Results:** 37 patients (median age 56.8 years [31.8 – 73.8]) were enrolled into 8 cohorts with median 3 (0-14) prior lines of palliative therapies. PC + V 500mg BD continuously (cont) was deescalated to 300mg BD intermittently (int) (4 days on, 3 days off) due to DLTs, most commonly febrile neutropenia (FN) and electrolyte disturbances, and was deemed intolerable. Recommended dose (RD) was V 300mg BD int with P alone; addition of T to RD of P+V was safe with no DLTs (Table). 20/37 had HER2+ metastatic breast cancer (MBC) with median 4 (0-14) prior treatment lines. 7 achieved partial response (PR) and 3 stable disease (SD); 6 had disease control with single agent V for a median 7.0 more months (4.3 – 13.3) after chemotherapy ceased. 2/17 with other tumor types achieved PR (HER2- MBC = 1, NSCLC = 1). 3/10 patients (HER2+ MBC = 2) in the V 300mg BD int cohorts achieved PR. No correlation was seen between V and P mean AUC (ng.h/mL) in those with and without DLTs (V 10336.5 vs 20758.8, p = 0.21; P 4882.1 vs 5197.6, p = 0.77). No interaction was seen between V dose/schedule with P PK. **Conclusions:** The RD of V combined with P is 300mg BD int, and is active in HER2+ MBC; T can be added safely. The triple combination will be evaluated as neoadjuvant therapy in HER2+ breast cancer. Clinical trial information: NCT02396108.

Cohorts	DLT in cycle 1	No. with PR/SD
N = 3 V 500mg BD cont CP	3/3 (G3 hyperbilirubinemia = 1, received < 75% intended V dose due to toxicities = 2)	1/0
N = 5 V 400mg BD cont CP	3/5 (FN = 3)	2/3
N = 4 V 400mg BD int CP	2/4 (G3 hypophosphatemia = 1, G3 hyponatremia, G3 hypokalemia, intolerable G2 fatigue = 1)	2/2

N = 4 V 400mg BD int P	2/4 (FN = 1, G3 transaminitis = 1)	1/1
N = 6 V 300mg BD cont P	4/6 (G3 diarrhea = 1, G4 neutropenia > 7days = 1, received < 75% intended V dose due to toxicities = 2)	1/1
N = 3 V 300mg int P SC T 600mg	0/3	Ongoing

2589 Poster Session (Board #415), Mon, 8:00 AM-11:30 AM

Phase 1 study of pegargiminase combined with cisplatin and pemetrexed in patients with ASS1-deficient uveal melanoma. *First Author: Pui Ying Chan, Barts Health NHS Trust, London, United Kingdom*

Background: Argininosuccinate synthetase (ASS1) loss is a biomarker to select for tumors sensitive to arginine deprivation therapy. In a phase 1 dose-escalation study of ASS1-deficient thoracic cancers, we demonstrated tolerability and a high disease control rate using weekly pegargiminase (ADI-PEG 20) combined with first-line pemetrexed (PEM) and cisplatin (CIS) chemotherapy (Beddowes *et al.*, JCO 2017; ADIPEMCIS). Here, we report the safety and early activity of ADIPEMCIS in an expansion cohort of patients (pts) with metastatic uveal melanoma (UM). **Methods:** Chemotherapy naïve pts aged 18 years or older with ASS1-deficient, histologically proven metastatic UM were eligible. ADI-PEG 20 (36 mg/m^2 i.m.) was administered weekly together with PEM (500mg/m^2) and CIS (75 mg/m^2) every 3 weeks for a maximum of 18 weeks. Pts with stable disease or better were eligible to continue on ADI-PEG 20 until disease progression. Adverse events (AEs) were graded using CTCAE v4.03. Radiological response was assessed by CT or MRI every 6-8 weeks according to RECIST 1.1, alongside pharmacodynamic and immunogenicity analyses, median progression-free and overall survival (PFS and OS) estimates. **Results:** 10 of 14 screened pts with ASS1-ve metastatic UM received ADIPEMCIS with a median of 1 line of prior therapy (i.e. ipilimumab monotherapy; range 0 to 5). Treatment was well tolerated; neutropenic sepsis was the only grade 3 AE (n = 1 pt). The best response was stable disease with a median PFS of 3.0 months (range, 1.3 to 8.1 months) and a median OS of 11.5 months (range, 3.2 to 24.0+ months). Despite the emergence of anti-ADI-PEG 20 antibodies, plasma arginine concentrations remained low by 18 weeks with a reciprocal increase in plasma citrulline. Tumor rebiopsies at progression revealed ASS1 re-expression (n = 2/2 pts). **Conclusions:** ADIPEMCIS is well tolerated and has activity in metastatic UM, for which there is no established therapy. Based on recent preclinical data showing synthetic lethality of combining ADI-PEG 20 with PD-1/PD-L1 inhibition, a phase 1 study of ADI-PEG 20 with immune checkpoint blockade is planned in advanced UM. ClinicalTrials.gov identifier: NCT02029690. Clinical trial information: NCT02029690.

2590 Poster Session (Board #416), Mon, 8:00 AM-11:30 AM

Outcomes of patients with gene fusion driven cancers treated on early phase clinical trials. *First Author: Roman Groisberg, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Gene fusions result in a constitutively activated tyrosine kinase that causes uncontrolled cell proliferation. Some fusions are actionable with multi-kinase inhibitors that are FDA approved or in development. We reviewed patients with gene fusions treated with a targeted agent in a large Phase 1 program. **Methods:** We reviewed charts of patients treated on trials with targeted therapies in our phase 1 clinic between 2009 and 2017. Targeted was defined as affecting either the fusion gene itself or a downstream pathway. Demographic information including diagnosis, age, sex, date of first dose on trial, date of progression, best response by RECIST, and date of death. Information on fusions was obtained from next generation sequencing or FISH performed as part of oncologic management. **Results:** A total 85 patients (M:F, 46:39) with gene fusions were identified and 59 (68.6%) were treated with a targeted agent. Tumors included sarcomas (N = 49, 57.6%), NSCLC (N = 17, 20%), cholangiocarcinoma (N = 7, 8.2%), salivary gland (N = 4, 4.7%), thyroid (N = 3, 3.5%), GBM (N = 2, 2.3%), HG neuroendocrine tumors (N = 2, 2.3%), colon and lymphoma (N = 1 each, 1.1%). Most common fusions were RET (KIF5B = 15, CCDC6 = 2, Other: 1) and EWS-FLI1 (N = 12, 20%). Other fusion partners in our dataset included FGFR2/3 (N = 9, 15.3%), NTRK1/3 (N = 7, 11.9%), ALK (N = 3, 5.1%), ROS1 (N = 2, 3.4%), and BRAF (N = 1, 1.7%). Most therapies targeted the fusion itself except in sarcomas where downstream pathways (c-MET, IGF1R, nuclear redistribution) were targeted. Best response was CR in three patients (5%), PR in 12 patients (20%), and SD in 21 patients (35.6%) for a clinical benefit rate of 61%. Median PFS was 7.1 months, 95% CI [4.8,15.4] and OS was 19.6 months, 95% CI [10.8, 29.4]. This compares favorably with historical unmatched (PFS = 2.2, OS = 9 mo) and matched therapy for mutations (PFS = 5.2, OS = 13.4 mo) in phase 1 trials (PMID: 22966018). **Conclusions:** Gene fusion driven cancers are actionable. Patients with fusions have comparable response rates to historical molecularly matched targeted therapy data in our phase 1 group, but have longer PFS and OS. Further study is needed for molecular mechanisms of response and resistance to fusion targeted therapies.

2591 Poster Session (Board #417), Mon, 8:00 AM-11:30 AM

Phase 1b trial of nintedanib in combination with bevacizumab in patients with advanced solid tumors. *First Author: Ravi Kumar Paluri, University of Alabama at Birmingham, Birmingham, AL*

Background: Vascular endothelial growth factor (VEGF) inhibitors have produced demonstrable but limited clinical benefit for various cancers. One mechanism of resistance includes revascularization secondary to up-regulation of alternative pro-angiogenic signals such as platelet derived growth factor receptor (PDGFR) and fibroblast growth factor receptor (FGFR) pathway. Nintedanib (Nin) is an oral triple kinase inhibitor that blocks the VEGFR, PDGFR and FGFR pathways and may improve antitumor activity by overcoming resistance to anti-VEGF therapies. This study evaluated the safety & tolerability (primary objective) of Nin in combination with bevacizumab (Bev). **Methods:** Patients (pts) were treated with escalating doses of Nin (150mg or 200mg oral twice daily) and Bev (15 mg/kg once intravenously every 3 weeks) until disease progression or unacceptable toxicity using standard 3 + 3 phase1 design. The plasma levels of angiogenic biomarkers were correlated with clinical outcomes. **Results:** Eighteen pts with advanced tumors [lung (9), colon (8) and cervical (1)] pretreated with at least two lines of chemo were enrolled. Fifty percent (9 patients) were pretreated with bev. The final dose of Nin is 200mg twice a day with no observed dose limiting toxicities (DLT). The common adverse events were fatigue (grade 1-3); nausea & diarrhea (grade 1-2). Two pts came off study due to grade 3 fatigue. The disease control rate (DCR) was 72% (1 CR,1 PR & 11 SD).The median progression free survival (PFS) was 4 months (m), and median overall survival (OS) was 14m. The PFS rate at 6, 12, and 18m was 22%, 11%, and 11% and the OS rate at 6, 12, and 18 m was 83%, 70% and 28% respectively. Durable clinical response was observed in pre-Bev treated pts (1CR, 4 SD). The median OS for colon (n = 8) not reachable with 57% alive at 18m; median OS for lung (n = 9) was 13m with 13% alive at 18m. Better DCR was correlated with lower baseline PIGF levels as well as increased level from baseline. Longer PFS was associated with higher than the median baseline values for VEFGR2, E-selectin and lower SDF-1α. **Conclusions:** Nin was well tolerated with Bev with no DLT's. Significant clinical activity was observed in Bev pretreated patients suggesting Nin can overcome Bev resistance. Clinical trial information: NCT02835833.

2592 Poster Session (Board #418), Mon, 8:00 AM-11:30 AM

A phase I, open-label, multicenter dose escalation study to assess the safety, tolerability, and pharmacokinetics of AZD2811 nanoparticle in patients with advanced solid tumors. *First Author: Melissa Lynne Johnson, Sarah Cannon Research Institute, Nashville, TN*

Background: Aurora kinases represent potential targets for anticancer therapy in solid tumors and hematological malignancies. The aurora B kinase inhibitor AZD1152 (barasertib) has shown benefit in patients (pts) with untreated AML versus low-dose AraC when given as a 7-day continuous infusion. AZD2811 nanoparticle is a novel, encapsulated slow release inhibitor of aurora kinase B which offers several advantages compared to AZD1152 (Ashton S et al., Sci Transl Med 2016). AZD2811 nanoparticle mimics the AZD1152 7-day continuous infusion as a 2-hr infusion on Day 1 and 4, and resulted in increased efficacy preclinically. We report the first-in-man dose-escalation of AZD2811 in pts with advanced solid tumors (NCT02579226). The objectives were to determine the MTD, safety profile, dosing schedule and preliminary efficacy of AZD2811. **Methods:** Adult pts with advanced solid tumors were given AZD2811 nanoparticle IV on Day 1 and 4 every 28 days. Pts were enrolled according to a standard 3+3 design. Pharmacokinetics (PK) were assessed in cycle 1. **Results:** 24 pts were treated in 6 cohorts: 15 mg (3 pts), 25 mg (3 pts), 38 mg (3 pts), 51 mg (3 pts), 100 mg (3 pts) and 200 mg (9 pts). Of those 24 pts, 20 pts discontinued due to disease progression, (1 pt) due to death, (1 pt) withdrew consent (1 pt), physician's decision. Preliminary efficacy indicated one confirmed ongoing partial remission in cohort 6 at 16 months. In Cohorts 1-5, common treatment-related AEs (any grade) were diarrhea, nausea, and fatigue; in Cohort 6 (200 mg per infusion) common treatment-related AEs (any grade) were fatigue, decreased appetite, and neutropenia (5 pts, all grade 4 including 1 DLT of $>$ 7 days without G-CSF), an expected pharmacodynamics marker of target engagement. There were no infections, fever of unknown origin or treatment-related deaths. AZD2811 total blood PK appear dose proportional with a $t_{1/2}$ of 30-50 hours. **Conclusions:** AZD2811 nanoparticle is safe and well tolerated at a dose of 200 mg Day 1 and 4 every 28-days. A single day 1 infusion once every 21 days with G-CSF is also being investigated. Further safety and updated efficacy data will be reported at the annual meeting. Clinical trial information: NCT02579226.

2593 Poster Session (Board #419), Mon, 8:00 AM-11:30 AM

A phase I study of a novel IAP inhibitor APG-1387 in patients with advanced solid tumors. *First Author: Ruihua Xu, Sun Yat-Sen University Cancer Center, Guangzhou, China*

Background: APG-1387 is a bivalent small molecule Smac mimetic that antagonizes the IAPs. Preclinical studies have shown its dose- and schedule-dependent, strong antitumor activities in multiple human cancer xenograft models. In addition, the preclinical results strongly support the notion that APG-1387 in combination with anti-PD1 antibody would be a very attractive approach for cancer therapy. **Methods:** Phase I dose-escalation study enrolled 28 patients with advanced solid tumors in China (#CTR20150161). During dose escalation, the patients received APG-1387 (0.3–45 mg) intravenous infusion for 30 minutes once every week for 3 out of 4 weeks in a 28-day cycle until disease progression. Endpoints included safety (primary), pharmacokinetics (PK), pharmacodynamics (PD), and antitumor activity assessed every 8 weeks per RECIST v1.1. **Results:** Till Jan 15, 2018, 28 patients had been treated in 8 cohorts of APG-1387(0.3mg, 0.6mg, 4mg, 7mg, 12mg, 20mg, 30mg, 45mg). Twenty-eight patients received at least 1 cycle of treatment. The MTD was not reached yet. No DLT was observed during Cycle 1 across dose levels. Twenty-five of 28 patients experienced at least 1 TEAE. The most common TEAEs were vomiting, abdominal pain, anemia, cough, headache, AST increased and ventricular arrhythmia. Of these, 4 grade 3/4 clinical TEAEs including blood bilirubin increased, ALT increased, hypokalemia , pain and soft tissue infection were documented across dose levels. A total of 12 definitively or possibly drug-related AE occurred to date. Human PK data of APG-1387 showed a dose proportionality in exposure, elimination appeared to be linear, no significant accumulation was observed in plasma. Preliminary results from the Human Cytokine 30-Ple analyses indicated that IL-12, IP-10 and MCP-1 were significantly increased in the patient plasma after treatment with APG-1387, indicating potential effects of APG-1387 on the host immune responses. **Conclusions:** APG-1387 was well tolerated and had manageable adverse events.Further evaluation of APG-1387 in combination with immunotherapy agents in patients with advanced solid tumors or hematologic malignancies is recruiting. Clinical trial information: NCT03386526. Clinical trial information: 20150161.

2594 Poster Session (Board #420), Mon, 8:00 AM-11:30 AM

A phase I study of novel dual Bcl-2/Bcl-xL inhibitor APG-1252 in patients with advanced small cell lung cancer (SCLC) or other solid tumor. *First Author: Nehal J. Lakhani, START Midwest, Grand Rapids, MI*

Background: We have developed a unique strategy to tactically reduce on-target platelet toxicity with APG-1252, a novel dual Bcl-2/Bcl-xL inhibitor, while maintaining strong *in vivo* antitumor activity. APG-1252 potently inhibits tumor growth in human cancer xenograft models including SCLC models while trigged significantly less platelet killing APG-1252 demonstrated a higher therapeutic index than ABT-263 in preclinical studies. **Methods:** This Phase I study (NCT03080311) enrolled patients with advanced SCLC or other solid tumors. In dose escalation, the patients received APG-1252 (10–400 mg) intravenously twice weekly for 3 weeks in a 28-day-cycle, until disease progression. Study objectives include safety (primary endpoint), pharmacokinetics (PK), pharmacodynamics (PD), and antitumor activity assessed every 8 weeks per RECIST v1.1. **Results:** As of Jan 31, 2018, 13 patients (including 6 pts with SCLC) have been treated in 5 cohorts of APG-1252. Current dose level being explored is 160 mg. The median number of prior systemic anticancer therapies was 2 (range 1-6). The pts received a median of 2 cycles of APG-1252 (range 1-6). MTD has not been identified yet. TRAEs were reported in 10 pts (77%). The most common AE's (reported in $\geq$10% of pts) included: arthralgia, AST/ALT increased, vomiting, and fatigue. All TRAEs were grade $\leq$ 2 in severity. There were no AEs leading to treatment discontinuation. No thrombocytopenia or other cytopenias have been observed six pts had $\geq$1 on-treatment tumor assessment. One confirmed partial response was observed in 1 patient with metastatic SCLC at the 40 mg dose, and the duration of response lasted for more than 6 cycles. PK analyses indicate that AUC and Cmax increase dose proportionally over 10-40 mg range on day 1, while AUC increases more than dose proportionally on Day 22. AUC at 40 mg on Day 22 is close to *in vivo* efficacious exposure. **Conclusions:** APG-1252 was well-tolerated across all dose levels tested. No hematologic toxicity has been reported so far. Dose escalation and further evaluation of APG-1252 in patients with SCLC and other advanced solid tumors is ongoing. Clinical trial information: 03080311.

2595 Poster Session (Board #421), Mon, 8:00 AM-11:30 AM

Safety and pharmacodynamics of the DRD2 antagonist ONC201 in advanced solid tumor patients with weekly oral administration. *First Author: Mark N. Stein, Columbia University Medical Center, New York, NY*

Background: ONC201 is a small molecule antagonist of DRD2, a G protein-coupled receptor overexpressed in several malignancies, that has prolonged antitumor efficacy in preclinical cancer models via induction of the CHOP/DR5-mediated integrated stress response pathway and caspase-dependent apoptosis. In addition to cytotoxic effects in tumor cells, DRD2 antagonism can induce the activation of NK and other immune cells. The first-in-human trial of ONC201 previously established a recommended Phase II dose (RP2D) of 625 mg once every three weeks. Here, we report the results of a Phase I study that evaluated the safety, pharmacokinetics (PK), and pharmacodynamics with weekly oral administration of ONC201. **Methods:** Patients $\geq$18 years old with an advanced solid tumor refractory to standard treatment were enrolled. Dose escalation proceeded with a 3 + 3 design from 375 mg to 625 mg of ONC201. One cycle, also the dose-limiting toxicity (DLT) window, was 21 days. The primary endpoint was to determine the RP2D of ONC201 with weekly oral administration, which was subsequently confirmed in an 11-patient dose expansion cohort. **Results:** A total of 20 patients were enrolled: 3 at 375 mg and 17 at 625 mg of ONC201. The RP2D was defined as 625 mg with no DLT, treatment discontinuation, or dose modifications due to drug-related toxicity. Pharmacokinetic profiles were consistent with every three week dosing and similar between the first and fourth dose. Serum prolactin and caspase-cleaved cytokeratin-18 were detected, along with intratumoral induction of integrated stress response (CHOP/DR5), apoptosis (TUNEL) and infiltration of granzyme B+ Natural Killer cells. Induction of immune cytokines and effector molecules was higher in patients who received ONC201 once every week versus once every three weeks. Stable disease of $>$ 6 months was observed in several prostate and endometrial cancer patients. **Conclusions:** Weekly, oral ONC201 is well-tolerated and results in prolonged stable disease, intratumoral apoptotic signaling and enhanced immunostimulatory activity that warrants further investigation. Clinical trial information: NCT02250781; NCT02324621.

TPS2596 Poster Session (Board #422a), Mon, 8:00 AM-11:30 AM

The GATTO study: A phase I of the anti-MUC1 Gatipotuzumab (GAT) in combination with the anti-EGFR Tomuzotuximab (TO) in patients with EGFR positive solid tumors. *First Author: Sebastian Ochsenreither, Charité Comprehensive Cancer Center, Berlin, Germany*

Background: TO (CetuGEX) is a second-generation anti-EGFR antibody that specifically binds to EGFR and acts as a competitive antagonist at the ligand binding site. GAT (PankoMab-GEX) is a novel humanized monoclonal antibody, which recognizes the tumor-specific epitope of mucin-1 (TA-MUC1) expressed on tumor cells. Both antibodies are glyco-engineered to potentiate antibody-dependent cellular cytotoxicity (ADCC). Compelling preclinical evidence suggests a complex interaction between EGFR and cell surface expressed TA-MUC1 in driving cancerogenesis processes as well as shows a synergistic ADCC activity with the dual targeting of these molecules. Based on this evidence, this study aims to assess the tolerability, safety and preliminary activity of a combination with anti-EGFR and anti-TA-MUC1 glyco-engineered antibodies. **Methods:** The GATTO is an open label phase Ib dose evaluation study in patients with EGFR positive metastatic solid tumors, for whom no standard treatment is available. The proposed doses and schedule are 1400 mg Q2W for GAT and 1200 mg Q2W for TO. A staggered approach will be utilized in order to minimize the number of patients exposed and to evaluate the safety of the combination treatment. The first 6 patients will be enrolled into a safety run-in phase where the number of dose-limiting toxicities (DLTs) will be evaluated. Assuming that the safety criteria are met (ie. observation of 0 or 1 DLT), the dose will remain unchanged and further patients will be recruited at this dose level. If this is not the case, a step-wise dose reduction approach will be applied. The antitumor activity of the combined treatment will be evaluated as secondary endpoints including best overall response rate (ORR), duration of objective response, progression-free (PFS) and overall (OS) survival. Extensive pharmacokinetics (PK) and pharmacodynamics (PD) (cellular immune status, serum and tissue biomarkers) will be also analyzed. As of January 2018, the study is ongoing and 2 patients have been treated. (ClinicalTrials.gov Identifier: NCT03360734). Clinical trial information: NCT03360734.

TPS2597 Poster Session (Board #422b), Mon, 8:00 AM-11:30 AM

AMC 095 (AIDS Malignancy Consortium): A phase I study of ipilimumab (IPI) and nivolumab (NIVO) in advanced HIV associated solid tumors (ST) with expansion cohorts in HIV associated solid tumors and classical Hodgkin lymphoma (cHL). *First Author: Lakshmi Rajdev, Montefiore Medical Center, Bronx, NY*

Background: Immune checkpoint blockade (ICB) using agents that target the priming phase (i.e. CTLA-4) and effector phase (e.g. PD-1) of host immunity, used individually or in combination, has emerged as a therapeutic strategy for cancers. Little is known about the safety, tolerability and efficacy of ICB in patients (pts) with HIV infection and cancer. **Methods:** AMC 095 (NCT02408861) is a multicenter, international phase I study of the PD-1 inhibitor, nivo alone or in combination with a CTLA-4 inhibitor, ipi, in 2 cohorts stratified by CD4 counts (Stratum 1: CD4 counts≥200/uL and Stratum 2: CD4 count 100-200/uL) with additional expansion cohorts at the recommended phase II dose in pts with ST and cHL. The primary study objective is to determine the safety and feasibility of nivo alone and the nivo +ipi combination. Secondary objectives are to evaluate the effects of single agent nivo, and ipi+ nivo, on HIV replication and immune function (HIV viral load in plasma using conventional assay, CD4+, and CD8+ cells), and to obtain preliminary information regarding response. Clinical trial information: NCT02408861. The trial was initiated in 8/15, as of 2/2/18, the study is ongoing, and 29 pts have been enrolled. Updated information on the safety and responses will be presented. Funded by the NCI Grant #UM1CA121947.

Agent/dose	Stratum 1-CD4 ≥ 200/uL 2-CD4 < 200 /uL	No. Treated
Nivo 3 mg/kg q 2 wk	1	6
Nivo 3 mg/kg q 2 wk	2	6
Nivo 240 mg q 2 wk + Ipi 1 mg/kg q 6 wk	1	6
Expansion cohort in Solid Tumors Nivo 240 mg q 2 wk	1/2	9
Expansion cohort in cHL Nivo 240 mg q 2 wk	1/2	2
Total		29

TPS2598 Poster Session (Board #423a), Mon, 8:00 AM-11:30 AM

MASTER KEY project: A basket/umbrella trial for rare cancers in Japan. *First Author: Hitomi Sumiyoshi Okuma, National Cancer Center Hospital, Tokyo, Japan*

Background: Establishment of standard therapies for patients with rare cancers have been poor compared to those of major cancers, due to lack of basis for clinical studies and investigations. The MASTER KEY Project is a biomarker driven basket/umbrella trial using a "master protocol", aiming to find more efficient ways to evaluate treatments for rare cancers and to build a treatment development infrastructure by collaborating with industries. Similar studies including NCI–MATCH trial are ongoing; however, MASTER KEY Project is the first to be reported for such large scale trials that proceeds concurrently with a quality assured registry study focused only on rare cancers. **Methods:** The project is a two–stage structured study: the prospective registry study part and the multiple clinical trials (sub–study) part. Patients with advanced rare cancers/cancers of unknown primary/rare pathological subtypes of major cancers, who have priorly been evaluated by a molecular diagnostic testing, such as a validated next generation sequencing assay, are enrolled into the registry study. Rare cancer is defined as "annual incidence less than 6 cases per 100,000 population". The primary objective of the registry study part is to collect consecutive data on biomarker, clinicopathological background, and prognosis of rare cancers to build a large–scale database that is highly reliable as historical control data for future use in clinical trials of rare cancers. In the sub–studies, drugs are provided by various industries, who are collaborators, and could be approved or investigational agents. Sub–studies are placed under a "master protocol", allowing new sub–studies to be added at any time. Each sub–study is ordinarily a single arm study and will enroll 5–20 patients with the appropriate biomarker of interest, regardless of histopathologic tumor type. Typically, the primary endpoint is response rate (set according to each sub–study), and Bayesian method will be used. A biomarker–negative sub–study will also be available so that all patients have a chance to be enrolled in a sub–study. The project opened in May 2017. As of Jan 2018, 154 of a planned 100 patients/year have been enrolled. There is one ongoing sub–study and three sub–studies will open in April 2018. Clinical trial information: UMIN000027552.

TPS2599 Poster Session (Board #423b), Mon, 8:00 AM-11:30 AM

A phase 1 dose escalation (DE) and cohort expansion (CE) study of ERY974, an anti-Glypican 3 (GPC3)/CD3 bispecific antibody, in patients with advanced solid tumors. *First Author: Yoshitaka Ogita, Chugai Pharma USA, Berkeley Heights, NJ*

Background: ERY974 is a bispecific T cell–redirecting antibody immunotherapy that redirects T cells to tumor cells by engaging CD3 on T cells and the glypican 3 (GPC3) antigen (which is selectively expressed on tumor cells). ERY974 T cell–dependent cellular cytotoxicity has been demonstrated in vitro and transient cytokine elevations have been observed in toxicology studies (Takahiro Ishiguro et al., Sci Transl Med 2017;9:eaal4291). The primary objective of DE is to determine the maximum tolerated dose (MTD) of ERY974 in patients with locally advanced or metastatic solid tumors expressing GPC3. The primary objective of CE is to assess ERY974's preliminary anti-tumor activity. **Methods:** The study includes adult subjects with a life expectancy ≥ 3 months, histologically confirmed, measurable malignant solid tumors and/or metastatic disease not amenable to standard therapy, including patients with ≤ 1cm and ≤ 1 brain metastasis. Patients with interstitial lung disease, or acute/active chronic infection are excluded. ERY974 is administered IV and dosed weekly. DE occurs per an accelerated titration design (ATD), followed by a one-parameter logistic mode modified continual reassessment method (mCRM) to determine MTD (where the DLT occurrence rate is ≤ 0.25). The ATD and mCRM permit rapid dose escalation and determination of MTD while minimizing the number of subjects exposed to sub-therapeutic doses. Within DE, a flexible study design has been implemented to include a stepped increase in steroid administration and an ERY974 Fixed Day 1, Day 8 and Day 15 dosing regimen. Seven cohorts have completed without DLT and Cohort 8 began in December 2017. Additional measures will be implemented to help induce CRS tolerance. The CE will utilize a 2-stage design with futility analysis and will include the following 3 arms: GPC3+ gastric/gastroesophageal junction adenocarcinoma; GPC3+ squamous esophageal cancer; and other GPC3+ tumors. Clinical trial information: NCT02748837.

TPS2600 Poster Session (Board #424a), Mon, 8:00 AM-11:30 AM

Trial design of a first-in-human phase 1 evaluation of SY-1365, a first-in-class selective CDK7 inhibitor, with initial expansions in ovarian and breast cancer. *First Author: Geoffrey Shapiro, Dana-Farber Cancer Institute, Boston, MA*

Background: SY-1365 is a selective and potent covalent CDK7 inhibitor. CDK7 activity has been implicated in various solid tumors with transcriptional dependencies. Recent preclinical studies have shown robust antitumor activity of SY-1365 in ovarian and breast cancer. In ovarian cancer, SY-1365 induced apoptosis in vitro and complete regressions in PDX models derived from heavily pre-treated patients (pts). In breast cancer, SY-1365 induced cell death in vitro across subtypes and displayed synergy when combined with fulvestrant in HR-positive models. These observations led to a change in the design of the expansion phase of this first-in-human study of SY-1365 to include a new focus on these tumors. The primary objectives of this study are to assess the safety and tolerability of SY-1365, and to determine dose-limiting toxicities, the MTD and the recommended Phase 2 dose. Secondary objectives include evaluation of pharmacokinetics and pharmacodynamic (PD) effects of SY-1365 in tumor and surrogate tissues, and assessment of preliminary antitumor activity. **Methods:** This is a multicenter, open-label Phase 1 trial expected to enroll approximately 117 pts. The dose escalation phase of the trial is open to solid tumor pts for whom standard curative or palliative measures do not exist or are no longer effective. SY-1365 is administered intravenously in two dose schedules, weekly and twice weekly for 3 weeks of each 4-week cycle. The expansion phase will evaluate preliminary antitumor activity in 3 ovarian cancer cohorts, either as a single agent or in combination with carboplatin, an HR+ breast cancer cohort in combination with fulvestrant in pts who failed treatment with a CDK4/6 inhibitor in combination with an AI, and a cohort in pts with tumors of any histology to evaluate PD endpoints in paired tumor biopsies. SY-1365 target engagement in PBMCs and available tumor biopsies will be assessed by measuring CDK7 occupancy over the course of treatment. Biological impact of SY-1365 will be assessed by quantifying gene expression and induction of tumor cell apoptosis when feasible. This trial opened in May 2017. Clinical trial information: NCT03134638.

TPS2601 Poster Session (Board #424b), Mon, 8:00 AM-11:30 AM

A phase 1, open label, dose escalation study of MGD009, a humanized B7-H3 x CD3 DART protein, in combination with MGA012, an anti-PD-1 antibody, in patients with relapsed or refractory B7-H3-expressing tumors. *First Author: Sadhna Shankar, MacroGenics, Inc., Rockville, MD*

Background: T cells naturally undergo activation-induced upregulation of co-inhibitory pathways, which may limit the antitumor immune response. Blocking these inhibitory pathways may enhance the antitumor activity of CD3 bispecifics. MGD009 is a clinical stage B7-H3 x CD3 DART protein designed to redirect T cells to kill B7-H3 expressing tumor cells. B7-H3, a member of B7 family of immune regulators, is overexpressed in a variety of solid tumors and has limited expression in normal tissues. In preclinical studies, MGD009 causes T-cell infiltration, activation and expansion in the tumors. It upregulates PD-1 on T cells and PD-L1 on tumor cells and immune cells in vitro. Preliminary observations in patients enrolled in the ongoing phase 1 dose escalation trial with MGD009 alone indicate evidence of PD-1 up-regulation on both peripheral CD4 and CD8 T-cells. MGA012 is an anti-PD-1 antibody under investigation in an ongoing Phase 1 clinical trial and has shown clinical responses. In vitro and in vivo studies have shown enhanced antitumor activity with the combination of MGD009 and MGA012 beyond that achieved with MGD009 alone. A combination approach that blocks checkpoint inhibition of T cells with MGA012, while recruiting cytotoxic and helper T cells to B7-H3-expressing tumors with MGD009, may show anti-tumor activity in a variety of tumors. **Methods:** This is a Phase 1, open-label, dose escalation, and cohort expansion study designed to characterize the safety, tolerability, PK, pharmacodynamics, immunogenicity, and preliminary antitumor activity of MGD009 in combination with MGA012, both administered by IV infusion. Patients with B7-H3-expressing unresectable, locally advanced or metastatic solid tumors of any histology will be enrolled in the Dose Escalation Phase. Prior checkpoint inhibitor therapy is allowed. Dose escalation uses a 3+3+3 design, with patients treated every 2 weeks with escalating doses of IV MGD009 (starting dose 3μg/kg) and MGA012 at a dose of 3mg/kg in all cohorts. Cohort expansions will be limited to 6 tumor types (N = 20/cohort) treated at the maximum tolerated dose of the combination. Clinical trial information: NCT03406949.

TPS2602 Poster Session (Board #425a), Mon, 8:00 AM-11:30 AM

A phase 1 study of MSC-1, a humanized anti-LIF monoclonal antibody, in patients with advanced solid tumors. *First Author: David Michael Hyman, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Leukemia Inhibitory Factor (LIF) is a pleiotropic cytokine involved in many physiological and pathological processes. LIF is highly expressed in a subset of tumors across multiple tumor types and shown to correlate with poor prognosis. LIF is hypothesized to contribute to tumor growth and progression by acting on multiple aspects of cancer biology, including immunosuppression of the tumor microenvironment (TME), and is a key regulator of cancer initiating cells (CICs), which are thought to underpin tumor growth, metastasis, and resistance to therapy. MSC-1, a first-in-class humanized IgG1 monoclonal antibody, is a potent and selective inhibitor of LIF. MSC-1 leads to robust STAT3 inhibition by disrupting the LIF signaling through the LIF receptor (LIFR). Blocking LIF with MSC-1 decreased tumor growth in multiple mouse tumor models and drove reprogramming of the TME through differentiation of immunosuppressive macrophages and modulation of several immune cell types. These findings form the basis of a robust therapeutic hypothesis, whereby MSC-1 treatment may lead to clinical activity in multiple cancer indications. **Methods:** The Phase 1 study of MSC-1 will enroll patients with advanced relapsed/refractory solid tumors. The study will employ an accelerated 3+3 escalation design to explore the safety, PK, immuno-regulatory activity and preliminary anti-tumor activity of MSC-1. Patients will receive treatment with MSC-1 intravenously once every three-weeks until confirmed disease progression or intolerable toxicity. Four tumor specific expansion cohorts will be initiated once dose and schedule are established from dose escalation and include NSCLC, ovarian cancer, pancreatic cancer and a basket of advanced solid tumors; enrollment will be restricted to patients with LIF-High expression in their tumors using a diagnostic selection assay. Response will be assessed every 6 weeks per RECIST v1.1.

TPS2603 Poster Session (Board #425b), Mon, 8:00 AM-11:30 AM

A phase 1 multicenter, open-label, dose-escalation and dose-expansion study to evaluate the safety, tolerability, pharmacokinetics, pharmacodynamics, immunogenicity, and antitumor activity of MEDI7247 in patients with select relapsed/refractory hematologic malignancies. *First Author: Amir Tahmasb Fathi, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Survival outcomes in patients with relapsed/refractory multiple myeloma (MM), acute myeloid leukemia (AML), or diffuse large B-cell lymphoma (DLBCL) remains poor, and there is a high unmet need for new therapeutic options in these patient populations. MEDI7247 is a first-in-class antibody-drug conjugate consisting of an anti–Na^+-dependent alanine-serine-cysteine transporter 2 (ASCT2) monoclonal antibody, site-specifically conjugated to highly cytotoxic DNA cross-linking pyrrolobenzodiazepine (PBD) dimers (drug-to-antibody ratio of close to 2) via a protease-cleavable linker. ASCT2 is overexpressed in a broad range of solid tumors and hematologic malignancies (e.g. MM, AML, and DLBCL), and has low expression in normal tissues. MEDI7247 has demonstrated potent and specific in vitro and in vivo antitumor activity in a variety of preclinical models with varying levels of ASCT2 expression. **Methods:** This is a first-in-human, phase 1, multicenter, open-label, dose-escalation and dose-expansion study in patients with selected hematologic malignancies (MM, AML, and DLBCL) who have relapsed after, or are refractory to prior standard therapy, and for whom there is no standard salvage regimen available (NCT03106428). The primary objectives are to assess safety and tolerability, describe dose-limiting toxicities, and determine the maximum tolerated dose or a recommended dose of MEDI7247. The secondary objectives are to evaluate the antitumor activity (best overall response, objective response rate, time to response, duration of response, progression-free survival, and overall survival as defined in the relevant response criteria), pharmacokinetics, and immunogenicity of MEDI7247. Recruitment is ongoing for this study; as of February 6, 2018, 19 patients have been enrolled (AML, n = 11; DLBCL, n = 6; MM, n = 2) with a target enrollment of up to 228 patients. Clinical trial information: NCT03106428.

TPS2604 Poster Session (Board #426a), Mon, 8:00 AM-11:30 AM

A phase 1 study evaluating the safety, pharmacology and preliminary activity of MM-310 in patients with solid tumors. *First Author: Marc S. Ernstoff, Cleveland Clinic, Cleveland, OH*

Background: Ephrin receptor A2 (EphA2) is expressed in cancer and stroma cells in a wide range of solid tumors. MM-310 is an EphA2-targeting liposomal form of a docetaxel prodrug. Preclinical investigation revealed a high correlation between EphA2 expression on cancer cells and MM-310 uptake. *In vivo* studies in multiple xenograft models demonstrated superior antitumor activity compared with standard of care agents, whereas toxicology analysis in rodents and non-rodent animal models revealed a favorable toxicity profile. The overexpression of EphA2 in a wide range of tumors, the high tumor specificity of MM-310 through the enhanced permeability and retention effect, and the EphA2 targeting support the investigation of MM-310 for potential clinical utility. **Methods:** This is a first-in-human, non-randomized, open-label Phase 1 study of MM-310 in patients with relapsed or refractory solid tumors. The clinical trial is divided into 3 parts. In the ongoing first part, MM-310 is assessed as a monotherapy, administered every 3 weeks at increasing dose levels (dose escalation), in patients with metastatic solid tumors, including urothelial carcinoma, gastric carcinoma, squamous cell carcinoma of the head and neck, ovarian cancer, pancreatic ductal adenocarcinoma, prostate adenocarcinoma, non-small cell lung cancer, small cell lung cancer, triple negative breast cancer, endometrial carcinoma and soft tissue sarcoma. The primary objective is to determine the maximum tolerated dose (MTD) of MM-310 monotherapy. Secondary endpoints include: characterization of adverse event profile, determination of pharmacokinetics and immunogenicity parameters, and assessment of preliminary activity of MM-310 monotherapy. In the dose-finding phase, the study uses a modified toxicity probability interval approach (mTPI) to determine the MTD of MM-310. After an MTD of monotherapy is established, an expansion cohort, and tolerability of MM-310 in combination with other therapies will be assessed. Enrollment was initiated in March 2017. Five sites in the United States are open for enrollment. Clinical trial information: NCT03076372.

TPS2605 Poster Session (Board #426b), Mon, 8:00 AM-11:30 AM

First-in-human phase 1 study of DS-1062a in patients (pts) with advanced solid tumors (AST). *First Author: Jacob M. Sands, Dana-Farber Cancer Institute, Boston, MA*

Background: DS-1062a is a trophoblast cell-surface antigen 2 (TROP2)-targeting antibody drug conjugate. TROP2 is overexpressed in epithelial cancers, including non-small cell lung cancer (NSCLC), and its overexpression is associated with poor survival in solid tumors. In preclinical studies, DS-1062a showed promising antitumor activity and an acceptable safety profile in TROP2-positive tumors with a long half-life, allowing for every-3-week (Q3W) dosing. This dose escalation (ESC) and dose expansion (EXP) study will investigate DS-1062a in pts with ASTs (NCT03401385). Primary objectives are to determine the maximum tolerated dose and recommended dose for expansion (RDE) based on the dose limiting toxicity (DLT) rate (ESC) and assess safety and tolerability (ESC + EXP). Secondary objectives include pharmacokinetics (PK), antitumor activity and anti-drug antibody (ADA) incidence. **Methods:** In this multicenter, open-label study in the US and Japan, pts aged ≥18 (US) or ≥20 (Japan) years with unresectable relapsed or refractory advanced NSCLC are eligible regardless of TROP2 expression; other ASTs may be included if safety and efficacy in NSCLC is demonstrated. In ESC, initial intravenous DS-1062a infusion will start at 0.27 mg/kg, followed by 21-day observation. Subsequent doses will be given Q3W. In EXP, pts will receive RDE Q3W. Pts will be treated until unacceptable toxicity, progressive disease, consent withdrawal or death. Endpoints include DLTs, adverse events (safety) and tumor response evaluated using RECIST v1.1 (efficacy). Pre-, on- and post-treatment tumor samples will be evaluated for TROP2 expression and other biomarker analyses. Immunogenicity will be assessed via ADA incidence and titer. Population PK and exposure-response analysis will be conducted. Pts will be enrolled in ESC using a modified continuous reassessment method and dose escalation with overdose control, with at least 3 DLT-evaluable pts per dose level. For EXP, 40 pts with NSCLC and up to 40 pts with other solid tumors will be enrolled. Enrollment is open. Clinical trial information: NCT03401385.

TPS2606 Poster Session (Board #427a), Mon, 8:00 AM-11:30 AM

CD205-Shuttle study: A first-in-human trial of MEN1309/OBT076 an ADC targeting CD205 in solid tumor and NHL. *First Author: Elena Garralda, Medical Oncology Department, Vall d'Hebron University Hospital; Molecular Therapeutics Research Group, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain*

Background: MEN1309/OBT076 is a DM4-loaded Antibody Drug Conjugate (ADC), directed against CD205/Ly75, a type I transmembrane surface protein belonging to the macrophage mannose receptor family. CD205 is therapeutically relevant, because of its broad expression in multiple cancer types, its emerging role at facilitating metastatic invasion and its effective internalization upon antibody binding. Extensive preclinical evidence demonstrated MEN1309 antitumor activity in vitro, in xenograft and patient-derived xenograft (PDX) models. **Methods:** The CD205-Shuttle study is a two-step, open-label, multicenter, dose-escalation FIH study. Step 1 involves patients affected by different solid tumors, following an Accelerated Titration Design (ATD) whereby 1 patient per dose cohort is enrolled and the dose doubled at each cohort. If grade ≥2 toxicity is observed the trial design is expected to revert to a 3+3 scheme with a Fibonacci ascending dose scheme. Step 2 is designed to test MEN1309/OBT076 at minus 2 levels of the tolerated doses during Step 1 in patients with Non-Hodgkin-Lymphoma (NHL). Each dose level escalation will be subject to the assessment of the Cohort Review Committee (CRC). CD205-positive patients are selected by IHC staining of archived tumor material. Patient with locally advanced or metastatic solid tumor in progression can be included if failed on ≥2 previous cancer treatments and if no standard therapy is available. The primary endpoint is to identify dose limiting toxicities (DLTs) and maximum tolerated dose (MTD) of MEN1309/OBT076 administered by i.v. infusion once every 21-days. The secondary endpoints includes assessment of pharmacokinetics (PK), immunogenicity, preliminary clinical efficacy of MEN1309/OBT076 and correlation with CD205 expression. Adverse Events (AE) will be graded according to NCI CTCAE v. 4.03. Responses will be evaluated according to RECIST v1.1 and Cheson criteria (2014). Study variables will be presented by dose-cohort and overall using appropriate descriptive statistics. The enrollment began in October 2017 in European sites; up to date 3 cohort levels have been achieved. NCT03403725. NOTE: First and Second author equally contributed to this work Clinical trial information: NCT03403725.

TPS2607 Poster Session (Board #427b), Mon, 8:00 AM-11:30 AM

Phase 1b multi-indication study of the antibody drug conjugate anetumab ravtansine in patients with mesothelin-expressing advanced or recurrent malignancies. *First Author: Alex A. Adjei, Mayo Clinic, Rochester, MN*

Background: Mesothelin expression is associated with poor prognosis in patients with a wide variety of tumors, including mesothelioma, pancreatic, gastric/gastroesophageal juncture, NSCLC, ovarian, triple-negative breast cancer, and thymic carcinomas. Anetumab ravtansine is a novel fully human anti-mesothelin IgG1 antibody conjugated to the maytansinoid tubulin inhibitor DM4. We are conducting a signal-generating study with anetumab ravtansine in five tumor types with high unmet medical need in patients prescreened for mesothelin expression (NCT03102320). **Methods:** Eligibility criteria include: ≥18 years, unresectable locally advanced or metastatic recurrent or relapsing disease, no prior (pancreatic adenocarcinoma) or one or more prior lines of therapy for their advanced stage of disease, and availability of tumor tissue for mesothelin expression testing as determined by the Ventana MSLN (SP74) immunohistochemistry assay. Mesothelin-positive patients with selected adenocarcinomas (gastric including gastro-esophageal junction, NSCLC, and triple negative breast) and thymic carcinoma will receive anetumab ravtansine as monotherapy at 6.5 mg/kg IV on a 21-day cycle. Following a safety run-in phase (18-24 patients each), patients with pancreatic adenocarcinoma will receive anetumab ravtansine in combination with gemcitabine (1000 mg/m2 IV day 1 and 8 on a 21-day cycle). The primary objective is objective response rate (ORR) of anetumab ravtansine as monotherapy or combination therapy in patients with either of two mesothelin expression levels: high (≥30% positive tumor cells with moderate and stronger membrane staining intensity) and low-mid (≥5% all intensities and < 30% positive tumor cells with moderate and stronger membrane staining intensity). Secondary objectives include safety, disease control rate, duration of response, durable response rate, and progression-free survival. Approximately 350 patients will be enrolled. Clinical trial information: NCT03102320.

TPS2608 Poster Session (Board #428a), Mon, 8:00 AM-11:30 AM

A phase II trial of the DNA methyl transferase inhibitor, SGI-110 (guadecitabine), in children and adults with wild type GIST, pheochromocytoma and paraganglioma associated with succinate dehydrogenase deficiency and HLRCC-associated kidney cancer. *First Author: Jaydira Del Rivero, Center for Cancer Research, NCI, NIH, Bethesda, MD*

Background: Loss of activity of Krebs cycle components succinate dehydrogenase (SDH) complex or fumarate hydratase (FH) has been identified as a mechanism of tumorigenesis in SDH-deficient gastrointestinal stromal tumor, pheochromocytoma and paraganglioma (PHEO/PGL), and hereditary leiomyomatosis and renal cell cancer (HLRCC). Accumulation of the metabolites succinate or fumarate inhibits α-ketoglutarate-dependent dioxygenases leading to DNA hypermethylation in these tumors. Guadecitabine is a small molecule derivative of decitabine that acts as a DNA methyltransferase inhibitor. We hypothesize that guadecitabine will impact tumor growth by reversing DNA hypermethylation in tumors with Krebs cycle abnormalities (NCT03165721). **Methods:** This single site, open label, phase II study uses a small optimal two-stage design to evaluate response in three groups of patients: SDH-deficient GIST, SDH-deficient PHEO/PGL and HLRCC-associated renal cell carcinoma. The primary objective is to assess the clinical activity (CR or PR) of guadecitabine in these patients. Adults and children (≥12 years of age) receive guadecitabine subcutaneously at a dose of 45mg/m^2/day for 5 consecutive days on a 28-day cycle. Activity is assessed by imaging response of measurable disease using RECISTv1.1 using CT, MRI and/or PET. Toxicity is graded using version 4.0 of the NCI Common Toxicity Criteria. Guadecitabine related toxicities ≥grade 3 will be considered treatment limiting, unless they are reversible within 72 hours with supportive care. Following recovery from toxicity up to 2 dose reductions will be allowed. Initially 7 evaluable patients in each group will be enrolled and if 1 or more (14.3%) have a response, accrual will continue until a total of 21 patients have enrolled. If at least 3 responses (14.3%) are observed among the 21 evaluable patients the agent will be considered worthy of further testing in this disease. Clinical trial information: NCT03165721.

TPS2609 Poster Session (Board #428b), Mon, 8:00 AM-11:30 AM

Phase 1/2 trial evaluating intratumoral administration of INT230-6 alone and in combination with an anti-PD1 antibody for advanced malignancies. *First Author: Yada Kanjanapan, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: INT230-6 is a supermolecular complex of cisplatin, vinblastine, and an amphiphilic penetration enhancer, formulated for intratumoral injection. This agent utilizes technology that facilitates drug dispersion throughout the tumor and enhances receptor independent transport into cancer cells. INT230-6 preferentially saturates cancer cells, due to their greater membrane fluidity over normal cells. In Colon26 mouse models, intratumoral injections of INT230-6 resulted in up to 80% complete responses(CRs) with generation of antigen specific CD8 T-cells. Responses were seen in both injected tumors as well as bystander lesions. Animals maintained lifelong protection from tumor rechallenge, and partial protection from 4T1 (a different tumor type) which was dependent on CD4 and CD8 T-cells. Clear benefit with anti-PD1 was shown preclinically (increased CR and OS). **Methods:** This adaptive Phase 1/2 trial evaluates intratumoral INT230-6 in advanced malignancies (NCT03058289). The first cohort examines injection into superficially palpable tumors, dosed at 1ml:4cc drug:tumor concentration and administered monthly for 5 cycles. Intrapatient dose escalation is allowed. Additional cohorts include deep tumor injection, more frequent administration every 2 weeks, increased proportion of drug to tumor (1ml:2cc), and combination with an anti-PD1 antibody. Eligible patients (pts) have metastatic cancer and progressed on or are not candidates for approved therapies, or non-resectable locally advanced disease recurring within 6 months post radiation, with tumors suitable for injection. The primary objective is assessment of safety, with secondary objectives of PK and preliminary analysis of response in injected and bystander tumors. Correlative endpoints include tumor infiltrating lymphocytes in pre and on-study biopsies of injected and bystander lesions, peripheral blood for flow cytometry and circulating cytokine analyses. The superficial cohort has been completed with no DLTs in 6 treated pts. The deep tumor and every 2 week dosing cohorts are ongoing with tumor type specific expansion cohorts as guided by the Study Steering Committee. Clinical trial information: NCT03058289.

TPS2610 Poster Session (Board #429a), Mon, 8:00 AM-11:30 AM

A Cancer Research UK phase I/IIa trial of BT1718 (a first in class Bicycle Drug Conjugate) given intravenously in patients with advanced solid tumours. *First Author: Udai Banerji, The Institute of Cancer Research and The Royal Marsden, London, United Kingdom*

Background: Membrane type I matrix metalloproteinase (MT1-MMP) is a member of the matrix metalloproteinase (MMP) family which are involved in tissue remodelling through proteolysis of extracellular matrix components. Overexpression of MT1-MMP is seen in multiple tumour types including non-small cell lung cancer (NSCLC), triple negative breast cancer (TNBC) and sarcoma. BT1718 is a novel first in class bicyclic targeting peptide that binds MT1-MMP and is linked to the maytansinoid tubulin inhibitor DM1 by a cleavable disulfide linker. Bicyclic peptides have a low molecular weight in comparison to other conjugated toxin approaches enabling rapid penetration and a short systemic half-life, potentially reducing toxicity. **Methods:** This is an open label first in human phase I/IIa study. The primary objective is to propose a recommended phase 2 dose (RP2D) and schedule of BT1718. Secondary objectives include pharmacokinetic (PK) parameters and preliminary clinical responses in biomarker pre-defined cohorts of patients. Tertiary objectives include correlative studies related to predictive biomarkers of response. Dose escalation (phase I) Stage 1: In keeping with preclinical PK and safety studies, initial cohorts of patients will be dosed twice a week. There will be single patient cohorts until either Grade 2 drug related toxicity occurs or the dose exceeds 6 mg/m^2 twice a week. A 3+3 design will then be followed until the RP2D has been established. Stage 2: Once a RP2D is established in Stage 1, Stage 2 will commence in a once weekly schedule using a 3+3 design until the RP2D has been established for this schedule. Dose expansion (phase IIa) Part A: 14 patients with MT1-MMP expressing NSCLC or TNBC will be treated with BT1718 in the twice a week schedule at the RP2D. At least 6 patients will have pre & post treatment biopsies. Part B: 14 patients with MT1-MMP expressing NSCLC or TNBC will be treated with BT1718 at the RP2D in the once weekly schedule. At least 6 patients will have pre & post treatment biopsies. Part C/D: following parts A & B a decision will be made to explore the selected schedule in tumour-specific cohort(s) of around 15 patients, with refined MT1-MMP biomarker selection. Clinical trial information: 2016-004633-24.

TPS2611 Poster Session (Board #429b), Mon, 8:00 AM-11:30 AM

Phase I study of the pan-HER inhibitor neratinib given in combination with everolimus, palbociclib or trametinib in advanced cancer subjects with *EGFR* mutation/amplification, *HER2* mutation/amplification or *HER3/4* mutation. *First Author: Sarina Anne Piha-Paul, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Over expression and aberrant function of ErbB receptor tyrosine kinases (EGFR, HER2, HER3 and HER4) contributes to tumorigenesis. Multiple drugs targeting EGFR or HER2 are already approved for various cancers. In spite of clinical successes with EGFR or HER2 inhibitors, single-agents are prone to drug resistance due to aberrant or compensatory activation of additional downstream signaling pathways. We sought to determine whether neratinib, a potent irreversible pan-HER tyrosine kinase inhibitor, would be safe and efficacious in combination with approved inhibitors of mTOR, CDK4/6, or MEK. **Methods:** This is an investigator-initiated, single-center, non-randomized, multi-arm phase I trial of subjects ≥18 years old with measurable advanced solid tumors with no curative therapeutic options and whose tumors harbor somatic mutations or amplifications in ErbB genes. Prior HER2 or EGFR directed therapy are allowed. The study will have 3-arms: Arm 1: neratinib + everolimus, Arm 2: neratinib + palbociclib, Arm 3: neratinib + trametinib. Patients are selected for each arm at investigator's discretion based on tumor type and molecular aberrations present. A standard 3 + 3 dose-escalation design will be utilized and patients will be recruited into five dose levels for each arm of the study. Additional subjects will be treated in dose-expansion cohort(s) once the MTD has been established. A treatment cycle is 28 days. Primary endpoint is determination of the maximum tolerated dose and dose limiting toxicities for each treatment arm. Secondary endpoints include pharmacokinetic and pharmacodynamic analysis along with preliminary anti-tumor efficacy. Prophylactic use of antidiarrheal medication is mandatory during first cycle. Imaging will be performed at 8 week intervals and response will assessed by RECIST v1.1. Enrollment to the study has already commenced. Clinical trial information: NCT03065387.

TPS2612 Poster Session (Board #430a), Mon, 8:00 AM-11:30 AM

A phase 1a / 1b first-in-human, open-label, dose-escalation, safety, pharmacokinetic, and pharmacodynamic study of oral TP-0903, a potent inhibitor of AXL kinase, administered daily for 21 days to patients with advanced solid tumors. *First Author: John Sarantopoulos, Institute for Drug Development, Mays Cancer Center at University of Texas Health San Antonio, San Antonio, TX*

Background: AXL kinase has emerged as a key regulator of the epithelial to mesenchymal transition (EMT), a process that enables cancer cells to develop migratory and invasive properties and acquire resistance to chemotherapeutics and targeted agents. AXL kinase is also known to serve to dampen the immune response to dying tumor cells. By activating EMT, AXL signaling allows cancer cells to engulf neighboring cancer cells undergoing apoptosis, reducing presentation of pro-inflammatory stimuli to the immune system. Consequently, the inhibition of AXL by TP-0903 may potentially reduce cancer cell metastasis, target cancer cells that demonstrate immunity to chemotherapeutics and activate the anti-cancer immune response. **Methods:** Patients with advanced solid tumors that are refractory or intolerant to established therapy have been enrolled in a standard 3+3 dose escalation trial of TP-0903 given orally once daily for 21 days of a 28-day cycle. Cohort dose levels 1 through 5 have been completed without DLT, enrollment into cohort 6 began January 2018. The primary objective is to determine the MTD and DLTs; secondary objectives are PK, radiographic response, PD activity (e.g. GAS6/AXL and other EMT markers), biological activity and RP2D. Key eligibility criteria include age $\geq$ 18 years, ECOG $\leq$1, adequate organ function, life expectancy of $>$ 3 mos. Once the MTD has been reached, the study will be expanded into 5 cohorts of 20 patients each: 1) Patients on immunotherapy who demonstrate progression but are clinically stable, 2) EGFR + NSCLC having progressed on $\leq$ 2 lines of TKIs, 3) BRAF, KRAS or NRAS mutated CRC with no standard therapy remaining, 4) Platinum refractory/resistant ovarian, 5) BRAF mutated melanoma that hasn't responded to immunotherapy or combination BFAF/MEK inhibitor. Patients will be biopsied in each cohort to explore changes to the EMT phenotype. Clinical trial information: NCT02729298.

TPS2613 Poster Session (Board #430b), Mon, 8:00 AM-11:30 AM

Toca 6: A phase 1b study of Toca 511 and Toca FC in patients with advanced solid tumors or lymphoma. *First Author: Jaime R. Merchan, University of Miami, Miami, FL*

Background: Toca 511 (vocimagene amiretrorepvec) is an investigational, conditionally lytic, retroviral replicating vector that selectively infects cancer cells. Toca 511 spreads through tumors, stably delivering an optimized cytosine deaminase (CD) gene that converts the prodrug, Toca FC (investigational, extended-release 5-FC), into 5-FU within the tumor microenvironment. Preclinical studies show 5-FU kills infected dividing cancer cells and diffuses and kills surrounding cancer cells, myeloid derived suppressor cells, and tumor associated macrophages, thus reestablishing tumor immunity. A prior clinical study showed CD protein expression in resected high grade glioma tumors after intravenous (IV) Toca 511 ([1]Cloughesy T, Walbert T, Bota D, et al. Neuro Oncol 2016; 18(suppl 6):vi17). In animal models of metastatic colorectal cancer, IV Toca 511 infected metastases; subsequent 5-FC treatment resulted in decreased tumor size, improved survival, and durable antitumor immunity ([2]Yagiz K, Rodriguez-Aguirre ME, Espinoza FL, et al. Molecular Therapy: Oncolytics. 2018; 8:14-26). **Methods:** Toca 6 is a Phase 1b, multicenter, open-label study (NCT02576665) investigating changes in immune activity after treatment with Toca 511 & Toca FC in patients with advanced solid tumors or lymphoma. Toca 511 is injected IV daily for 3 days, then intratumorally following biopsy or, for patients with brain metastases, into resection cavity walls following resection. Oral Toca FC is started ~4 weeks later and repeated every 4-6 weeks. Changes from baseline in intratumoral immune activity (infiltrating T-cell subpopulations, B cells, monocytes) at 4 weeks after start of Toca FC are assessed. Peripheral blood is analyzed for effector, memory, Treg, and myeloid lineage cells. Viral RNA, DNA, and CD protein expression in tumor after IV Toca 511 are measured. Safety and efficacy are assessed. Approximately 30 patients will be enrolled at 4 sites in the United States. Enrollment progress by tumor type will be provided at the time of the meeting. Clinical trial information: NCT02576665.

TPS2614 Poster Session (Board #431a), Mon, 8:00 AM-11:30 AM

A modular, multi-arm, multi-part, first time in patient study to evaluate the safety and tolerability of the dual MET kinase/OCT2 inhibitor, OMO-1, alone and in combination with anti-cancer treatments, in patients with locally advanced, unresectable or metastatic solid malignancies. *First Author: Elizabeth Ruth Plummer, Northern Institute for Cancer Research, Newcastle University, Newcastle-upon-Tyne, United Kingdom*

Background: OMO-1, a highly selective, oral, small molecule MET kinase/OCT2 inhibitor, demonstrated single agent cellular and in vivo anti-tumour activity, including regression in MET driven xenograft models. Preclinical studies to identify optimal drug combinations Predicted efficacious exposures of OMO-1 were reached without clinically relevant adverse events in healthy volunteers, data from this study expedited the ongoing patient study. **Methods:** This novel study design consists of distinct study modules, each investigating a different hypothesis. Module 1, investigating OMO-1 monotherapy, commenced in Aug 2017. It consists of Part A (dose finding) and an optional Part B (cohort expansions in relevant clinical indications eg MET amplification or exon 14 skipping mutation). Part A is a traditional 3 + 3 dose escalation design. Part B expansions are powered to compare response rates to historical data. The option to start Part B and add further modules will be based on emerging data, a substantial protocol amendment being put in place before starting a new module. The dosing schedule/sequence of OMO-1 in each module may be adapted in response to emerging data. The maximum tolerated dose of OMO-1 for individual modules may differ based on the emerging safety profile for each combination. For all modules, Part A cohorts may be expanded by up to 12 additional patients, mandatory serial tumour biopsies will be taken and assessed for relevant PD biomarkers. This design allows one protocol to respond to emerging data, supporting studies in both monotherapy and multiple combinations, reducing the time to 'first subject in study' compared with multiple individual studies. It also allows investigators to pre-empt emerging data and changes to the treatment landscape. These challenges emphasize the need for flexible designs as the landscape of drug development continues to quickly evolve. Clinical trial information: NCT03138083.

TPS2615 Poster Session (Board #431b), Mon, 8:00 AM-11:30 AM

An explorative phase 2 study of afatinib for advanced cancers carrying an EGFR, a HER2 or a HER3 mutation: A Precision trial of the Belgian Society of Medical Oncology. *First Author: Lore Decoster, UZ Brussel, Brussels, Belgium*

Background: Next generation sequencing of solid tumors will increasingly reveal mutations in cancer genes, including EGFR, HER2 and HER3 mutations. Afatinib is a small molecule, which selectively and irreversibly inhibits EGFR, HER2 and HER4 and which blocks transphosphorylation of HER3. Afatinib monotherapy has shown activity in EGFR and HER2 mutated lung cancer and preclinical activity in rare HER3 mutated lung cancer. In addition, synergy has been reported between afatinib and paclitaxel. The aim of this Belgian multicentre multicohort basket trial is to study the activity of afatinib in cancers of any type with an EGFR, a HER2 or a HER3 mutation and to study the efficacy of adding paclitaxel to afatinib at disease progression, regardless of tumor type. **Methods:** Methods: This is a multicenter, open-label, phase 2 study of afatinib in three cohorts of patients with advanced cancer harbouring an EGFR mutation, a HER2 mutation or a HER3 mutation. For each cohort an optimal Simon's two-stage design is used (p0 = 0.10; p1 = 0.30; alpha = 0.05; power 80%). The primary endpoint for each cohort is objective response as determined according to RECIST 1.1. Secondary endpoints are progression free survival, overall survival and toxicity. At progression, paclitaxel weekly will be added to afatinib and response rate, progression free survival and toxicity will be evaluated. In addition to genotype specific response determination, the activity of afatinib in each cancer type will also be evaluated. Rebiopsy will be performed at progression. Major eligibility criteria are: Patients with locally advanced or metastatic cancers harbouring an EGFR, HER2 or a HER3 mutation, excluding EGFR mutated lung cancer. Failure of at least one line of standard systemic therapy. ECOG performance status $\leq$2. Adequate organ function. This study is in progress and has currently recruited 4 patients (2 lung cancers, 2 breast cancers) in the HER2 mutated cohort. No patients have yet been recruited in the EGFR or HER3 mutated cohorts. EudraCT No.: 2016-003411-34 Clinical trial information: 2016-003411-34.

TPS2616 Poster Session (Board #432a), Mon, 8:00 AM-11:30 AM

A phase 2, open-label study of the combination of spartalizumab (PDR001) and LAG525 for patients with advanced solid tumors and hematologic malignancies. *First Author: Sarina Anne Piha-Paul, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Spartalizumab is an immunoglobulin G4 humanized monoclonal antibody that binds with subnanomolar affinity to PD-1. LAG525 is an immunoglobulin G4 humanized monoclonal antibody that binds LAG-3 with low nanomolar affinity, inhibiting the LAG-3 interaction with MHC class II and potentially restoring the activity of antitumor effector cells and enhancing anti–PD-1 antitumor activity. Preclinical studies demonstrated that simultaneous inhibition of PD-1 and LAG-3 resulted in synergistic antitumor activity (Woo SR. *Cancer Res.* 2012). PDR001XUS01 will evaluate the clinical benefit of combination checkpoint blockade (CPB) with LAG525 plus spartalizumab across multiple tumor types that are associated with low response rates (overall response rate [ORR] $< 30\%$) to monotherapy CPB. **Methods:** This phase 2, open-label, parallel-cohort study will enroll patients aged $\geq$18 years with documented progression of small cell lung cancer, gastric/esophageal adenocarcinoma, castration-resistant prostate adenocarcinoma, soft tissue sarcoma, ovarian adenocarcinoma, advanced well-differentiated neuroendocrine tumors, or diffuse large B-cell lymphoma who received 1-5 prior lines of therapy, including $\geq$1 line of CPB monotherapy. A minimum of 5 patients and a maximum of 30 patients will be enrolled in each of the 7 tumor-type cohorts for a total planned enrollment between 35 to 210 patients. Patients will receive spartalizumab in combination with LAG525, administered intravenously every 3 weeks. The primary endpoint is the clinical benefit rate (CBR) at 24 weeks of treatment. CBR will be assessed by RECIST 1.1 for solid tumors and the Revised Response Criteria for Malignant Lymphoma for lymphoma (Cheson BD. *J Clin Oncol*. 2007). Secondary endpoints include ORR, time to response, duration of response, time to progression, and safety/tolerability. Accrual is ongoing. Clinical trial information: NCT03365791.

TPS2617 Poster Session (Board #432b), Mon, 8:00 AM-11:30 AM

A phase 2A open-label, multicenter trial of the safety and efficacy of LYC-55716, a first-in-class oral, small-molecule RORγ agonist to treat select solid tumors. *First Author: Karen Kelly, University of California Davis Comprehensive Cancer Center, Sacramento, CA*

Background: LYC-55716 is a first-in-class, oral, small-molecule agonist of the retinoic acid receptor–related orphan receptor γ (RORγ) under development as a novel immuno-oncology agent for solid tumors. Preclinical evidence suggests that LYC-55716 alters immune cell anti-tumor effector functions and immunosuppressive mechanisms, leading to reduced tumor growth and enhanced survival. In the Phase 1 portion of an ongoing Phase 1/2A trial, LYC-55716 was well tolerated with no dose-limiting toxicities. Evidence of pharmacodynamic target engagement was demonstrated and disease stabilization with tumor reduction was noted in patients after failure of PD-1 therapy. The Phase 2A trial (NCT02929862) is underway in patients with advanced non–small cell lung, head and neck, gastroesophageal, renal cell, urothelial, and ovarian cancers. **Methods:** The Phase 2A portion of the trial will enroll ~70 adult patients who will receive 28-day treatment cycles of LYC-55716 administered twice daily. The primary endpoint is to determine the objective response rate (ORR). Secondary endpoints will include duration of response, progression-free survival, overall survival, safety, and pharmacokinetics. As an exploratory endpoint, immune-related biomarkers will be assessed in blood samples from all patients, taken at screening and every 2-4 weeks through treatment cycle 4, and in tissue biopsy samples of selected patients, taken at screening and 4-12 weeks after beginning cycle 1. Immune markers of interest will be evaluated using a NanoString platform and immunohistochemistry. Results will be analyzed using descriptive and summary statistics. Clinical trial information: NCT02929862.

TPS2618 Poster Session (Board #433a), Mon, 8:00 AM-11:30 AM

Safety, dose tolerance, pharmacokinetics and pharmacodynamics study of CPX-POM in patients with advanced solid tumors. *First Author: Scott James Weir, University of Kansas Cancer Center, Westwood, KS*

Background: Ciclopirox (CPX) is an antifungal agent contained in a number of FDA-approved topical drug products. CPX possesses anticancer activity in a number of *in vitro* and *in vivo* preclinical models, however, it's clinical utility is limited due to low oral bioavailabilty, gastrointestinal toxicity, and poor water solubility. Ciclopirox Prodrug (CPX-POM) selectively delivers its active metabolite, CPX, to the entire urinary tract following systemic administration. In a chemical carcinogen mouse model of bladder cancer, CPX-POM treatment resulted in significant decreases in bladder weight, a clear migration to lower stage tumors, dose-dependent reductions in Ki67 and PCNA staining, and inhibition of Notch 1 and Wnt signaling pathways. **Methods:** Study CPX-POM-001 (NCT03348514) is an ongoing US multicenter, Phase I, open-label, dose escalation study to evaluate dose-limiting toxicities (DLTs), define the maximum tolerated dose (MTD), and to determine the recommended Phase II dose of IV CPX-POM. Approximately 24 patients with any histologically- or cytologically-confirmed solid tumor type refractory to standard therapy, and also meet other standard Phase I eligibility criteria, will be enrolled in dose escalation cohorts. The MTD will be defined as the dose BELOW that dose which causes DLTs in $\geq$33% of patients. Safety and tolerability will be based on an assessment of adverse events, physical examinations, vital signs, electrocardiogram, clinical laboratory tests, ophthalmologic assessments, and concomitant medications. Single dose and steady-state pharmacokinetics of CPX-POM, CPX and ciclopirox glucuronide are being characterized in both plasma and urine. Urine ß-glucuronidase activity is also being determined. Single and multiple dose pharmacodynamics of CPX-POM are being characterized by measuring circulating biomarkers of Wnt and Notch cell signaling pathways. Enrollment began in January 2018 at a starting IV CPX-POM dose of 30 mg/m^2. Doses are currently being escalated in 100% increments until a $\geq$Grade 2 is encountered, at which point that cohort and all subsequent cohorts will follow a classical "3 + 3" dose escalation design. Clinical trial information: NCT03348514.

TPS2619 Poster Session (Board #433b), Mon, 8:00 AM-11:30 AM

First-in-human phase 1-2A study of CB-103, an oral Protein-Protein Interaction Inhibitor targeting pan-NOTCH signalling in advanced solid tumors and blood malignancies. *First Author: Jose Manuel Perez Garcia, Medical Oncology Department (IOB), Quiron Hospital, Barcelona, Spain*

Background: NOTCH signalling is a key development pathway whose aberrant activation is recognised to play an oncogenic role in human cancers. When NOTCH signalling is inappropriately activated by genetic alterations, it becomes an oncogenic driver for NOTCH-dependent cancers, while upregulation of NOTCH receptors is linked to resistance to standard of care. CB-103 is a new small molecule protein-protein interaction (PPI) inhibitor able to target assembly of the NOTCH transcription complex in the cell nucleus leading to downregulation of NOTCH target genes (c-MYC, CCND1, HES1) and inhibition of NOTCH signalling independently of NOTCH mechanisms of activation. CB-103 has demonstrated efficacy and tolerability in different preclinical tumor models derived from various NOTCH-driven cancer indications and in blood from NOTCH-activated leukemia pts. **Methods:** This study is a multi-centre, open label, non-randomised, phase 1-2A dose escalation study in adult patients (pts), with expansion arms of oral CB-103. Aim of phase 1 is to find the MTD/RP2D. The starting dose is targeting a plasma exposure (daily AUC) that has reasonable safety margin and allows reliable determination of pharmacokinetics (PK). An adaptive Bayesian logistic regression model for dose escalation is implemented in phase 1 to guide determination of MTD/RP2D. Full PK sampling profiles will be taken on days 1 & 8 of cycle one (28 days) and day 1 of cycle two. NOTCH-related PD and Biomarker exploratory analyses are planned on tumour biopsies, hair follicles and blood samples (liquid biopsy). Administration schedule (once-daily) may be adapted depending on PK and safety. 3-6 eligible pts regardless of NOTCH pathway activation status are enrolled per dose group in phase 1, while pts in phase 2A will be selected for NOTCH pathway genetic alterations. Phase 2A will assess preliminary efficacy of CB-103 in expansion arms across different indications using Bayesian design. Enrolment into 1st dose group (15mg) started with first pt treated on 20Dec17: 7 pts registered with 2 screen failures, 1 discontinued due to early cancer progression and 4 in treatment in their first treatment cycle. Clinical trial information: NCT03422679.

TPS2620 Poster Session (Board #434a), Mon, 8:00 AM-11:30 AM

Phase 1 study of an oxidative phosphorylation inhibitor IM156 in patients with advanced solid tumors. *First Author: Sun Young Rha, Severance Hospital, Seoul, Republic of Korea*

Background: IM156 is a novel oral agent with a biguanide structure, which has anticancer activity through AMPK activation and reduction of oxidative phosphorylation. Inhibition of oxidative phosphorylation (OXPHOS) is detrimental to OXPHOS dependent drug resistant cancer cells which adapt metabolic shift upon cancer treatment or are intrinsically OXPHOS dependent cancer cells. OXPHOS dependent cancer cells are prone to energy stress such as OXPHOS inhibition that ultimately cause cancer cell death. Preclinical in vitro and in vivo experiments demonstrated that IM156 can be effective in glioblastoma, and other solid tumors. Therefore, a phase I dose-escalation study to determine safety and preliminary signals of activity of IM156 has been designed and activated (NCT03272256). **Methods:** This is an open label, single center, dose-escalation study using the 3+3 design to determine the maximum tolerated dose and/or recommended phase 2 dose, dose limiting toxicities (DLT), safety, pharmacokinetics, pharmacodynamics and preliminary signals of anticancer efficacy of IM156 in patients with advanced solid tumors refractory to standard therapies. Eligible patients are adults with advanced solid tumors refractory to standard therapies with adequate performance status (ECOG $\leq$2) and organ function with measurable disease per RECIST 1.1 (or RANO for gliomas). IM156 is administered orally every other day starting on day 1 of each 28 days cycle. The study has total of 6 dose levels ranging from 100 mg to 1,800 mg and the dose escalation continues per 3+3 design as long as the proportion of DLTs $<$ 33% ($<$ 2/6). DLTs are evaluated during the first 28 days of therapy (cycle 1). Efficacy per RECIST 1.1 (RANO for gliomas) is evaluated every two cycles. Pharmacokinetics studies have been designed to determine Cmax, AUC, T1/2 and other parameters. Pharmacodynamics studies include PET scans with FDG and acetate probes, tissue and blood biomarkers including lactate levels. As of 2/8/18 the study enrolled 6 patients into two dose levels (100mg and 200mg respectively) and enrollment continues. Clinical trial information: NCT03272256.

TPS2621 Poster Session (Board #434b), Mon, 8:00 AM-11:30 AM

Phase I study of procaspase activating compound-1 (PAC-1) for treatment of advanced malignancies. *First Author: Oana C. Danciu, University of Illinois at Chicago, Chicago, IL*

Background: Dysregulation in apoptotic pathways is a hallmark feature of cancer, offering opportunities for pharmacologic intervention in its treatment. Caspases, a family of proteases, play several roles in apoptosis. Caspase-3 catalyzes the intra-cellular proteolysis that characterizes part of the apoptotic process. Caspase-3 levels are low in many tumors including: glioblastoma; breast, colon, lung, and liver cancers: lymphoma: neuroblastoma; and melanoma. In contrast, procaspase-3, the precursor of caspase-3 is elevated in these tumors. We describe a phase I study of PAC-1, a drug that catalyzes the conversion of procaspase -3 to caspase-3. It induces apoptosis in tumor cell lines *in vitro*. *In vivo* activity has also been shown, when combined with alkylating chemotherapy, in rodent glioma models and in canines diagnosed with malignant glioma. **Methods:** This Phase I dose escalation study has two components: the first (C1) to determine the maximum tolerated dose (MTD) of PAC-1 in advanced malignancies; the second (C2) to determine the MTD of PAC-1 when combined with temozolomide (TMZ) in patients with recurrent anaplastic astrocytoma (AA) or glioblastoma (GBM). A modified Fibonacci 3 + 3 design is used, expanding to nine subjects at the MTD level in each component. PAC-1 pharmacokinetics is assessed in all subjects during the first cycle. Secondary objectives include pharmacodynamics and correlations of PAC-1 activity with procaspase-3 expression in tumor tissue. Neurologic toxicity is closely monitored throughout the study. Inclusion criteria: diagnoses of advanced malignancies (C1) and recurrent AA or GBM (C2), ECOG PS 0-2, adequate organ function. Exclusion criteria: prior cytotoxic therapy in the last 3-6 weeks (varying with drug class) or uncontrolled chronic illness. Administration and design: For C1, PAC-1 (orally administered) is dosed at 75-1,000 mg daily on days 1-21 of each 28 day cycle. For C 2, the first PAC-1 dose is 375 mg daily with potential for escalation to 1,000 mg daily. TMZ, PO, is dosed at 150 mg/m2 daily, days 8-12, of each cycle. Enrollment to date for C1 is 27, (dose level 6); and for C2 is 4 (dose level 1). The study is open to accrual. Clinical trial information: NCT02355535.

3000 **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

ICONIC: Biologic and clinical activity of first in class ICOS agonist antibody JTX-2011 +/- nivolumab (nivo) in patients (pts) with advanced cancers. *First Author: Timothy Anthony Yap, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: ICOS is a costimulatory molecule expressed on the surface of activated T cells. JTX-2011 is an ICOS agonist designed to stimulate CD4 T effector (T eff) cells and deplete intratumoral T regulatory (Treg) cells. Preclinical efficacy was seen with mouse JTX-2011 monotherapy (mono) and combination (combo) with anti-PD-1 in ICOS+ tumors. **Methods:** Relapsed/refractory cancer pts received escalating doses of JTX-2011 mono or combo with nivo in Phase 1 (P1), and the recommended P2 dose (RP2D) in P2, based on safety, target engagement (TE), immunophenotyping and cytokines. P2 gastric (GC) and triple negative breast (TNBC) combo cohorts completed enrollment. ICOS was assessed by IHC in archival (arch) and fresh pre-treatment tumor biopsies (bx) or by flow in peripheral blood. **Results:** 164 pts had ≥1 dose of JTX-2011; 71 P1 (40 mono, 31 combo); 93 P2 (25 mono, 68 combo) including 7 GC mono, 24 GC and 16 TNBC combo. Pts ≥3 prior therapies: 57% GC mono, 48% GC combo, 56% TNBC combo. JTX-2011 RP2D: 0.3mg/kg q3w mono and combo with nivo 240 mg q3w. DLTs: raised AST/ALT and pleural effusion at 1 mg/kg mono. At 0.3mg/kg: TE > 70% sustained through 3wks; no substantial change in # of peripheral T eff or Tregs; dose dependent increase in IFN-γ at 1-6 hrs. P2 adverse events (AEs): drug-related G3-4 8% mono, 13% combo; immune-related 4% mono, 21% combo; infusion related 12% mono, 19% combo. Of 13 GC combo pts with paired arch and fresh bx, 6 were ICOS hi on both, 5 changed from low to hi. Of 7 TNBC combo pts with paired bx, 5/7 archival were ICOS hi, 4/7 fresh were ICOS hi. RECIST antitumor activity: JTX-2011 mono: 1/7 partial response (PR) in GC; 2/5 stable disease (SD) in P1 TNBC. JTX-2011 combo: 2 PRs (0.1, 0.3mg/kg) and 2 ongoing SD in 19 P1/2 GC; 1 PR in 15 P2 TNBC. Of 17 evaluable pts, 4 had emergence of peripheral CD4 T cell ICOS hi subsets during JTX-2011 therapy, including 1 PR mono, 2 PR combo and 1 SD; none were seen in pts with progressive disease. **Conclusions:** JTX-2011 mono and combo with nivo were well tolerated with antitumor responses in heavily pre-treated GC and TNBC pts. Emergence of peripheral blood CD4 ICOS hi T cell subsets may be a surrogate biomarker of response. Further trials of JTX-2011 are planned. Clinical trial information: NCT02904226.

3001 **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

Anti-CD27 agonist antibody varlilumab (varli) with nivolumab (nivo) for colorectal (CRC) and ovarian (OVA) cancer: Phase (Ph) 1/2 clinical trial results. *First Author: Rachel E. Sanborn, Earle A. Chiles Research Institute, Providence Cancer Institute, Portland, OR*

Background: Preclinical studies demonstrate synergistic antitumor activity of PD-1 blockade and varli, a CD27 agonist antibody. Ph1 results were previously presented from a Ph1/2 study assessing the safety of nivo with varli; we now report Ph1/2 results for CRC and OVA. **Methods:** Pts with advanced, treatment refractory (anti-PD-1/L1 naïve) solid tumors received nivo (Ph1: 3 mg/kg; Ph2: 240 mg) every two weeks (Q2W). Ph1 cohorts also received varli at 0.1, 1, or 10 mg/kg Q2W. Ph2 cohorts received varli at 3 mg/kg Q2W (CRC and OVA), 0.3 mg/kg Q4W (OVA), or 3 mg/kg Q12W (OVA). Primary study objectives: safety (Ph1) and overall response rate (Ph2). **Results:** 42 CRC and 66 OVA pts received nivo and varli. Toxicity was consistent with the safety profile of each agent; treatment-related serious events occurred for 3 pts with CRC (mixed motor sensory neuropathy, pneumonitis, elevated ALT) and 2 pts with OVA (acute kidney injury, hepatitis, small bowel obstruction). Of 49 (8 Ph1, 41 Ph2) evaluable OVA pts, 5 (10%; all Ph2) had RECIST 1.1 Partial Response (PR) and 19 (39%; 6 Ph1, 13 Ph2) had Stable Disease (SD). On-treatment biopsies revealed an increase in PD-L1 expression ($p < 0.006$), and CD8+ T cells ($p < 0.005$), which was more prevalent among pts with better outcome (PR or ≥ 16 weeks of SD), $p < 0.017$ and $p < 0.002$. Of 41 (21 Ph1, 20 Ph2) evaluable CRC pts, 2 (5%; 1 Ph1, 1 Ph2) had PR (Ph1 pt MSI-low, Ph2 pt MSI-high; both PD-L1 neg) and 7 (17%; 3 Ph1, 4 Ph2) had SD. 89% of CRC pts had PD-L1 neg tumors at baseline. In contrast to OVA, increase in tumor PD-L1 expression or CD8+ T cells during treatment in CRC patients was infrequent, correlating with less overall clinical impact. **Conclusions:** Varli with nivo was well tolerated without evidence of additive toxicity. In OVA pts, treatment induced significant tumoral changes that correlate with better outcome. Remaining analyses of OVA pts will examine the impact of varli dosing schedule on clinical outcome and biomarkers. The mechanisms that mediate the lack of T cell and PD-L1 increase in some pts are being explored by further tumor molecular profiling. Clinical trial information: NCT02335918.

3002 **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

A first-in-class, first-in-human phase 1 pharmacokinetic (PK) and pharmacodynamic (PD) study of Hu5F9-G4, an anti-CD47 monoclonal antibody (mAb), in patients with advanced solid tumors. *First Author: Branimir I. Sikic, Stanford University School of Medicine, Stanford, CA*

Background: Hu5F9-G4 (5F9) is a humanized mAb that inhibits CD47, a "don't eat me" signal for macrophages, and can enhance tumor cell phagocytosis and T-cell priming. Preclinically, 5F9 is active against a wide range of tumors. **Methods:** Patients (pts) were enrolled in 3 dose escalation groups using a 3+3 design (NCT02216409). Part A (11 pts) defined 1 mg/kg of 5F9 as the optimal week (wk) 1 priming dose that was used subsequently in Parts B & C. Part B (14 pts) evaluated higher weekly (wkly) maintenance doses starting wk 2 and Part C (18 pts) evaluated an additional loading dose in wk 2. Safety, PK, PD and efficacy data are presented here. **Results:** In 58 pts (median age 60 y; median prior treatments 5) the common tumor types were colorectal (CRC), ovarian, adenoid cystic, breast, pancreatic, and squamous cell head & neck cancers. Using a priming + load/maintenance dose, no maximum tolerated dose (MTD) was reached in Part B where 14 pts received ≥20 mg/kg of 5F9 wkly, nor in Part C where doses of 20 (7 pts), 30 (8 pts) and 45 mg/kg (3 pts) were well tolerated. Common Part C drug-related adverse events were fatigue 50%, chills 50%, pyrexia 45%, anemia 39%, headache 34%, lymphopenia 28%, hemagglutination 17%, transient hyperbilirubinemia 17%, and myalgias 11%. Most AEs were Grade (Gr) 1 or 2 occurring in cycle 1 (28 days) with Gr 3+ being uncommon and no cumulative effects. Transient Grade 1/2 acute anemia due to CD47 blockade on older RBCs was common but was mitigated by the priming dose strategy. Saturation of nonlinear PK occurred at ≥10 mg/kg resulting in a prolonged $t_{1/2}$ ~14 days, 5F9 levels exceeding preclinical antitumor activity thresholds (200 ug/mL) and resulting in > 99% WBC CD47 receptor occupancy. The recommended Phase 2 dose is 1 mg/kg priming dose wk 1 followed by 30 mg/kg wkly x 3 and then 30 mg/kg Q2 wks thereafter. Two pts (ovarian and fallopian tube cancers) had confirmed partial responses and were treated for 23 and 41+ weeks, respectively. In 13 CRC pts treated at doses ≥20 mg/kg, 6 had stable disease with a median treatment duration of 18 wks. **Conclusions:** 5F9 prime + maintenance doses are well tolerated and demonstrate monotherapy antitumor activity. Clinical trial information: NCT02216409.

3003 **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

Durability of response in ZUMA-1, the pivotal phase 2 study of axicabtagene ciloleucel (Axi-Cel) in patients (Pts) with refractory large B-cell lymphoma. *First Author: Frederick Lundry Locke, Moffitt Cancer Center, Tampa, FL*

Background: Axi-cel, an anti-CD19 CAR T cell therapy, demonstrated significant clinical benefit and a manageable safety profile for pts with refractory large B cell lymphoma in ZUMA-1 (Neelapu & Locke et al. *NEJM*. 2017). These results led to its approval by the US FDA for the treatment of adult pts with relapsed or refractory large B cell lymphoma after ≥ 2 prior lines of therapy. Here, we examined responses over time in phase 2 of ZUMA-1. **Methods:** Pts with refractory large B cell lymphoma received 2×10^6 CAR T cells/kg after low-dose conditioning (Neelapu & Locke et al. *NEJM*. 2017). Best objective response rates (BOR) were analyzed locally by investigators (local) and centrally by independent review committee (IRC; Cheson et al. *J Clin Oncol*. 2007); concordance was measured as the percentage of pts whose IRC matched local. **Results:** As of 8/11/17, median follow-up (f/u) was 15.1 mo for the 101 pts treated with axi-cel. While the BOR of 82% at primary analysis (PA; median f/u 8.7 mo) by local remained consistent (83%) at long-term f/u (LTFU; median of 15.1 mo), complete response (CR) rates increased from 54% to 58% (Table). Out of 34 pts with partial response (PR) at 1 mo, 11 (32%) converted to CR by the LTFU. High concordance (77% - 79%) was observed for objective response rates (ORR [CR + PR]) between local and IRC at all times assessed. Landmark analysis of progression-free survival (PFS) by response status (per local) revealed that most of the 60 pts with disease control (stable disease or better) at 3 mo had prolonged disease control with a 73% 12-mo PFS rate. Of the 42 pts with CR and 9 with PR at 3 mo, the 12-mo PFS rates were 79% and 78%, respectively. **Conclusions:** Treatment with axi-cel induces high response rates in pts with refractory large B cell lymphoma. CR rates increased through the LTFU, suggesting that responses deepen over time and that pts with PR can achieve CR as late as a year post-infusion. ORR at 3 mo may be prognostic for prolonged PFS. Drs Locke and Neelapu contributed equally. Clinical trial information: NCT02348216.

Treatment of metastatic human papillomavirus-associated epithelial cancers with adoptive transfer of tumor-infiltrating T cells. *First Author: Sanja Stevanovic, National Cancer Institute at the National Institutes of Health, Bethesda, MD*

Background: Adoptive T-cell therapy (ACT) is a promising cancer treatment modality. However, its study in epithelial cancers has been limited. Human papillomavirus (HPV)-associated cancers are difficult to treat epithelial malignancies for which better systemic treatments are needed. We conducted a clinical trial of ACT for the treatment of metastatic HPV-associated cancers. **Methods:** The clinical trial was a phase II design with two disease cohorts (cervical cancers and non-cervical cancers). Patients were treated with a single infusion of tumor-infiltrating lymphocytes (TIL), which were generated, when possible, from TIL subcultures with HPV-oncoprotein reactivity (HPV-TIL). HPV-TIL infusion was preceded by a lymphocyte-depleting conditioning regimen followed by systemic high-dose aldesleukin. **Results:** Objective tumor responses occurred in 5/18 (28%) patients in the cervical cancer cohort and 2/11 (18%) patients in the non-cervical cancer cohort. In the cervical cancer cohort, two patients experienced complete responses that are ongoing 53 and 67 months after treatment. Three patients experienced partial responses that were three months in duration. In the non-cervical cancer cohort, partial responses were observed in a patient with anal cancer (four months duration) and a patient with oropharyngeal cancer (five months duration). The latter patient had previously been treated with six systemic anti-cancer agents. Multiple thoracic metastases responded completely after HPV-TIL infusion. A brain metastasis developed five months after treatment and was surgically resected. He is without evidence of disease 51 months after treatment. **Conclusions:** HPV-TIL can mediate regression of metastatic HPV-associated cervical, oropharyngeal and anal epithelial cancers in some patients. These findings support the study of ACT for HPV-associated cancers and possibly other epithelial malignancies. Clinical trial information: NCT01585428.

3005 **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

Pilot study of NY-ESO-1^{c259} T cells in advanced myxoid/round cell liposarcoma. *First Author: Sandra P. D'Angelo, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY*

Background: Metastatic myxoid/round cell liposarcoma (MRCLS) has a poor prognosis. NY-ESO-1 is expressed in 80-90% of MRCLS tumors. This study evaluates affinity enhanced autologous NY-ESO-1^{c259}T cells recognizing an NY-ESO-1 derived peptide complexed with HLA-A*02 (SPEAR T-cells) in MRCLS (NCT02992743). **Methods:** This open label phase I/II single arm pilot study evaluates efficacy, safety and translational research endpoints. Eligible pts are $\geq$ 18 yr; HLA-A*02:01^{+}, *02:05^{+} or *02:06^{+}; have advanced MRCLS expressing NY-ESO-1 at 2+/3+ intensity in $\geq$30% of tumor cells by IHC; measurable disease; received anthracycline therapy; ECOG status 0 or 1; and adequate organ function. Following apheresis, T cells are isolated, expanded, transduced with a lentiviral vector containing the NY-ESO-1^{c259}TCR, and 1–8 $\times$ 10^{9} transduced T-cells are infused on day 1 after lymphodepletion with Flu 30 mg/m^{2}/d and Cy 600 mg/m^{2}/d on d -7 to -5. Response is assessed at 4, 8, 12, and 24 wk and then every 3 mo until disease progression. **Results:** 37 patients were screened; 19 had the requisite HLAs. NY-ESO-1 was present at required levels in 13/14 tumors tested. 2 patients received the TCR therapy (as of 30Jan18). The tumors of treated pt expressed NY-ESO-1 at 3+ in 100% and 2 or 3+ in 60% of tumor cells. The 1st patient received 5.00 $\times$ 10^{9} transduced T-cells and achieved an unconfirmed partial response; the target lesions showed 32% reduction from baseline at wk 12. AEs include grade (G) 4 lymphopenia, neutropenia, leukopenia, G3 thrombocytopenia and G2 anemia; all were considered related to lymphodepletion and resolved. G1 CRS with fever, G1 AST elevation, and G2 ALT elevation were also reported. The CRS resolved and was considered related to TCR therapy. Transduced cells were detected in peripheral blood 12 wk post infusion. The 2nd patient received 1.04 $\times$ 10^{9} transduced T-cells and achieved an unconfirmed partial response; target lesions showed 37% reduction from baseline at wk 4. AEs include G4 lymphopenia, G3 anemia, G2 thrombocytopenia, G2 CRS with fever and rash. Confirmatory scans are pending. **Conclusions:** The data indicate that treatment with NY-ESO-1^{c259}T cells in MRCLS is feasible with potential for anti-tumor effects. We will report updated results. Clinical trial information: NCT02992743.

3006 **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

NKTR-214 (CD122-biased agonist) plus nivolumab in patients with advanced solid tumors: Preliminary phase 1/2 results of PIVOT. *First Author: Adi Diab, Department of Melanoma Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: PIVOT is an ongoing, open-label, phase 1/2 study of NKTR-214 (214; CD122-biased agonist) plus PD-1 inhibitor nivolumab (N) in patients (pts) with advanced cancers (MEL, RCC, NSCLC, TNBC, and UC). 214 monotherapy increases newly proliferative CD8^{+} T cells in tumors and increases cell surface PD-1 and PD-L1 expression, demonstrating a potentially synergistic mechanism with anti-PD-1 therapy. **Methods:** In P1 dose escalation, pts received 214 (0.003, 0.006 or 0.009 mg/kg) with N (240 mg or 360 mg) administered IV as outpatient Q2W or Q3W; in P2 expansion, the RP2D of 214 (0.006 mg/kg) with N (360 mg) Q3W was administered concurrently. Response was assessed Q8W by RECIST v1.1. Matched tumor samples were evaluated for changes from baseline in immune cell populations, gene expression, and T cell receptor repertoire. Tumor baseline and on treatment PD-L1 protein expression was assessed (28-8 IHC assay). **Results:** As of 7FEB2018, 162 pts (P1, n = 38; P2, n = 124) were evaluable for safety. The most common TRAEs of all grades at the RP2D ($>$ 25%) in pts were flu-like symptoms (63%), fatigue (39%), rash (38%) and pruritus (30%). G3+ TRAEs at the RP2D were 11%. No pts discontinued treatment or died from TRAEs. A total of 60 IO-treatment naïve stage IV pts (P1, n = 30; P2, n = 30) were efficacy evaluable ($\geq$1 scan) (23 MEL, 24 RCC, 6 NSCLC, 4 UC, 3 TNBC). 22/30 P2 pts had only 1 scan. ORR (CR+PR) and DCR (CR+PR+SD) in 23 MEL (1L) pts was 52% and 78%. 18/23 MEL pts had known PD-L1 status. ORR was 5/9 (56%) for PD-L1(+) pts and 4/9 (44/%) for PD-L1(-) pts. ORR and DCR in 24 RCC (1L) pts was 54% and 79%. 20/24 RCC pts had known PD-L1 status. ORR was 4/7 (57%) for PD-L1(+) pts and 7/13 (54%) for PD-L1(-) pts. ORR and DCR in 6 NSCLC (1-2L) pts was 50% and 67%. 5/6 pts had known PD-L1 status. ORR was 3/5 (60%) in PD-L1(-) pts. ORR and DCR in 4 UC (1L) was 75% and 100%. ORR/DCR in 3 TNBC (1- 2L) pts was 33%. In 60 evaluable pts, 32/32 responses are ongoing (0.3+ to 12.0+ mos) with 45/60 pts still on treatment. **Conclusions:** 214 plus N was well-tolerated with no TRAE discontinuations. Preliminary efficacy shows encouraging ORR/DCR with responses observed in 5 of 5 tumor types in I-O treatment naïve 1-2L pts. Updated data to be presented. Clinical trial information: NCT02983045.

3007 **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

Safety and activity of M7824, a bifunctional fusion protein targeting PD-L1 and TGF-β, in patients with HPV associated cancers. *First Author: Julius Strauss, National Cancer Institute at the National Institutes of Health, Bethesda, MD*

Background: Therapies targeting PD-1/L1 have produced response rates of 15-20% in patients (pts) with HPV associated cancers (HAC) including cervical (cerv), anal or head and neck squamous cell carcinoma (HNSCC). Another potential target for these diseases is transforming growth factor-β (TGF-β) as genome wide association studies in HPV+ cancers have shown TGF-β to be significantly overexpressed. M7824 is a bifunctional fusion protein targeting PD-L1 and TGF-β comprised of a human IgG1 monoclonal antibody against PD-L1 fused to 2 extracellular domains of TGF-β receptor II, which functions as a TGF-β "trap". We report data from pts with HAC on a fully enrolled dose escalation portion of a phase 1 trial of M7824. **Methods:** NCT02517398 is a phase 1, 3+3 dose-escalation study. Pts received M7824 at 1, 3, 10, 20, or 30 mg/kg Q2W until PD or unacceptable toxicity. The primary objective was safety and maximum tolerated dose (MTD). A key secondary objective was best overall response per RECIST v1.1. **Results:** As of Feb 5 2018, 16 pts with HAC (9 cerv, 4 anal and 3 HNSCC) were enrolled. HPV was + in 11 pts and unknown (uk) in 5 pts. Grade 3 treatment related adverse events (TRAEs) occurred in 3/16 (colitis, cystitis, gastroparesis; all cerv). Notably all 3 also had disease reduction. Grade 4 hypokalemia accompanied the gastroparesis. No other grade 4-5 TRAEs were seen. The only DLT was colitis (at 20 mg/kg) and no MTD was reached. 9/16 (56%) have had disease reduction on treatment including 1 pt (cerv; HPV+) with a durable CR, 4 pts (2 HNSCC, 2 anal; all HPV+) with durable PRs, 1 pt (cerv; HPV uk) with an unconfirmed PR, 2 pts (2 cerv; both HPV uk) with near PRs (-25%, -27%) and 1 pt (anal; HPV uk) with modest reduction (-9%). In all, 6/16 (37.5%) have ongoing responses, 5/6 confirmed. Of pts with known HPV+ disease, 5/11 (45.5%) have ongoing confirmed responses. **Conclusions:** Data from a phase 1 trial of M7824 suggests a manageable safety profile and an ORR of 37.5% in pts with HAC including a confirmed ORR of 45.5% in pts with known HPV+ disease. M7824 is a promising drug for pts with HAC or HPV+ cancers and continues to be evaluated in phase I and II trials. Clinical trial information: NCT02517398.

3008 Oral Abstract Session, Sat, 3:00 PM-6:00 PM

ALT-803, an IL-15 superagonist, in combination with nivolumab in metastatic non-small cell lung cancer: Ongoing experience and biomarker development from a non-randomized, open-label, phase Ib/II trial. *First Author: John M. Wrangle, Johns Hopkins Univ School of Medcn, Baltimore, MD*

Background: PD-1/PD-L1 blockade fails to yield a response in about 80% of unselected non-small cell lung cancer (NSCLC) patients and acquired resistance will lead to treatment failure in most responders. Cytokine therapy with IL-2/IL-15Rbg agonists has demonstrated durable responses in select solid tumors, though the response rates are low. There have been no published reports of combination trials of IL-2/IL-15Rbg agonists cytokines with anti-PD1 immunotherapy. **Methods:** In this phase Ib/II trial NSCLC patients received anti-PD1 immunotherapy in combination with ALT-803, an IL-15 super-agonist. Eligibility criteria include measurable disease, no history of auto-immune disease, and ECOG performance status of 0 or 1. Nivolumab was administered IV every 14 days and ALT-803 was administered subcutaneously weekly for six months. The primary objective of the phase Ib study was to define safety, tolerability and to define a recommended phase II dose (RP2D) of ALT-803 in combination with nivolumab. Phase II enrollment is ongoing. **Results:** As of February 13, 2018, 38 subjects have been enrolled to trial. No dose-limiting toxicities have been observed. Common adverse events are injection site reactions and flu-like symptoms. The RP2D of ALT-803 is weekly subcutaneous 20 mcg/kg in combination with intravenous nivolumab 240mg every two weeks. The most common grade 3 adverse event, occurring in two patients each, was lymphocytopenia and fatigue. A Grade 3 myocardial infarction occurred in one patient. No grade 4 or 5 toxicity was observed. Among patients in the phase Ib experience who had PD1 immunotherapy relapsed or refractory tumors, the disease control rate was 91% (10 of 11) patients, with 27% (3 patients) partial responses and 64% (7 patients) stable disease noted. Among 10 patients with PD-L1 negative tumors, the disease control rate was 70% and a 30% partial response rate. **Conclusions:** The combination of nivolumab with ALT-803 can be safely administered in an outpatient setting. There is encouraging anti-tumor activity with the combination of nivolumab with ALT-803. Phase II study of the combination is ongoing. Clinical trial information: NCT02523469.

Cardiovascular adverse events in immune checkpoint inhibitor clinical trials: A U.S. Food and Drug Administration pooled analysis. *First Author: Laleh Amiri-Kordestani, U.S. Food and Drug Administration, Bethesda, MD*

Background: Immune checkpoint inhibitors (ICI) have been approved for numerous cancers and have transformed patient outcomes. There is a growing recognition of immune-related adverse events (AE), including cardiovascular (CV) AE. While rare cases of fulminant myocarditis have been reported, the full extent of CV AE remains unknown. **Methods:** This exploratory observational study pooled data from prospective ICI trials submitted to FDA in initial or supplemental Biologics License Applications until 1/2018. To systematically categorize CV AE, we combined CV MedDRA Preferred terms with a focus on the underlying pathology. Descriptive statistics were used to characterize the incidence of CV AE by exposure to ICI and calculate relative risks (RR) between arms of interest. To account for bias with respect to duration of exposure, we based our analyses on the first 6-month treatment window. **Results:** Within 59 trials (N = 21,664), ICI therapy was associated with higher rates of myocarditis, vasculitis, ischemia, arrhythmia, and pericardial disease compared to non-ICI therapy. When ICIs were used in combination, CV AE increased across most categories compared to monotherapy. Five fatal cases of myocarditis were reported with ICI therapy. **Conclusions:** To our knowledge, this is the largest report of CV AE associated with ICI in clinical trials. Our results show that combination ICI therapy appears to be associated with an increase in observed incidence rates of CV AE relative to ICI monotherapy.

CV AE for patients with/without ICI.

	Incidence Rates (%)			Relative Risks

Cumulative antibiotic use and efficacy of immune checkpoint inhibitors in patients with advanced cancer. *First Author: Nadina Tinsley, Christie Hospital, Manchester, United Kingdom*

Background: Efficacy of immune checkpoint inhibitors (CKIs) for treatment of cancer may be affected by the use of antibiotics (ABX). The gut microbiome is involved in immunotherapy responses therefore ABX known to alter the gut microbiome may affect tumour inflammation and microenvironment, leading to decreased CKI efficacy. **Methods:** Retrospective data analysis was undertaken on metastatic cancer patients (pts) treated with CKIs between January 2015 and March 2017 at the Christie NHS Foundation Trust. Melanoma, renal and non-small cell lung cancer (NSCLC) pts were included. Demographics, prior systemic treatment, extent of disease, CKI agent and use of ABX (route, duration, multiple concurrent/successive courses) were collected. Progression free survival (PFS) and overall survival (OS) were compared between ABX groups (ABX^+ defined as pts treated with ABX within 2 weeks of CKI initiation or 6 weeks after, ABX^- as pts with no ABX during specified period). Statistical analyses were performed with univariate and multivariate models. **Results:** Of 303 included pts (201 (66%) melanoma, 56 (18%) NSCLC and 46 (15%) renal) 94 (31%) received ABX (commonest beta-lactam ABX and macrolides). In multivariate analysis, ABX^+ pts had shorter PFS and OS when compared to ABX^- pts: PFS 97 days (95% CI 84-122) vs 178 days (95% CI 155-304) p = 0.049; OS 317 days (95% CI 221-584) vs 651 days (95% CI 477-998) p = 0.001. Cumulative ABX ($>$ 10 days, multiple concurrent/successive courses) demonstrated particularly shortened PFS 87 days (95% CI 83-122) p = 0.0093 and OS 193 days (95% CI 96-355) p = 0.00021. Pts treated with ABX prior to CKI initiation had shorter PFS and OS than those treated after CKI initiation (HR 1.37 and HR 1.72) p = 0.29 and 0.08 respectively. **Conclusions:** To our knowledge, this is the largest multivariate analysis showing ABX use is an independent predictor of shorter PFS and OS in cancer pts treated with CKI. It is the first analysis to demonstrate cumulative ABX use is associated with even poorer outcomes across multiple tumour types independent of clinical factors. The data suggests a trend towards reduced PFS in pts who received ABX prior to CKI initiation, warranting further validation in a larger cohort.

3011 Poster Discussion Session; Displayed in Poster Session (Board #225), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 11:30 AM-12:45 PM

Association of gut microbiome with immune status and clinical response in solid tumor patients who received on anti-PD-1 therapies. *First Author: Shota Fukuoka, Division of Cancer Immunology, Exploratory Oncology Research and Clinical Trial Center, National Cancer Center Hospital East, Kashiwa, Japan*

Background: Significant advances have been made in cancer immunotherapy with immune check point blockade (ICB). Yet, most patients with various tumor types finally experienced disease progression after ICB. Therefore, to investigate predictive biomarker(s) and resistance mechanism (s) against ICB are of importance. While modulation of the gut microbiome reportedly augments anti-tumor immune responses induced by ICB in murine models, the association between gut microbiome and immune status in tumor microenvironment remains unclear. Here, we addressed this issue with a Japanese patient cohort harboring solid cancers (non-small cell lung cancer and gastric cancer) who received anti-PD-1 therapies. **Methods:** We performed Meta-sequencing analyses of bacterial 16S ribosomal DNA amplified from stools from 38 solid tumor (lung cancer, 14: gastric cancer, 24) patients. Tumor-infiltrating lymphocytes (TIL) were analyzed from 17 patients. Patients were classified as follows: Responder (R) with an objective response (complete or partial response, or stable disease lasting at least 6 months) and Non responder (NR) with disease progression or stable disease lasting less than 6 months) based on REICIST criteria. **Results:** We observed significant differences in the diversity and composition of gut microbiome in R (n = 7) versus NR (n = 31). No significant differences were observed in patient base-line characteristics between Rs and NRs including PD-L1 expression. Rs had a significantly higher alpha diversity compared with NR using Shannon's index (p = 0.0047). Progression-free survival was significantly longer in patients with high diversity than patients with lower diversity patients (median 93 vs. 28 days, p = 0.002). Particularly, Ruminococcaceae family in Clostridiales order was enriched in R with LEfSe analysis. Immune profiling revealed a statistically significant positive correlation between $PD\text{-}1^+CD8^+$T cell in TIL and abundance of Ruminococcaceae (r = 0.57, p = 0.020). **Conclusions:** The diversity of and composition of gut microbiome could predict the effect of ICB, suggesting that gut microbiome potentially augment therapeutic responses to ICB in patients with solid tumors.

Phase I/II study of LAG525 ± spartalizumab (PDR001) in patients (pts) with advanced malignancies. *First Author: David S. Hong, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: LAG525 and spartalizumab (PDR001), humanized IgG4 mAbs, block binding of LAG-3 to MHC class II and PD-1 to PD-L1 and PD-L2, respectively. Preclinical studies show synergistic anti-tumor activity when blocking PD-1 and LAG-3. Here, we report dose escalation results from a Phase I/II study of LAG525 ± spartalizumab in advanced malignancies (NCT02460224). **Methods:** LAG525 was dosed Q2W (1–15 mg/kg, or 240/400 mg) or Q4W (3–10 mg/kg, or 400 mg); LAG525 + spartalizumab was dosed at 15 dose levels/schedules from 0.3 mg/kg LAG525 + 1 mg/kg spartalizumab Q2W to 1000 mg LAG525 + 400 mg spartalizumab Q4W. Phase I endpoints (dose-limiting toxicities [DLTs], additional safety, pharmacokinetics, efficacy, and biomarkers) were used along with an adaptive Bayesian logistic regression model guided by escalation with overdose control to support future study dosing. Baseline and on-treatment tumor samples were collected. **Results:** As of 31 Jul 2017, 115/119 pts (97%) receiving LAG525 and 99/121 pts (82%) receiving LAG525 + spartalizumab had discontinued treatment, primarily due to progressive disease (79% and 67%, respectively). DLTs occurred in 4 pts in each arm (LAG525 arm: Gr 3 intra-abdominal fluid collection, lipase increase, vomiting; Gr 4 acute kidney injury. Combination arm: Gr 3 hyperglycemia, pneumonitis, brain tumor edema, fatigue; Gr 4 autoimmune hepatitis) without clear dose relationship. Common (≥10%) related AEs were fatigue (10%) for LAG525 alone and fatigue (18%), diarrhea (15%), and nausea (12%) for the combination. Gr 3–4 related AEs were reported in 10 pts (8%) in the LAG525 arm and 10 pts (8%) in the combination arm. Approximately dose-proportional increases in LAG525 exposure were seen. No MTD was identified for either arm. LAG525 + spartalizumab led to durable RECIST responses (11 PR, 1 CR) in a variety of solid tumors, including mesothelioma (2/8 pts) and triple-negative breast cancer (TNBC; 2/5 pts). In TNBC tumor biopsies, a trend in conversion of immune-cold to immune-activated biomarker profiles was seen. **Conclusions:** Treatment was well tolerated with preliminary anti-tumor activity and immune profile modulation observed for LAG525 + spartalizumab. Phase II is ongoing in selected indications. Clinical trial information: NCT02460224.

Initial results from first-in-human study of IPI-549, a tumor macrophage-targeting agent, combined with nivolumab in advanced solid tumors. *First Author: Ryan J. Sullivan, Massachusetts General Hospital, Boston, MA*

Background: IPI-549 is a potential first-in-class, oral, selective PI3K-γ inhibitor that in preclinical studies reprograms macrophages from an immune-suppressive to an immune-activating phenotype and can overcome resistance to checkpoint inhibitors. **Methods:** Ph 1/1b study IPI-549-01 (NCT02637531) is evaluating the safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD), and immunomodulatory activity of IPI-549 to determine its recommended Ph 2 dose (RP2D) and preliminary efficacy, as monotherapy and combined with nivolumab (nivo), in advanced solid tumor pts. Pre- and on-treatment blood samples were obtained for flow cytometry, gene expression, and serum analysis. **Results:** Initial combination dose-escalation results are reported. 31 pts (30 evaluable), median age 57 yrs and median 4 prior therapies (8 with prior anti PD-(L)1 therapy), received IPI-549 20, 30, and 40 mg QD + nivo 240 mg Q2W in a 6+6 design. IPI-549 PK/PD were unaffected by nivo. The MTD was not reached. Most treatment-emergent adverse events (TEAEs) were Gr 1-2. The most common (≥ 2 pts) treatment-related TEAEs included rash (23%); pruritus (10%); and nausea, anemia, ALT increase, AST increase, and pyrexia (6% each), with no treatment-related deaths. 2 DLTs each occurred at IPI-549 30 mg (Gr 3 rash) and 40 mg QD (Gr 3 rash; Gr 3 ALT/AST increase). 2 pts demonstrated partial responses at first assessment (8 wks): 1 with adrenocortical carcinoma and 1 with microsatellite-stable gallbladder carcinoma receiving IPI-549 30 and 40 mg QD, respectively. 40% of pts (n = 12) remained on study ≥ 12 wks and 6 pts were ongoing at the 05 Feb data cutoff. Based on safety + PK/PD data, the RP2D was IPI-549 40 mg QD + nivo 240 mg Q2W. On-treatment blood samples show evidence of immune activation and reduced immune suppression, including upregulation of IFNg-responsive factors, such as PD-L1 and CXCL9/10, and dose-dependent re-invigoration/proliferation of exhausted PD1+CD8+CD45RA- T cells, evidenced by Ki67 increases. **Conclusions:** IPI-549 + nivo demonstrates favorable tolerability, early signs of clinical activity, and evidence of immune modulation. Combination expansion cohorts are enrolling at the RP2D. Clinical trial information: NCT02637531.

Phase Ib/II study of lacnotuzumab (MCS110) combined with spartalizumab (PDR001) in patients (pts) with advanced tumors. *First Author: Aitana Calvo, Hospital General Universitario Gregorio Marañón, Madrid, Spain*

Background: Tumor-associated macrophages mediate intrinsic/acquired resistance to programmed death-1 (PD-1) inhibitors; these cells can be reduced by inhibiting the colony-stimulating factor-1 (CSF-1)/receptor pathway. Targeting CSF-1 with lacnotuzumab (MCS110), a high-affinity, humanized mAb, combined with spartalizumab (PDR001), a humanized anti-PD-1 mAb, is hypothesized to result in synergistic antitumor activity. **Methods:** This Phase Ib/II study (NCT02807844) assesses lacnotuzumab with spartalizumab in pts with advanced melanoma, endometrial, pancreatic (PC), or triple-negative breast cancer. During dose escalation, pts received lacnotuzumab at 1 or 3 mg/kg with 100 mg spartalizumab, or 3, 5, 7.5, or 10 mg/kg lacnotuzumab with 300 mg spartalizumab, every 3 weeks. For the Phase Ib part, primary endpoints are safety, tolerability, and recommended Phase II dose; secondary endpoints include antitumor activity and PK. Tumor biopsies are collected before and during treatment. **Results:** At data cut-off 24 Nov 2017, 50 pts (median age 60 years) were enrolled at 6 combination dose levels. The most common (≥30%) all-grade AEs regardless of study drug relationship were increased aspartate aminotransferase (AST; 32%), nausea (32%), vomiting (32%), asthenia (30%), and fatigue (30%); the most common (≥10%) Grade ≥3 AEs were increased AST (12%), asthenia (10%), and hyponatremia (10%). Frequent AEs suspected as drug-related were periorbital edema* (30%), increased AST (24%), and increased blood creatine phosphokinase (24%), which was the most frequent Grade ≥3 AE suspected as drug-related (6%). By RECIST 1.1, there was 1 partial response (PR); stable disease (SD) was 19% (9/48). By immune-related response criteria, disease control rate (irPR or irSD) was 27% (13/48); of note, 6/13 had PC. Out of 30 pts with PC, 1 pt achieved PR (on study for 346 days) and 2 pts had durable SD (on study for 328 and 319 days, respectively). PK and biomarker studies are ongoing. **Conclusions:** Lacnotuzumab with spartalizumab was well tolerated overall. Preliminary antitumor activity, notably in the PC cohort, was observed. Ongoing studies are evaluating this combination. *Includes eyelid edema and face edema. Clinical trial information: NCT02807844.

Predicting outcomes of advanced non-small cell lung cancer patients treated with PD-1/PDL-1 inhibitors: Independent international validation of the iSEND model. *First Author: Wungki Park, University of Miami, Sylvester Comprehensive Cancer Center, Miami, FL*

Background: There is an unmet need for affordable and readily available biomarkers to predict outcomes to PD-1/PD-L1 inhibitors (PD-1/L1i) in advanced non-small cell lung cancer patients (aNSCLC pts). We previously developed a multivariate risk prediction model called the iSEND in a cohort of 159 patients with aNSCLC pts (n = 159) treated with nivolumab in second-line or above setting (2L+). Here, we report the independent multicentric validation. **Methods:** The iSEND model includes simple clinical and laboratory characteristics: Sex, ECOG performance status, and baseline and post-treatment change after 1st cycle of NLR (Neutrophil-to-Lymphocyte Ratios), intended to reflect reactive increase of the myeloid-lymphoid balance. For independent validation, we used a retrospective cohort of 230 aNSCLC pts from the authors' institutions in the United States, France and Japan who received 2L+ PD-L/L1i. The outcomes for the iSEND Good, Intermediate, and Poor groups were compared. The performance was assessed using receiver operating characteristic (ROC) curves. **Results:** The median follow-up was 15.2 months (M) (95% Confidence Interval [CI]: 12.4-17.9). The median OS for iSEND Good, Intermediate, and Poor was 15.9 M (CI: 2.8-29.0), 12.4 M (CI: 9.6-15.1), and 4.0 M (CI: 3.0-5.0), respectively. And log-rank test was significant (p = 0.001). The median Progression Free Survival (PFS) was 2.6 M (CI: 2.0-3.1), 2.9 M (CI: 1.6-4.2), and 1.6 M (CI: 1.3-1.8), respectively. (Log-rank: p = 0.002) Time-dependent area under curves (AUC) of the iSEND model for OS at 6, 12, 18, 24, and 36 M were 0.63 (CI: 0.56-0.71), 0.61 (CI: 0.54-0.69), 0.59 (CI: 0.50-0.68), 0.60 (CI: 0.47-0.73), and 0.70 (CI: 58-0.82). The iSEND Poor group had significant correlation with progressive disease compared to the iSEND Good group (HR: 2.7, CI: 1.2-6.1, p = 0.013). **Conclusions:** This study validates the iSEND model in an independent international cohort confirming that it predicts outcomes of aNSCLC pts treated with 2L+ PD-1/L1i. Exploring its validity in a prospective cohort as well as in aNSCLC pts treated with effective myeloid modulating combination strategy is strongly supported and underway.

Medical image computing to assess tumor infiltrating CD8 T cells, tumor immune phenotype and response to anti-PD-1/PD-L1 immunotherapy in prospective phase 1 trials. *First Author: Roger Sun, Gustave Roussy Cancer Campus, Radiation oncology department,, Villejuif, France*

Background: The aim was to develop a radiomic estimator of tumor infiltrating CD8 T-cells, to assess its association with tumor immune phenotype, and to evaluate outcomes of cancer patients enrolled in phase 1 trials of anti-PD-1/PD-L1 monotherapy. **Methods:** Radiomic features were extracted from contrast-enhanced CTs for 135 patients from the prospective trial MOSCATO. For each patient, RNA-seq data were available and used to quantify CD8 T-cells. A radiomic signature of the expression of CD8 T-cells was trained using elastic-net method. Three independent cohorts were used for validation: (I) 119 patients from The Cancer Genome Atlas (TCGA) to validate the association with gene expression, (II) 100 tumors assumed as either immune-inflamed or immune-desert to analyze the association with the immune-phenotype, (III) 137 patients treated with anti-PD-1/PD-L1 monotherapy in phase 1 trials to assess clinical outcome. Clinical responses were defined according to RECIST1.1. Median value of the radiomic score was used to separate patients into two groups to assess the overall survival (OS). **Results:** The final radiomic signature kept eight features from the 83 initial ones, and was associated with the gene expression signature of CD8 T-cells in the TCGA validation set (AUC = 0.67, P = 0.002), and the inflamed tumors in the assumed immune-phenotype cohort (AUC = 0.76, $P < 0.001$). In the cohort of patients treated with immunotherapy, the radiomic score at baseline was higher in patients with objective response (CR + PR) or a controlled disease (SD + CR + PR) at 3 months (P = 0.049 and P = 0.050 respectively) and at 6 months (P = 0.025 and P = 0.013 respectively). OS was higher in patients with a high radiomic score (median OS: 24.3 vs 11.5 mo, HR = 0.58, P = 0.008), which remained significant when taking into account the number of lines of treatment, the Royal-Marsden-Hospital prognostic score, and the volume of the tumor (P = 0.002). **Conclusions:** The radiomic signature of CD8 T-cells was validated in three independent cohorts. It appears promising in estimating tumor immune phenotype and inferring outcomes of patients treated with anti-PD1/PD-L1 in a non-invasive way.

Correlation of survival outcomes with progression heterogeneity in patients (pts) treated with pembrolizumab (pembro). *First Author: Lawrence H. Schwartz, Columbia University College of Physicians and Surgeons, and New York Presbyterian Hospital, New York, NY*

Background: The relevance of RECIST v1.1 measures of progression in pts treated with immunotherapy is unclear. We conducted analyses of KEYNOTE-001 (KN; exploratory) and KN052 (confirmatory) to assess associations of progression heterogeneity by CT imaging with survival outcomes among pts treated with pembro. **Methods:** KN001 and KN052 enrolled pts with advanced melanoma and urothelial cancer, respectively. Blinded independent central review was performed per RECIST v1.1. Beyond RECIST v1.1, pts subgroups (SG) with progressive disease (PD) were defined as *No Growth* (NG; no individual target lesion [TL] Growth (G) $\geq$20% from baseline [BL]) with (NG+) and without (NG–) new metastatic lesions; *Mixed Growth* (MG; any individual TL G $\geq$20% from BL and not aggregate G [AG] $\pm$ new lesion G); and, *AG* (G $\geq$20% from BL $\pm$ new lesion G). SG were assigned at first documented PD. OS between SG was assessed using KM analysis. A Cox model with time-varying covariates related to PD SG and pembro treatment status was used to assess the relative mortality risk between SG on treatment and the effects of discontinuing treatment within each SG. KN001 findings were tested in KN052. **Results:** Of 511 KN001 (N = 655) pts with a post-BL scan, 301 (59%) had RECIST-PD on study, of which 42 (14%) were NG–, 78 (26%) NG+, 75 (25%) MG, and 106 (35%) AG. Median OS was 32.5, 23.2, 16.1, and 8.1 mo, respectively, and 43.6 mo for non-PD. Of 331 KN052 (N = 370) pts with a post-BL scan, 223 (67%) had PD on study, of which 29 (13%) were NG–, 66 (30%) NG+, 35 (16%) MG, and 93 (42%) AG. Median OS was 14.2, 10.2, 6.7, and 5.3 mo, respectively, and not reached for non-PD. Relative to non-PD and consistent with overall study KM estimates, model-derived "on-treatment" HRs were highest for AG, followed by MG, NG+, NG–. Treatment discontinuation was associated with increased mortality risk (HR $>$ 1) in all PD SG, but with differing magnitude. All KN001 findings were confirmed in KN052. Similar analyses will be shown for pts with NSCLC in KN010 (pembro vs docetaxel). **Conclusions:** These analyses suggest there may be distinct populations of PD phenotypes with unique survival outcomes. RECIST v1.1 does not fully capture these PD phenotypes and may not accurately identify treatment failure. Clinical trial information: NCT01295827 for KEYNOTE-001, NCT02335424 for KEYNOTE-052.

VANCE: First-in-human phase I study of a novel ChAdOx1-MVA 5T4 vaccine in low and intermediate risk prostate cancer. *First Author: Irina Redchenko, The Jenner Institute, University of Oxford, Oxford, United Kingdom*

Background: Prostate cancer (PCa) has been under investigation as a target for antigen-specific immunotherapies in metastatic disease settings. However, neither of the two clinically most advanced PCa vaccines, Sipuleucel-T and ProstVac, induced strong T cell immunity. In our study, we evaluated a novel vaccination platform based on two replication-deficient viruses, chimpanzee adenovirus and MVA, targeting an oncofetal self-antigen 5T4 in early stage PCa. **Methods:** 40 patients, either newly diagnosed with early stage PCa and scheduled for radical prostatectomy or patients with stable disease on active surveillance protocol, were randomised to a "standard" immunisation regimen to receive 3 vaccinations four weeks apart, or to an "accelerated" immunisation protocol to receive 2 vaccinations at one week interval. Study primary endpoints were vaccine safety and immunogenicity. Secondary endpoints included immune infiltration into the prostate and PSA level change secondary to treatment. As exploratory endpoints, phenotype and functionality of antigen-specific T cells and breadth of induced T cell responses were assessed. **Results:** 39 patients completed the study and were eligible for analysis. The vaccine had an excellent safety profile, with the majority of vaccine-related AEs graded as mild. Vaccination-induced 5T4-specific T cell responses were measured in blood by *ex vivo* IFNγ ELISPOT and were detected in the majority of patients. Flow cytometry analysis demonstrated the presence of both CD8+ and CD4+ polyfunctional 5T4-specific T cells in the circulation. 5T4-reactive TILs were isolated from post-treatment prostate tissue. Some of the patients had a transient PSA level increase 2-8 weeks following vaccination possibly indicating an inflammatory response in the target organ. Quantitative immunohistochemical analysis of paired pre- and post-treatment prostate tissue samples will be reported. **Conclusions:** We report for the first time, that *ex vivo* T cell responses to a tumour self-antigen can be elicited in the majority of PCa patients. A Phase II study is starting to test this vaccine in combination with PD1 blockade in early stage and metastatic PCa. Clinical trial information: NCT02390063.

Genetically engineered T-cell therapy for HPV-associated epithelial cancers: A first in human, phase I/II clinical trial. *First Author: Stacey L. Doran, National Cancer Institute at the National Institutes of Health, Bethesda, MD*

Background: Engineered T-cell therapy is an emerging treatment for hematological cancers. In epithelial cancers, its study has been limited. Human papillomavirus (HPV)-16+ epithelial cancers constitutively express the HPV E6 oncoprotein. We investigated treatment of metastatic HPV-16+ cancers with T cells that target E6 by an engineered T-cell receptor (E6 T cells). **Methods:** A phase I/II, single-center, clinical trial was conducted. Eligible subjects had a metastatic HPV-16+ cancer from any primary tumor site and had received prior platinum-based therapy. Treatment consisted of a one-time, intravenous infusion of E6 T cells. A lymphocyte-depleting conditioning regimen and systemic aldesleukin were also administered. **Results:** Twelve subjects were treated on this protocol. Dose-limiting toxicity was not encountered (maximum dose was 1.7×10^{11} T cells). Transduction efficiency range was 45-76%. Infused E6 T cells demonstrated engraftment at one month post-treatment in all patients (range 4-53%). Two of nine subjects in the highest dose cohort experienced tumor responses. A subject with a 6-month partial response had complete regression of one lesion and partial regression of two lesions, which were subsequently resected; the subject has no evidence of disease three years after treatment. Resected tumor from this subject demonstrated infiltration by E6 T cells that showed increased expression of the inhibitory molecule PD-1 as compared to E6 T cells in the peripheral blood (26% vs 2%). Genomic analyses were performed on the tumors of two subjects who did not respond to treatment. One subject displayed a frameshift deletion in the interferon-gamma response gene, *IFNGR1*. Another demonstrated loss of heterozygosity (LOH) in chromosome 6 with deletion of *HLA-A*02:01*, the necessary restriction element for this therapy. A subject who responded to treatment did not demonstrate genomic alterations in these pathways. **Conclusions:** Engineered T cells targeting E6 can induce regression of HPV+ epithelial cancers. Treatment resistance may be related to T-cell inhibition by PD-1, tumor evasion by antigen processing and presentation loss, and defects in interferon-response pathways. Clinical trial information: NCT02280811.

3020 Poster Discussion Session; Displayed in Poster Session (Board #234), Mon, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Mon, 11:30 AM-12:45 PM

Pharmacodynamics (PD) and genomic profiling of pts treated with cabiralizumab (cabira) + nivolumab (NIVO) provide evidence of on-target tumor immune modulations and support future clinical applications. *First Author: Michael Carleton, Bristol-Myers Squibb, Princeton, NJ*

Background: Colony stimulating factor 1 receptor (CSF-1R) signaling supports recruitment, development, and maintenance of immune suppressive macrophages within the tumor. Combining anti–CSF-1R with anti–PD-1 showed enhanced efficacy in preclinical models. Cabira, a humanized IgG4 monoclonal antibody, disrupts CSF-1R binding to ligands CSF-1 and IL-34, thus blocking receptor activation. We report immunohistochemistry (IHC) and transcriptomic evidence of on-target PD effects of cabira + NIVO in treated pts, as well as the first insight into genotypic characteristics of pancreatic tumors exhibiting durable PRs with cabira + NIVO (Wainberg et al. *J Immunother Cancer* 2017;5(suppl 2) [abst 042]). **Methods:** PD activity of cabira + NIVO in pts with advanced tumors treated in a ph 1a/b trial (NCT02526017) was evaluated using peripheral and tumor biomarkers. **Results:** Cabira + NIVO induced increases in serum CSF-1 and decreases in peripheral nonclassical monocytes sustained during the 2-week dose interval. IHC analysis of pre- and on-treatment biopsies across tumor types showed increases in CD8 T-cell infiltrates and decreases in macrophage markers CSF-1R and CD163. Transcriptomes of paired biopsies showed increased CD8 and cytolytic gene signatures with concurrent increased expression of M1 macrophage-associated genes, supporting blockade of CSF-1R–driven M2 responses. Genomic analyses demonstrated 91 of 94 pts with low tumor mutation burden (TMB) below 10 mutations/megabase with only 1 microsatellite instability tumor identified. Responses were observed across tumor types. Of note, in the 4 PRs observed in pts with pancreatic cancer, all were microsatellite stable (MSS) and low TMB. **Conclusions:** Orthogonal IHC and transcriptome-wide analyses demonstrated cabira-mediated CSF-1R blockade in the periphery and tumor microenvironment in pts with advanced cancer. Ongoing analyses include identification of transcriptomic signatures associated with response. These data support further clinical development of cabira + NIVO in multiple indications, including MSS pancreatic cancer (NCT03336216). Clinical trial information: NCT02526017.

3021 Poster Session (Board #235), Mon, 8:00 AM-11:30 AM

CD8 and PD-L1 determination in lung tumor tissue as prognostic biomarker and a predictive marker of anti PD-1 efficacy. *First Author: Jean-David Fumet, Department of Medical Oncology, Center GF Leclerc, Dijon, France*

Background: With recent approval of mAb targeting PD-1 and PD-L1 for non–small cell lung cancer (NSCLC), extensive efforts are under way to develop predictive biomarkers for anti PD-1/PD-L1 response. PD-L1 expression upon histology is currently the only clinically available biomarker, but mRNA immune signatures are also emerging. While the efficacy of these drugs is dependent on CD8 T-cells, no study has evaluated both CD8 and PD-L1 as biomarkers. **Methods:** CD8 and PD-L1 expression was studied by RNA sequencing and immunohistochemistry (IHC). We used RNA sequencing data from The Cancer Genome Atlas (TCGA) lung cancer samples as a prognostic cohort. We validated the results obtained from the transcriptomic data with IHC data using another prognostic cohort of 34 metastatic NSCLC tumor samples untreated by immunotherapy and stained using CD8 and PD-L1. A predictive study was conducted on 85 NSCLC patients treated with nivolumab, for whom outcome was known. To evaluate our signature, we used IFN and Immune Expanded Signature (IES), previously described as gold standards. Data were externally validated using public data (GSE93157). **Results:** In the prognostic TCGA mRNA cohort, we observed that high CD8 expression is associated with better overall survival, while PD-L1 expression is associated with poor prognosis. CD8 and PD-L1 determined upon IHC also had prognostic value in the prognostic cohort. In the predictive cohort, CD8 and PD-L1 expression evaluated using mRNA or IHC are associated with better progression-free survival in patients treated with nivolumab. Use of mRNA improved discrimination when compared with histological measures. A combination of both CD8 and PDL1 variables was highly predictive of outcome and remained significant after adjustment for usual clinical variables (age, sex, histology performance status). This 2-gene signature using CD8 and PD-L1 outperformed both IFN and EIG signatures, even with IHC data. Similar results were obtained in the external validation cohort (GSE93157). **Conclusions:** CD8 and PD-L1 mRNA or IHC could be used to address NSCLC outcomes for patients treated with nivolumab.

3022 Poster Session (Board #236), Mon, 8:00 AM-11:30 AM

Mismatch repair deficiency testing for immune checkpoint therapy: Immunohistochemistry vs microsatellite instability. *First Author: Sucha Sudarsanam, NeoGenomics Laboratories, Aliso Viejo, CA*

Background: DNA mismatch repair deficiency (dMMR) can be tested by immunohistochemistry (IHC) or microsatellite instability (MSI). While either IHC and MSI is adequate for establishing Lynch syndrome, the relevance of discordant results in selecting patients for immune checkpoint treatment is unknown. We investigated MSI and IHC in detecting dMMR and correlated with PD-L1 expression. **Methods:** Community-based practice tissue samples were submitted for PD-L1 expression and dMMR by both IHC and MSI. PD-L1 testing was performed by IHC using clone 22C3, dMMR using IHC against four MMR proteins (MHL1, MSH2, MSH6, and PMS2), and MSI using PCR with five Bethesda markers. **Results:** Of the 396 cases tested for both PD-L1 and dMMR by IHC, 18 (4.5%) were reported dMMR positive. Of the 610 cases tested for both PD-L1 and dMMR by MSI, 27 (4.4%) were dMMR positive. The dMMR positivity was determined as having at least one MMR protein expressed at $\leq$ 6%. There was no statistically significant correlation between PD-L1 expression and the presence or absence of dMMR as detected by IHC. In contrast, patients with MSI had significantly higher PD-L1 positive cells when PD-L1 expression is considered as a continuous variable (P = 0.04), and at cut-offs of 5% (P = 0.003) and 10% (P = 0.004). When a cut-off point of 6% for IHC is used, 8.9% of positive cases by MSI were negative (FN) by IHC and 2.6% of MSI negative cases were positive (FP) by IHC. If a 20% cut-off for IHC is used, FP was at 4.4% but FP was at 3.6%, and if a 30% IHC cut-off is used, FP was at 3.1% and FP was at 5.7%. This difference between cut-off points was statistically significant (P = 0.0008 for 20% and P = 0.0001 for 30% cut-off). **Conclusions:** There is significant correlation between PD-L1 expression and dMMR as detected by MSI, but not by IHC testing. Based on this and the established association between tumor mutation burden and MSI, MSI should be considered the gold standard for dMMR testing for checkpoint blockade therapy consideration.

Relationship between checkpoint molecule B7-H3 and refractoriness to anti-PD-1 therapy in non-small cell lung cancer. *First Author: Kimio Yonesaka, Department of Medical Oncology, Kindai University Faculty of Medicine, Osaka, Japan*

Background: While anti-PD-1 therapy improves survival in non-small cell lung cancer (NSCLC), some patients do not respond, indicating the need for alternative strategies. Some cancers express B7-H3, an immune checkpoint molecule. Herein, we evaluated B7-H3 expression and analyzed its relationship with anti-PD-1 therapy efficacy in NSCLC. **Methods:** Eighty-two patients with advanced NSCLC were enrolled in this retrospective study; 50 had been treated with anti-PD-1 therapy. The response rate (RR) and progression-free survival (PFS) were assessed by RECIST v 1.1. B7-H3, PD-L1, and CD8 expression were evaluated by immunohistochemistry; PD-L1 expression levels were scored by tumor proportion score (TPS). For statistical tests, the unpaired t-test was used for continuous variables; Fisher's exact test, categorical variables; and Cox regression and log-rank tests, time to event (two-sided p-values were obtained). **Results:** B7-H3 was positive in 74% of patients and correlated with responsiveness to anti-PD-1 therapy (p = 0.0007). The RR was 88% for B7-H3-negative patients and 29% for B7-H3-positive patients. Multivariate analysis for PFS revealed that PD-L1 expression favorably correlated with PFS [TPS $<$ 50 vs. $\geq$50; HR 3.559, p = 0.006]. In contrast, B7-H3 unfavorably correlated with PFS [negative vs. positive; HR 0.082, p = 0.003]. The median PFS was 427 days for B7-H3-negative patients, but 148 days for B7-H3-positive patients [p = 0.024]. There was no correlation between PD-L1 and B7-H3 expression, indicating these biomarkers were independent. $CD8^+$ T cells were greater in tumors with PD-L1 TPS $\geq$50% than in those with $<$ 50% [median 104 vs. 11/mm^2; p = 0.0038]. However, among patients with PD-L1 TPS $<$ 50%, B7-H3-negative tumors still had more $CD8^+$ T cells than B7-H3-positive tumors [median 47 vs. 8/mm^2; p = 0.0103]. Consistently, patients with PD-L1 TPS $<$ 50% and B7-H3 negativity demonstrated 86% RR. **Conclusions:** NSCLCs lacking B7-H3 had inflammatory microenvironments and responded to anti-PD-1 therapy, despite low PD-L1 expression. Although our sample size was small, our results encouragingly suggest that B7-H3-targeting therapies will enhance the antitumor efficacy of anti-PD-1 antibodies.

3024 Poster Session (Board #238), Mon, 8:00 AM-11:30 AM

Co-mutations of DNA damage response system as predictive biomarker for immune checkpoint blockades. *First Author: Zhijie Wang, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Abstract Background: Selecting appropriate biomarkers for immune checkpoint blockades (ICBs) remains a clinical challenge. Quantitative biomarkers, for instance, PD-L1 expression or tumor mutation burden, are limited by their vague cut-off value, intra-tumor heterogeneity distribution and dynamic alterations. Qualitative biomarkers, including dMMR/MSI-H, are potent predictors, but merely a minority of patients harbor this abnormality. Therefore, a more prevalent biomarker would be highly desirable. In humans, DNA damage response (DDR) system is indispensable in maintaining genomic integrity. We hypothesize genetic mutations of DDR pathways may increase genomic instability and manifest as up-regulated neoantigen load and TMB, contributing to higher susceptibility to immune checkpoint blockades (ICBs). **Methods:** Whole-exome sequencing data from 8552 solid tumors, across 29 cancer types from The Cancer Genome Atlas were included for analysis. The expression signatures of immune genes were compared across distinct DDR subgroups. Statistics concerning the correlation between DDR pathway mutations and treatment outcomes were evaluated in four cohorts treated with ICBs. **Results:** Co-mutations of HRR-MMR or HRR-BER pathways (defined as co-mut +) were correlated with higher neoantigen load and TMB. Co-mut + exhibited anabatic levels of immune gene expression signatures, including genes related to T-effector, IFNγ pathway, T cell receptors and tumor microenvironment. In these four validation cohorts, the progression-free survival (PFS) was longer in co-mut + patients with non-small cell lung cancer (NSCLC) than co-mut – (median, not reached vs. 4.1 months, P = 0.02) and the overall survival was longer in co-mut + melanoma patients than co-mut – (median, 32.4 vs. 10.8 months, P = 0.04). Subgroup analysis of NSCLC cohort demonstrated that co-mut + is predictive to longer PFS in patients with PD-L1 expression $< 50\%$ (median, 8.3 vs. 2.7 months, P = 0.03) or low TMB (median, not reached vs. 3.8 months, P = 0.04). **Conclusions:** Co-mutations of HRR-MMR or HRR-BER are a potential prognostic biomarker for ICBs immunotherapy, and warrant future prospective investigations.

Serum interleukin 8 (IL-8) may serve as a biomarker of response to immuno-oncology (I-O) therapy. *First Author: Michael Carleton, Bristol-Myers Squibb, Princeton, NJ*

Background: Biomarkers are needed to identify pts responsive to I-O therapies. IL-8 is a proinflammatory chemokine that promotes tumor immune escape. High serum IL-8 levels are associated with poor prognosis (Sanmamed et al. *Clin Cancer Res.* 2014); changes in serum IL-8 levels were associated with response to antiPD-1 therapy in a small cohort of pts with melanoma (MEL) and NSCLC (Sanmamed et al. *Ann Oncol.* 2017). Here we report a large, cross-study, retrospective association analysis of baseline (BL) serum IL-8 levels with clinical efficacy and biomarkers in pts receiving nivolumab (NIVO)-based therapy. **Methods:** Data were analyzed from ≈2000 pts with MEL, NSCLC, and renal cell carcinoma enrolled in 8 clinical trials. Serum IL-8 was measured using an immunoassay platform (Myriad RBM, Austin, TX). Correlative efficacy metrics included BL tumor burden, overall survival (OS), progression-free survival (PFS), and objective response rate (ORR). Receiver operating characteristic (ROC) curve analyses for 12-month OS were used to determine IL-8 cutoffs associated with response. Additional tumor and peripheral correlative markers were assessed. **Results:** Quartile stratification of serum IL-8 levels showed that elevated BL IL-8 was associated with poor OS. ROC analysis of NIVO-based therapy from pooled study data identified 23 pg/mL as an IL-8 threshold that could be used to enrich for pts who may be more likely to benefit from I-O. Additional IL-8 correlates were identified, including elevated tumor *CXCL8* mRNA and peripheral neutrophil count, but these were not statistically significant across all indications. Detailed analyses in pts with MEL showed the correlation of BL IL-8 with OS was independent of BL tumor burden or PD-L1 tumor expression. Absolute BL and post-BL IL-8 levels were more strongly associated with OS, PFS, and ORR than changes from BL. **Conclusions:** Association of serum IL-8 with response to NIVO-based therapy suggests that IL-8 may serve as a clinically useful biomarker to select for pts who can benefit from I-O therapy. We hypothesize that IL-8 neutralization in pts with elevated BL IL-8 may restore sensitivity to antiPD-1 therapy; this will be tested clinically with an antiIL-8 antibody (NCT03400332).

3026 Poster Session (Board #240), Mon, 8:00 AM-11:30 AM

Human leukocyte antigen (HLA) B44 supertype and immunotherapy outcomes in non-small cell lung cancer (NSCLC). *First Author: Henry Lu, University of Virginia School of Medicine, Charlottesville, VA*

Background: In melanoma (mel) patients (pts) treated with immune checkpoint inhibitors, presence of HLA class I (HLA-1) B44 supertype (B44+) correlated with survival (Chowell, Science). B44 preferentially binds negatively charged (neg) peptides and those with glutamic acid (E) at the anchor position. Positively charged (pos) peptides impede binding. In mel, B44 benefit was driven by glycine (G) > E changes. We evaluated the predictive role of HLA-I supertypes in NSCLC as neoepitopes are likely different as tranversions (Tv) predominate in smokers compared to transitions (Ti) in mel. **Methods:** 58 advanced NSCLC pts treated with pembrolizumab with 3 years follow up and sufficient PBMCs and/or tumor sample had multiplexed paired-end WES with Illumina HiSeq 2000/3000. HLA typing used BWA-ALN and Athlates software; supertype was determined by 2008 criteria (Sidney, BMC Immunol). Overall survival (OS) and progression-free survival (PFS) were compared by supertype using non-parametric log-rank tests. Tumor variant amino acids (vAA) were identified by GATK best practices, and AA charge was derived from standard charts with stop codons considered uncharged (unc). Ti/Tv and charge change analysis used two-proportion z-tests. Statistical analyses were performed with SPSS V24 (Armonk, NY). **Results:** Of 9 supertypes evaluated, only absence of B44 supertype (B44-) had longer OS [median OS of 14.9 months (m) vs 9.2 m in B44+ (HR 0.55, 95% CI 0.30-0.99, p = 0.048)], driven by B44- smokers [median OS 21.5 m vs 8.5 m in all other pts (HR 0.50, 95% CI 0.26-0.995, p = 0.048)]. PFS and response rate trends were similar to OS. vAA charge changes from unc/pos to neg in 14/384 (3.6%) Tv and 8/192 (4.2%) Ti (NS) and from unc/neg to pos in 48/384 (12.5%) Tv vs 12/192 (6.3%) Ti (p = 0.019). G > E is not possible from Tv. Among pts with evaluated tumors, Ti/Tv, vAA charge, and G > E were as predicted. **Conclusions:** Like mel, the B44 supertype associates with OS in NSCLC, however with the opposite effect direction, driven by favorable OS in B44- smokers. A potential mechanism for these histology-specific results is the greater likelihood of Tv in smokers that may lead to neoepitopes with characteristics less favorable for presentation on HLA B44.

3028 Poster Session (Board #242), Mon, 8:00 AM-11:30 AM

Somatic *STK11/LKB1* mutations to confer resistance to immune checkpoint inhibitors as monotherapy or in combination in advanced NSCLC. *First Author: Maria Jure-Kunkel, MedImmune, Gaithersburg, MD*

Background: Although PD-1/PD-L1 checkpoint blockade has become standard of care for non-small cell lung cancer (NSCLC), some treated patients (pts) do not respond. A deeper understanding of mechanisms of resistance to PD-(L)1 blockade is needed to improve therapeutic decisions. The aim of this study was to identify molecular alterations associated with innate resistance to durvalumab (D) and durvalumab + tremelimumab (D + T) combination therapy in advanced non-squamous (Non-SQ) NSCLC. **Methods:** CP1108/NCT01693562 and ATLANTIC/NCT02087423 were nonrandomized phase 1/2 and 2 trials of D (10 mg/kg, Q2W). D4190C00006/NCT02000947 was a nonrandomized phase Ib trial of D + T (20 mg/kg + 1 mg/kg, Q4W). Circulating tumor DNA (ctDNA) analysis (Guardant360 70 gene cancer panel) was conducted in pre-treatment plasma samples for 119 and 63 Non-SQ NSCLC pts in CP1108 and ATLANTIC, respectively. Targeted sequencing of pre-treatment tumors (FoundationOne CDx™) was conducted in 120 Non-SQ NSCLC pts in D4190C00006. Association of tumor mutations and objective response rate (ORR) by RECIST v1.1 and overall survival (OS) is presented. Immune contexture of *STK11* mt Non-SQ NSCLC tumors was investigated in the TCGA. **Results:** In two independent trials evaluating D as monotherapy (CP1108/Atlantic), and in a D + T combination trial (D4190C00006), reduced ORR and shorter survival were observed in Non-SQ NSCLC pts harboring *STK11* non-synonymous mutant tumors compared to pts harboring *STK11* wild type (wt) tumors (Table 1). In TCGA, STK*11* mutations were not prognostic and were associated with low IFNγ signature and high G-CSF and IL-6 expression. **Conclusions:** In Non-SQ NSCLC, somatic *STK11* mt may confer innate resistance to immune checkpoint inhibitors. Optimal therapeutic combinations for this subset of patients are being explored in HUDSON/NCT03334617. Table 1. ORR and OS in *STK11* mt or wt Non-SQ NSCLC pts treated with D or D + T Clinical trial information: NCT01693562, NCT02087423, NCT02000947.

	ORR (n/N)			Median OS (months)		
	STK11 mt	*STK11* wt	X^2	*STK11* mt (mo.)	*STK11* wt (mo.)	log-rank p
CP1108 (D)	6 (1/15)	16 (17/104)	0.05	4.9	14.2	0.008
Atlantic (D)	0 (0/6)	25 (14/57)				
D4190C00006 (D + T)	4 (1/23)	25 (24/97)	0.02	6.7	15.6	0.001

3029 Poster Session (Board #243), Mon, 8:00 AM-11:30 AM

First-in-human phase 1 study of MK-1248, an anti-human glucocorticoid-induced tumor necrosis factor receptor (GITR) monoclonal antibody, as monotherapy or in combination with pembrolizumab in patients with advanced solid tumors. *First Author: Ravit Geva, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel*

Background: MK-1248 is a humanized IgG4 agonist monoclonal antibody (mAb) that targets GITR. GITR is expressed on regulatory T cells (T_{reg}), resting CD4+ and CD8+ T cells, NK (natural killer) cells and NK T cells. Ligation of GITR decreases T_{reg}-mediated suppression and enhances T cell proliferation, effector functions, and survival. **Methods:** MK-1248 was tested alone or in combination with pembrolizumab at a starting dose of 0.12 mg in both arms. Pembrolizumab dose was fixed at 200 mg. Both study drugs were administered intravenously every 3 weeks. Total number of intended doses of MK-1248 and pembrolizumab was 4 and 35, respectively. The study objective was to determine safety and tolerability, maximum tolerated dose (MTD), pharmacokinetic (PK), and pharmacodynamic (PD) profiles of MK-1248 as a monotherapy and in combination with pembrolizumab. **Results:** Data were available from 37 pts: 20 pts treated with MK-1248 monotherapy and 17 pts treated with MK-1248 + pembrolizumab combination therapy. Tumor types: colorectal cancer (8 pts), melanoma (5 pts), renal cell carcinoma (4 pts) and 20 pts with 16 other solid tumors. Maximum dose of MK-1248 tested: 170 mg (monotherapy) and 60 mg (combination). MK-1248 was well tolerated. Of the 37 pts treated, 36 pts (97.3%) had ≥1 adverse event (AE) and 17 pts (48.6%) had ≥1 treatment-related AE. Common AEs were: vomiting, anemia, decreased appetite, abdominal pain, cough, diarrhea, nausea, fatigue, headache and pyrexia. Infusion related reactions occurred in 6 (16.2%) pts. Eighteen pts had Grade 3-5 AEs (48.6%), 3 (8.1%) were treatment-related. Serious adverse events (SAE) occurred in 6 pts (30.0%) in monotherapy arm and 5 pts (29.4%) in combination arm. No DLT or treatment-related deaths were observed. One CR and 2 PR were observed in the study. **Conclusions:** MK-1248 at the dose up to 170 mg as monotherapy and 60 mg in combination with pembrolizumab was well tolerated with no dose limiting toxicities or treatment-related deaths. Responses were observed when MK-1248 was administered in combination with pembrolizumab. Clinical trial information: NCT02553499.

3030 Poster Session (Board #244), Mon, 8:00 AM-11:30 AM

Underlying host immune dysregulation in cancer patients developing immune-related adverse events. *First Author: David E. Gerber, University of Texas Southwestern Medical Center, Dallas, TX*

Background: Immune checkpoint inhibitors may cause potentially severe immune-related adverse events (irAEs). To determine the role of host immune status in the development of irAEs, we evaluated baseline and post-treatment serum cytokine and IgG levels in patients receiving checkpoint inhibitors. **Methods:** We collected serum from patients treated with checkpoint inhibitors before treatment, after 2-3 weeks, and after 6 weeks. We quantified cytokine profiles using a multiplex panel. Total IgG was determined using ELISA. We analyzed the association between these biomarkers and the presence of irAEs using t tests and ANOVA. **Results:** A total of 78 subjects were enrolled, including 65 cancer patients receiving checkpoint inhibitors and 13 healthy controls. Among cancer patients, mean age was 65 years, 55% were women, and 83% had lung cancer. Immune-related AEs occurred in 35% of cases as follows: pneumonitis (n = 11), endocrinopathy (n = 6), dermatitis (n = 2), arthritis (2), encephalitis (1), complex (2). There was a significant increase in chemokines CXCL9, CXCL10, CXCL11 and CXCL13 in patients at 2 weeks post-immunotherapy and in chemokines CXCL9, CXCL10, CXCL11, CXCL13, IL-10, and CCL26 at 6 weeks post treatment. Patients who developed irAEs had significantly lower levels of CXCL9, CXCL10, CXCL11 and CCL19 at baseline and exhibited far greater increases in CXCL9 and CXCL10 levels at 6 weeks post treatment compared to patients without irAEs ($P< 0.05$ for all analyses). Baseline total serum IgG levels were significantly lower in patients who developed irAEs ($P< 0.05$). Cytokine and IgG levels were stable over time in healthy controls. **Conclusions:** In this study, patients with irAEs had lower baseline levels and greater post-treatment increases in multiple cytokine levels, as well as lower baseline levels in total IgG. Analogous to the elevated risk of autoimmune disease in individuals with HIV/AIDS, these findings suggest that immune dysregulation may be associated with the development of irAEs.

3031 Poster Session (Board #245), Mon, 8:00 AM-11:30 AM

Association of TGF-β responsive signature with anti-tumor effect of vactosertib, a potent, oral TGF-β receptor type I (TGFBRI) inhibitor in patients with advanced solid tumors. *First Author: Vicki Leigh Keedy, Vanderbilt University Medical Center, Nashville, TN*

Background: Stromal signature regulated by TGF-β pathway is one of the major mechanisms of tumor immune surveillance, leading to resistance to immune checkpoint inhibitors (ICI). Moreover, TGF-β responsive signatures (TBRS) of stromal cells have been associated with poor prognosis. Vactosertib (TEW-7197) is a potent, highly selective, oral inhibitor of TGFBR1. The safety, anti-tumor effect of vactosertib and its association with TBRS levels were evaluated in patients with advanced solid tumors. Based on in-house TCGA analysis, high fibroblast TBRS (F-TBRS) levels were seen in pancreatic, lung, colorectal (CMS4 subtype), and stomach (GS subtype) cancers in association with poor prognosis (adjusted hazard ratio 1.27; $P = 1.06 \times 10^{-8}$). **Methods:** 29 patients were enrolled in a phase I modified 3+3 dose-escalating study (NCT02160106) and received vactosertib once daily at the dose range of 30~340 mg for 5 days with 2 days off. RNA sequencing of pre-treatment tumor samples in 16 patients were analyzed to evaluate F-TBRS levels defined as geometric mean values of 171 corresponding gene expressions. **Results:** Vactosertib was safe and well tolerated, and the maximum tolerated dose was not determined. The most common treatment-related AE (TRAE) was fatigue, while G3/4 abdominal pain, AST elevation, and pulmonary edema were each reported in one patient, respectively. One DLT of stroke was seen at 100mg QD. In per-protocol analysis, 6 out of 17 patients who received ≥140 mg achieved stable disease (35.3%) and showed higher F-TBRS levels than those with progressive disease. **Conclusions:** Vactosertib, a potent and highly selective oral TGFBR1 inhibitor, showed excellent safety with the current dosing schedule. Furthermore, since high F-TBRS levels are well recognized as one of the main mechanisms related to resistance to ICI, vactosertib would be an ideal therapeutic strategy in combination with ICIs or conventional anti-tumor therapies for solid tumors with high F-TBRS levels. Clinical trial information: NCT02160106.

3032 Poster Session (Board #246), Mon, 8:00 AM-11:30 AM

Incidence and clinical implications of a new definition of hyperprogression (HPD) with immune checkpoint inhibitors (ICIs) in patients treated in phase 1 (Ph1) trials. *First Author: Ignacio Matos, Vall d'Hebron University Hospital Institute of Oncology (VHIO), Barcelona, Spain*

Background: HPD with ICIs has been recently described as progression disease (PD) by RECIST with a ≥ two-fold increase in tumor growth rate experimental vs. reference. However, the implementation of such assessment is challenging and its clinical implications have not been clearly established. **Methods:** Patients (pts) treated with ICIs in Ph1 trials at Vall d´Hebron Institute Oncology (VHIO) were analysed (n = 214). We defined HPD based on RECIST 1.1 as time to treatment failure (TTF) < 2 months (m) and minimum increase in measurable lesions of 10 mm plus: 1) increase of ≥40% (upper decile of our cohort) in target tumor burden compared to baseline or 2) increase of ≥20% plus the appearance of multiple new lesions. The aim of this study was to correlate HPD with overall survival (OS) in pts who achieved PD as best response, by using a Kaplan-Meier analysis. **Results:** From Jan'12 to Oct'17, 214 pts were treated, mostly with antiPD1/PDL1 ICIs (53% in combinations with other ICI). Median age 58y (20-85). Tumor types: melanoma 22%, lung 14%, breast 10%, colon 6%, others 48%. 20% had received prior ICI. Best response was PD in 47% pts (n = 101). In total, 33 pts (15%) were considered HPD, representing 40% of evaluable pts with PD as best response. HPD was not associated with age, tumor type, ICI regimens, previous ICI or metastatic site (Fisher test). Median OS was 4.8 m (95% CI: 3.4-7.3) in HPD group versus 8.7 m (95% CI 6.3-10.2) in non-HPD progressors group (HR = 1.87; 95% CI 1.1-3.3; p = 0.03). Overall, 48 pts (22%) received treatment beyond progression (TBP). Time from initial progression to study discontinuation was 0.4 m (95% CI 0.1-NA) in HPD group versus 0.96 m (95% CI 0.7-1.5) in non-HPD progressors (HR = 2.9; 95% CI 1.4-6.2). Only 10 pts with HPD received further therapy: 2 achieved partial responses with chemotherapy and 1 pt had stabilization with erlotinib, whilst the other 6 pts progressed (4 treated with ICI). **Conclusions:** In our Ph1 Unit population, we established a definition of HPD that is intuitive and easy-to-use in daily clinical practice. Importantly, it correlates with poor OS and represents a clear contra-indication for TBP or switch to alternative ICIs as rescue therapy.

3033 Poster Session (Board #247), Mon, 8:00 AM-11:30 AM

Pilot trial of an Indoleamine 2,3-dioxygenase-1 (IDO1) inhibitor plus a multipeptide melanoma vaccine in patients with advanced melanoma. *First Author: Craig L. Slingluff, University of Virginia School of Medicine, Charlottesville, VA*

Background: Melanoma metastases limit infiltration and function of anti-tumor T cells in part by immunosuppression with IDO1. INCB024360 (epacadostat) is an IDO1 inhibitor that normalizes serum kynurenine/tryptophan (Kyn/Trp) ratios. MELITAC 12.1 multipeptide vaccine induces CD8 T cell responses to melanoma antigens. A clinical trial was designed to test hypotheses that IDO1 inhibition (IDO1i) plus vaccine will be safe, that IDO1i will increase CD8 T cell infiltration into metastases and will enhance immune signatures in tumor, which will be further increased by the vaccine. **Methods:** Patients (pts) with stage IIIB-IV melanoma were treated with INCB024360 days(d) 1-98 (300 mg po bid), and with MELITAC 12.1 emulsified in incomplete Freund's adjuvant d21, 28, 35, 56, 77, 98. Prior checkpoint blockade therapy was allowed. Tumors were biopsied pre-treatment, d21, and d42, when feasible. Safety was assessed by CTCAE v4. The primary immunologic endpoint was tumor infiltration with CD8+ T cells. The biologic effect of INCB024360 on IDO1 function was assessed by serum Kyn/Trp ratio. Clinical outcomes were assessed by RECIST 1.1. **Results:** Eleven eligible pts were enrolled and treated. There were dose-limiting toxicities (DLTs) in 2 pts: grade 3 transaminase elevation, grade 3 syncope, both of which resolved. Six pts had all evident sites of disease resected in protocol biopsies and 1 had non-measurable disease. Of 4 pts with measurable disease beyond d42, best overall responses were PR (1), SD (3). INCB024360 reduced serum Kyn/Trp ratios 44% (mean) by d21 (normalized in 10/11 pts). In 5 pts with evaluable biopsies d0 and d42, with multispectral immunofluorescence histology, CD8 T cell infiltrates increased significantly to d42. **Conclusions:** Combination therapy with INCB024360 and multipeptide vaccine was considered safe with transient DLTs in only 2 patients (18%). INCB024360 normalized serum Kyn/Trp ratios in 91% of patients at 300 mg bid. Clinical activity was observed. There is evidence of enhanced CD8 T cell infiltration with the combination. Ongoing studies will assess the impact of INCB024360 on immune signatures and tumor infiltrating T cell function. Clinical trial information: NCT01961115.

3034 Poster Session (Board #248), Mon, 8:00 AM-11:30 AM

Germinal immunogenetics as a predictor of anti-PD1/PD-L1 treatment outcome. *First Author: Gerard A. Milano, Centre Antoine Lacassagne, Nice, France*

Background: In the context of the checkpoint inhibitors (CPI) era and the strong demand for identification of predictive biomarkers, the role of the host must be considered. We developed a custom-designed panel of single nucleotide polymorphisms (SNPs) of relevant genes implicated in immune response. The prognostic value of this panel was explored in this study. **Methods:** Clinical data of advanced lung carcinoma patients treated by second-line anti-PD(L)1 in Centre Antoine Lacassagne (Nice, France) were collected. High-throughput genotyping of germinal DNA was performed by MassARRAY (AGENA Bioscience) using the custom-panel of 166 SNPs-86 selected genes (minor allelic frequency $>$ 5% in a Caucasian population). Univariate and multivariate analyses for PFS were assessed, respectively, by means of log-rank tests and the Cox proportional hazards model. Multicollinearity was tested between all variables. P values $\leq$ 0.05 were considered statistically significant. **Results:** From October 2014 to April 2017, 48 patients were identified. Median age was 64-years-old; 29 were males (61%), 43 smokers (90%), 34 had radiotherapy (70%), 32 had adenocarcinoma (67%). Median follow-up was 12.5 months (95%CI: 11.0-16.3). All tested SNPs were in Hardy-Weinberg equilibrium. In univariate analyses, 25 individual SNPs significantly discriminated PFS. Multivariate analyses for PFS showed independent CPI prediction for *ICOS* rs11889031 (HR = 8.4 $p < 0.001$), *TLR3* rs3775291 (HR = 4.9; $p < 0.001$), *FAS* rs1800682 (HR = 2.9; p = 0.03), *FAS* rs2234767 (HR = 4.8; p = 0.04), and *INFL4* rs12979860 (HR = 4.3; p = 0.003). These genes and rs are closely involved in immunologic communication and auto immune disease. A composite score of favorable alleles (0-5) was dramatically associated with PFS ($p <$ 0.001), median 2 months (95%CI: 0.6-2.3) for 0-1 (n = 7), median 8.3 months (95%CI: 0.3-13) for 2-3 (n = 29) and median-PFS not reached for 4-5 (n = 12). All SNPs concerned were located in intronic regions, according to https://www.ensembl.org., suggesting a variable impact on alternative splicing. **Conclusions:** This study points to the germinal immunogenetics as a significant piece in the CPI predictors puzzle.

3035 Poster Session (Board #249), Mon, 8:00 AM-11:30 AM

Exploration of baseline derived neutrophil to lymphocyte ratio (dNLR) and lactate dehydrogenase (LDH) in patients (pts) with metastatic non-small cell lung cancer (mNSCLC) treated with immune checkpoint inhibitors (ICI) or cytotoxic chemotherapy (CCT). *First Author: Dickran Garo Kazandjian, Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: Previous studies have suggested the importance of dNLR and LDH as prognostic markers and indicators of inflammation in cancer and other inflammatory diseases. More recently, the lung immune prognostic index (LIPI), the combination of dNLR and LDH, was found to be associated with progression free survival (PFS) and overall survival (OS) in pts with NSCLC treated with ICI but not CCT suggesting its potential use as a predictive marker. We performed an exploratory retrospective analysis of LIPI on pooled clinical trial data from studies evaluating ICI in 2nd line mNSCLC submitted to the FDA. **Methods:** We identified 5 randomized, second line trials (N = 3399) evaluating ICI versus docetaxel submitted to FDA between 2014-2017 for mNSCLC. Only pts with available dNLR/LDH data were included (71.8%). LIPI scores were calculated based on dNLR and LDH values per Mezquita et al. (JAMA Oncol. 2018). Univariate and multivariate COX proportional PFS and OS hazard ratios (HR) were generated for dNLR, LDH, and other major covariates including age, smoking status, histology, and ECOG. Median PFS and OS estimates based on the LIPI score (0,1, or 2) were generated using the Kaplan–Meier method. **Results:** In the final analysis, 1368 ICI and 1072 CCT were evaluable for low (0), intermediate (1), and high (0) LIPI (TABLE). **Conclusions:** This exploratory retrospective analysis indicates that LIPI may be a prognostic biomarker for both ICI and CCT for 2nd line mNSCLC.

3036 Poster Session (Board #250), Mon, 8:00 AM-11:30 AM

Genomic correlates of response to immune checkpoint blockade in microsatellite stable solid tumors. *First Author: Natalie Vokes, Dana-Farber Cancer Institute, Boston, MA*

Background: Immune checkpoint inhibitors have improved survival in multiple malignancies, but genomic biomarkers for efficacy in microsatellite stable tumors are incompletely characterized. **Methods:** Tumor and germline whole exome sequencing (WES) from pre-treatment tumors in immune checkpoint-treated patients were assembled from 7 published studies and from 78 newly sequenced tumors (total n = 249). Tumor types included were melanoma (n = 151), non-small cell lung cancer (n = 57), bladder cancer (n = 27), head and neck cancer (n = 12), sarcoma (n = 1), and anal cancer (n = 1). The sequencing data were processed through a uniform pipeline, and the results were correlated with clinical outcomes to immune checkpoint therapy to identify tumor genomic features that contribute to response. RECIST (v1.1) was used to define responders as those with complete or partial response, and those with progressive disease as non-responders. **Results:** Although tumor mutational burden was correlated with response, its univariate predictive power in this cohort was low (AUC = 0.66). Further analyses identified additional correlates of response, including individual driver genes in kinase signaling and chromatin regulators, global mutational signatures, and specific HLA-restricted neoantigens. Copy number analysis corroborated associations between specific pathways and absence of response to immunotherapy, including increased copy number events in the interferon-γ pathway in nonresponders (19/123 vs 3/70, p = 0.034). However, many of these molecular features were interrelated and potentially confounded with one-another. Power simulations showed that significantly larger sample sizes are necessary to disentangle these features, highlighting the complexity of identifying genetic driver events that generate an immunoresponsive tumor environment. **Conclusions:** This study represents the largest analysis to date of WES obtained from solid tumors in patients treated with immune checkpoint inhibitors. This work defines a path for gathering insights from multiple cohorts, and advances hypotheses of biological mechanisms and biomarkers of response to immune checkpoint therapy for further study.

3038 Poster Session (Board #252), Mon, 8:00 AM-11:30 AM

Demonstration of anti-tumor immunity via intratumoral regulated platform ad-RTS-hIL-12 in advanced breast cancer and recurrent glioblastoma patients. *First Author: Francois M. Lebel, ZIOPHARM Oncology, Inc., Boston, MA*

Background: Ad-RTS-hIL-12 (Ad) is a novel gene therapy candidate expressing IL-12 under the control of an orally administered activator ligand, veledimex (V), through a proprietary RheoSwitch Therapeutic System (RTS) gene switch. This platform reduces systemic toxicity and stimulates anti-cancer T cell immune response. **Methods:** Two open label trials evaluated the tolerability of local inducible IL-12 expression in heavily pretreated patients with metastatic breast cancer (mBC) or recurrent glioblastoma (rGBM). Ad was administered as a single intratumoral injection with V 80 mg PO Qdx7 in mBC and 10-40 mg Qdx15 PO in rGBM. **Results:** We observed local expression of IL-12 and downstream IFNg demonstrating biological activity with a mean increase in tumor cytotoxic T cells ($CD3^+CD8^+$) baseline: 0.4 ± 0.2 to biopsy:1.9±0.8% cells with a mean reduction in T_{reg} ($CD4^+FOXP3^+$) baseline: 0.8 ± 0.4 to biopsy: 0.6±0.3% cells. Sustained increases in tumor IFNg were documented in both mBC (by biopsy at Day 42 post injection) and rGBM (biopsy range:130 - 175 days post injection) while tumor IL-12 returned to baseline and systemic levels of IFNg and IL-12 were undetectable. In mBC, injected and non-injected lesions (abscopal effect) showed a reduction in lesion diameter. In the mBC study, 9 iRECIST evaluable subjects showed PR/stable disease in 5 subjects, for a disease control rate of 44% at Week 6 and 22% at Week 12. In the ongoing rGBM study we observe a mOS of 12.5 months with 5 of 15 subjects alive in the 20 mg V cohort with survival follow up ongoing. Across studies, the adverse event profile of Ad+ V, was predictable, controllable, and fully reversible upon stopping V including a dose response to frequency and severity of cytokine release syndrome. **Conclusions:** Local regulated controlled IL-12 expression using the Ad + V platform in advanced mBC and rGBM patients is promising, eliciting sustained increases in cytotoxic T cells, reduces T_{reg}, including in non-injected lesions (abscopal effect) turning cold tumors hot, with a good safety profile. This platform warrants further evaluation in multiple tumor types in monotherapy and in combination with immune checkpoint inhibitors. Clinical trial information: NCT02026271; NCT02423902.

3039 Poster Session (Board #253), Mon, 8:00 AM-11:30 AM

Outcomes by prior lines of therapy (LoT) in ZUMA-1, the pivotal phase 2 study of axicabtagene ciloleucel (Axi-Cel) in patients (Pts) with refractory large B cell lymphoma. *First Author: Frederick Lundry Locke, Moffitt Cancer Center, Tampa, FL*

Background: In ZUMA-1 (NCT02348216), axi-cel, an anti-CD19 chimeric antigen receptor (CAR) T cell therapy, demonstrated significant benefit in patients (pts) with refractory large B cell lymphoma with an objective response rate (ORR) of 82% (complete response [CR] 58%; Neelapu & Locke et al. *NEJM*. 2017). These results supported the recent approval of axi-cel by the US FDA for the treatment of adult pts with relapsed or refractory large B cell lymphoma after ≥ 2 prior lines of systemic therapy. Here, we assessed outcomes of axi-cel by prior lines of therapy (LoT) in pts from Phases 1 and 2 of ZUMA-1. **Methods:** Pts with refractory large B cell lymphoma were leukapheresed and received 2×10^6 CAR T cells/kg after low-dose conditioning (Neelapu & Locke et al. *NEJM* 2017). Pts were evaluated by number of prior LoT: 2 – 3 vs ≥ 4. Autologous stem cell transplant (ASCT) was considered a prior LoT. **Results:** As of 8/11/17, median follow-up was 15.4 mo for the 108 pts treated with axi-cel. Sixty-two (57%) pts had 2 – 3 prior LoT and 43 (40%) had ≥ 4. Pts with 2 – 3 and ≥ 4 prior LoT had median ages of 60 and 55 y, 65% and 47% of pts had ECOG performance status 1, 18% and 42% had prior ASCT, and 76% and 93% had disease stage III/IV, respectively. ORRs were 94% and 67% for pts with 2 – 3 and ≥ 4 prior LoT, respectively, with CR rates of 65% and 53%; 44% and 42% of pts had ongoing responses as of the data cutoff (Table). Overall survival (OS) at 12 mo was 65% and 51% for pts with 2 – 3 and ≥ 4 prior LoT, respectively. Grade ≥ 3 treatment-emergent adverse events were reported for nearly all (100% and 93%) pts with 2 – 3 and ≥ 4 LoT, with similar rates of Grade ≥ 3 cytokine release syndrome (11% and 12%) and neurologic events (32% and 30%). There were 1 and 3 Grade 5 AEs unrelated to disease progression in the 2 – 3 and ≥ 4 LoT groups, respectively. **Conclusions:** Axi-cel demonstrated long-term clinical benefit for pts with refractory large B cell lymphoma regardless of the number of prior LoT. Drs Locke and Neelapu contributed equally. Clinical trial information: NCT02348216.

3040 Poster Session (Board #254), Mon, 8:00 AM-11:30 AM

First-in-human study of KHK2455, a long-acting, potent and selective indoleamine 2,3-dioxygenase 1 (IDO-1) inhibitor, in combination with mogamulizumab (Moga), an anti-CCR4 monoclonal antibody, in patients (pts) with advanced solid tumors. *First Author: Timothy Anthony Yap, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: IDO-1 inhibitors have shown antitumor activity in combination with immunotherapeutic agents in multiple cancers. KHK2455 is a novel and selective oral IDO-1 inhibitor. Unlike other inhibitors, KHK2455 inhibits IDO-1 apo-enzyme, with long-lasting and potent activity. Moga is a monoclonal antibody with enhanced ADCC activity that has shown synergy with KHK2455 in preclinical models. **Methods:** Pts with advanced solid tumors received escalating doses of KHK2455 alone (0.3, 1, 3, and 10 mg once daily) for 4 weeks (Cycle 0), followed by combination with 1 mg/kg weekly of IV Moga for 4 weeks (Cycle 1) and then on Days 1 and 15 (from Cycle 2) in a standard 3+3 Phase I design. Dose escalation was based on safety, tolerability, pharmacokinetics and IDO activity (kynurenine [Kyn] and tryptophan [Trp] levels and *ex vivo* Kyn production). **Results:** 21 pts were enrolled in cohorts that received KHK2455 at 0.3, 1, 3, and 10 mg dose levels. No DLTs were observed. The most frequent adverse events (≥5%) included maculopapular rash, thrush, dysphagia, thrombotic event, and tachycardia, none of which were considered related to KHK2455. One case of rash (Gr 3) was considered related to Moga but not a DLT. Plasma KHK2455 concentrations reached steady state by Day 8 (Cycle 0) and increased dose-dependently. Potent dose-dependent inhibition of IDO activity was demonstrated in plasma samples (67% and 66% inhibition in Kyn concentrations and Kyn:Trp ratio, respectively, compared to baseline) and *ex vivo* stimulation assays (> 95% inhibition in Kyn production) at 10 mg KHK2455, confirming target modulation. Four patients (n = 3 head and neck; n = 1 ovarian) from all dosing groups have achieved durable RECIST disease stabilization for more than 6 months, and one (salivary gland carcinoma) for more than 14 months. **Conclusions:** KHK2455 in combination with Moga is safe and well tolerated at all doses tested, suppresses Kyn production in a dose-dependent and sustained manner, and demonstrates early signals of antitumor activity. These data support the continued development of this promising combination. Clinical trial information: NCT02867007.

3041 Poster Session (Board #255), Mon, 8:00 AM-11:30 AM

Which is better in CD19 CAR-T treatment of r/r B-ALL, CD28 or 4-1BB? A parallel trial under the same manufacturing process. *First Author: Peihua Lu, Hebei Yanda Lu Daopei Hospital, Langfang, China*

Background: Second-generation CARs have been shown to improve the overall functional activity and persistence of CAR-T cells. KYMRIAH and YESCARTA used 4-1BB and CD28 co-stimulatory signaling domains, respectively. **Methods:** A parallel trial under the same manufacturing process to compare the CD28 and 4-1BB CD19 CAR-T. **Results:** This study enrolled 47 relapsed or refractory CD19-positive B-cell acute lymphoblastic leukemia (B-ALL) patients, including 19 patients in CD28 group and 28 patients in 4-1BB group. 47 patients who received at least one infusion treatment and one clinical evaluation were available for assessing safety and efficacy. The overall objective response rate (ORR) was 96%. The ORR of 4-1BB group (100%) was higher than that of CD28 group (89%). All of the patients achieving objective response were MRD negative. CAR-T cell expansion in peripheral blood was detected by Flow cytometry, and the peak of CAR-T cells of 4-1BB group was significantly higher than that of CD28 group. Different degrees of cytokine release syndrome (CRS) occurred in 45 of 47 patients (95%). 5 patients who had grade III-IV of CRS were all in CD28 group. Cytokine release peak in CD28 group was significantly higher than that of the 4-1BB group. 9 patients experienced different levels of neurotoxicity (19%). 5 patients who had grade III-IV of neurotoxicity were all in CD28 group, too. All adverse events were effectively controlled within 1 month. **Conclusions:** The study illustrates that 4-1BB CAR-T cells show enhanced safety, efficacy, and expansion than CD28 CAR-T cells, suggesting a superior therapeutic strategy in the treatment of relapsed or refractory CD19-positive B-ALL patients. Clinical trial information: NCT03173417.

3042 Poster Session (Board #256), Mon, 8:00 AM-11:30 AM

Ex vivo expanded multi-antigen specific lymphocytes for the treatment of solid tumors. *First Author: Amy Houghtelin, Children's National Medical Center, Washington, DC*

Background: Patients with solid tumors refractory to standard therapies have poor prognoses, and most salvage therapies are toxic and ineffective. Antigen-specific T cell therapies offer a promising alternative for targeted therapy with the ability to target multiple antigens in a single product. Hence, we hypothesize that patient-derived tumor-associated antigen-specific T cells (TAA-T) targeting WT1, PRAME, and survivin expressed by pediatric solid tumors can be safely administered to treat patients with relapsed/refractory disease. The objective of this phase I clinical trial is to determine the safety of administering TAA-T to these patients. The secondary objectives include determining disease response and tumor-specific immune reconstitution following infusion. **Methods:** T cells expanded from patient peripheral blood were stimulated weekly with antigen presenting cells pulsed with an overlapping peptide library spanning the TAAs WT1, PRAME, and survivin. Following release testing, patients were infused with TAA-T on a dose escalation study, ranging from 1 x $10^7/m^2$ (dose level 1) to 4 x $10^7/m^2$ (dose level 3). Clinical and immune studies were performed post-infusion to monitor for adverse effects and assess immune and disease responses. **Results:** We have generated TAA-T products from 14 patients (age range 6-54 years) with relapsed/refractory solid tumors (neuroblastoma, osteosarcoma, Wilms tumor, Ewing sarcoma, soft tissue sarcoma, rhabdomyosarcoma). 14 patients have received a median of 2 (range 1-8) infusions without product-related SAEs post-infusion. Epitope spreading was identified in 86% of responding patients. Preliminary outcome data (N = 10) show overall survival of 82% and event-free survival of 54% at 3 months. **Conclusions:** This unique immunotherapeutic has been well tolerated without causing life-threatening adverse events. Despite aggressive and multiply relapsed disease, 75% of patients have demonstrated evidence of disease control after TAA-T with epitope spreading identified in the majority of responding patients post-infusion. These clinical and laboratory data suggest that TAA-T may safely prolong survival in patients with relapsed/refractory solid tumors. Clinical trial information: NCT02789228.

3043 Poster Session (Board #257), Mon, 8:00 AM-11:30 AM

Regression of epithelial cancers in humans following t-cell receptor gene therapy targeting human papillomavirus-16 E7. *First Author: Nisha Nagarsheth, Experimental Transplantation and Immunology Branch, Center for Cancer Research, NIH, Bethesda, MD*

Background: Adoptive T-cell therapy with gene-engineered T cells is an emerging cancer treatment strategy. Study of this approach in epithelial cancers, the most common types of malignancies, has been limited. We initiated a clinical trial of gene-engineered T cells that target human papillomavirus (HPV)-16-E7 for the treatment of patients with metastatic HPV-16+ cancers. **Methods:** The clinical trial was designed as a phase I study with three dose levels (DL) of gene-engineered T cells (DL1: 1 x 10^9, DL2: 1 x 10^{10}, DL3: 1 x 10^{11}). Patients had metastatic HPV-16+ cancers from any primary tumor site. Patients received a single infusion of autologous T cells that were gene-engineered to express an HLA-A*02:01-restricted T-cell receptor that targets HPV-16 E7 (E7 T cells). A lymphocyte-depleting conditioning regimen was administered before treatment. E7 T cell infusion was followed by high-dose systemic aldesleukin. We report the early results of the ongoing study. **Results:** Eight patients were treated. No dose-limiting toxicity, off-target T-cell toxicity, or cytokine-release syndrome occurred. Objective clinical responses were observed in 3/7 evaluable patients. Responses occurred in patients with vulvar, oropharyngeal, and anal cancer. Two of these patients had been previously treated with anti-PD-1 checkpoint blockade. One response occurred at DL1. The patient had extensive metastatic vulvar cancer involving the lungs, retroperitoneum, pelvis, and thigh. She had been previously treated with seven systemic anti-cancer agents. The response lasted 8 months after treatment. Two responses occurred at DL2. One was in a patient with metastatic anal cancer with lung, pleura, and kidney tumors. The response is ongoing after 7 months. In the initial six patients, the E7 TCR was expressed by 90-99% of the infused T cells, and E7 T cells were detectable in the peripheral blood six weeks following treatment (1% to 4% at DL1, 5% to 45% at DL2). **Conclusions:** Tumor regression can occur following treatment of an epithelial cancer with gene-engineered T cells. These findings support continued study of E7 T cells and possibly other types of gene-engineered T cells in epithelial cancers. Clinical trial information: NCI-16-C-0154.

3044 Poster Session (Board #258), Mon, 8:00 AM-11:30 AM

Immunogenicity of tisagenlecleucel in relapsed/ refractory (R/R) B-cell acute lymphoblastic leukemia (B-ALL) and diffuse large B-cell lymphoma (DLBCL) patients. *First Author: Karen Thudium Mueller, Novartis Institutes for BioMedical Research, East Hanover, NJ*

Background: Tisagenlecleucel, a chimeric antigen receptor (CAR) T-cell therapy, contains a murine single chain variable fragment (mCAR19) binding domain. Humoral immunity to anti-mCAR19 had no impact on safety or efficacy in pediatric r/r B-ALL patients (pts) (Mueller ASH 2017); immunogenicity in r/r DLBCL has not been studied. **Methods:** Tisagenlecleucel immunogenicity was measured in r/r B-ALL (ELIANA [NCT02435849, n = 75]; ENSIGN [NCT02228096, n = 29]) and r/r DLBCL (JULIET [NCT02445248, n = 99]) ≤ 12 months after infusion. Cellular immunity was measured in PBMCs and tested for mCAR19 peptide-activated T cell responses by stimulated intracellular interferon-gamma production. Anti-mCAR19 antibodies (Ig) were measured by flow cytometry at baseline and after treatment. Treatment-induced Ig was defined as the ratio of postbaseline Ig levels to baseline. The impact of preexisting and treatment-induced Ig and T-cell activation on cellular kinetics, efficacy and safety were determined. **Results:** 84.6% of r/r B-ALL and 91.4% of r/r DLBCL pts had preexisting humoral immunogenicity. Treatment-induced humoral immunogenicity occurred in 34.6% of r/r B-ALL and 5% of r/r DLBCL pts. No relationship was found between tisagenlecleucel expansion ($AUC_{0\text{-}28d}$) and preexisting humoral responses in r/r B-ALL (r^2= 0.002) or r/r DLBCL (r^2= 0.008), or treatment-induced humoral responses in r/r B-ALL (r^2= 0.006). Results for C_{max} were similar. Treatment induced humoral responses did not impact expansion or persistence of CARs in B-ALL, but sample size prevented correlation analysis in DLBCL as only 5% of pts had treatment-induced Ig. Preexisting humoral immunity did not appear to impact transgene persistence, duration of response, event-free survival or safety in either indication. T-cell responses were consistent over time with net responses < 1% at baseline and postinfusion for the majority of pts. T-cell responses did not appear to impact transgene expansion or persistence or pt outcomes. **Conclusions:** Preexisting/treatment-induced humoral and antigen-specific cellular immunity did not impact tisagenlecleucel expansion, persistence, efficacy or safety. Clinical trial information: NCT02435849, NCT02228096, NCT02445248.

3045 Poster Session (Board #259), Mon, 8:00 AM-11:30 AM

Durable clinical responses observed from non-Hodgkin lymphoma patients treated with autologous CAR-T cells targeting CD19. *First Author: Yarong Liu, HRAIN Biotechnology, Shanghai, China*

Background: Cellular immunotherapy based on chimeric antigen receptor (CAR)-engineered T (CAR-T) cells has shown to be one of the most promising immunotherapeutic strategies for cancer treatment. Herein we report an encouraging result from a phase 1 clinical trial to evaluate a CD19 CAR-T therapy for treating relapse/refractory B-cell non-Hodgkin's lymphoma (NHL). **Methods:** A phase 1 clinical trial was conducted to evaluate safety and efficacy of CD19 CAR-T therapy for patients with relapsed and/or refractory NHL. A total of 22 patients with $CD19^+$ B-cell NHL at stage III/IV were enrolled in this study; these patients had received 4-12 (median 8) rounds of various chemotherapies prior to the enrollment. All patients were pre-conditioned with Cy (800 mg/m^2) once (d -5) and Flu (25 mg/m^2) daily for 3 days (d -5 to d -3) followed by administration of a total dose of 1x10^6 cells/kg CD19 CAR-T cells via either a single infusion or a 3-day split-dose (10, 30, and 60%) infusion regimen. The efficacy was assessed by RECIST1.1 and the toxicity was evaluated by CTCAE 4.02. The CAR-T cell expansion and persistence were measured by quantitative PCR (qPCR) and flow cytometry. **Results:** Of the 22 patients, only one exhibited over grade 3 cytokine release syndrome (CRS) and was resolved after active treatments. Moreover, no central nervous system toxicity was observed. The overall response rate (ORR) for the 18 evaluable patients was 72.2%. Complete remission (CR) and ORR for six months were both at 36.7%. The median progress-free survival was 4 months (95% confidence interval (CI), 0.5 to 7.5) and a median overall survival was 11 months (95% CI, 4.7 to 17.3). It was observed that local radiation prior to cell therapy could enhance CAR-T cell infiltration. Further analysis revealed a biomarker which could be used to identify beneficial patients. Interestingly, pseudo-progression occurred on some patients and two rounds of CAR-T expansion were seen in several patients. One patient has experienced ongoing CR, B cell deficiency, and persistence of CAR-T cells for > 21 months. **Conclusions:** Our data indicate that this CD19 CAR-T product can offer substantial clinical benefit for NHL patients with manageable toxicities. Clinical trial information: NCT02652910.

3046 Poster Session (Board #260), Mon, 8:00 AM-11:30 AM

A phase I trial of T4 CAR T-cell immunotherapy in head and neck squamous cancer (HNSCC). *First Author: Sophie Papa, Guy's And St Thomas NHS Foundation Trust, London, United Kingdom*

Background: Recent FDA approvals make CAR T-cell therapy a clinical reality for hematologic malignancy. Toxicity and antigen loss-mediated resistance remain problematic. Solid tumors impose additional challenges, foremost the paucity of safe targets. Moreover, CAR T-cells need to home to, penetrate and persist in an active state within a profoundly immunosuppressive tumor microenvironment. To address these issues, we developed T4-immunotherapy: T-cells that co-express: (i) T1E28ζ, a CAR containing a promiscuous ErbB ligand coupled to a CD28+CD3ζ endodomain; and (ii) 4αβ, an IL-4-responsive chimeric cytokine receptor. T1E28ζ engages 8/9 ErbB homo/heterodimers, providing broad anti-tumor scope while minimizing risk of antigen escape. 4αβ enables IL-4-driven selective CAR T-cell enrichment/expansion during manufacture. Pre-clinical data demonstrate potent anti-tumor activity of T4-immunotherapy. However, risk of on-target off-tumor toxicity is significant, due to normal tissues low-level ErbB expression. **Methods:** We undertook a Phase I dose-escalation trial of T4-immunotherapy in HNSCC. T4-immunotherapy was manufactured using a blood draw (40-130mL) in a two-week closed process, employing IL-4 as the sole cytokine stimulus post transduction. CAR T-cell dose was escalated through 5 cohorts from $1x10^7$ -$1x10^9$ $T4^+$ T-cells administered as a single treatment, by multifocal intra-tumoral injection without lymphodepletion. **Results:** Despite a lymphopenia rate of 62%, T4 manufacture was successful in 13/13 cases, yielding 2.5-7.5Bn T-cells (69+/-13% transduced). Treatment-related AEs were ≤ grade 2, with no dose-limiting toxicities (CTCAE v4.0). Frequent AEs were steroid-responsive tumor swelling, pain, pyrexias, chills and fatigue. Circulating $T4^+$ T-cells were undetectable in all patients at all times. At 6-weeks, stable disease (SD) was seen in patients treated with $\geq 10x10^7$ $T4^+$ T-cells. Overall disease control rate was 69% (RECIST 1.1), despite rapidly progressing tumors on trial entry. Subsequent PD1 + oncolytic virus therapy in one patient achieved a rapid complete clinical response. **Conclusions:** These data demonstrate the safe intratumoral administration of T4 in patients with advanced HNSCC. Clinical trial information: NCT01818323.

3047 Poster Session (Board #261), Mon, 8:00 AM-11:30 AM

Acquired resistance to T cell adoptive transfer by inflammation-induced melanoma dedifferentiation. *First Author: Arnav Mehta, Massachusetts General Hospital, Boston, MA*

Background: Many patients that initially respond to cancer immunotherapy with adoptive cell therapy (ACT) using T cell receptor (TCR) engineered autologous T cells eventually develop resistance and experience relapse (termed acquired resistance) through mechanisms that remain poorly understood. **Methods:** We analyzed baseline and on-therapy tumor samples from 15 patients with metastatic melanoma that were treated with transgenic lymphocytes expressing a MART-1 TCR administered with a MART-1 peptide-pulsed dendritic cell vaccine. We studied *in vitro* the effect of inflammatory mediators and MART-1-specific T cells on human patient-derived melanoma cell lines, and performed bulk RNA-sequencing and methylation analysis of melanosome genes to gain further insight into mechanisms of acquired immunotherapy resistance in these cells. **Results:** Progression biopsies of metastatic melanoma lesions in one of the patients demonstrated phenotypic dedifferentiation as a resistance mechanism to ACT, a phenomenon previously only reported in murine models (Landsberg et al., Nature, 2012). After a three month period of tumor regression, the patient presented in relapse with tumors lacking melanocytic antigens (MART-1, gp100) but expressing the inflammation-induced neural crest marker NGFR (or CD271). We validated inflammation-induced tumor dedifferentiation of 8 melanoma cell lines *in vitro* after stimulation with TNFa for 3 days, and identified gene pathways altered in dedifferentiated cells by RNA-sequencing. Gene set enrichment analysis revealed that TNFa treatment enriched for genes involved in epithelial to mesenchymal transition (NES = 1.92, FDR < 0.001) and neural crest stem cell identity (NES = 1.49, FDR = 0.016), and pathways in the innate anti-PD-1 resistance signature (IPRES). TNFa treatment also downregulated genes in the MITF pathway (NES = -2.38, FDR < 0.001). **Conclusions:** Inflammation-induced dedifferentiation is a new mechanism that can lead to acquired resistance to cancer immunotherapy.

3048 Poster Session (Board #262), Mon, 8:00 AM-11:30 AM

Screening of neoantigen-specific T cells and establishment of T-cell receptor-engineered T cells: Implications for head and neck squamous carcinoma. *First Author: Lili Ren, The University of Chicago, Chicago, IL*

Background: Due to the high immune-suppressive condition in tumor microenvironment in growing tumors, the numbers of neoantigen-specific T cells is in general very limited. To improve adoptive T cell transfer (ACT) immunotherapy targeting neoantigens, we attempted to rapidly identify neoantigen-specific T cell receptors (TCRs) and establish T-cell receptor-engineered (TCR-engineered) T cells. **Methods:** To screen the neoantigen-specific T cells, we performed whole exome sequencing (WES) and transcriptome analysis, and selected candidate neoantigen epitopes to induce cytotoxic T lymphocytes (CTLs) in 20 patients with squamous head and neck cancer. 64 potential neoantigen peptides as well as 16 minigenes, each of which were designed to express peptides carrying 20 somatic missense mutations, were examined for induction of neoantigen-reactive cytotoxic T cells *in vitro* using patient-derived dendritic cells and peripheral blood, or expanded TILs isolated from corresponding tumors. Neoantigen-specific T cells were screened by 4-1BB expression levels as well as ELISPOT assay and TCR sequences were determined using isolated T cell clones. We then cloned TCR cDNAs into T lymphocytes and generated the neoantigen-reactive TCR-engineered T cells. **Results:** We have so far confirmed 8 neoantigen-reactive T cells and established 6 TCR-engineered T cells which showed HLA-restricted neoantigen-reactive cytotoxic activity *in vitro*. We also tested HLA A*02:01 restricted engineering T cells with the antigen-negative humanized mice model we generate previously, which showed very specialized antigen reactivity *in vivo*. **Conclusions:** We here demonstrate the establishment of a more effective and rapid protocol to generate neoantigen-specific T cells, identify neoantigen-specific TCRs for individual patients, and establish TCR-engineered T cells applicable for the clinical use.

3049 Poster Session (Board #263), Mon, 8:00 AM-11:30 AM

ET190L1-ARTEMIS T cell therapy to induce complete remission of relapsed and refractory (r/r) B-cell lymphoma with no cytokine release syndrome in the first-in-human clinical study. *First Author: Zhi Tao Ying, Peking University Cancer Hospital & Institute, Beijing, China*

Background: To ameliorate CRS commonly associated with CAR T-cell therapy, we developed a novel T cell therapy, the ARTEMIS platform, which functionally matches the potency of CAR-T cells, but triggers significantly less cytokine release upon target engagement. Herein we describe the first-in-human clinical studies of anti-CD19 ET190L1-ARTEMIS™ T cell therapy in r/r B-cell lymphoma at multiple sites. **Methods:** Patients are assigned to 1 of 3 cohorts: single infusion of ET190L1-ARTEMIS™ T cells at 1, 3 or 6×10^6 cells/kg. The primary objective is to evaluate safety. Additional objectives include assessment of T cell engraftment and tumor response. **Results:** As of Jan 23, 2018, twelve heavily pretreated adult patients received autologous ET190L1-ARTEMIS T cells, 3 in the 1×10^6/kg cohort and 9 in the 3×10^6/kg cohort. Expansion of ARTEMIS T cells after infusion was observed in all patients. No CRS or neurotoxicity was observed. Plasma levels of IL-2, 4, 6, 8, 10, IFNg, TNFa, and GM-CSF were below detection at most time point post-infusion. Vital signs were normal except for 3 patients in the 3×10^6/kg cohort who had transient fever (37.5-39°C) from day 2 to day 4 post-infusion. One patient from the 1×10^6/kg cohort developed a transient skin rash. The overall response rate is 78% (7/9) (See Table 1). Six month follow-up data for the first 9 patients and early data from additional patients will be presented. **Conclusions:** In the studies, ET190L1-ARTEMIS T cell therapy demonstrated a favorable safety profile with no observed CRS or neurotoxicity and shows promising efficacy in r/r lymphoma patients. Durability of the responses will be evaluated with longer follow-up. Based on its observed response rate and lack of CRS and neurotoxicity, the ARTEMIS platform is potentially a major improvement over existing CAR-T cell therapy.

Tumor response (using Cheson criteria) and treatment-related safety events.

3050 Poster Session (Board #264), Mon, 8:00 AM-11:30 AM

A phase I trial of PD-1 deficient engineered T cells with CRISPR/Cas9 in patients with advanced non-small cell lung cancer. *First Author: You Lu, Department of Thoracic Oncology, Cancer Center, West China Hospital, West China School of Clinical Medicine, Sichuan University, Chengdu, China*

Background: We performed the first phase I clinical trial (NCT02793856) to assess safety of CRISPR/Cas9-mediated knockout of PD-1 gene in autologous T lymphocytes (PD-$1^{-/-}$ T) therapy in patients with metastatic non-small cell lung cancer (NSCLC). **Methods:** We assigned patients with advanced NSCLC with positive PD-L1 expression who had progressed after 3rd line standard therapeutic regimens. Two patients were enrolled in Pre-A cohort who received PD-$1^{-/-}$ T therapy with 2 x 10^7 cells/kg for one cycle and were observed for another cycle. Then 3 cohorts (A, B, C) enrolled 3 patients in each group receiving PD-$1^{-/-}$ T cells therapy with 1×10^7/kg, 2×10^7/kg, 4×10^7/kg in each cycle, respectively. Patients received PD-$1^{-/-}$ T therapy until disease progression or study withdrawal. Primary outcome was safety. Secondary end points were 8 weeks disease control rate (DCR) and progression-free survival (PFS). In exploratory analyses, next-generation sequencing was performed on PD-1 editing region of T cells and CDR3 region of T-cell receptor. **Results:** Nine patients were enrolled and eight patients received totally 17 cycles of PD-$1^{-/-}$ T therapy. Twenty-three adverse events (AEs) related to PD-$1^{-/-}$ T cell infusion occurred (Table 1). No 3-5 AEs were observed. Of note, one patient in Pre-A group suffered grade 1 arrhythmia (premature beat) that lasted for 42.4 weeks. Seven patients were response evaluable. Two patients experienced stable disease (SD) with 17.6 and 22.0 weeks, respectively. Other 5 patients had progression disease (PD). Eight-week DCR was 28.6% and median PFS was 7.6 weeks. In exploratory data, two patients with SD showed higher diversity of T cell repertoire in PBMC than other 5 patients with PD. **Conclusions:** Patients receiving PD-$1^{-/-}$ T therapy seemed safe. Further larger size studies are warranted to explore effective dose and related immune response. Clinical trial information: NCT02793856.

3051 Poster Session (Board #265), Mon, 8:00 AM-11:30 AM

Correlation of pre-CAR CD19 expression with responses and relapses after CAR T cell therapy. *First Author: Vinodh Pillai, The Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Chimeric antigen receptor (CAR) T cells targeting CD19 have shown excellent responses in patients with relapsed/refractory B-ALL. However, a subset of patients either do not respond or relapse after CAR T cell therapy, the causes of which are unclear. The use of CD19-directed therapy has increased the incidence of CD19 dim or CD19 negative B-ALL. We assessed whether pre-treatment CD19 expression level or prior targeted therapy impacts response to CAR therapy. **Methods:** Cases of B-ALL treated with CAR therapy from 2012-2017 at Children's Hospital of Philadelphia were evaluated. CD19 in blasts was classified as dim, normal or bright compared to normal B cells by flow cytometry. CD19 expression and immunophenotype of blasts pre and post-CAR therapy were correlated with responses to CAR T cell therapy. Failure to reach an MRD-negative remission was considered as non-response. Presence of aberrant blasts ($>$ 0.01%) at any time point after remission was considered as relapsed disease. **Results:** 150 cases treated with CAR therapy were evaluated of which 10 were non-response (NON), 20 were CD19 positive relapses (CD19PR) and 33 were CD19 negative relapses (CD19NR). 15 patients received prior CD19 targeted therapy. Rate of responses and relapses in CD19dim B-ALL were not significantly different from the CD19 normal/bright group. However, prior CD19-targeted therapy was associated with a significantly higher rate (60%; p = 0.014) of NON and CD19NR compared to 25% in patients who did not receive any prior CD19 targeted therapy. Immunophenotype of CD19PR were identical to that of pre-therapy disease in 85% of cases, consistent with loss of CAR T cells as the etiology of those relapses. Blasts from CD19NR patients did not show any CD19-negative events by flow prior to CAR T cell therapy in 75% of cases suggesting that CD19-negative blasts may be de novo events. **Conclusions:** CAR T cell therapy is effective in B-ALL with dim CD19 expression. Prior targeted therapy is associated with increased non-response and relapse, likely due to CD19 escape. CD19PR after CAR T cell therapy are due to early loss of CAR T cells while CD19NR are likely due to expansion of de novo CD19-negative B lymphoblasts under treatment pressure.

3052 Poster Session (Board #266), Mon, 8:00 AM-11:30 AM

Clinical anti-lymphoma activity and toxicity of T cells expressing a novel anti-CD19 chimeric antigen receptor with fully-human variable regions. *First Author: Jennifer N. Brudno, Experimental Transplantation and Immunology Branch, National Cancer Institute, Bethesda, MD*

Background: T cells expressing chimeric antigen receptors (CARs) targeting CD19 have powerful activity against B-cell lymphoma. A limitation to CAR T-cell therapy for lymphoma is occurrence of toxicities, especially neurologic toxicities. **Methods:** We designed an anti-CD19 CAR with fully human variable regions (Hu19CAR). This CAR has CD8α hinge and transmembrane domains and a CD28 costimulatory domain; T cells expressing this CAR release relatively low levels of cytokines. A phase I dose-escalation trial was conducted to investigate the safety of Hu19CAR T cells and to assess efficacy for patients with previously treated B-cell lymphoma. Patients received cyclophosphamide and fludarabine chemotherapy to enhance CAR T-cell activity. Two days after the completion of chemotherapy, Hu19CAR T cells were infused. **Results:** Twenty patients have received Hu19CAR T-cell infusions. Of these patients, 75% had lymphoma that was chemotherapy-refractory or relapsed after autologous stem cell transplant. Patients received a median of 4 prior lines of therapy. The overall response rate is 75%, with 55% complete remissions (CRs). CRs were observed in patients with chemotherapy-refractory lymphomas and in patients with double-hit diffuse large B-cell lymphoma. Durations of response currently range from 1 to 17 months. Forty percent of patients are in ongoing remissions. Only one patient experienced greater than Grade 2 neurotoxicity (5%), which is a neurotoxicity rate lower than that of many anti-CD19 CAR trials. This patient had Grade 4 neurotoxicity which reversed in less than 24 hours with corticosteroid therapy. Three patients had Grade 3 cytokine release syndrome (CRS), and 1 patient had Grade 4 CRS; all other patients had Grade 2 or lower CRS. CRS and neurotoxicities resolved completely in all patients. Loss of CD19 expression by lymphoma cells was observed in 4 of the 8 patients who underwent biopsies of recurrent or residual lymphoma after Hu19CAR T-cell infusions. CAR T cells were detected in the blood of all patients at levels ranging from 4-2216 cells/μL. **Conclusions:** Hu19CAR T cells have substantial activity against advanced lymphoma with a low rate of neurotoxicity. Clinical trial information: NCT02659943.

3053 Poster Session (Board #267), Mon, 8:00 AM-11:30 AM

Impact of the influenza vaccination on cancer patients undergoing therapy with immune checkpoint inhibitors (ICI). *First Author: Ragisha Gopalakrishnan, Vanderbilt University Medical Center, Nashville, TN*

Background: Immune checkpoint inhibitors (ICI) are standard of care for many cancer patients (pts). There have been conflicting reports on the effect of the influenza (flu) vaccines (flu-V) on pts being treated with ICI, and some suggest that flu-V may impact survival outcomes in ICI treated pts. **Methods:** We conducted a retrospective review of patients at Vanderbilt Ingram Cancer Center treated with ICI from 2010-2017. Data collected included age, gender, race, cancer type, comorbidities, type of ICI (single v. combo), time of drug administration, time of flu-V, rate of flu prodromal, rate of admissions for flu related complications, rate of immune related adverse events (irAE) and admissions, and the impact of flu-V on PFS and OS. Statistical analysis was performed using Graph PAD prism and SPSS. **Results:** 534 patients were included, 72.1% received flu vaccine. Median age was 54, 76% male, 64.1% stage IV. Cancer types included were lung (37%), melanoma (34%), GU (18%), breast 7.2%, and lymphoma (3.4%). 93% received single agent ICI. Vaccinated and unvaccinated pts (37.4 v. 42.6, p = 0.067) developed equal rates of irAEs. Unvaccinated pts who developed irAEs were more likely to develop pneumonitis (37.23 v. 17.17, p = 0.023) and more likely to be admitted than vaccinated pts (41.53% v. 23.2% p = 0.016). Unvaccinated pts were less likely to experience flu prodrome (32.2 % v 43.7%, p = 0.067), but were more likely to be admitted for influenza related complications (62.4% 23.2 %, p = 0.032). Most common reason for admission was sepsis. Flu-V did not change PFS (vaccinated 47.2 m vs. unvaccinated 43.2 m, p = 0.0621) but improved OS (vaccinated 72 months v. 62 months unvaccinated, p $<$ 0.001). In multivariate analysis, age and abstaining from flu-V were predictive for developing irAEs. Type and stage of malignancy, # of prior lines of therapy, type of ICI, and timing of flu-V was not predictive for developing for irAE. **Conclusions:** Our results suggest that seasonal flu vaccination is safe and beneficial for patients on ICI and reduces the rate of hospital admissions from flu related and irAEs. Furthermore, our study also demonstrates that vaccination with influenza may improve OS in patients receiving ICI.

3054 Poster Session (Board #268), Mon, 8:00 AM-11:30 AM

Safety and activity of programmed cell death-1 gene knockout engineered t cells in patients with previously treated advanced esophageal squamous cell carcinoma: An open-label, single-arm phase I study. *First Author: Zhao Jing, Hangzhou Cancer Hospital, Hangzhou, China*

Background: We designed the clinical trial to investigate the safety and activity of Programmed death-1 (PD-1) knockout engineered T cell in patients with advanced esophageal squamous cell carcinoma (ESCC). **Methods:** Patients (aged ≥18 years) with advanced ESCC whose disease had progressed after at least two systemic therapies were enrolled. Peripheral blood will be collected and PD-1 gene will be knocked out by clustered regularly interspaced short palindromic repeats (CRISPR)/Cas9 in the laboratory. T lymphocytes will be selected, expanded and reinfused back into patients after about 2-3 weeks. Response was assessed 4 weeks after each infusion. Patients continued receiving treatment until disease progression, intolerable toxicity, or consent withdrawal. The primary endpoint was to evaluate the safety of PD-1 knockout engineered T cells treatment. **Results:** Between Mar, 2017, and Jan, 2018, we enrolled 21 patients who received at least one cycle PD-1 knockout engineered T cells treatment. Among 21 treated patients, 7 accepted only 1 cycle of cell infusion, 12 accepted 2 cycles, and 2 accepted 3 cycles. Up to the study cutoff date of Jan 31, 2018, the most common adverse events were transient fever (7 patients, the highest was 39.1℃) and chills (3 patients) and moderate skin rash (1 patient). No grade 3 or 4 adverse events were observed in the study. Of the 17 evaluable patients, no complete or partial responses were observed. 6 patients had stable disease, and 11 patients had progressive disease. Disease control rate was 35% (6/17) and median overall survival was 127 days (95% CI 45–209). During the trial, 10 cancer progression related deaths occurred. Immunofluorescence analysis showed that the PD-1 knockout engineered T cells could infiltrate into and persist for a durable time in ESCC that responded to therapy. **Conclusions:** The results showed that PD-1 knockout engineered T cells infusion might be an effective treatment in patients with heavily pretreated advanced ESCC. The treatment was well tolerated with no unexpected safety concerns. The regimen warrant further clinical investigation. Clinical trial information: NCT03081715.

3055 Poster Session (Board #269), Mon, 8:00 AM-11:30 AM

Adoptive cellular immunotherapy with APN401, autologous cbl-b silenced peripheral blood mononuclear cells: Data from a phase I study in patients with solid tumors. *First Author: Hans Loibner, Apeiron Biologics AG, Vienna, Austria*

Background: Casitas-B-lineage lymphoma protein – b (cbl-b), an E3 ubiquitin ligase is an important intracellular checkpoint limiting activation of lymphocytes and NK cells. Silencing of cbl-b enhances T cell and NK cell antitumor activity in mouse tumor models and in-vitro in human immune cells. APN401, an autologous cellular therapy consisting of ex-vivo cbl-b-silenced PBMCs, was evaluated in patients with solid tumors. **Methods:** Patients with metastatic solid tumors not eligible for standard therapies were included. Patients with autoimmune disease or requirement for immunosuppressive drugs were excluded. PBMCs were obtained by leukapheresis and were transfected with cbl-b- siRNA ex vivo by electroporation, and 5, 10 or 50 x 10^5 /PBMCs/kg were infused once shortly thereafter over 30 min. **Results:** 16 patients were treated with APN401. As a consequence of cbl-b silencing, all patient PBMC preparations produced enhanced amounts of cytokines IL-2 and IFN-g upon TCR stimulation in vitro. Moreover, evaluation of patient PBMCs responses to common tumor antigens were stronger over the course of the follow-up period. Four patients (2 pancreas 1colon cancer, 1 renal cancer) had stable disease as best tumor response during the study. The strongest response to tumor antigens was observed in the patient with the best objective clinical response (metastatic colon cancer; disease stabilization > 1 year). Infusions were well tolerated. Dose-limiting toxicities were not observed. Mild chills were the most commonly observed related adverse event, followed by mild anemia and fatigue. There was no immediate hypersensitivity or evidence for autoimmune adverse effects. **Conclusions:** Cbl-b-silenced PBMCs (APN401) from cancer patients respond to TCR stimulation and activation with tumor antigens. Strongest cell activation was seen in the patient with the best objective clinical response. 50 x 10^5 / kg APN401 was safe and well tolerated. Multiple infusions of APN401 are currently clinically tested. Clinical trial information: NCT03087591.

3056 Poster Session (Board #270), Mon, 8:00 AM-11:30 AM

Initial safety assessment of MAGE-A10^{c796}TCR T-cells in two clinical trials. *First Author: Vincent K. Lam, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: MAGE-A10 is expressed in 10-50% of urothelial, melanoma, head and neck (HNC), and non-small cell lung cancers (NSCLC). Affinity-enhanced autologous MAGE-A10^{c796}T cells directed towards MAGE-A10 tumor antigen in the context of HLA*02 (SPEAR T-cells) are being tested in 2 ongoing clinical trials (NCT02592577: NSCLC/NCT02989064: urothelial, melanoma, HNC). **Methods:** These first-in-human T-cell dose escalation studies utilize a modified 3+3 design to evaluate safety. Patients are enrolled after progression on at least one line of therapy. In the first treatment groups, lymphodepletion with Flu 30 mg/m^2/day and Cy 600 mg/m^2/day (NCT02989064) or Cy 600 mg/m^2/day (NCT02592577) is administered on days -7 to -5. The initial dose is 0.1×10^9 transduced cells; additional dose levels are 1×10^9 and 5×10^9. Dose-limiting toxicities (DLT) are determined regardless of attribution to cell infusion and adjudicated by a Safety Review Committee. Cohort expansion will occur at the maximum tolerated dose. **Results:** 8 patients were treated with 0.1×10^9 MAGE-A10^{c796}TCR T-cells (29Dec17). Adverse events (AEs) in ≥3 patients included anemia, thrombocytopenia, lymphopenia, leukopenia, neutropenia, vomiting, constipation, dyspnea and tachycardia. Grade (G) 3 AEs in ≥2 patients included thrombocytopenia, lymphopenia, leukopenia, neutropenia, anemia, pancytopenia, and hyponatremia; these were not reported as related to T-cell infusion. 1 event of cytokine release syndrome (CRS) and 1 increase in serum amylase were reported as related to T-cell infusion. SAEs included G5 disease progression, G4 CRS, G4 neutropenia, G4 thrombocytopenia, G4 sepsis, G4 abdominal pain, G4 supraglottic airway obstruction, G3 shortness of breath and G2 respiratory failure. There was 1 DLT of G4 CRS in a patient with NSCLC that resolved with tocilizumab and steroids. While no anti-tumor effects were observed at this dose, transduced cells were detectable in peripheral blood. **Conclusions:** MAGE-A10^{c796}TCR T-cells at the 0.1×10^9 transduced cell dose show no evidence of on target or off target toxicity. 1 DLT of CRS was observed. The available data support continued investigation of MAGE-A10^{c796}TCR T-cells at higher doses. Clinical trial information: NCT02592577; NCT02989064.

3057 Poster Session (Board #271), Mon, 8:00 AM-11:30 AM

Association of efficacy and adverse events of special interest of avelumab in the JAVELIN solid tumor and JAVELIN Merkel 200 trials. *First Author: Karen Kelly, University of California Davis Comprehensive Cancer Center, Sacramento, CA*

Background: Immune checkpoint inhibitors (ICIs) are associated with unique adverse events of special interest (AESI), including infusion-related reactions (IRRs) and immune-related AEs (irAEs). It has been observed that patients (pts) responding to treatment might have a higher likelihood of AEs, potentially due to longer treatment duration. Understanding the association between AESIs and efficacy outcomes may improve the assessment of benefit/risk and thus aid in informed treatment decisions. **Methods:** We pooled and analyzed efficacy/safety data from NCT01772004 and NCT02155647. We performed an association analysis between response and IRRs. The association of efficacy and irAEs was analyzed using approaches that accounted for time dependency: Cox models analyzed overall survival under consideration of time-varying indicators for irAEs; multistate models were used to gain insight into underlying mechanisms. **Results:** 1783 pts were included in this analysis. 25.5% of pts had ≥ 1 IRR; 0.7% of pts had a grade 3-4 IRR. 97.3% of pts with IRRs had first onset during the first 3 infusions. No association between response and IRRs was observed. irAEs were observed in 16.8% of pts, most commonly hypothyroidism (6.7%) and rash (6.6%); grade 3-4 irAEs occurred in 2.7% of pts. 2.2% of pts discontinued avelumab treatment due to an irAE. An improved probability of survival was observed for pts who experienced irAEs (HR, 0.74 [95% CI, 0.61-0.88]). The multistate model did not suggest that occurrence of irAEs predicted response; however, responders were more likely to develop irAEs than others who remained on treatment. The discontinuation rate did not increase upon occurrence of irAEs. **Conclusions:** The overall incidence of AESI was low, and most were grade ≤ 2. The occurrence of IRRs did not impair the rate of response. The data suggest a survival benefit for pts who experienced an irAE; however, not having an AE did not preclude a response to avelumab. Continued awareness of irAEs may improve clinical outcomes in all pts, with particular vigilance needed if a pt is responding and remains on treatment. Clinical trial information: NCT01772004, NCT02155647.

3058 Poster Session (Board #272), Mon, 8:00 AM-11:30 AM

Circulating miRNA and extracellular vesicle containing miRNA as response biomarkers of anti PD-1/PD-L1 therapy in non-small-cell lung cancer. *First Author: Takehito Shukuya, The Ohio State University, Division of Medical Oncology, Columbus, OH*

Background: Anti PD-1/PD-L1 antibody is a standard first or second-line treatment for advanced non-small cell lung cancer (NSCLC), and PD-L1 immunohistochemisty is used as a predictive biomarker for therapeutic response. However, because patients with lower PD-L1 expression also show durable response in NSCLC, and the usefulness of PD-L1 immunohistochemisty results has not been shown in the other malignancies, more accurate and non-invasive predictive biomarkers are needed. Circulating miRNA and that packaged in extracellular vesicles (EVs) are considered to play a role in intercellular communication among immune cells and between immune cells and tumor cells. **Methods:** Pretreatment plasma of advanced NSCLC patients treated with single agent anti PD-1 or PD-L1 antibody was used in this study. Circulating miRNA was extracted from plasma by miRNAeasy kit (QIAGEN). EVs were isolated using size-exclusion chromatography column (Izon), and miRNA was extracted by miRNAeasy kit. Modified small-RNA library construction was used to make small RNA sequencing libraries, and sequenced on a NextSeq 500 sequencer (Illumina). The sequencing results were analyzed with sRNAnalyzer (http://srnanalyzer.systemsbiology.net/). **Results:** Samples from 14 responders (patients who showed PR or SD $\geq$ 6 months) and 15 non-responders (patients who showed PD in RECIST) were analyzed. Extraction of EVs was confirmed by electron microscopy. Quality and quantity of circulating miRNA and EV encapsulated miRNA were assessed by Bioanalyzer. In total, 26 circulating miRNAs ($p = 0.0030 – 0.049$) and 4 EV associated miRNAs ($p = 0.019 – 0.043$) showed significant concentration differences between responders and non-responders. Of these, 2 miRNAs were in common. **Conclusions:** Circulating miRNA and EV containing miRNA have potential as predictive biomarkers for anti PD-1/PD-L1 treatment response. We are in the process of identifying and validating circulating miRNA and EV miRNA signatures associated with response to anti PD-1/PD-L1 therapy.

3059 Poster Session (Board #273), Mon, 8:00 AM-11:30 AM

Activity of ramucirumab (R) with pembrolizumab (P) by PD-L1 expression in advanced solid tumors: Phase 1a/b study in later lines of therapy. *First Author: Roy S. Herbst, Yale University School of Medicine, New Haven, CT*

Background: R (anti-VEGFR2) and P (anti-PD-1) are active in patients (pts) with previously-treated non-small cell lung carcinoma (NSCLC), gastric or gastroesophageal adenocarcinoma (G/GEJ) and urothelial carcinoma (UC). Because PD-L1 expression may be a predictive biomarker, we examined the effect of R + P in relation to PD-L1. **Methods:** Eligible pts had progressive advanced or metastatic G/GEJ, NSCLC and UC, ECOG PS 0-1, and baseline tumor tissue. PD-L1 was assessed using the PD-L1 IHC 22C3 pharmDx assay, where the number of stained tumor cells (tumor proportion score; TPS) or tumor and immune cells (combined positive score; CPS) is relative to total tumor cells. PD-L1 positivity was defined by CPS $\geq$1% in G/GEJ and UC, and defined by TPS $\geq$1% in NSCLC. Primary objective was safety and tolerability of R + P. **Results:** As of 31-July-2017, 92 pts received P 200 mg on Day 1 q3W with R at 10 mg/kg on Day 1 (G/GEJ, n = 17; NSCLC, n = 27; and UC, n = 24) or R at 8 mg/kg, Day 1 and 8 q3W (G/GEJ, n = 24). Baseline demographics and characteristics were as expected for an advanced, previously treated population. Median follow-up duration for G/GEJ, NSCLC, and UC, was 17.9 months (mo), 20.1 mo, and 17.5 mo, respectively. The safety profile was consistent with that of each individual drug, with no additive toxicities. 84 (91%) of 92 pts were evaluable for PD-L1. Objective response rate (ORR), progression-free survival (PFS), and overall survival (OS) by PD-L1 are shown in the table. 13 pts remained on study treatment (G/GEJ, n = 4; NSCLC, n = 8; and UC, n = 1). Clinical trial information: NCT02443324. NR = not reached **Conclusions:** In previously treated G/GEJ, NSCLC, and UC, R + P appears to provide more benefit in PD-L1 positive compared to PD-L1 negative pts. Randomized trials are warranted. Updated safety and efficacy results will be presented at the meeting.

Cost of inpatient admissions for immune-related adverse effects from immune checkpoint inhibitor therapy: A single center experience. *First Author: Jacqueline N. Chu, Massachusetts General Hospital, Boston, MA*

Background: Immune checkpoint inhibitors such as anti-CTLA4 and anti-PD1 antibodies represent a paradigm shift in the treatment of many advanced malignancies. However, immune related adverse effects (irAEs) result in increasing inpatient admissions and the cost burden related to irAEs is unknown. We describe the cost of admissions for irAEs to a tertiary academic center. **Methods:** Data were collected on patients treated with checkpoint inhibitors who were admitted to Massachusetts General Hospital (Feb 2011 to June 2017). Admissions were classified as irAE-related or non irAE-related after review by two independent physicians, including one subspecialist. Admission costs were obtained using our institution's platform, a transition cost accounting system (TSI), to estimate total, variable, and direct costs, which were converted to 2017 USD. **Results:** The annual cumulative cost of all admissions for irAEs rose from $218,700 in 2011 to $1.3 million in 2016. However, the average cost of irAE admissions was significantly lower than that of non-irAE admissions ($3,142/day vs. $8,257/day, $p = 10^{-10}$). irAE cost by therapy was not significantly different. irAE costs by organ varied from $1,990 to $6,674/day. **Conclusions:** Although total costs for irAE admissions have risen almost six-fold from 2011 to 2016, these admissions are less costly compared to other oncologic admissions, possibly because irAEs are more readily intervenable. The added cost burden to usual oncologic care from irAEs may be less than anticipated.

Year	N	Annual cumulative cost of irAE admissions (US$)				
2011	15	218,739				
2012	14	247,592				
2013	21	302,538				
2014	44	774,399				
2015	37	715,601				
2016	59	1,271,187

3061 Poster Session (Board #275), Mon, 8:00 AM-11:30 AM

Veliparib in combination with nivolumab and platinum doublet chemotherapy (CT) in metastatic/advanced NSCLC. *First Author: Jeffrey Melson Clarke, Duke University Medical Center, Durham, NC*

Background: Veliparib (V), a PARP inhibitor, combined with platinum (Pt) doublet CT has shown promise in a Phase 2 study of NSCLC. Nivolumab (N), a PD-1 inhibitor, has demonstrated single-agent activity in relapsed NSCLC. This is the first study evaluating dose and safety of V combined with N + Pt-doublet CT. **Methods:** This Phase 1, dose-escalation study (NCT 02944396) enrolled adult patients (pts) with metastatic or advanced NSCLC, ECOG 0-1, and no prior cytotoxic CT, anti-PD-1 or PARPi. Primary objective was to establish the recommended Phase 2 dose (RP2D) of oral V BID combined with N (360 mg) and carboplatin (C, AUC 6)/paclitaxel (Pac, 200 mg/m^2) or C (AUC 6)/pemetrexed (Pem, 500 mg/m^2). Combined with N, dose cohorts were 120 mg V + C/Pac or 80-200 mg V + C/Pem for 6 cycles (cycle = 21 d), or until unacceptable toxicity or disease progression, followed by N + Pem maintenance as indicated. DLTs incl. hematologic and non-hematologic AEs delaying treatment (tx), requiring dose modifications, and attributed to V. Safety, PK, and anti-tumor activity by RECIST 1.1 were assessed. **Results:** As of December 15, 2017, 17 pts (median age 61) with Stage IV NSCLC were enrolled (11 non-squamous for V + N + C/Pem; 1 non-squamous and 5 squamous for V + N + C/Pac). Median drug exposure was 105 d (range 3-284). Primary discontinuation of V occurred in 41% due to AE (2), PD (1), physician decision (1), pt withdrawal (1), death (1), or other (1). No DLTs were reported. Tx-emergent AEs incl. fatigue (47%), nausea (35%), anemia (35%), neutropenia (29%) and thrombocytopenia (29%). Grade 3/4 AEs additionally incl. febrile neutropenia, increased lipase, pneumonitis, and rash (6% each). SAEs additionally incl. sinus arrhythmia, acute kidney injury, pleural effusion, pulmonary embolism, and sudden death (6% each). ORR was 27% [95% CI 6, 61] for V + N + C/Pem and 17% [0, 64] for V + N + C/Pac. For V + N + C/Pem, best response was PR (50%) or SD (50%). For V + N + C/Pac, best response was PR (50%). PK data will be presented. **Conclusions:** RP2D is 120 mg for V + N + C/Pac, and has not been determined for V + N + C/Pem (to date, highest tolerated dose is 200 mg). V combined with N + Pt-doublet CT showed anticipated safety signals, with no additional toxicity of V when added to these regimens. Clinical trial information: NCT 02944396.

3062 Poster Session (Board #276), Mon, 8:00 AM-11:30 AM

A six-weekly (Q6W) dosing schedule for pembrolizumab based on an exposure-response (E-R) evaluation using modeling and simulation. *First Author: Mallika Lala, Merck & Co, Inc., Rahway, NJ, US*

Background: Pembrolizumab is currently approved for use in multiple cancer indications at a dose of either 200 mg or 2 mg/kg Q3W. An alternative extended dosing regimen would provide convenience and flexibility to patients and prescribers. Robust characterization of pembrolizumab pharmacokinetics (PK) and E-R relationships for efficacy and safety allow the use of model-based approaches to support alternative dosing regimens. **Methods:** The dose for a Q6W schedule was selected by matching exposures with the approved Q3W (200 mg and 2 mg/kg) regimens; efficacy and safety are bridged based on E-R assessments. Exposures were simulated using the established population PK model of pembrolizumab that adequately described PK across multiple tumor types. Regimens are compared on - A) Exposure metrics at steady state: AUCss or time-averaged concentration (Cavg,ss) and trough concentrations (Cmin,ss); B) Predicted clinical endpoints (e.g., objective response rate) in patients with multiple approved tumor types. Safety at the Q6W schedule is bridged by ensuring predicted peak concentrations at steady state (Cmax,ss) are below those at the maximum clinically administered and well-tolerated dose of 10 mg/kg Q2W. **Results:** The 400 mg Q6W dosing regimen had similar predicted exposures (Cavg,ss or AUCss, geometric mean (GM) ~1% higher) compared to those achieved at 200 mg Q3W. Less than 1% subjects had Cmin,ss lower than that for 200 mg Q3W. The GM of predicted Cmax,ss for 400 mg Q6W was ~65% lower than for 10 mg/kg Q2W. Given the similar exposures and established E-R relationships for pembrolizumab over a 5-fold range of clinically tested doses, the clinical outcomes achieved with 400 mg Q6W are predicted to be similar as with 200 mg Q3W across tumor types. **Conclusions:** A 400 mg Q6W dosing regimen of pembrolizumab leads to exposures that are similar to the approved 200 mg Q3W dosing regimen. Based on the robust understanding of pembrolizumab clinical pharmacology, including well-established E-R profiles, such a less frequent dosing regimen is expected to produce similar efficacy, safety, and benefit-risk profile in all clinical treatment settings where 200 mg Q3W pembrolizumab is currently approved.

3063 Poster Session (Board #277), Mon, 8:00 AM-11:30 AM

Hyperprogressive disease (HPD) in early-phase immunotherapy (IO) trials. *First Author: Yada Kanjanapan, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: A subset of patients (pts) treated with immune checkpoint inhibitors experience an accelerated tumor growth rate (TGR) compared with pre-treatment kinetics, known as hyperprogression. The aim of this study was to explore the relationship between HPD, treatment-related toxicity and clinical factors. **Methods:** Consecutive pts enrolled in early-phase trials involving checkpoint inhibitors and/or costimulatory molecules at Princess Margaret Cancer Centre between 8/2012 – 9/2016 with CT scans available for RECIST 1.1 assessment in the pre-IO treatment (reference, REF) and post-IO treatment (experimental, EXP) periods were reviewed. HPD was defined as RECIST progression at the first on-treatment scan and ≥2-fold increase in TGR between EXP and REF periods. Pts who had prior IO were excluded. Treatment-related toxicities requiring systemic corticosteroids, hormone replacement, IO delay or cessation were considered clinically significant adverse events (CSAEs). **Results:** 182/352 pts were eligible for analysis. Median age was 61, 54% were male and ECOG performance status (PS) 0 (32%)/1 (68%). Tumor types were head and neck (18%), gynecological (16%), lung (15%), gastrointestinal (15%), genitourinary (12%), melanoma (8%), sarcoma (7%), endocrine (5%) and breast (4%) cancers. Median prior lines of therapy was 1 (range 0 – 7). Royal Marsden Hospital (RMH) prognostic score was 2 or 3 in 59% of pts. 146 pts (80%) received IO monotherapy. IO agents included checkpoint inhibitors in 97% and/or costimulatory molecules in 10% of pts. 13/182 (7%) had HPD, with TGR EXP 2-14 folds greater than TGR REF. CSAEs occurred in 20% of pts and was not associated with HPD. There was also no association between HPD and age, PS, tumor type, RMH prognostic score or use of single agent vs combination IO. Median follow-up was 8.4 months. One-year survival was 57% in HPD and 53% in non-HPD pts; with no significant differences in survival adjusted for RMH score between the 2 groups (HR 0.75, 95% CI 0.32 – 1.76, p = 0.5). **Conclusions:** We observed a 7% rate of HPD within a range of solid tumors treated IO, comparable to other reports. There was no association between HPD and CSAEs, age, tumour type or type of IO therapy. Further studies are needed to identify predictors of HPD.

3064 Poster Session (Board #278), Mon, 8:00 AM-11:30 AM

Correlation between immune-related adverse events (irAEs) and efficacy in patients with solid tumors treated with immune-checkpoints inhibitors (ICIs). *First Author: Mariona Riudavets, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain*

Background: ICIs are associated with irAEs. We describe the incidence of irAEs in patients with solid tumors receiving ICIs and its correlation with efficacy. **Methods:** We retrospectively analyzed all patients with solid tumors receiving ICIs in our center. IrAEs were graded according CTCAE v4.0. Kaplan Meier and log-rank tests were used to evaluate progression-free (PFS) and overall survivals (OS). Analyses were performed using SPSS v24 package. **Results:** From March 2014 to January 2018, 178 patients received ICIs. Median age was 64.1 [33-88] years, 72% were male. Most frequent tumors were lung (63.5%), bladder (14.6%) and melanoma (11.8%). 96% presented advanced disease. Most common used ICIs were nivolumab (38.2%), pembrolizumab (28.7%) and atezolizumab (17.4%). ICIs were used as monotherapy (74.7%) or in combination with ICI (3.4%), chemotherapy (17.4%) or targeted therapies (4.5%). Median duration of immunotherapy was 6.9 [0.7-46.3] months. 95 (53.4%) patients developed 158 irAEs with a median number per patient of 1.2 [0-4]. Most frequent irAE was rash (24.7%) followed by diarrhea (17.7%), hypothyroidism (9.5%), arthritis (6.9%), hyperthyroidism (3.8%), pneumonitis (3.2%) and mucositis (3.2%). Median time to the onset irAEs was 53.2 [11-490] days. 12 (6.7%) patients presented grade (G) 3-4 irAEs: 5 G-3 diarrhea, 2 G-3-4 liver dysfunction, 1 G-3 pneumonitis, 1 G-3 hypopituitarism, 1 G-3 mucositis, 1 G-3 arthritis and 1 G-3 nephritis. There were 2 (1.1%) treatment-related deaths due to pneumonitis. 21.3% patients required steroids for irAEs management. 8.4% patients discontinued treatment due to irAEs. 73.9% irAEs had improved at the time of analysis. OS was superior in patients with advanced disease experiencing irAEs: 37.3 [95%CI, 19.2-51.4] *vs* 7.8 [95%CI, 4.9-10.8] months ($p < 0.0001$). Similarly, PFS was longer: 7.9 [95%CI, 4.4-11.4] *vs* 2.6 [95%CI, 2.0-3.2] months ($p < 0.0001$). **Conclusions:** There was a significant correlation between presence of irAEs and outcomes in patients with advanced solid tumors treated with ICIs.

3065 Poster Session (Board #279), Mon, 8:00 AM-11:30 AM

A meta-analysis to indirectly compare the safety and efficacy of PD-1 and PD-L1 antibodies across solid tumors using a Bayesian hierarchical model. *First Author: Mythili Koneru, Eli Lilly and Company, New York, NY*

Background: Many PD-1/PD-L1 mAb are in development across a broad range of tumors. The expanded literature provided an opportunity to address a critical question: if PD-1 mAbs targeting the receptor have a different safety/efficacy profile than the PD-L1 mAbs targeting the ligand. Direct comparison of these mAb would be ideal but highly unlikely. **Methods:** We performed a meta-analysis using a Bayesian model to provide indirect comparison based on data in the public domain including PubMed and key medical conference abstracts (eg ASCO, ESMO etc.). Key inclusion/exclusion criteria include patients 1) with any specific solid tumor, 2) PD-L1 status if tested using one of the approved assays, 3) received one of the five approved mAbs as a monotherapy, and 4) with disclosure date between June 4th, 2013 and June 6th, 2017. The search resulted in about 70 clinical trials in 31 tumors and 12,025 patients. The endpoints include ORR, PFS for efficacy and the overall G3/4 AE rate for safety. **Results:** For efficacy, in all solid tumors except for HNSCC, ORR is slightly greater for PD-1 than PD-L1 mAb, with the largest odds ratio (OR) in 2L+ NSCLC favoring the PD-1 mAb [$ORR_{PD\text{-}1}$= 19.8% vs $ORR_{PD\text{-}L1}$= 16.5%, OR = 1.27, 95% CI = (0.96, 1.70)] and the smallest OR in 1L HNSCC favoring the PD-L1 mAb [$ORR_{PD\text{-}1}$= 27.4% vs. $ORR_{PD\text{-}L1}$= 28.7%, OR = 0.975, 95% CI = (0.38, 1.50)]. Overall, there is 81% posterior probability that ORRs are equivalent for PD-1 and PD-L1 mAb. For safety, the Gr 3/4 AE rate (e.g. pneumonitis) is numerically higher for PD-1 than PD-L1 mAb [OR = 1.48, 95% CI = (0.19, 12.39)] across tumors. Overall, there is 79% posterior probability that the safety profile in terms of G3/4 AE rate is equivalent for PD-1 and PD-L1 mAb. **Conclusions:** There was no significant difference between PD-1 and PD-L1 mAb across tumor types for ORR, PFS and Gr 3/4 AE rate. Moreover, when the information was analyzed across tumor types, the small magnitude of the difference relative to the variability across tumor types suggests strong interchangeability of efficacy and safety profile of the antibodies targeting either PD-1 or PD-L1. Ultimately, the variability within this class of antibodies is not likely to be clinically meaningful.

3066 Poster Session (Board #280), Mon, 8:00 AM-11:30 AM

Clinical and pharmacological parameters associated with nivolumab toxicity. *First Author: Laure Hirsch, Department of Medical Oncology, Cochin Hospital, Paris Descartes University, AP-HP, CARPEM, Immunomodulatory Therapies Multidisciplinary Study group (CERTIM), Paris, France*

Background: The occurrence of severe, acute limiting toxicity in patients receiving anti-PD-1 monoclonal antibodies, such as nivolumab, is largely unpredictable. Sarcopenia was found associated with anti-CTLA4 acute toxicity (Daly LE et al, Br J Cancer 2017). We studied the clinical and pharmacological parameters influencing nivolumab toxicity, including body composition. **Methods:** From June 2015 to December 2016, all consecutive patients treated with nivolumab in our institution were prospectively included. We studied the relationship, using logistic regression, between muscle mass, assessed by computed tomography and by Janmahasatian formula, nivolumab trough levels (C_{min}) assayed using ELISA method, and the occurrence of grade 3 or 4 toxicity or any toxicity leading to treatment discontinuation (ALT). Univariate and multivariate analysis were made for parameters associated with nivolumab concentration. **Results:** Out of 92 patients, 81 were analyzable for body composition and 84 for nivolumab pharmacokinetics. The population included 63% males, median age 65 years, a majority had lung cancer (72%). We observed 20 ALT including 4 pneumonitis and 4 colitis in 20 (21.7%) patients and 825 (2.4%) nivolumab infusions. The ALT events were more frequent in sarcopenic patients (OR = 3.29, 95% CI: 0.96-11.28, p = 0.06). Sarcopenic overweight patients were the most susceptible to experience ALT (OR = 5.08, CI: 0.53-48.9; p = 0,16), as already reported by our group in melanoma patients (Heidelberger V et al, Invest N Drugs, 2017). The nivolumab C_{min} was 17.0 $\pm$ 5.9 μg/mL on day 14. In multivariate analysis, low nivolumab C_{min} was independently associated with hypoalbuminemia ($<$ 35g/L) (OR = 0.03, 95% CI: 0.002-0.34, p = 0.005) and sarcopenia (OR = 0.13, 95% CI: 0.03-0.54, p = 0.005). The recycling of albumin and nivolumab is both mediated by the neonatal Fc receptor (FcRn) and therefore albumin levels may reflect the abundance and efficiency of FcRn. **Conclusions:** Body composition influences both nivolumab pharmacokinetics and acute toxicity.

3067 Poster Session (Board #281), Mon, 8:00 AM-11:30 AM

Intestinal microbiota to predict lung cancer patients at risk of immune-related diarrhea. *First Author: Tian Liu, Department of Medical Oncology, Chinese PLA General Hospital, Beijing, China*

Background: Anti-programmed cell death protein-1 (PD-1) antibodies represent an effective treatment for lung cancer. However, previous studies showed that a number of patients treating with anti-PD-1 antibodies experience immune-related diarrhea. Intestinal microbiota plays a vital role in gastrointestinal dysregulation including diarrhea. Nevertheless, The association between intestinal microbiota and immune-related diarrhea is still elusive. Our study aims to identify specific intestinal microbiota as potential biomarkers for immune-related diarrhea in patients treating with anti-PD-1 antibodies. **Methods:** Fecal samples of 26 advanced lung cancer patients were obtained before the first dose of anti-PD-1 antibodies. Based on whether they develop diarrhea or not, the patients were subgroup into progressed to diarrhea(PtD) group and diarrhea-free(D-F) group. Immune-related diarrhea was graded according to CTC version 4.0. And 16S rRNA sequencing was used to profile fecal bacterial composition.The onset of diarrhea and fecal bacterial composition were retrospectively analyzed. **Results:** Of the 26 patients, 8 patients experienced diarrhea after the treatment of anti-PD-1 antibodies. Compared to the diarrhea-free patients, patients with diarrhea had similar microbial richness and diversity based on Alpha diversity analysis. While referring to Beta diversity, weighted-UniFrac PCoA analysis demonstrated significant differences in bacterial composition among the two group. Moreover, At the phylum level, Bacteroidetes were significantly richer in D-F group than that in PtD group, and Firmicutes were poorer. Whereas, Veillonella from Proteobacteria phylum was obviously lower in D-F group than that in PtD group. At the genus level, two families of the Bacteroidetes phylum (Bacteroides and Parabacteroides) and a family of the Firmicutes phylum (Phascolarctobacterium) were more abundant in D-F group. Veillonella from Proteobacteria phylum was lower in D-F group than that in PtD group. **Conclusions:** Intestinal microbiota variation is associated with the onset of immune-related diarrhea. Identifying these biomarkers may help to diagnose and prevent the side effect earlier.

3068 Poster Session (Board #282), Mon, 8:00 AM-11:30 AM

A phase 1 study of ALX148, a CD47 blocker, alone and in combination with established anticancer antibodies in patients with advanced malignancy and non-Hodgkin lymphoma. *First Author: Nehal J. Lakhani, START Midwest, Grand Rapids, MI*

Background: CD47, a marker of self, is a myeloid checkpoint that is upregulated by tumor cells to evade the host's immune response. ALX148 is a fusion protein comprised of an engineered high affinity CD47 binding domain of SIRPα genetically linked to an inactive Fc region of human immunoglobulin. We have previously shown ALX148 blocks CD47 and safely enhances the activity of targeted anticancer antibodies and checkpoint inhibitors through Fc dependent and independent mechanisms in nonclinical models (ASH 2017 #112). **Methods:** As of Feb 07, 2018, 30 patients (pts) were enrolled to escalating dose cohorts of ALX148 (0.3 mg/kg [mpk] IV every week [QW] - 30 mpk every other week [QoW]) as a single agent (Part 1) or in combination with standard regimens of pembrolizumab (P), trastuzumab (T), or rituximab (R) (Part2). The primary endpoint for each Part is first cycle dose limiting toxicity (DLT). Tumor response, pharmacokinetics (PK), and CD47 target occupancy (TO) are also characterized. **Results:** Part 1 results are summarized. 25 pts received single agent ALX148. 22 pts experienced any AE. Maximum CTCAE treatment related AEs that occurred in $>$ 1 pt were Dizziness 2G1; Fatigue 3G1; Headache 4G1; Rash 1G1,1G2; and Thrombocytopenia 2G3. Two pts experienced a DLT (Neutropenia with infection, 3mpk; Thrombocytopenia with significant bleed, 30 mpk). There were 4 pts who reported $\geq$G3 AE (Infection 1G3, 3mpk; Pancreatitis 1G3, 30 mpk; Thrombocytopenia 1G3, 3 mpk and 1G3, 30 mpk; Neutropenia 1G4, 3mpk) and 1G5 Death (30mpk; etiology being investigated). No single agent MTD was identified, and the maximum administered dose (MAD) was 30 mpk QoW. Four pts achieved stable disease including 1 pt with NSCLC who had a 15% tumor reduction. ALX148 demonstrated linear PK at doses $\geq$ 10 mpk QW and full TO at doses $\geq$ 3 mpk QW. To date, 5 Part 2 pts received ALX148 (10 mpk QW) in combination (3 with P; 1 with T; 1 with R). **Conclusions:** ALX148 is generally well tolerated in pts with advanced tumors with favorable PK/TO characteristics at doses evaluated. The MAD of single agent ALX148 is 30 mpk QoW. Accrual to the Part 2 combination cohorts is ongoing. Clinical trial information: NCT03013218.

3069 Poster Session (Board #283), Mon, 8:00 AM-11:30 AM

Can body composition (BC) be predictive for outcomes and severe toxicities (ST) in metastatic solid tumors patients (pts) treated with checkpoint inhibitor (CPI)? An analysis of 145 patients. *First Author: Sophie Cousin, Institut Bergonié, Bordeaux, France*

Background: BC parameters have previously been associated with treatments toxicities, and worst outcomes in metastatic solid tumors pts. We studied association between BC parameters and their changes, with ST and outcomes in pts receiving CPI. **Methods:** Pts consecutively treated with CPI between December 2013 and December 2016 in our institute (Institut Bergonié, Bordeaux, France) for metastatic solid tumor and with a baseline computed tomography (CT0) scan $<$28 days before CPI beginning were included. BC parameters were assessed with Slice-O-Matic software V4.3 (Tomovision, Montreal, Canada), using third lumbar vertebra as standard landmark, normalized for height (cm2/m2). **Results:** 145 pts were included (73 female, median age: 62). 124 had a CT scan after 2 months of CPI (CT2). Tumor type was non small cell lung cancer in 80 (55%) pts. 68 pts had received $>$1 line of chemotherapy before. CPI treatment was: anti PD-1, anti PD-L1, anti PD-L1/CTLA-4 combination in 113, 13, and 19 pts, respectively. ST included: Grade III-V toxicity according to NCI-CTC v4.0, unscheduled hospitalization, definitive CPI treatment discontinuation. 15 pts (10.3%) had ST. None of the baseline clinical, nutritional, and BC parameters was associated with ST. In multivariate analysis, subcutaneous adipose tissue index (SATI) decrease $>$-10% between CT0 and CT2 was significantly associated with occurrence of ST (OR=5.3, p=0.027). Median Overall survival (OS) was 402 days. Median progression free survival (PFS) was 86 days. In multivariate analysis, 3 BC-related parameters were significantly associated with worse OS: body mass index $<$ 25 (HR=2.375, p=0.030), Skeletal muscle index (SMI) decrease $>$-10% (HR=4.603, p=0.007), and visceral adipose tissue index (VATI) decrease $>$-10% (HR=8.470, p=0.030). Only SMI decrease $>$-10% was predictive of PFS (HR=3.643, p=0.001). **Conclusions:** Our results demonstrates that body composition is associated with clinical outcomes of cancer patients treated with CPI. Early decrease of SATI is predictive of ST whereas early decrease of skeletal muscle index and of VATI are associated with worse OS.

3070 Poster Session (Board #284), Mon, 8:00 AM-11:30 AM

Comparative analysis of durable responders on immune checkpoint inhibitors (ICI) versus other systemic therapies: A meta-analysis of phase III trials. *First Author: Elvire Pons-Tostivint, Department of Medical Oncology, Institut Curie, Paris, France*

Background: Durable responses have been reported with ICI. We aimed at quantifying the proportion of patients experiencing a durable response on ICI, and comparing it to the proportion observed with other systemic therapies including targeted therapy and chemotherapy. **Methods:** We retrieved all phase III trials that included at least one ICI arm. The proportion of durable responders was evaluated for each treatment arm by estimating the proportion of patients who had a progression-free survival (PFS) exceeding 3 times the median PFS. The proportion of patients who experienced an overall survival (OS) that exceeded 2 times the median OS was also estimated in each arm, from the published survival curves. The impact of the tumor type and the line of treatment were evaluated. Groups were compared using the Mann-Whitney test. **Results:** 20 phase III trials involving 12,834 pts (8275 in ICI arms) treated for 8 different types of cancer in 44 treatment arms were retrieved. Median follow up was 15 months [range: 5.6-36.6]. Treatment was ICI alone, chemotherapy, a tyrosine kinase inhibitor, a vaccine, a placebo and ICI + chemotherapy in 24 (54.5%), 13 (29.5%), 1 (2.3%), 1 (2.3%), 2 (4.5%), and 3 (7%) arms. The mean median PFS was 3.8 [95%CI: 3-4.7] *vs* 3.5 months [95%CI: 2.9-4.1] in the ICI alone arm and in the control arms. Mean median OS was 13.9 [95%CI: 10.6-17.2] *vs* 9.7 months [95%CI: 7.8-11.6] in the ICI alone arm and in the control arms ($p = 0.01$). The proportion of patients who experienced a durable response defined as a PFS exceeding 3 times the median PFS was 24.6% [95%CI:20.9-28.3] *vs* 11% [95%CI:8.5-13.5] in the ICI alone and control arms, respectively ($p < 0.0001$). The proportion of patients who survived longer than 2 times the median OS was 29.7% [95%CI: 28-31.3] in the ICI alone group *vs* 21.8% [95%CI: 19.4-24.2] in the control group ($p < 0.0001$). The effect was similar even in patients treated beyond the first-line metastatic setting and in non-melanoma tumor types. **Conclusions:** The proportion of patients experiencing a durable response was more than twice higher on ICI than on other treatments, even in patients treated beyond the first-line metastatic setting and in non-melanoma tumor types.

3071 Poster Session (Board #285), Mon, 8:00 AM-11:30 AM

Preliminary results of the first-in-human, dose-finding PROCLAIM-CX-072 trial of the PD-L1 Probody therapeutic CX-072 as monotherapy in patients (pts) with advanced solid tumors. *First Author: Karen A. Autio, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: In single-agent trials, antibodies (Abs) targeting programmed cell death ligand 1 (PD-L1) improve survival in many cancers but are associated with immune-related toxicities (most commonly in skin, thyroid, liver, and lung), particularly when administered with other anticancer agents in combination. CX-072 is an anti–PD-L1 Probody therapeutic designed to be preferentially activated by proteases in the tumor microenvironment and not in healthy tissue. Preclinically, Probody therapeutics exhibited anticancer activity of the parent Ab but reduced toxicities in models of autoimmunity. **Methods:** This part (A) of the ongoing phase 1-2 PROCLAIM-CX-072 study (Probody Clinical Assessment In Man; NCT03013491) is evaluating CX-072 as monotherapy in a dose escalation cohort in pts with advanced, heavily pretreated solid tumors. Eligible pts include those who are PD-1, PD-L1, and CTLA-4 inhibitor naive, with immunotherapy (IMT) unavailable as a standard of care (SOC) for their disease. CX-072 is given every 14 days in cohorts of doses ranging from 0.03-30 mg/kg IV. **Results:** Escalation is complete (n=22). Median age is 65 years (range, 32-81); pts had 6 (range, 1-13) prior anticancer treatments. One DLT was observed (grade 3 febrile neutropenia; 3 mg/kg); MTD was not reached. Grade 3-4 treatment-related events were observed in 2 pts: febrile neutropenia/thrombocytopenia (3 mg/kg) and elevated AST/ALT (30 mg/kg). Across all dose levels, best response based on change in target lesions from baseline in 17 evaluable pts included 2 PR (thymoma and PD-L1-negative TNBC), 11 SD, and 4 PD. Target lesions decreased from baseline in 7/17 pts (41%) evaluable as per RECIST v1.1. Target lesions decreased from baseline at dose levels ≥3 mg/kg in 5/8 pts (63%). **Conclusions:** Preliminary data for CX-072 in heavily pretreated pts with IMT-naive solid tumors where checkpoint blockade is unavailable as SOC for their disease show a manageable safety profile with signals of antitumor activity. These data warrant further exploration of CX-072 as monotherapy and in combination with other checkpoint inhibitors or targeted therapies. Clinical trial information: NCT03013491.

3072 Poster Session (Board #286), Mon, 8:00 AM-11:30 AM

Preliminary interim results of the first-in-human, dose-finding PROCLAIM-CX-072 trial of the PD-L1 Probody therapeutic (Pb-Tx) CX-072 in combination with ipilimumab (ipi) in patients (pts) with advanced solid tumors. *First Author: Rachel E. Sanborn, Earle A. Chiles Research Institute, Providence Cancer Institute, Portland, OR*

Background: CX-072 is a Pb-Tx directed against programmed cell death ligand 1 (PD-L1), designed to be preferentially activated by tumor-associated proteases but not in healthy tissue. Preclinically, the combination of a PD-1 Pb-Tx with an anti–CTLA-4 antibody showed comparable efficacy but improved safety compared to the non–Pb-Tx combination control. This dose-escalation cohort of CX-072 + ipi in pts with advanced solid tumors was designed to examine the safety and tolerability of combination therapy. Preliminary safety and antitumor activity are reported. **Methods:** In this ongoing phase 1-2 study (NCT03013491), pts receive CX-072 + ipi in a concomitant dosing schedule (study Part B1). Eligible pts are PD-1, PD-L1, and CTLA-4 inhibitor naive. Planned doses are CX-072 0.3-30 mg/kg IV every 21 days + ipi 3 mg/kg or 10 mg/kg IV every 21 days for 4 cycles, followed by CX-072 monotherapy every 14 days. **Results:** As of data cut (Nov 30, 2017), part B1 enrolled 9 pts. Median age was 44 years (range, 28-70); 6 pts (67%) were male. Median number of prior anticancer treatments was 4 (range, 2-18). At the time of data cut, 6 pts remained on treatment. Median number of doses of CX-072 (0.3 and 1 mg/ kg) and ipi (3 mg/kg) was 2 (range, 2-10) and 2 (range, 2-4), respectively. 1 DLT (grade 3 dyspnea, 0.3 mg/kg CX-072 + 3 mg/kg ipi) was observed. MTD has not been reached and dose escalation continues. Grade 1-2 treatment-related adverse events (TRAEs) occurred in 6 pts (67%). 4 grade 3 TRAEs were experienced by 2 pts (22%) and included colitis, pneumonitis, and AST and ALT increases (0.3 mg/kg CX-072 + 3 mg/kg ipi). At cutoff, 1 of 4 evaluable pts showed target lesion reduction of 31% from baseline (0.3 mg/kg CX-072, anal SCC, MSI stable, and intermediate tumor mutation burden). As of Dec 4, this patient had a confirmed PR with 56% reduction in target lesion. **Conclusions:** Preliminary data for CX-072 + ipi show a manageable safety profile and signals of antitumor activity. The study is ongoing, and all cohorts through 10 mg/kg CX-072, the dose selected for monotherapy cohort expansion, are now enrolled. Escalation of ipi dose to 10 mg/kg is pending. Clinical trial information: NCT03013491.

3073 Poster Session (Board #287), Mon, 8:00 AM-11:30 AM

Quality of life in patients with advanced renal cell carcinoma in the randomized, open-label CheckMate 214 trial. *First Author: David Cella, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: In CheckMate 214, overall survival (OS) with nivolumab + ipilimumab (N+I) was superior to sunitinib (S; HR, 0.63; $P<0.001$) with a manageable safety profile as first-line treatment for intermediate/poor (I/P)-risk patients (pts) with advanced renal cell carcinoma (aRCC). We report analyses of health-related quality of life (HRQoL). **Methods:** Pts were randomized 1:1 to receive N 3 mg/kg + I 1 mg/kg every 3 wk for 4 doses then N 3 mg/kg every 2 wk, or S 50 mg/d orally for 4 wk (6-wk cycle). Exploratory HRQoL analyses were conducted on RCC-specific symptoms from the Functional Assessment of Cancer Therapy-Kidney Symptom Index (FKSI-19) and general cancer symptoms were assessed using the Functional Assessment of Cancer Therapy-General (FACT-G) instruments. Analyses used *t* tests (change from baseline [BL] analysis) and mixed-model repeated measures (MMRM; using a predefined 6-m landmark). **Results:** A total of 847 I/P-risk pts were randomized (N+I, 425; S, 422). HRQoL assessment completion rates were >80% in the first 6 m. Statistically significant differences in change from BL on FKSI-19 total scores (mean BL scores: 60.1 [N+I]; 59.1 [S]) favoring N+I were observed at all but 2 post-BL time points through 2 years of follow-up ($P<0.05$). MMRM analysis found a statistically significant difference between arms at 6 m favoring N+I in FKSI-19 total score and most subscores (table). Change from BL results for the FACT-G trended in a similar direction, with N+I scores exceeding those in the S arm throughout 2 years of follow-up. Similarly, MMRM of FACT-G total scores showed significant benefit of N+I at 6 m. **Conclusions:** In addition to the OS benefit and superior safety profile, descriptive data suggest that N+I offers significant and sustained HRQoL improvement vs S in I/P-risk pts with untreated aRCC. Clinical trial information: NCT02231749.

MMRM analysis: FKSI-19.

3074 Poster Session (Board #288), Mon, 8:00 AM-11:30 AM

Single-cell RNA-sequencing and -imaging of melanoma ecosystems reveals sources of resistance to immune checkpoint blockade. *First Author: Benjamin Izar, Dana-Farber Cancer Institute, Boston, MA*

Background: While immune checkpoint blockade (ICB) produces durable responses in some patients with melanoma, most patients derive no clinical benefit, and the molecular underpinnings of ICB resistance (ICR) are elusive. **Methods:** We applied single-cell RNA-sequencing (scRNA-Seq) to > 10,000 malignant and non-malignant cells derived from 31 melanoma tumors, including 15 from patients with ICB, 15 treatment-naïve patients, and 1 patient with clinical response. We applied a novel data-driven method to systematically map cancer programs that promote ICR and T cell exclusion. **Results:** We demonstrate that cancer cell-autonomous ICR programs identified by scRNA-Seq predict comprise several putative mechanisms of resistance, including several that have previously not been described. In addition to functional implications, we generated a clinically applicable signature that was predictive of clinical response (per RECIST criteria) and progression-free survival (PFS): one of patients who underwent RNA-seq of matched pre-treatment and progression (ICR) specimens; and another of 112 melanoma patients with pre-treatment RNA-seq who receive anti-PD-1 monotherapy. This scRNA-Seq derived predictive signature was superior to all interrogated previously published signatures. Furthermore, we demonstrated that pharmacological reversal of these oncogenic cell states can be achieved by CDK4/6-inhibition, and explored the impact of this treatment in melanoma at the single cell level. To determine the role of T cell exclusion from the TME as a potential mechanism of ICR, we performed spatially resolved 30-plex single-cell protein analysis of matching FFPE specimens from 16 of patients who also underwent scRNA-seq. While the integration of these data sets is pending, the presented analytical platforms provide a promising approach to understanding drug resistance within preserved tumor ecosystems. **Conclusions:** Our study provides a high-resolution landscape of oncogenic ICR states, identifies clinically predictive signatures, and forms a basis to developing novel therapeutic strategies that could overcome immunotherapy resistance in melanoma.

3075 Poster Session (Board #289), Mon, 8:00 AM-11:30 AM

Phase I open-label, ascending dose trial of AGEN1884, an anti-CTLA-4 monoclonal antibody, in advanced solid malignancies: Dose selection for combination with PD-1 blockade. *First Author: Breelyn A. Wilky, Sylvester Comprehensive Cancer Center, Miami, FL*

Background: AGEN1884 is a novel fully human IgG1 monoclonal antibody targeting cytotoxic T lymphocyte-associated protein 4 (CTLA-4). **Objective:** Assess the safety, maximum tolerated dose, and pharmacokinetic (PK) and pharmacodynamic characteristics of AGEN1884 in patients with advanced and refractory malignancies. **Methods:** Patients (≥18 years old) with relapsed/refractory lymphoma or solid cancers without curative treatment options received AGEN1884 at 0.1, 0.3, 1, 3 or 6 mg/kg in a "3+3" trial design. An additional 10 patients were enrolled in both 1 and 3 mg/kg dose expansion cohorts. AGEN1884 was administered intravenously (IV) every 3 weeks for 4 doses and then every 3, 6, or 12 weeks at the Investigator's discretion. **Results:** As of 03Jan2018 data cutoff, 33 patients were enrolled in the following cohorts: 0.1 mg/kg (n = 5, 2 not evaluable [NE] for dose-limiting toxicity [DLT]), 0.3 mg/kg (n = 3), 1 mg/kg (n = 10), 3 mg/kg (n = 12, 2 NE for DLT) and 6 mg/kg (n = 3). Median age was 61 years (range 26–88), baseline ECOG scores were 0 (N = 4), 1 (N = 25), unknown (4), with a median of 10 (range 3–26) prior therapies. As of Jan 31, 2018, no DLT's have been reported. Immune-related adverse events were reported in 10 (30.3%) of patients as follows: 0.1 mg/kg (1 [20.0%]), 0.3 mg/kg (1 [33.3%]), 1 mg/kg (1 [10%]), and 3 mg/kg (6 [50%]) and included hypophysitis, colitis, diarrhea, rash and pruritus. Most were mild-moderate consistent with published reports of other CTLA-4 inhibitors. 6 patients (18.2%) came off study due to disease progression or AE's but none related to treatment. Of 11 subjects evaluable for response, 1 with angiosarcoma treated at 0.1 mg/kg attained a CR at 7 months after achieving a PR. Three subjects with SD: 1 at 0.3 mg/kg with adenoid cystic carcinoma at Week 21 who had SD for 53 weeks; 2 subjects at 3 mg/kg: 1 with breast cancer with SD at Week 6 and 1 with invasive metaplastic breast cancer at Week 12 on study. **Conclusions:** AGEN1884 was well tolerated at 0.1, 0.3, 1 and 3 mg/kg dose levels. Enrollment continues at 6 mg/kg. Updated safety and PK data will be presented. A starting dose level of 1 mg/kg has been selected for combination with PD-1 blockade. Clinical trial information: NCT02694822.

3076 Poster Session (Board #290), Mon, 8:00 AM-11:30 AM

Association between PD1 mRNA and response to anti-PD1 monotherapy across multiple cancers. *First Author: Laia Pare, 1Translational Genomic and Targeted Therapeutics in Solid Tumors, August Pi i Sunyer Biomedical Research Institute (IDIBAPS), Barcelona, Spain*

Background: In advanced cancer, the overall response rate (ORR) following anti-PD1 monotherapy is variable (0% to 50%). Here, we hypothesized that this observation is partly explained by different amounts of the drug target (i.e. PD1) in the tumor. **Methods:** RNA-seq data from 10,078 tumors representing 34 cancer-types were obtained from TCGA. The expression of PD1 and 566 immune-related genes/signatures were evaluated. Correlations between each gene/signature and ORRs reported in the literature were calculated. We included only studies of anti-PD1 monotherapy that enrolled at least 20 patients (pts) who were not selected for PDL1 expression. To translate the in-silico findings to the clinical setting, we analyzed the expression of PD1 mRNA using the nCounter platform in 694 formalin-fixed paraffin embedded (FFPE) tumor samples from 16 cancer-types. Finally, we evaluated FFPE-based PD1 mRNA from an independent dataset of 102 pts with advanced solid tumors treated with anti-PD1 monotherapy. **Results:** PD1 expression varied significantly across TCGA ($p < 0.001$) with 0% to 84% of tumors within a cancer-type being PD1-high (H) (defined as %ile 80). Interestingly, % of PD1-H tumors within a cancer-type were found highly correlated with ORRs reported in the literature (correlation coefficient [CC] = 0.91), suggesting that 83% of the differences in the ORR across cancer-types may be explained by the abundance of PD1. Lower CCs were identified with different PD1 cutoffs, other genes/signatures and tumor mutational burden. To translate these findings in clinical samples, the expression of PD1 was evaluated in 773 FFPE tumor samples across 17 cancer-types. Using the optimal cutoff (%ile 80), similar proportions of PD1-H tumors within each cancer-type were identified in our in-house FFPE-based cohort compared to TCGA (CC = 0.92). Finally, the optimal PD1 FFPE-based cutoff was found significantly associated with ORR (PD1-H 42.8% vs. PD1-low 17.6; P = 0.018) in 102 pts with advanced cancer treated with anti-PD1 monotherapy. **Conclusions:** Our findings highlight the strong relationship between PD1 mRNA expression and the activity of anti-PD1 therapies across multiple cancers.

3077 Poster Session (Board #291), Mon, 8:00 AM-11:30 AM

Impact of immune checkpoint inhibitor dose on toxicity, response rate, and survival: A pooled analysis of dose escalation phase 1 trials. *First Author: Shiraj Sen, The University of Texas Southwestern Medical School, Dallas, TX*

Background: PK and PD studies demonstrate drug exposure and target saturation of immune checkpoint inhibitors (ICI) at doses below MTD. MTD remains a primary endpoint in ICI phase 1 trials and the optimal dosing to minimize toxicity and optimize response remains unclear. **Methods:** We analyzed clinical data from pts treated in phase 1 ICI dose escalation trials at MD Anderson Center for Targeted Therapy. Patients were stratified into a low-dose [LDG] (< 33% MTD), medium dose [MDG] (34-66% MTD), high dose [HDG] (67-100% MTD), or very high dose [VHDG] (> 100% MTD) group. Groups were compared for irAE, PFS, OS, ORR (CR + PR), and DCR (CR + PR + SD > 6 months). **Results:** Among 90 pts treated with escalating doses of ICI (57 CTLA4- and 33 PD1-based) between April 2013 and December 2015, median age was 59 years (range: 20-86 years) and 37 (41%) were females. The most common tumor types treated included renal cell carcinoma (n = 23; 25%), melanoma (n = 16; 18%), sarcoma (n = 10; 11%), and GIST (n = 10; 11%). PFS in the LDG (n = 16) was 2.76 months (mo) (95% CI 1.48-NA), MDG (n = 21) was 2.76 mo (95% CI 1.48-NA), HDG (n = 36) was 2.46 mo (95% CI 1.84-3.29), and VHDG (n = 17) was 3.68 mo (95% CI 2.76-NA). Log rank p = 0.22. OS in LDG was 6.18 mo (95% CI 3.45-NA), MDG was 17.05 mo (95% CI 3.94-NA), HDG was 5.16 mo (95% CI 4.24-7.62), and VHDG was 7.49 mo (95% CI 5.59-NA). Log rank p = 0.0070. In all evaluable patients, ORR in LDG, MDG, HDG, and VHDG was 0%, 6%, 6%, and 12% (p = 0.47) and DCR was 62%, 71%, 41%, and 81% (p = .027), respectively. irAE rates in LDG, MDG, HDG, and VHDG were 6%, 10%, 17%, and 29% (p = .045). **Conclusions:** Despite a dose-dependent increase in irAE, we identify no improvement in PFS, OS, or DCR with escalating doses of ICI administered in phase I trials but do detect an improvement in ORR. Prospective dose-/exposure-response relationships and biomarker-driven RP2D are warranted on all ICI dose-escalation phase 1 trials. Lower doses may reduce toxicity and cost without compromising disease control or survival.

Dosing	PFS, months (95% CI)	OS, months (95% CI)	ORR (%)	DCR (%)	irAE (%)
LDG	2.76 (1.48-NA)	6.18 (3.45-NR)	0	62	6
MDG	2.76 (1.84-NA)	17.05 (3.94-NR)	6	71	10
HDG	2.46 (1.84-3.29)	5.16 (4.24-7.62)	6	41	17
VHDG	3.68 (2.76-NA)	7.49 (5.59-NR)	12	81	29

3078 Poster Session (Board #292), Mon, 8:00 AM-11:30 AM

Phase II open-label, multi-centre study of bemcentinib (BGB324), a first-in-class selective AXL inhibitor, in combination with pembrolizumab in patients with advanced NSCLC. *First Author: James Lorens, BerGenBio ASA, Bergen, Norway*

Background: Bemcentinib (BGB324) is a first-in-class, oral, potent and highly selective inhibitor of the AXL tyrosine kinase currently in phase II clinical development across several cancer types. AXL over-expression has been observed in pts failing PD-1 therapy in several cancers whereas AXL inhibition via bemcentinib has shown synergistic effect with checkpoint blockade in pre-clinical models of NSCLC. **Methods:** In this single-arm, two-stage Phase 2 study, pts with documented Stage IV lung adenocarcinoma progressed on a single line of platinum-based chemotherapy chemotherapy and – if applicable – at least one line of licensed therapy for EGFR mutations or ALK re-arrangements received 200 mg/d bemcentinib po and 200 mg/q3wk pembrolizumab iv. Patients were required to consent to a fresh pre-treatment biopsy. Tumour assessments were done 9-weekly. The primary endpoint was objective response. Predefined secondary endpoints included disease control rate (DCR), progression free survival (PFS), overall survival (OS) and safety. Tumour biopsies were analysed for PD-L1 and AXL, and infiltrating immune cells. Plasma protein biomarker levels were measured using the DiscoveryMap v3.3 panel (Myriad RBM) in patients pre-dose and at C2D1. **Results:** As of February 2018, 13 pts (median age 66 years) initiated therapy and 11 pts remain on treatment. Combination therapy was well tolerated with the overall serious adverse event profile being similar to that reported for pembrolizumab monotherapy. 1 of 4 pts (25%) who had reached their first scan showed a PR and another patient (25%) had SD. There were no grade 4 treatment-related events. Dose reduction from 200 to 100 mg/d of bemcentinib as a consequence of adverse events was required in 12% of patients. **Conclusions:** Combination treatment of bemcentinib and pembrolizumab was well tolerated. A preliminary analysis of response to combination treatment during the first stage of this study as well as biomarker correlation will be presented at the meeting. Clinical trial information: NCT03184571.

3079 Poster Session (Board #293), Mon, 8:00 AM-11:30 AM

Autoimmune genetic variants as germline biomarkers of response in melanoma immunotherapy treatment. *First Author: Vylyny Chat, New York University School of Medicine, New York, NY*

Background: Immune checkpoint inhibition (ICI) has improved clinical outcomes for metastatic melanoma patients. However, ~ 60% of patients do not respond to ICI and 65-80% experience immune-related adverse events (irAEs). Currently, the personalized biomarkers predicting ICI efficacy or toxicity are limited. Given the link between immunotherapy, irAEs and autoimmunity, we investigated if the baseline genetic susceptibility to multiple autoimmune diseases can modulate clinical efficacy of ICI. **Methods:** By performing a comprehensive search of autoimmune genome wide association studies, we identified 25 SNPs, each associated with at least 3 autoimmune diseases. Using the Agena MassArray, we genotyped 25 SNPs in 389 Caucasian metastatic melanoma patients receiving ICI treatment (N = 214 anti-CTLA4, N = 175 anti-PD1) at one of our collaborative centers. Multivariate logistic regression adjusting for age at treatment and gender was used to test for association of germline variants with ICI efficacy. **Results:** We identified two variants previously associated with multiple autoimmune diseases that may predict ICI efficacy: rs1893217 in PTPN2 (OR = 0.35; 95%CI = 0.17-0.73; p = 0.005) and rs17388568 in the IL2, IL21 cluster (OR = 3.28; 95%CI = 1.62-6.64; p = 0.0009) were associated with clinical benefits in anti-CTLA4 and anti-PD1 ICI, respectively. These variants predict efficacy in opposite direction - rs1893217 was associated with anti-CTLA4 treatment resistance while rs17388568 was associated with anti-PD1 response sensitivity. **Conclusions:** Our study reports two autoimmune germline variants as potential biomarkers of anti-CTLA4 or anti-PD1 ICI efficacy in melanoma and suggests that underlying genetic susceptibility to autoimmunity may play an important role during ICI treatments. rs1893217 in PTPN2, involved in cytokine signaling, has been associated with colitis, celiac disease, inflammatory bowel, rheumatoid arthritis and type 1 diabetes. Similarly, rs17388568 was mapped to important immune-related genes (IL2, IL21 and ADAD1) and associated with allergy, colitis and type 1 diabetes. Additional genetic and functional validation of these findings is underway in a large collaborative setting.

3080 Poster Session (Board #294), Mon, 8:00 AM-11:30 AM

Safety and efficacy results from a phase I dose-escalation trial of Nintedanib in combination with Pembrolizumab in patients with advanced solid tumors (PEMBIB trial). *First Author: Andreea Varga, Gustave Roussy Cancer Campus, Villejuif, France*

Background: We aimed to determine the safety and activity of the nintedanib +pembrolizumab combination. Nintedanib is an oral angiokinase inhibitor targeting the vascular endothelial, platelet-derived and fibroblast growth factor receptors as well as RET. Pembrolizumab is a highly selective, humanized monoclonal IgG4–kappa isotype antibody against PD-1 designed to block the negative immune regulatory signaling of the PD-1 receptor expressed by T cells. **Methods:** PEMBIB is a monocentric phase Ib trial which evaluated escalating doses of nintedanib (Dose level 1 (DL1) = 150 mg BID; DL2 = 200 mg BID) in combination with intravenous flat dose of pembrolizumab at 200 mg every 21 days in patients with advanced solid tumors using the rolling 6 design. A lead-in monotherapy of nintedanib was performed 7 days prior starting pembrolizumab. The primary objective was to establish MTD of this combination based on DLT occurrence during the first 4 weeks (28 days since C1D1) and to determine the recommended phase 2 dose (RP2D). **Results:** As of November 24, 2016, 13 patients (12 evaluable for DLT) have been enrolled in the escalation part : 2 cervical carcinoma, 1 MSI colorectal cancer, 1 triple negative breast cancer, 2 thymic carcinoma, 1 malignant pleural mesothelioma, 1 peritoneal mesothelioma, 1 gastric adenocarcinoma, 1 renal carcinoma, 1 neuroendocrine tumor, 1 nasopharyngeal cancer. The median age was 54, of these 50% were male, all ECOG 0 (83%) or 1. There were no grade 4-5 toxicities. The adverse events reported for more than 2 patients were alanine & aspartate aminotransferase increase, fatigue, anorexia, diarrhea, nausea, vomiting, hypothyroidism. Three dose-limiting toxicities of liver enzymes elevation were observed in 200 mg BID nintedanib thus recommending 150 mg BID nintedanib for the phase II part. Three patients have developed an objective RECIST partial response (ORR = 25%). **Conclusions:** Toxicity was consistent with the safety profile of each drug. Additional data for safety and efficacy is being further evaluated in the expansion part of this trial. The efficacy of the combination is currently further explored in 8 expansion cohorts of 30 patients. Clinical trial information: NCT02856425.

3081 Poster Session (Board #295), Mon, 8:00 AM-11:30 AM

Role of melanoma cell-intrinsic RIG-I and STING signaling for checkpoint inhibitor-mediated anticancer immunity. *First Author: Simon Heidegger, Klinikum rechts der Isar, Technical University Munich, Munich, Germany*

Background: Strong inter-individual variation in clinical response to immune checkpoint inhibitors (ICB) including anti-CTLA-4 remains a major challenge, but the molecular pathways that modulate ICB efficacy remain ill defined. **Methods:** Using CRISPR/Cas9 technology to generate melanoma cells lines that lack nucleic acid receptors or downstream signaling molecules together with available genetically deficient mouse models, we addressed the importance of nucleic acid receptor signaling in both tumor and host cells for the efficacy of anti-CTLA-4 immunotherapy. **Results:** We demonstrate that anti-CTLA-4 immunotherapy relies on melanoma cell-intrinsic activation of the cytosolic RNA receptor RIG-I (*DDx58*) but not the DNA sensing adaptor protein STING. Mechanistically, RIG-I signaling induced caspase-3-mediated tumor cell death, cross-presentation of tumor-associated antigen by $CD103^+$ dendritic cells, subsequent expansion of tumor antigen-specific $CD8^+$ T cells and the accumulation of $CD8^+$ T cells within the tumor tissue. These processes were independent of tumor-cell derived type I IFN (IFN-I), but additionally required host STING, MAVS and IFN-I signaling. Consistently, therapeutic targeting of RIG-I with 5'-phosphorylated-RNA in both tumor and non-malignant host cells potently augmented the efficacy of CTLA-4 checkpoint blockade. **Conclusions:** Our data are consistent with the finding that expression of RIG-I in human melanomas has been associated with clinical benefit to CTLA-4 blockade and identify activation of RIG-I/MAVS signaling in tumors and their microenvironment as a crucial component for checkpoint inhibitor-mediated immunotherapy of cancer. These findings not only nominate tumor intrinsic RIG-I activity as potential biomarker for treatment response to checkpoint inhibitors, but predict that targeting this pathway may serve as a basis for the development of new combined modality approaches to increase the response rate of checkpoint inhibitor-based immunotherapy, particularly in individuals that do not have a sufficient spontaneous antitumor T-cell immune response.

3082 Poster Session (Board #296), Mon, 8:00 AM-11:30 AM

Allo-immunity and graft rejection after checkpoint inhibitor therapy (CPI) in solid organ transplant (SOT) recipients. *First Author: Noha Abdel-Wahab, Section of Rheumatology & Clinical Immunology, Department of General Internal Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The safety of CPI in patients (pts) with prior SOT was never fully assessed because they were always excluded from clinical trials due to the risk of allo-immunity and organ rejection, and being on immunosupresive therapy (IST). **Methods:** We identified from pharmacy records pts who had received CPI between January 2004 and June 2017 at our institution (n = 4,406). Claims data were obtained for all pts from 6 months prior to first infusion to last follow-up or death. ICD 9 & 10 diagnostic codes were used to identify pts with organ transplant (n = 173). Medical records were reviewed to identify SOT pts. We systematically reviewed the literature databases through September 2017 to identify similar pts. **Results:** A total of 24 pts were retrieved, 6 from institutional databases and 18 from literature. Median age was 61.5 (14-79) years; 75% were male; 67% had metastatic melanoma. Other cancer types included cutaneous squamous cell, non-small cell lung, hepatocellular, and duodenal carcinomas. Renal transplant was reported in 67%. Other SOT included liver and heart. Median time to initiation of CPI after SOT was 8 (1-25) years. Most received anti-PD1 agents (79%). At CPI initiation, all pts were kept on prednisone ($\leq$ 10 mg), mTOR inhibitors, or other IST to maintain graft tolerance. Graft rejection occured in 50% of pts (8/16 kidney, 3/6 liver, and 1/2 heart transplants); 92% received anti-PD1 therapy. Median time to rejection was 21 (5-60) days. In 8 pts with biopsies, 6 had a T-cell mediated rejection, and 2 had mixed cellular and antibody infiltrates. Management of rejection included appropriate IST, and 29% remained dependent on dialysis. CPI was discontinued in all pts. Among all rejected cases, only one pt with cardiac transplant recovered. Interestingly, other irAEs occurred mainly in non rejected cases. They all improved with appropriate IST. In melanoma pts, 27% (4/15) responded to CPI. In all pts, death was reported in 35% (n = 8), in 4 pts was due to organ rejection (2 liver and 2 kidney). **Conclusions:** High rejection rate was evident in SOT pts shortly after CPI and was associated with high mortality rate. Further studies are needed to establish the risk-benefit profile in this population.

3084 Poster Session (Board #298), Mon, 8:00 AM-11:30 AM

Neurologic immune related adverse events (irAEs) in patients treated with immune checkpoint blockade. *First Author: Bianca Santomasso, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Neurologic irAEs are uncommon but potentially fatal toxicities of immune checkpoint blockade (ICB). Their incidence, clinical and pathologic features, and association with therapy received are poorly understood. **Methods:** An IRB approved retrospective study was conducted to identify neurologic irAEs of all patients (pts) treated with ICB (anti-CTLA4, anti-PD1, anti-PDL1 monotherapy or in combination) from January 2010 to August 2017 at our institution. Clinical, radiologic, and pathologic features of neurotoxicity were collected. We excluded pts with primary CNS tumors or neurologic symptoms that were attributable to their CNS disease. **Results:** Of 4,864 pts who received anti-CTLA4, anti-PD1, or anti-PDL1 either as monotherapy or in combination, neurologic irAEs developed in 81 (1.67%; 95% CI, 1.34% to 2.06%). Clinical, radiographic, and radiologic features of neurotoxicity were diverse. Time to onset ranged from 3 days to 17 months with a median of 2 doses (1 to 20) received. The incidence was higher with combination therapy versus monotherapy (36 of 1,448 [2.49%] v 45 of 3416 [1.32%]; P = 0.0047), and there was no significant difference in incidence among patients age $\leq$ 65 at time of treatment versus patients age $>$ 65 (41 of 2,705 [1.90%] v 40 of 2,159 [1.85%]; P = 0.3692). Of pts who experienced neurotoxicity, 60% (49 of 81) were hospitalized, 5 (10%) in the ICU. Fifty nine percent (48 of 81) had a concurrent non-neurologic irAEs. Sixty nine percent (56 of 81) had grade 1-2 neurologic events and 77% (63 of 81) improved/resolved with drug holding/immunosuppression. Eight patients worsened clinically or died during the course of neurotoxicity treatment. **Conclusions:** Neurologic irAEs have variable clinical presentation and are more common when anti-CTLA-4 or anti-PD1/PD-L1 mAbs are combined with each other or with other checkpoint inhibitors. Incidence is similar among pts of advanced age and younger pts. Most events improve/resolve with drug holding/immunosuppression, but pts may require hospitalization and experience worsening despite immunosuppression. This underscores the need for earlier identification, as patient outcomes may improve with earlier treatment.

3085 Poster Session (Board #299), Mon, 8:00 AM-11:30 AM

Efficacy and immune modulation by BXCL701 a dipeptidyl peptidase inhibitor, NKTR-214 a CD122-biased immune agonist with PD1 blockade in murine pancreatic tumors. *First Author: Luca Rastelli, bioxcel therapeutics, Branford, CT*

Background: BXCL701 targets DPP8/9 and stimulates migration and cytotoxicity of T and NK cells in addition to targeting fibroblast activator protein (FAP) which forms an immunological barrier to the tumor microenvironment. NKTR-214 is a CD122-biased agonist designed to provide sustained signaling through the heterodimeric IL2 receptor pathway (IL2R$\beta\gamma$) to preferentially activate and expand effector CD8+ T and NK cells. NKTR-214 has demonstrated robust anti-tumor activity when combined with anti-PD1 in multiple murine tumor models and recently, with nivolumab in multiple human cancers. We hypothesized that BXCL701 could further potentiate NKTR-214/anti-PD1 anti-tumor activity by removing fibrotic barriers to immune cells. **Methods:** NKTR-214, BXCL701 and anti-PD1 were dosed in mice bearing established (~100mm^3) murine pancreatic tumors (Pan02) as single agents, doublets and the triplet (0.8mg/kg q9d, 20μg qd, and 200 μg qw2 respectively). Tumors were profiled using IHC and multiplex serum cytokine/chemokine analysis. Tumor-free mice were re-challenged with either Pan02 or murine lung tumor (LLC). **Results:** Of the mice treated with the triplet combination, 100% became tumor-free (9/9) by day 21. These animals remained tumor free for more than 60 days when a subset were re-challenged with new tumor cells. Of these, 5/6 mice rejected tumor regrowth suggesting durable immunity after the triplet therapy. IHC of the tumors from satellite animals sacrificed on day 3 revealed that the triplet significantly reduced FAP expression while increasing the number of immune cell infiltrates in the tumor. **Conclusions:** The triplet of NKTR-214, BXCL701 and anti-PD1 provided 100% tumor-free mice in established pancreatic tumors with concomitant reduction in FAP expression. The results suggest that removal of fibrotic barriers to immune infiltration is an important mechanism for overcoming immune escape by tumors otherwise resistant to immune therapy. These results provide therapeutic rationale for treatment of pancreatic cancer patients with this triple combination.

3086 Poster Session (Board #300), Mon, 8:00 AM-11:30 AM

Phase 1/2 open-label, multiple ascending dose trial of AGEN2034, an anti-PD-1 monoclonal antibody, in advanced solid malignancies: Results of dose escalation. *First Author: Kathleen N. Moore, University of Oklahoma Health Sciences Center, Oklahoma City, OK*

Background: Agenus AGEN2034 is a fully-human IgG4 monoclonal antibody antagonist targeting Programmed Cell Death Protein-1 (PD-1). The objective was to assess safety, MTD, pharmacokinetic (PK) and pharmacodynamics (PD) characteristics of AGEN2034 in patients (pts) with advanced, refractory malignancies. Analyses of PD-1 receptor occupancy on circulating CD8+ and CD4+ effector memory T lymphocytes was completed. **Methods:** Thirty pts were enrolled in escalating dose cohorts of 1, 3, and 10 mg/kg. AGEN2034 is administered intravenously Q2W for up to 2 years with cohorts evaluating q3wk dosing at 6 and 10 mg/kg are underway. **Results:** Ten subjects were enrolled at each dose level. Median age was 58 years (range 23–77) with ECOG 0–1. No DLTs were observed. Immune-related adverse events consistent with this drug class were observed of pneumonitis, colitis, diarrhea, rash and pruritus. 21 of 30 pts had treatment-related adverse events (TRAEs). 13 subjects (43%) discontinued (d/c) due to disease progression and 2 pts d/c due to TRAEs of hepatitis (n = 1) and pneumonitis (n = 1). In 25 evaluable heavily pre-treated pts, three partial responses (two confirmed) were noted in patients with cervical, ovarian and breast cancers in 1mg/kg and 3mg/kg cohorts. At the time of data cut-off, 13 patients had stable disease, including 5 of 5 with ovarian cancer. AGEN2034 demonstrates a dose-proportional C_{max} of 19.6 μg/mL at 1 mg/kg and 73.6 μg/mL at 3 mg/kg in 12 patient samples analyzed in the first two cohorts. Average PD-1 receptor occupancy on circulating CD8+ and CD4+ effector memory T lymphocytes (n = 18) demonstrated $>$ 59% saturation at all dose levels at day 15. **Conclusions:** AGEN2034 is a pharmacologically active, well-tolerated PD-1 antagonist antibody, demonstrating early signals of clinical activity in cervical and ovarian cancers. PK and RO results are comparable to commercial PD-1 antagonists. A phase 2 expansion in pts with relapsed/refractory cervical cancer is underway. Clinical trial information: NCT03104699.

3087 Poster Session (Board #301), Mon, 8:00 AM-11:30 AM

Characterization of immune related hepatitis (irH) from immune checkpoint inhibitors (ICIs). *First Author: Justine Vanessa Cohen, Massachusetts General Hospital, Boston, MA*

Background: Immune related hepatitis (irH) occurs in a subset of patients receiving ICIs. Although the pathologic features of irH have been described, no studies have correlated the histologic findings on liver biopsy with steroid responsiveness. **Methods:** 25 patients with cancer (22 melanoma, 1 cutaneous squamous cell carcinoma, 1 glioblastoma, 1 non-small cell lung cancer) who had a liver biopsy for elevated transaminases were included. 23 patients received anti-PD1, anti-CTLA4 or a combination of ICI with a non-ICI agent. 2 patients underwent biopsies after targeted therapy. Liver biopsies were reviewed for pattern of injury. Steroid response and requirement for secondary immunosuppression was determined from clinical notes. The pattern of hepatic injury was correlated with response to steroids. **Results:** 15 biopsies showed evidence of lobular injury that was often centrizonal, but in some was panlobular, with a histiocytic inflammatory response. In 6, the histiocytes formed granulomas that were loose, well-formed, or fibrin ring type. 5 of the 15 had central vein endothelialitis. Another 3 patients had mild lobular or portal inflammation without typical features of irH. 2 patients had cholestatic patterns, with portal edema, duct injury, or pericholangitis. 2 had fatty liver disease. 3 remaining patients had non-inflammatory patterns of hepatocyte injury such as hepatocyte cytoplasmic rarefaction. 19 (76%) patients required steroids and 6 (24%) required secondary immunosuppression. 11 (73%) of the 15 cases with characteristic irH were steroid responsive (resolution of transaminitis with < 2 months). The 2 cholestatic cases were less responsive to steroids (one required > 2 months of steroids and the other required secondary immunosuppression). Patients with fatty liver and non-inflammatory injury had variable response to steroids. **Conclusions:** ICI hepatitis has a characteristic pattern of lobular injury with histiocytic infiltration, granuloma formation, and endothelialitis on liver biopsy is highly likely to be steroid responsive. A cholestatic pattern of injury predicts less steroid responsiveness. Non-inflammatory hepatic injury on liver biopsy has variable steroid responsiveness.

3088 Poster Session (Board #302), Mon, 8:00 AM-11:30 AM

Identifying new biomarkers and targeted molecules for immunotherapy using targeted RNA next generation sequencing. *First Author: Wanlong Ma, NeoGenomics Laboratories, Aliso Viejo, CA*

Background: Predictive biomarkers for selecting of patients who may benefit or experience serious adverse effects from checkpoint blockade therapy are urgently needed. These biomarkers may vary from one type of tumor to next. Developing a broad approach for the discovery of new tissue-specific predictive biomarkers may also help guide combination therapy. We used targeted RNA sequencing for the discovery of biomarkers that are co-regulated with PD-L1. **Methods:** We used RNA sequencing of 1385 genes to profile tissues from solid tumors and lymphomas and correlated RNA levels with PD-L1 expression as detected by IHC in tumor and inflammatory cells. **Results:** After normalization, adjusting for group effect and multiple hypothesis testing, 21 genes correlated with PD-L1 expression; fourteen genes correlated positively and 7 correlated negatively. Using the first principle component, we demonstrated that these 21 genes are highly redundant in predicting levels of IHC PD-L1 expression and practically any one can be used as a biomarker. Using LASSO to develop a multivariate model, we demonstrated that RNA levels of *CD274*, *PLAU* (*uPA*), and *RAC1* are independent biomarkers predictive of IHC PD-L1 expression. **Conclusions:** RNA expression, measured using targeted NGS, is a reliable alternative to IHC PD-L1 expression testing. We showed that RNA levels of *CD274*, which codes for PD-L1, and 20 other genes can be used interchangeably in predicting IHC PD-L1 expression. Further, as RNA expression of *PLAU* and *RAC1* are independent from *CD274*, targeting *PLAU* and *RAC1* in combination with PD-L1 inhibitors potentially may augment the therapeutic effects of anti-PD-L1 therapy.

3089 Poster Session (Board #303), Mon, 8:00 AM-11:30 AM

Pelareorep to promote the expression of a IFN-gamma-related gene signature that predicts response to checkpoint blockade therapy. *First Author: Grey A Wilkinson, Oncolytics Biotech Inc., Calgary, AB, Canada*

Background: A clinical study in patients (pts) with metastatic breast cancer (mBC) treated with pelareorep resulted in significant improvements in overall survival. Clinical studies with checkpoint blockade inhibitors (CBIs) have also resulted in noteworthy clinical responses in a small subset of mBC pts. In pts who do not respond to CBIs, the absence of IFN-γ signalling in the tumor microenvironment has been proposed as a key mediator of innate resistance. IFN-γ signalling upregulates the expression of checkpoint ligands and promotes lymphocyte activation and infiltration to the tumor microenvironment. Thus, the expression of IFN-γ-related genes can be used to both facilitate and predict response to CBIs. Given pelareorep's known capacity to promote an inflamed tumor phenotype, we hypothesised that pelareorep could also stimulate the expression of IFN-γ-related genes associated with response to CBIs. **Methods:** Cell lines derived from breast cancer (BC: MCF7, T47D, MD-231), colorectal cancer (CRC: HT-29, SW620), hepatocellular carcinoma, (HCC: SNU-387) and non-small cell lung cancer (NSCLC: H522) were infected with pelareorep at a multiplicity of infection equal to 50. We examined changes in gene expression and conducted cell viability assays at 6, 12, and 18 hours post-infection (including a non-infected control). To monitor changes in gene expression we employed a 780-gene panel (nanoString) to monitor for changes in the expression of key IFN-γ-related and other immunity-related genes. **Results:** All cell lines were susceptible to pelareorep induced cytopathic effect. Strikingly, BC and HCC cells lines significantly upregulated IFN-γ-related genes while CRC and NSCLC cell lines demonstrated only a modest and variable ability to promote IFN-γ pathway activation. Moreover, BC and HCC cells lines also upregulated key chemokines that are known to promote response to immunotherapy. **Conclusions:** These results suggest that various tumor types are amenable to immune priming for CBIs therapy with pelareorep. The role of pelareorep in the treatment of BC and HCC deserves further investigation, particularly in combination with other immunotherapies.

3090 Poster Session (Board #304), Mon, 8:00 AM-11:30 AM

Analysis of inflammatory signatures of cancer spheroids in blood and their role in metastasis. *First Author: Peter Geck, Tufts University School of Medicine, Boston, MA*

Background: Cancer mortality correlates with metastatic progression where genetic/epigenetic changes in the cancer are important. Recent data indicate, however, that the host thrombotic and inflammation responses are also critical in the metastatic process, but not well understood. We performed exploratory observational studies by filter-capturing cancer spheroids/clusters in blood and studied inflammatory signatures. We investigated the hypothesis that thrombotic/inflammatory factors can stabilize circulating cancer stem cell clusters and critical in metastasis. **Methods:** Cancer spheroids were collected from the blood of 25 metastatic patients (clinically verified metastasis; > 6 months post-treatment) and 25 samples from controls. Gene expression studies in the spheroids targeted EpCAM (epithelial cancer origin); SOX2, NANOG and OCT4 (stem cells); platelet specific selectin (Sel-P) and CD41; IL1beta (innate immunity/inflammatory signature); and PD-L1 (tumor immunity) markers. Poisson regression with overdispersion and the NCSS/PASS package was used for statistical calculations. **Results:** Flow cytometry detected cancer spheroids in 60 % of metastatic blood samples, while only 5 % in primary non-metastatic samples. Filtration collected circulating cancer stem cell spheroids in 72.7 % of metastatic patients and a striking 95.5 % of them showed markers for immune/inflammatory response. In contrast, filtration found circulating cancer stem cell spheroids in only 15.8 % of the non-metastatic samples and only 5.2% showed immune/inflammation response. On the other hand, 90 % of the primary cancer patients were positive for non-cancer related thrombo-embolic micro-clusters (epithelial negative). As it was not found in healthy controls, it may indicate upregulated innate immunity as early as the primary cancer **Conclusions:** The findings support our previous results that circulating cancer spheroids may disseminate metastasis and suggest that innate immunity/inflammation is critical to stabilize cancer stem cell spheroids in circulation. The new inflammation checkpoint in metastatic progression raises the possibility of anti-inflammation modalities to prevent metastasis.

3091 Poster Session (Board #305), Mon, 8:00 AM-11:30 AM

Phase I trial of BMS-986253, an anti-IL-8 monoclonal antibody, in patients with metastatic or unresectable solid tumors. *First Author: Julie Marie Collins, National Cancer Institute, Bethesda, MD*

Background: BMS-986253 is a novel fully human monoclonal antibody that binds to and inhibits IL-8, a chemokine that promotes immune escape and tumor progression. High serum IL-8 levels correlate with poor prognosis in various tumors (Sanmamed et al. *Clin Cancer Res.* 2014). IL-8 stimulates recruitment of myeloid-derived suppressor cells (MDSCs) and promotes epithelial-mesenchymal transition (EMT) in tumors conferring resistance to immune-mediated killing (David et al. *Vaccines* 2016). We have previously shown the ability of BMS-986253 to reduce mesenchymal features in cancer cells leading to enhanced susceptibility to NK and T cell-mediated lysis, and to decrease the frequency of granulocytic MDSCs in xenograft models. Decreases in serum IL-8 were also associated with response to anti–PD1 therapy in a small cohort of patients with melanoma and NSCLC (Sanmamed et al. *Ann Oncol.* 2017). **Methods:** Patients with metastatic or unresectable locally advanced malignant solid tumors were treated with BMS-986253 monotherapy at 4, 8, 16, or 32 mg/kg IV Q2W in a phase I, open-label, 3+3 dose-escalation study. The primary objective was to determine the safety and tolerability and establish the maximum tolerated dose (MTD). Pharmacokinetics and changes in serum cytokine levels including IL-8 were also evaluated. **Results:** Amongst 15 patients, no serious treatment-related adverse events (TRAEs) were observed and MTD was not identified through 32mg/kg. TRAEs occurred in 5 pts (33%), and all were Grade 1 except for Grade 2 fatigue, hypophosphatemia and hypersomnia in two patients receiving 32mg/kg. Eleven pts (73%) achieved stable disease (per RECIST v1.1) and 4 patients had progressive disease (27%). The progression free survival rate at 24 weeks for all patients was 73% with two-sided 95% CI [44%, 89%]. Reductions in serum IL-8 levels were observed at all dose levels. **Conclusions:** BMS-986253 monotherapy is well tolerated and associated with decreases in serum IL-8 across all doses tested. These data have informed combining this drug with Nivolumab and potentially other agents to evaluate the potential for synergetic activity in selected patient populations. Clinical trial information: NCT02536469.

3092 Poster Session (Board #306), Mon, 8:00 AM-11:30 AM

Single intravenous preoperative administration of the oncolytic virus Pexa-Vec to prime anti-tumor immunity. *First Author: Alan Anthoney, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*

Background: Oncolytic viruses (OV) constitute a promising modality of cancer therapy. Intra-tumoral administration has yielded encouraging clinical results, but restricted the use of OV to tumors that are readily accessible. Pexa-Vec, a Thymidine Kinase-Deactivated Vaccinia Virus expressing GM-CSF, has been shown previously to successfully target tumor tissue after intravenous administration (Breitbach C.J. *et al.*, 2011). Herein, we report data on the immunostimulatory effects of a single intravenous (*i.v.*) administration of Pexa-Vec prior to surgical resection in patients with advanced solid tumors. **Methods:** Patients with operable tumors received a single *i.v.* administration of $1x10^9$ plaque forming units of Pexa-Vec, 14 days prior to surgical resection. Up to six blood samples were collected pre- and post-injection for each patient. Tumor tissue was collected at surgery for histologic and translational assessments. **Results:** The study included 3 patients with metastatic melanoma and 5 with colorectal cancer metastases to the liver (CRLM). Pexa-Vec injection was well tolerated in all cases. Histologic examination of tumor tissue indicates the presence of virus in tumor at the time of surgery. Of the 3 evaluable CRLM, 2 showed signs of inflammation and fibrosis, within a normal background liver. Phenotyping of peripheral blood mononuclear cells showed robust activation of Natural Killer (NK) and professional antigen presenting cells ($CD14^+$), as well as $CD4^+$ and $CD8^+$ cells, with high CD69 expression. Functional assays revealed increased patient NK cell degranulation in the presence of tumor cell lines. Consistent with cellular markers, Pexa-Vec induced a significant elevation of serum cytokines associated with immune response including IFNα, IL3, IL12p40, IL16, IL18. **Conclusions:** When administered intravenously, Pexa-Vec exhibited a selective persistence in tumor tissues suggesting a targeted oncolytic action in the tumor. Concurrently, Pexa-Vec triggered a robust immune activation of both innate and adaptive immune cells. These data strongly support the rationale for sequential JX-594 and anti-PD-1 viro-immunotherapy, which is the focus of the ongoing study, NCT03071094. Clinical trial information: ISRCTN13913966.

3093 Poster Session (Board #307), Mon, 8:00 AM-11:30 AM

SEA-CD40, a non-fucosylated CD40 agonist: Interim results from a phase 1 study in advanced solid tumors. *First Author: Juneko E. Grilley-Olson, UNC Lineberger Comprehensive Cancer Center/University of North Carolina Chapel Hill, Chapel Hill, NC*

Background: SEA-CD40 is a non-fucosylated, humanized IgG1 monoclonal antibody which binds CD40, an immune-activating TNF receptor. Binding to antigen presenting cells and crosslinking via FcγRIIIa stimulates inflammatory cytokine production and induction of immune co-stimulatory receptors, leading to T-cell activation and antitumor activity. On CD40-expressing malignant cells, SEA-CD40 can induce antibody-dependent cellular cytotoxicity through enhanced NK-cell binding. **Methods:** This is an ongoing phase 1 dose-escalation study in patients (pts) with relapsed/refractory metastatic solid tumors (NCT02376699). Antitumor activity is assessed q4 cycles (~12 wks) by immune-related response criteria and RECIST. **Results:** 48 pts (median age 62 yrs [range, 28–81]; median of 4 prior systemic therapies [range, 1–11]) have received a median of 2 cycles (range, 1–16) of SEA-CD40 at doses 0.6–60 mcg/kg on Day 1 (n = 38), or 30 mcg/kg on Days 1 and 8 (n = 10) IV q3 wks. SEA-CD40 maximum concentrations increased dose-proportionally (10–60 mcg/kg; Day 1 dosing), with mean half-life estimates of 32–95 hrs and no accumulation upon repeat dosing. Dose-limiting toxicities occurred in 5 pts; all were infusion-related reactions (IRRs). Treatment-emergent AEs in ≥25% of pts were IRR (69%), chills (65%), fatigue (54%), nausea (52%), vomiting (35%), and dyspnea and headache (27% each). No treatment-related G5 AEs were reported. Chemokine/cytokine changes and associated immune-trafficking changes observed in the peripheral blood and tumor microenvironment support the proposed mechanisms of action. Best response in 34 efficacy-evaluable pts was 1 PR (basal cell carcinoma) and 10 SD, for a 32% disease control rate (DCR = CR+PR+SD) by RECIST. 5 pts had continued disease control as assessed at Cycle 8 (~6 mos). **Conclusions:** SEA-CD40 monotherapy shows clinical (32% DCR) and biological activity in heavily pre-treated pts with advanced solid tumors. SEA-CD40 has a generally tolerable safety profile; strategies to manage IRRs are being evaluated as dose escalation continues at ≥45 mcg/kg. Combination therapy dose escalation (SEA-CD40 + pembrolizumab) in solid tumors is underway, as is monotherapy dose escalation in lymphomas. Clinical trial information: 02376699.

3094 Poster Session (Board #308), Mon, 8:00 AM-11:30 AM

A phase I/II study of the oncolytic peptide LTX-315 combined with checkpoint inhibition generates *de novo* T-cell responses and clinical benefit in patients with advanced solid tumors. *First Author: James F. Spicer, King's College London, London, United Kingdom*

Background: LTX-315 disintegrates cytoplasmic organelles and induces immunogenic cell death and systemic immune responses preclinically. Systemic efficacy can be enhanced *in vivo* by combination with immune checkpoint inhibitors (ICI). Clinical safety has been demonstrated as a single agent administered intratumorally in a phase I study **Methods:** Patients with heavily pretreated advanced solid tumors were treated twice weekly with intratumoral LTX-315 over 3 weeks; as monotherapy, or in combination with ipilimumab or pembrolizumab. Primary endpoint was safety of LTX-315 combined with ICI. Anti-tumor activity was assessed by using immune-related response criteria (irRC). Immunohistochemistry and gene expression analysis were performed on tumor biopsies pre and post treatment. T-cell receptor (TCR) repertoire in peripheral blood and biopsies was assessed by TCRb-gene sequencing. **Results:** Fifty-nine patients were treated. Eleven experienced LTX-315-related grade 3/4 adverse events, mainly allergic/anaphylaxis, all resolving without sequelae. Out of 36 patients treated with LTX-315 monotherapy, best overall response of SD at 2 months was seen in 28%. Out of 17 TNBC patients treated with LTX-315 plus pembrolizumab, 12 were evaluable, of which 17% had PR, and 25% SD. Six melanoma patients received LTX-315 plus ipilimumab, of those SD was observed in 33%. LTX-315 monotherapy resulted in increased number of CD8+ T-cells in treated lesions in 89% of evaluable biopsied patients. TCR sequencing revealed clonal expansion of T-cells in blood after LTX-315 monotherapy, and 50% of these clones were detected in post-treatment biopsied tumors. **Conclusions:** Intratumoral LTX-315 is generally safe and tolerable when combined with ICI. The combination has anti-tumor activity. LTX-315 monotherapy enhances TIL population and induces polyclonal T-cell responses, demonstrating the potential of LTX-315 as a T-cell primer combined with other immunotherapies. Clinical trial information: NCT01986426.

3095 Poster Session (Board #309), Mon, 8:00 AM-11:30 AM

Pharmacodynamic and clinical activity of RGX-104, a first-in-class immunotherapy targeting the liver-X nuclear hormone receptor (LXR), in patients with refractory malignancies. *First Author: Monica M. Mita, Cedars-Sinai Comprehensive Cancer Center, Los Angeles, CA*

Background: RGX-104 is a small-molecule LXR agonist that modulates innate immunity via transcriptional activation of the *ApoE* gene. RGX-104 depletes myeloid derived suppressor cells (MDSCs) and stimulates dendritic cells (DCs), activating cytotoxic lymphocytes (CTLs) with anti-tumor activity as monotherapy and in combination with checkpoint blockade in murine models. **Methods:** We are conducting a Phase 1 dose escalation and expansion study of RGX-104 in patients with refractory solid tumors. Safety, PK, PD, and efficacy are being assessed. **Results:** RGX-104 was dosed orally in 23 patients with a broad array of tumors on 5 cohorts at doses ranging from 120 mg QD for 3 of 4 weeks to 200 mg BID continuously. Following single dosing, PK analysis demonstrated high inter-patient variability with $t_{1/2}$ from 6 – 8 hr. *ApoE* gene expression measured in whole blood leukocytes correlated with RGX-104 dose and exposure, demonstrating robust LXR target engagement. Peripheral immune-cell monitoring revealed substantial MDSC depletion ($CD33^+CD15^+HLA\text{-}DR^{-/low}$; median 78% decrease), DC stimulation ($HLA\text{-}DR^+Lin^-$; median 34% increase in PD-L1) and CTL activation (median 257% increase in $PD\text{-}1^+GITR^+$ $CD8^+$ T-cells) in 10/12 evaluable patients. Peak PD effects began ~2 weeks after RGX-104 initiation. Three patients experienced grade 3-4 neutropenia and 1 patient had grade 3 elevated cholesterol, reversible with a statin, likely on-target adverse events. A patient with a platinum-refractory, high-grade neuroendocrine carcinoma with small cell features had a 53% reduction in index hepatic metastases–a partial response pending confirmation, and 5 patients had stable disease at 8 weeks. **Conclusions:** Proof of principle has been demonstrated for immunologic and anti-tumor activity of the first-in-class LXR-agonist RGX-104 in advanced cancer patients. RGX-104 was well tolerated at doses up to 160mg BID and demonstrated robust PD effects on ApoE expression and relevant immune cell populations. Dose escalation with a PD-1 inhibitor has begun with plans to study RGX-104 both as monotherapy and in combination with a PD-1 inhibitor in select malignancies. Clinical trial information: NCT02922764.

3096 Poster Session (Board #310), Mon, 8:00 AM-11:30 AM

Severe immune-related adverse effects (irAE) requiring hospital admission in patients treated with immune checkpoint inhibitors for advanced malignancy: Temporal trends and clinical significance. *First Author: Kerry Lynn Reynolds, Massachusetts General Hospital, Boston, MA*

Background: Disruption of the immune system using immune checkpoint inhibitors can result in a multitude of immune-related adverse effects (irAE). While irAEs have been well-reported in clinical trials, the impact and magnitude in the real world is unclear. **Methods:** Data was collected on patients with advanced malignancy who experienced a suspected irAE requiring admission to an academic hospital (02/11-06/17). Each case was comprehensively reviewed by a minimum of two reviewers, including one sub-specialist. In addition, oncologists were surveyed regarding their confidence about managing irAEs. **Results:** From 2011-2017, there were 343 hospitalizations for suspected irAEs, and the majority (65%; N = 223) were confirmed irAEs from immunotherapy: PD1 (31.8%), CTLA4 (29.2%), CTLA4 + PD1 (15.7%), PD1 à CTLA4 (14.8%), CTLA4àPD1 (8.5%), and PDL1 (3.1%). The most common irAEs were gastrointestinal (43.9%), pulmonary (16%), hepatic (15%), neurologic (8.9%), endocrine (7.1%), rheumatologic (4%), dermatologic (3%), cardiac (3%), renal (1.8%), and allergy (1.3%). Mean length of stay was 6.4 days, readmission rate for irAE 25%, and inpatient mortality 4%. Majority of patients (92%) required continuation of immunosuppressive medication on discharge. Disposition was to home (87%), skilled facility (8.8%), or hospice (4.2%). Inpatient admissions due to irAEs has increased significantly over time (2016 vs 2011, odds ratio = 3.07; $p < 0.01$). However, a survey (N = 26) revealed that oncologists do not feel very comfortable managing irAEs, and 48% felt irAEs should be managed by different service. **Conclusions:** irAEs from immune checkpoint inhibitors can result in prolonged hospitalizations, need for immunosuppression, inpatient mortality, and high readmission rate. The number of admissions due to irAEs has increased by more than three-fold in the recent years, but comfort level in managing these complications is low. Consequently, there is a critical need for coordinated multidisciplinary approach, comprehensive provider education, and translational research programs for early detection and intervention.

3098 Poster Session (Board #312), Mon, 8:00 AM-11:30 AM

First-in-man study of Ad-sig-hMUC1/ecdCD40L vaccine for immunotherapy of MUC1 overexpressing epithelial cancers. *First Author: Tira Jing Ying Tan, Division of Medical Oncology, National Cancer Centre Singapore, Singapore, Singapore*

Background: Ad-sig-hMUC1/ecdCD40L vaccine is an adenoviral vector encoding the human MUC-1 epithelial antigen bound to an immune stimulant, the extracellular domain of the CD40 ligand (CD40L) and an adenovirus signal sequence encoding the secretory signal peptide. Pre-clinical studies have demonstrated efficacy of CD40L in activating endogenous dendritic cells to elicit potent anti-MUC1 immunity. We report results of the dose-escalation cohort in a phase 1 study of Ad-sig-hMUC-1/ecdCD40L vector vaccine. **Methods:** Patients (pts) with advanced adenocarcinoma of the breast, ovary, lung, colon or prostate with tumor overexpressing MUC-1 on immunohistochemistry or elevated serum CA 15-3 were recruited on a 3+3 design phase 1 dose escalation study. Study endpoints were safety, tolerability, maximum tolerated dose (MTD) and antitumor activity. Serum CA 15-3 measurements performed monthly and initial CT evaluation of disease in month 2. Immune biomarkers for analysis included antigen-specific T-cell interferon-gamma Elispot assays, and serum cytokine multiplex assays. **Results:** Eighteen pts were treated, median age 58 (range 34-88 years), 17 females, 1 male, 11 (61%) breast, 6 (33%) ovarian and 1 (6%) lung cancer. Six cohorts of 3 pts recruited. The first 4 cohorts were single injections starting at 1×10^9 viral particles (VP) escalating to 1×10^{11} VP. Cohorts 5 and 6 involved 2 (days 1 and 7) and 3 (days 1, 7 and 21) 1×10^{11} VP injections. The most common adverse events (AE) were injection site reaction 13 (72%) and rash 5 (28%). All drug related AE were of low grades 1-2. There were no dose limiting toxicities and MTD not reached. 16 patients were evaluable for serum CA 15-3, 2 recorded > 30% decline. 13 pts had measurable disease, 5 demonstrated a reduction in tumor size not amounting to partial response. 1 ovarian cancer pt in cohort 5 received 2×10^{11} VP recorded a 60% CA 15-3 decrease and 25% decrease in tumour size. Immune and translational correlates will be reported. **Conclusions:** This first-in-man study of Ad-sig-hMUC-1/ecdCD40L vector vaccine in cancers expressing MUC1 has demonstrated low toxicity and encouraging antitumor activity. Our data supports further clinical evaluation in a larger study cohort. Clinical trial information: NCT02140996.

3099 Poster Session (Board #313), Mon, 8:00 AM-11:30 AM

Cervical microbiome role in outcomes of therapeutic HPV vaccination for cervical intraepithelial neoplasia. *First Author: Rahul Ravilla, University of Arkansas for Medical Science, Little Rock, AR*

Background: Clinical trials have suggested that the gut microbiome can modulate immunotherapy outcomes with checkpoint inhibitors (Kroemer et al, Nat rev immunology. Jan 2018). However, the role of cervical microbiome has not been investigated. We studied the effect of cervical microbiome on outcomes of a novel therapeutic HPV vaccine in women with high grade cervical neoplasia. **Methods:** We collected 65 cervical samples (34 pre-screen and 31 post-vaccination) from 34 women enrolled in a phase 1 therapeutic vaccine trial (Coleman et al. Cancer Immunol Immunotherapy. May 2016). Whole DNA was isolated from cervical Thinprep samples using the Qiagen DNA Mini Kit and amplified by PCR using a bacterial 16sRNA gene primer. eOTUs were identified using V1-V9 16S rRNA gene hybridization with G4 Phylochip™ (Second Genome, South San Francisco, CA). Alpha and beta diversity metrics were calculated. We used PERMANOVA analysis to test for associations of phylogenetic composition with patient demographics; HPV status; HLA type; circulating Th1, Th2, and Treg cells; local TFoxp3 cells and clinical response to the vaccine. Responders and non-responders were defined based on histological regression of cervical lesions. **Results:** Richness ranged from 72 to 365 eOTUs per sample, and Prevotellaceae and Lactobacillaceae were the most abundant families observed. We found that pre-screen samples from vaccine non-responders, as compared to responders, were enriched with the phyla Caldithrix, Nitrospirae and family Mycoplasmataceae and an unclassified family from order Entomoplasmatales. HPV16 status and HLA B40 status were significantly associated with beta diversity. Measures of pre- and post-vaccination alpha and beta diversity were not statistically significantly associated with response to vaccine. Also, we observed no correlations of microbiome metrics with immune parameters. **Conclusions:** Study findings suggest that cervical microbial composition may predict non-responsiveness to a therapeutic vaccine given to treat high-grade cervical neoplasia. Observed associations of cervical microbial composition with HLA B40 and HPV 16 status are of interest but require further investigation. Clinical trial information: NCT01653249.

3100 Poster Session (Board #314), Mon, 8:00 AM-11:30 AM

Utility of comprehensive genomic profiling (CGP) for personal cancer vaccine development via neoantigen analysis. *First Author: Dana Vuzman, KEW, Inc., Cambridge, MA*

Background: Cancer vaccines against neoantigens have shown promise in treating advanced stage cancers [1,2]. Typically, detection of somatic mutations underlying neoantigen expression is done using WES, a cost and time-ineffective platform for routine clinical use. Here, we assess the feasibility of a large NGS panel for use in cancer vaccine development through discovery of somatic mutations and prediction of neoantigen load. **Methods:** Various patient tumor samples with a range of mutational loads [n = 30; mean: 84 mutations, range: 34-248] were profiled using CANCERPLEX, a 435-gene panel for identifying clinically-relevant genomic alterations in cancer [3]. For each mutation, all possible 9- and 10-mer peptides were enumerated. For mutations that result in novel open reading frames (neoORF), peptides overlapping the entire neoORF were considered. The 28 most frequent HLA-A and HLA-B alleles in the Caucasian, African, and Asian populations were used. Peptides were computationally evaluated for binding to HLA using the NetMHCpan-3.0 algorithm [4]. For each neoantigen, the rank relative to the collective mutant and wildtype 9- or 10-mers was determined. Neoantigens were classified as strong binders if $rank_{mutant}/rank_{wt} \geq 0.5$. For each HLA allele, the neoantigen load was calculated as the number of strong binders per given allele. **Results:** The number of neoantigens was significantly correlated with mutational load. The neoantigen load was dependent on the HLA allele binding partner, with HLA alleles B07:02, A33:03, A30:01, and B42:01 predicted to have higher binding affinity. This allele dependent distribution suggests that certain HLA alleles are better binding partners for potential neoantigens or preferential for certain peptide. **Conclusions:** The high number of neoantigens identified suggests that CGP is a feasible alternative to WES for cancer vaccine development. CANCERPLEX accurately detects somatic mutations [3] thus enabling prediction of tumor neoantigens, an emerging biomarker in immune-oncology [5]. Future studies incorporating HLA transcription testing with CGP are warranted to further establish the platform for cancer vaccine development.

TPS3101 Poster Session (Board #315a), Mon, 8:00 AM-11:30 AM

Phase 1, open-label, adaptive biomarker trial that informs the evolution of combination immuno-oncology (IO) therapies (ADVISE), a precision IO approach to personalized medicine. *First Author: Jason J. Luke, University of Chicago Comprehensive Cancer Center, Chicago, IL*

Background: Immune checkpoint inhibitor therapies have revolutionized treatment paradigms for numerous tumor types. However, improved understanding of the tumor microenvironment (TME) and tumor immune biology is needed to enhance and extend benefits to more patients. Personalized pairing of IO agents to the immune biomarkers in the TME of individual patients using pretreatment biopsies could transform cancer care, but the feasibility of using biomarkers to study IO combinations in specific patient populations has not been established. The ADaptiVe biomarker trial that InformS Evolution of therapy (ADVISE; NCT03335540) was designed to assess the clinical feasibility and utility of real-time biomarker data to allow specific IO agents in combination with nivolumab to be selected for individual patients across various tumor-specific cohorts. **Methods:** Approximately 50 patients with selected solid tumors will initially be enrolled. Patients must be ≥ 18 years of age, have an ECOG PS ≤ 1, and have had ≥ 1 prior therapy. Prior IO therapy is permitted; however, patients will not be assigned to receive an IO regimen containing an agent directed against the same target (aside from PD-[L]1). Treatment selection will be driven by biomarker analyses in pretreatment biopsies. Patients will receive nivolumab in combination with a second IO agent that is implicated in tumor immune escape (lirilumab [anti-KIR], relatlimab [antiLAG-3], cabiralizumab [antiCSF-1R], ipilimumab [antiCTLA-4], BMS-986205 [IDO-1 inhibitor], or BMS-986156 [anti-GITR]) or nivolumab with stereotactic body radiation therapy (for noninflamed tumors). The primary endpoint is the ratio of patients with qualified tumor biopsy specimens at baseline providing sufficient biomarker data and analysis time to guide treatment decisions. Other endpoints include safety, preliminary clinical activity, and biomarker analyses. Clinical trial information: NCT03335540.

TPS3102 Poster Session (Board #315b), Mon, 8:00 AM-11:30 AM

ZUMA-2: Phase 2 multicenter study evaluating efficacy of kte-C19 in patients with relapsed/refractory mantle cell lymphoma. *First Author: Michael Wang, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Mantle cell lymphoma (MCL) is an aggressive B cell malignancy, and accounts for ≈6% of non-Hodgkin lymphomas. Despite high initial response rates, MCL is generally considered incurable, as almost all patients (pts) eventually progress (Cheah et al. *J Clin Oncol.* 2016). Bruton tyrosine kinase (BTK) inhibition can lead to high rates of prolonged responses in relapsed/refractory (R/R) MCL, as noted with ibrutinib (Wang et al. *NEJM.* 2013) and acalabrutinib (Wang et al. *Lancet.* 2017). However, many pts develop ibrutinib-resistance and outcomes to salvage regimens (including investigational agents) are poor with a response rate of 32% and median overall survival of 8.4 months (Cheah et al. *Ann Oncol.* 2015). This phase 2, multicenter, open-label study examines efficacy and safety of KTE-C19, an autologous anti-CD19 chimeric antigen receptor (CAR) T cell therapy, in pts with R/R MCL who have progressed on prior chemotherapy, an anti-CD20 antibody, and a BTK inhibitor. **Methods:** ZUMA-2 (NCT02601313) is enrolling pts with R/R MCL sequentially into 2 separate dose level cohorts (~40 pts each). After leukapheresis and manufacturing, pts will receive conditioning chemotherapy with fludarabine 30 mg/m^2/d and cyclophosphamide 500 mg/m^2/d × 3 d and then receive a single infusion of KTE-C19 cells at a dose of 0.5×10^6 CAR T cells/kg. The primary endpoint is objective response rate by Independent Review Committee assessment; secondary and exploratory endpoints include duration of response, progression-free survival, overall survival, incidence of adverse events and levels of CAR T cells and cytokines in blood. Eligible adult pts with pathologically confirmed R/R MCL and an ECOG of 0-1 must have received ≤ 5 prior therapies that must have included an anthracycline or bendamustine-containing chemotherapy, anti-CD20 monoclonal antibody therapy, and ibrutinib or acalabrutinib. Pts who received allogenic stem cell transplant or prior CD19-directed therapy or those with clinically significant infection or a history of central nervous system lymphoma or central nervous system disorders are not eligible. Accrual is ongoing. Clinical trial information: NCT02601313.

TPS3103 Poster Session (Board #316a), Mon, 8:00 AM-11:30 AM

A phase 1 multicenter study evaluating KITE-585, an autologous anti-BCMA CAR T-cell therapy, in patients with relapsed/refractory multiple myeloma. *First Author: Robert F. Cornell, Vanderbilt University Medical Center, Nashville, TN*

Background: In the United States there are > 30,000 new cases of multiple myeloma (MM) and an estimated > 12,000 deaths annually (Howlader et al. *SEER Cancer Statistics Review.* 2017). Despite an increasing number of treatment options, the disease remains incurable. KITE-585, an autologous, fully-human anti-B cell maturation antigen (BCMA) chimeric antigen receptor (CAR) T cell therapy, potently and specifically targets MM cells in preclinical studies (Adams et al. AACR. 2017 #2135, #4979). This Phase 1, open-label, multicenter, first-in-human study evaluates the safety and efficacy of KITE-585 in patients (pts) with relapsed/refractory MM (RRMM; NCT03318861). **Methods:** Planned enrollment is ≤ 64 pts. After leukapheresis and manufacturing, pts undergo lymphodepleting chemotherapy with fludarabine (30 mg/m^2/d) and cyclophosphamide (300 mg/m^2/d) for 3 d followed by a single infusion of KITE-585. The study follows a standard 3 + 3 cell-dose-escalation design with an option to expand enrollment at doses that have passed dose-limiting toxicity (DLT) criteria. Pts in the first dose cohort will receive 3×10^7 CAR T cells. Pts may receive optional bridging chemotherapy after leukapheresis and before conditioning. The primary endpoint is incidence of adverse events (AEs) defined as DLTs. Secondary endpoints include overall response rate per International Myeloma Working Group criteria, duration of response, progression-free survival, time to next treatment, overall survival, incidence of AEs, and clinically significant changes in laboratory values. Eligible pts (≥ 18 y) must have RRMM (defined as ≥ 3 prior lines of therapy including both a proteasome inhibitor [PI] and an immunomodulatory drug [IMiD] or MM that is refractory to a regimen containing both a PI and an IMiD), an ECOG performance status of ≤ 1, and adequate bone marrow and organ function. BCMA expression is not required for eligibility. Key exclusion criteria include plasma cell leukemia, nonsecretory MM, active infection, a history of central nervous system involvement, active autoimmune disease, or prior allogeneic stem cell transplant. The study opened to accrual in October 2017. Clinical trial information: NCT03318861.

TPS3104 Poster Session (Board #316b), Mon, 8:00 AM-11:30 AM

A phase 1 multicenter study evaluating the safety and efficacy of MHC class II-restricted MAGE-A3/A6 T-cell receptor engineered T cells (KITE-718) in patients with advanced cancers. *First Author: Partow Kebriaei, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Melanoma-associated antigens 3 and 6 (MAGE-A3/A6) are among the most commonly expressed cancer testis antigens in a variety of tumors and are associated with poor disease prognosis. Antitumor activity, including partial and complete responses, has been observed with MHC class II-restricted T cell receptor (TCR)-engineered T cells targeting MAGE-A3 and MAGE-A6 (Lu et al. *J Clin Oncol.* 2017). In this study, the safety and antitumor activity of KITE-718, an autologous TCR-engineered T cell therapy targeting MAGE-A3/A6, will be evaluated in HLA-DPB1*04:01-positive patients with advanced cancers. **Methods:** Phase 1A of the study (NCT03139370) uses a single-patient dose-escalation scheme to evaluate safety and determine the recommended Phase 1B dose of KITE-718, enrolling up to 30 patients. Phase 1B will include ≈45 patients with non-small cell lung cancer, urothelial cancer, and all other MAGE-A3/A6–positive tumors treated at the recommended KITE-718 dose. For both portions of the study, after leukapheresis patients may receive optional bridging therapy prior to conditioning chemotherapy. After manufacturing, patients will receive cyclophosphamide and fludarabine conditioning chemotherapy followed by KITE-718 at a dose of 1×10^6 to 1×10^8 TCR-transduced T cells/kg. Following KITE-718 infusion, patients will receive daily subcutaneous IL-2 therapy for a maximum of 14 days. The primary endpoint for Phase 1A is incidence of adverse events defined as dose-limiting toxicities. The Phase 1B primary endpoint is investigator assessment of objective response rate per modified RECIST v1.1 or IMWG criteria. Secondary endpoints include duration of response, progression-free survival, overall survival, and safety. Patients aged ≥18 y must be HLA-DPB1*04:01–positive, have relapsed/refractory MAGE-A3/A6–positive advanced cancer, ECOG ≤ 1, and adequate bone marrow and organ function. Patients amenable for loco-regional therapy or with history of stroke, myocardial infarction, or symptomatic deep vein thrombosis/pulmonary embolism are not eligible. The study is open and accruing patients. Clinical trial information: NCT03139370.

TPS3105 Poster Session (Board #317a), Mon, 8:00 AM-11:30 AM

A phase 1b/2, multicenter, open-label trial to evaluate the safety of talimogene laherparepvec (T-VEC) injected into primary and metastatic liver tumors alone and in combination with pembrolizumab (pembro) (MASTERKEY-318). *First Author: J. Randolph Hecht, David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, CA*

Background: Combining the intralesional oncolytic immunotherapy T-VEC with systemic immunotherapy may enhance the systemic efficacy of both agents through complementary mechanisms of action. The open-label MASTERKEY-318 study (ClinicalTrials.gov, NCT02509507) was designed to evaluate the safety of intrahepatic injection of T-VEC, with or without intraveneous (IV) pembro, in pts with liver metastases (met) from solid tumors (non-HCC; from breast cancer [BC], colorectal cancer [CRC], gastroesophageal cancer [GEC], melanoma, non-small cell lung cancer [NSCLC], or clear cell renal cell carcinoma [RCC]) or from primary hepatocellular carcinoma (HCC). The study consists of 2 parts. **Methods:** In Part 1, the safety of administering increasing concentrations (Initial 10^6 plaque forming unit [PFU]/mL followed 3 weeks (wk) later by 10^7 PFU/mL or 10^8 PFU/mL q3 wk) and volumes of T-VEC will be determined in the monotherapy and combination (combo) cohorts. The primary objective for Part 1 is to evaluate the maximum tolerated volume and concentration (MTV and MTC) of injection of T-VEC into tumors in the liver alone and in combo (MTC only) with systemic pembro (200 mg IV q3 wk) as measured by incidence of dose limiting toxicities. Once the MTC is determined, Part 2 will evaluate the efficacy and safety of the T-VEC/pembro combo in the respective tumor types. For Part 2, the primary objective is objective response rate and incidence of treatment-emergent and treatment-related adverse events. Key eligibility criteria include age ≥18 years, confirmed BC, CRC, GEC, melanoma, NSCLC, or RCC with liver met or HCC. Generally, non-HCC pts must have received ≥1 prior standard of care systemic therapy for their locally advanced or metastatic disease. However, for the combo cohorts, pts with melanoma or NSCLC do not need to have received prior therapy. Pts must have measurable liver tumors suitable for injection, an Eastern Cooperative Oncology Group performance status of 0 or 1, and life expectancy ≥5 months. MASTERKEY-318 will enroll up to 244 pts from ~50 sites. 21 pts have enrolled onto the monotherapy cohorts so far. Clinical trial information: NCT02509507.

TPS3106 Poster Session (Board #317b), Mon, 8:00 AM-11:30 AM

Phase I adoptive cellular therapy trial with ex-vivo stimulated autologous CD8+ T-cells against multiple targets (ACTolog IMA101) in patients with relapsed and/or refractory solid cancers. *First Author: Apostolia Maria Tsimberidou, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Adoptive cellular therapy (ACT) has demonstrated substantial clinical progresses in hematologic cancers; however, only a small proportion of solid tumor patients have benefited from these advances due to i) lack of suitable immunotherapy targets with high specificity in solid tumors, ii) frequent relapse following immunotherapy to single targets often associated with loss of target expression in the tumor. The ACTolog® concept, utilizing antigen specific T cells (IMA101) against targets identified by the Immatics' proprietary XPRESIDENT® technology, is intended to overcome these limitations by addressing multiple novel tumor antigens per patient. One key defining feature in this trial is the generation of robust T cells, where autologous T cells are primed against the expressed ACTolog targets in the presence of IL-21 followed by HLA tetramer-guided cell sorting and rapid expansion. This process has been shown to result in higher frequencies of central memory T cells, extended *in vivo* persistence, and a more robust clinical response. **Methods:** This study is a first-in-human phase I trial in patients with relapsed or refractory solid tumors expressing up to 4 targets from a warehouse of 8 cancer targets in which autologous T-cell products are manufactured against the most relevant tumor target peptides for individual patients. Key eligibility criteria include: HLA-A*02:01 phenotype, qPCR biomarker positive from a tumor biopsy, RECIST v1.1 measurable lesions, and ECOG status 0 or 1. At baseline, patients will undergo leukapheresis to collect mononuclear cells for manufacturing of IMA101 cells. Patients will receive anti-cancer therapy during the production phase. IMA101 will be infused after lymphodepletion regimen followed by low dose IL2. The primary objective is to assess safety and tolerability of IMA101. Secondary endpoints include overall response rate, PFS and OS. The translational objective includes the assessment of *in vivo* persistence and *ex vivo* characterization of transferred T cells in addition to evaluation of target expression in tumors. Enrollment in the study is currently ongoing. Clinical trial information: NCT02876510.

TPS3107 Poster Session (Board #318a), Mon, 8:00 AM-11:30 AM

A phase 2 study to assess the efficacy and safety of autologous tumor-infiltrating lymphocytes (TIL, LN-145) alone and in combination with anti-PD-L1 inhibitor durvalumab in patients with locally advanced or metastatic NSCLC. *First Author: Sylvia Mina Lee, University of Washington - Seattle Cancer Care Alliance, Seattle, WA*

Background: Adoptive cell therapy with TIL has demonstrated durable complete responses in immunogenic tumors with high mutational burden. Durvalumab, which enhances T-cell antitumor cytotoxicity through blockade of the PD-1/PD-L1 axis, has demonstrated clinical activity in NSCLC. Despite recent advances in the treatment of NSCLC using checkpoint inhibitors, the majority of patients do not respond, leaving an unmet need to improve therapeutic outcomes, warranting this investigation of TIL therapy alone and in combination with durvalumab. IOV-LUN-201 is a phase 2 multicenter, open-label study designed to evaluate the efficacy and safety of autologous LN-145 therapy alone or in combination with durvalumab, for previously-treated, anti-PD-1/PD-L1-naïve NSCLC patients. **Methods:** LN-145 is a preparation of TIL extracted from surgically-resected tumors and manufactured in a 22-day process at a central GMP facility. LN-145 infusion is preceded by a non-myeloablative lymphodepletion regimen of cyclophosphamide and fludarabine, and followed by up to 6 infusions of IV IL-2. Cohort 1 patients receive LN-145 therapy alone. Patients in Cohort 1 who do not receive LN-145 or those who progress following LN-145 therapy can receive durvalumab 1500 mg IV Q4W until progression or unacceptable toxicity. Cohort 2 patients receive durvalumab 2 weeks prior to and 2 weeks after tumor harvest, and then following LN-145 infusion resume durvalumab 1500 mg IV Q4W until progression or unacceptable toxicity. Patients unable to receive LN-145 are allowed to receive durvalumab alone. Patients ≥ 18 years of age must have confirmed stage III/IV NSCLC and have received ≥1 line of prior systemic therapy, excluding anti-PD-1/anti-PD-L1. Other major eligibility criteria include: minimum of 2 tumor lesions, adequate organ function, and ECOG PS 0 or 1. Primary endpoints are efficacy as defined by ORR and safety of LN-145 as a single agent or in combination with durvalumab; secondary endpoints are DOR and PFS per RECIST 1.1, and OS. Key exploratory objectives include CR rate, DCR, immune correlates of response, and HRQoL. Clinical trial information: NCT03419559.

TPS3108 Poster Session (Board #318b), Mon, 8:00 AM-11:30 AM

Evaluating immune checkpoint inhibition in solid tumor patients with homologous recombination repair deficiency. *First Author: Fernando Manuel Vargas Madueno, Miami Cancer Institute, Baptist Health South Florida, Miami, FL*

Background: Recent studies have shown that patients with mismatch repair deficiency have an increased response rate to immune checkpoint inhibitors (ICI). This led to the tissue-agnostic FDA approval of pembrolizumab (PEM). Stemming from this, we are investigating the interplay between homologous recombination (HR) repair deficiency, another mechanism of DNA repair, and solid tumor response to ICI using an all-inclusive functional immunofluorescence assay of the Fanconi Anemia pathway (FATSI) that we developed and which can be performed in paraffin embedded tumors. **Methods:** This is a phase 2 open-label single center trial evaluating the role of PEM in patients with metastatic solid tumors who have progressed on first-line standard of care chemotherapy and for whom PEM does not have an FDA approved indication. FATSI will be performed in all patients, as well as stool analyses for microbiome composition evaluation. We hypothesize that FATSI negative tumors will be associated with improved responses. Other eligibility criteria include measurable disease by imaging, 18 years of age or older and no previous exposure to ICI. Patients with known microsatellite instability (MSI) high tumors are not eligible. The primary objective is to evaluate the immune-related objective response rate (iORR) achieved in patients with FA Repair Pathway functionally competent and functionally deficient tumors. Secondary objectives include 20-week progression free survival and overall survival. Other exploratory objectives include evaluation of the mutation load, markers of neo-antigenicity, T cell receptor clonotype analyses (before and after treatment) and alterations in HR repair genes. We will utilize a two-stage phase II trial design to detect an iORR $\geq$ 20% in the whole population tested vs. the null hypothesis that the true iORR $\leq$5%, representing a response by chance alone, or other infrequent unknown mechanism. An interim analysis requires that at least 2 of the first 20 evaluable patients enrolled have an objective response. If this occurs, we will accrue 19 additional patients for a total of 39. Enrollment is ongoing and seven patients are currently on treatment. Clinical trial information: NCT03274661.

TPS3109 Poster Session (Board #319a), Mon, 8:00 AM-11:30 AM

Phase 1b/2 study of nivolumab in combination with an anti–IL-8 monoclonal antibody, BMS-986253, in a biomarker-enriched population of patients with advanced cancer. *First Author: Ignacio Melero Bermejo, Clinica Universidad de Navarra, Pamplona, Spain*

Background: Interleukin 8 (IL-8) is a chemokine that has been suggested to play a predominant role in tumor immune escape by promoting an immunosuppressive tumor microenvironment (TME). High levels of serum IL-8 are associated with a poor prognosis in various tumors (Sanmamed, MF, et al. Clin Cancer Res. 2014;20:5697-5707), such as melanoma, non-squamous small cell lung cancer (NSCLC), and renal cell carcinoma, and decreases in serum IL-8 levels have been suggested to be associated with response to antiPD-(L)1 therapy with nivolumab in a small cohort of pts with melanoma and NSCLC (Sanmamed, MF et al. Ann Oncol. 2017;28:1988-1995). Preclinical studies showed synergetic antitumor activity by combining anti-CXCR2 with antiPD-1 vs either agent alone in mouse. BMS-986253 is a fully human-sequence IgG1κ antiIL-8 monoclonal antibody that abrogates signaling through both IL-8 receptors (CXCR1 and CXCR2), resulting in a complete blocking of IL-8 mediated pathway, and as such, can be used to assess the mechanistic role of this pathway in IO resistance. Here we describe a phase 1b/2 study of the combination of BMS-986253 plus nivolumab in a biomarker-enriched population of pts with advanced cancers (NCT03400332). **Methods:** This is a 2-part study with an enrollment of $\approx$ 260 target selected pts, aged $\geq$ 18 y with advanced solid tumors. Pts must have $\geq$ 1 measurable lesion at baseline per RECIST v1.1. Outcomes include safety, tolerability, efficacy, pharmacokinetics, immunogenicity of BMS-986253 plus nivolumab, and measurement of serum IL-8 levels at baseline and during treatment. This study will also explore various peripheral and intra-tumor pharmacodynamic effects of blocking IL-8 in a target selected pt population. Clinical trial information: NCT03400332.

TPS3110 Poster Session (Board #319b), Mon, 8:00 AM-11:30 AM

A phase 3, randomized, open-label, multicenter study to compare the efficacy and safety of tislelizumab, an anti-PD-1 antibody, versus sorafenib as first-line treatment in patients with advanced hepatocellular carcinoma. *First Author: Shukui Qin, People's Liberation Army (PLA) 81 Hospital, Nanjing, China*

Background: Advanced hepatocellular carcinoma (HCC) accounts for 70% of diagnosed HCC. Tislelizumab (also known as BGB-A317) is a humanized, IgG4 monoclonal antibody with high affinity and binding specificity for programmed cell death receptor-1 (PD-1). Furthermore, tislelizumab was specifically engineered to minimize F_cgR binding on macrophages, thereby abrogating antibody-dependent phagocytosis, a potential mechanism of T-cell clearance. A first-in-human, phase 1A/1B study (NCT02407990) demonstrated that single-agent tislelizumab was generally well tolerated and showed evidence of antitumor activity in patients with advanced solid tumors, including HCC. A recommended phase 3 dose of 200 mg administered intravenously (IV) every 3 weeks (Q3W) has been established for tislelizumab. **Methods:** This global, phase 3, randomized, multicenter, non-inferiority study (NCT03412773) was designed to evaluate the efficacy and safety of tislelizumab compared with sorafenib as a first-line treatment of advanced HCC. Adult patients, aged $\geq$18 years, with unresectable, histologically confirmed HCC, an ECOG score $\leq$1, Child-Pugh A classification, BCLC Stage C disease or BCLC Stage B disease that has relapsed after locoregional therapy, and who have not received prior systemic therapy, are being enrolled. Approximately 640 patients from 100 international centers will be randomized (1:1) to receive tislelizumab 200 mg IV Q3W or sorafenib 400 mg orally BID. The primary outcome of this non-inferiority study is overall survival (OS) of patients treated with tislelizumab compared with OS of patients treated with sorafenib; secondary outcomes include objective response rate, progression-free survival, duration of response, time to progression, and quality-of-life outcomes. Safety/tolerability assessments include monitoring adverse events (AEs), including immune-related AEs, as well as physical examinations, vital signs, and electrocardiograms. Clinical trial information: NCT03412773.

TPS3111 Poster Session (Board #320a), Mon, 8:00 AM-11:30 AM

A phase 3, randomized, open-label study to compare the efficacy of tislelizumab (BGB-A317) versus chemotherapy as second-line therapy for advanced unresectable/metastatic esophageal squamous cell carcinoma (ESCC). *First Author: Lin Shen, Peking University Cancer Hospital & Institute, Beijing, China*

Background: Approximately 40% of patients (pts) with esophageal cancer are diagnosed with advanced unresectable or metastatic disease; the 5-year survival rate for advanced disease is $<$ 5%. Inhibition of programmed cell death protein-1 (PD-1) has demonstrated promising antitumor activity and manageable safety in pts with advanced unresectable or metastatic ESCC. Tislelizumab (also known as BGB-A317), a humanized IgG4 monoclonal antibody, has high affinity and specificity for PD-1. Tislelizumab was specifically engineered to minimize F_cgR binding on macrophages, thus abrogating antibody-dependent phagocytosis, a potential mechanism of T-cell clearance. A first-in-human study (NCT02407990) demonstrated that single-agent tislelizumab was generally well tolerated and had preliminary antitumor effects in pts with solid tumors, including ESCC. A recommended phase 2 dose of 200 mg administered IV every 3 weeks (Q3W) has been established for tislelizumab. **Methods:** This phase 3, randomized study (NCT03430843) was designed to evaluate the efficacy, safety, and tolerability of tislelizumab compared with chemotherapy for second-line treatment of advanced unresectable/metastatic ESCC. Adult pts, aged $\geq$18 years, with histologically or cytologically confirmed ESCC that has progressed with first-line therapy, have $\geq$1 measurable/evaluable lesion, and have an Eastern Cooperative Oncology score $\leq$1 will be enrolled. Approximately 450 pts will be randomized (1:1) to receive either tislelizumab 200 mg IV Q3W or investigator-chosen chemotherapy (paclitaxel 135–175 mg/m^2 IV Q3W or 100 mg/m^2 IV weekly for 6 weeks with 1 week of rest [Japan only], docetaxel 75 mg/m^2 or 70 mg/m^2 IV Q3W, or irinotecan 125 mg/m^2 IV Q3W). Overall survival is the primary endpoint; secondary endpoints include objective response rate, progression free survival, duration of response, and health-related quality-of-life outcomes. Safety/tolerability will be assessed by monitoring adverse events (AEs), including immune-related AEs, as well as physical examinations, vital signs, and electrocardiograms. Clinical trial information: NCT03430843.

TPS3112 Poster Session (Board #320b), Mon, 8:00 AM-11:30 AM

A phase 3, open-label, multicenter, randomized study to investigate the efficacy and safety of tislelizumab, an anti-PD-1 antibody, versus docetaxel in patients with non-small cell lung cancer who have progressed on a prior platinum-containing regimen. *First Author: Dingzhi Huang, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China*

Background: Non-small cell lung cancer (NSCLC) accounts for 80–85% of all lung cancers and has a poor prognosis in later stages. Although lung cancers are not typically immunogenic, recent studies of immune checkpoint inhibitors have shown efficacy in patients with advanced NSCLC. Tislelizumab (also known as BGB-A317) is a humanized, IgG4 monoclonal antibody with high affinity and binding specificity for programmed cell death receptor-1 (PD-1). Furthermore, tislelizumab was specifically engineered to minimize F_cgR binding on macrophages, thereby abrogating antibody-dependent phagocytosis, a potential mechanism of T-cell clearance. A first-in-human, phase 1A/1B study (NCT02407990) demonstrated that single-agent tislelizumab was generally well tolerated and showed evidence of antitumor activity in patients with solid tumors, including NSCLC. A recommended phase 3 dose of 200 mg administered intravenously (IV) every 3 weeks (Q3W) has been identified for tislelizumab. **Methods:** This phase 3, randomized, multicenter study (NCT03358875) was designed to evaluate the efficacy, safety, and tolerability of tislelizumab compared with docetaxel in the second- or third-line treatment of NSCLC. Adult patients aged $\geq$18 years with locally advanced or metastatic NSCLC (Stage IIIB or IV, squamous or non-squamous), who have progressed on $\geq$1 prior platinum-containing therapy, have adequate hematologic and end-organ function, and an ECOG score $\leq$1 are eligible to enroll. Patients with a known EGFR sensitizing/driver mutation or ALK rearrangement are excluded. Approximately 800 patients from ~100 global clinical sites will be randomized (2:1) to receive tislelizumab 200 mg IV Q3W or docetaxel 75 mg/m^2 IV Q3W. Randomization will be stratified by histology, line of therapy, and PD-1 ligand tumor cell expression ($<$ 25% vs $\geq$25% [PD-L1$^+$]). Co-primary endpoints are overall survival in the intent-to-treat population and in the PD-L1$^+$ population; secondary endpoints include objective response rate and health-related quality-of-life outcomes. Clinical trial information: NCT03358875.

TPS3113 Poster Session (Board #321a), Mon, 8:00 AM-11:30 AM

Phase 1/2 study investigating safety, tolerability, pharmacokinetics, and preliminary antitumor activity of anti-PD-L1 monoclonal antibody bgb-A333 alone and in combination with anti-PD-1 monoclonal antibody tislelizumab in patients with advanced solid tumors. *First Author: Jayesh Desai, Peter MacCallum Cancer Centre and Royal Melbourne Hospital, Melbourne, Australia*

Background: Programmed cell death-1 (PD-1) and its ligand, programmed death-ligand 1 (PD-L1), play critical roles in the immune modulation of tumor progression. Tislelizumab is a humanized IgG4 monoclonal antibody against PD-1. A first-in-human, phase 1A/1B study (NCT02407990) demonstrated that single-agent tislelizumab was generally well tolerated and showed evidence of antitumor activity in patients with advanced solid tumors at the recommended dose of 200 mg administered every 3 weeks (Q3W). BGB-A333 is a humanized IgG1 monoclonal antibody against PD-L1 which increased functional activities of human T cells in *in vitro* studies, and showed antitumor activity in various cancer xenograft models. BGB-A333 blocks the interaction between PD-L1 and CD80 (B7-1), which in turn release the inhibitory signals to T-cells, enhances T-cell expansion, and prevents T-cell energy induction. Therefore, a combination of anti-PD-1 and anti-PD-L1 can potentially elicit stronger antitumor immunity through blockade of multiple complementary immune-suppressive signals in tumor microenvironments. **Methods:** This open-label study (NCT03379259) consists of two phases, each phase consisting of two parts. Phase 1 is designed to investigate the safety and tolerability of the BGB-A333 RP2D alone and in combination with tislelizumab. Phase 1A (BGB-A333 dose escalation) will follow a 3+3 design to establish the RP2D of BGB-A333. Phase 1B (combination dose confirmation) explores safety and tolerability of IV BGB-A333 (determined from dose escalation) in combination with IV tislelizumab (200 mg Q3W). Phase 2 is designed to evaluate the antitumor activity of BGB-A333 alone and in combination with tislelizumab. Phase 2A (BGB-A333 dose expansion) will enroll patients into two cohorts: non-small cell lung cancer and urothelial carcinoma. Phase 2B (combination dose expansion) will enroll patients with specific tumor types, which will be chosen based on data from phase 2A and other studies. The primary endpoint of the phase 2 study is overall response rate. Clinical trial information: NCT03379259.

TPS3114 Poster Session (Board #321b), Mon, 8:00 AM-11:30 AM

A phase 3, double-blind, randomized study of pamiparib versus placebo as maintenance therapy in patients with inoperable, locally advanced, or metastatic gastric cancer that responded to platinum-based first-line chemotherapy. *First Author: Fortunato Ciardiello, University of Campania "Luigi Vanvitelli", Naples, Italy*

Background: Gastric cancer is the fifth most common cancer, and is the third leading cause of cancer deaths worldwide. A subset of gastric cancers exhibit platinum sensitivity and genomic instability that is characteristic of homologous recombination deficiency (HRD). Poly(ADP-ribose) polymerase proteins 1 and 2 (PARP1/2) are involved in DNA damage repair, and their inhibition is cytotoxic for cells with HRD. Pamiparib (previously known as BGB-290) is a selective PARP1/2 inhibitor that crosses the blood-brain barrier, has shown potent DNA–PARP trapping, and has demonstrated robust antitumor activity in preclinical models. In early phase clinical studies (NCT02361723; NCT03333915), pamiparib was generally well tolerated and showed promising antitumor activity. These studies also established 60 mg orally twice daily as the recommended pivotal dose. **Methods:** This double-blind, placebo-controlled, randomized, multicenter phase 3 study (NCT03427814) conducted in Asia, Australia, Europe, and North America is designed to compare the efficacy, safety, and tolerability of pamiparib with placebo as maintenance therapy in ~540 patients with advanced gastric cancer who have responded to first-line, platinum-based chemotherapy. Patients who are $\leq$8 weeks after their last platinum dose of first-line chemotherapy will be randomized 1:1 to receive either pamiparib 60 mg twice daily or placebo. Patient randomization will be stratified by genomic loss of heterozygosity status (ie, high versus low), region, and ECOG status. Radiologic assessments will be centrally evaluated per RECIST every 8 weeks after first dose. The primary endpoint is progression-free survival; key secondary endpoints include safety/tolerability, overall survival, objective response rates, and duration of response. Clinical trial information: NCT03427814.

TPS3115 Poster Session (Board #322a), Mon, 8:00 AM-11:30 AM

PROPEL: A phase 1/2 trial of NKTR-214 (CD122-biased agonist) combined with anti-PD-1 (pembrolizumab) or anti-PD-L1 (atezolizumab) in patients (pts) with advanced solid tumors. *First Author: Daniel A. Vaena, West Cancer Center, Germantown, TN*

Background: NKTR-214 is an investigational cytokine designed to target CD122 (IL-2Rβ) expressed on immune cells (CD8$^+$ T cells and NK cells) in order to expand these tumor-killing cells. NKTR-214 monotherapy increases newly proliferative CD8$^+$ T cells and NK cells in tumors and increases cell surface PD-1 and PD-L1 expression, demonstrating a potentially synergistic mechanism with anti-PD-1 therapy. NKTR-214 plus nivolumab resulted in rapid tumor responses in pts with metastatic melanoma (mM), non-small cell lung cancer (mNSCLC), and renal cell carcinoma. Given the early efficacy data and favorable safety profile of NKTR-214 plus nivolumab, PROPEL will evaluate the clinical benefit, safety and tolerability of NKTR-214 combined with pembrolizumab or atezolizumab. **Methods:** PROPEL (NCT03138889) will enroll approximately 60 pts in 2 separate arms concurrently. The first arm will evaluate NKTR-214 plus pembrolizumab in up to 30 select pts with locally advanced or mM, mNSCLC, or locally advanced or metastatic urothelial bladder cancer (UBC) within the FDA-approved pembrolizumab indications and dosage regimen. The second arm will evaluate NKTR-214 plus atezolizumab in up to 30 select pts with locally advanced or metastatic UBC or mNSCLC within the FDA-approved atezolizumab indications and dosage regimen. NKTR-214 is administered intravenously over 30 ($\pm$5) minutes every 3 weeks in an outpatient setting; the first studied dose of NKTR-214 will be 0.006 mg/kg. The primary objectives are to evaluate safety and tolerability and to define the maximum tolerated dose or recommended phase 2 dose of NKTR-214 combined with pembrolizumab or atezolizumab. The secondary objectives are to evaluate preliminary anti-tumor activity and efficacy by assessing overall survival and progression-free survival. In addition, the study will assess the immunological effects of treatment and the association between efficacy measures and PD-L1 expression in tumors. Treatment may continue beyond progression if there is clinical benefit as determined by the investigator. Enrollment is ongoing in the U.S. Clinical trial information: NCT03138889.

TPS3116 Poster Session (Board #322b), Mon, 8:00 AM-11:30 AM

A phase Ib study evaluating the safety and tolerability of durvalumab in combination with eribulin in patients with HER2-negative metastatic breast cancer and recurrent ovarian cancer. *First Author: Chrystal Ann Landry, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Recent studies have revealed only modest responses to single-agent immune checkpoint blockade in metastatic breast cancer (MBC) and recurrent ovarian cancer (ROC) patients as compared to other more immunogenic tumors. Methods to improve response employing the rational combination of cytotoxic chemotherapy with immunotherapies have shown promise. Eribulin (E), a novel microtubule inhibitor, is an effective single-agent chemotherapy in metastatic breast cancer with promising results observed in ovarian cancer patients. Preclinical studies have shown that E may induce intratumoral vascular remodeling through novel anti-vascular activity. It is hypothesized that the combination of E with durvalumab (D), a PD-L1 inhibitor, will result in increased T cell infiltration and activation leading to improved systemic and tumor site immune responses. **Methods:** This is a single center Phase Ib study to evaluate the safety, dose-limiting toxicity (DLT) rate, and the recommended phase II combination dose of E with D. Patients must have metastatic HER-2 negative MBC or ROC, adequate organ function, no prior treatment with E or anti-PD-1/PD-L1, and a history of prior metastatic therapy with no more than 5 prior lines. A 3+3 dose-escalation design is employed to evaluate 3 dose levels of E given by intravenous (IV) injection. The starting dose is 1.1mg/m^2 with dose escalation to 1.4mg/m^2 on day 1 and day 8 of a 21-day cycle. In the event that multiple DLTs are observed at the initial dose level, a dose de-escalation to 0.7 mg/m^2 will be utilized. A fixed dose of D (1.12g by IV) is given on day 1 of each cycle. Secondary objectives include preliminary evaluation of anti-tumor activity as measured by objective response rate, progression-free survival, and overall survival. Responses will be assessed per iRECIST every 9 weeks. Patients will be treated until unacceptable toxicity or disease progression. Optional blood samples will be collected at various time points for quantification and characterization of immune responses and evaluation for potential biomarkers of response. We estimate accrual of 6-12 patients. Clinical trial information: NCT03430518.

TPS3117 Poster Session (Board #323a), Mon, 8:00 AM-11:30 AM

An open label phase I study to evaluate the safety and efficacy of OBP-301 with pembrolizumab in patients with advanced solid tumors. *First Author: Takashi Kojima, Department of Gastroenterology and Gastrointestinal Oncology, National Cancer Center Hospital East, Kashiwa, Japan*

Background: PD-1 blockade showed promising efficacy in facilitating tumor shrinkage for broad type of cancer patients, but objective response rates are very limited. The antitumor potential of oncolytic adenoviruses has been demonstrated in preclinical and clinical studies. In addition to the specific killing of cancer cells via oncolytic virus, these agents prompt the immune system to stimulate an antitumor immune response. OBP-301 is an oncolytic adenovirus in which gene is modified to be able to selectively replicate in cancer cells by introducing human telomerase reverse transcriptase (hTERT) promotor. Further antitumor effect will be expected activating of two different antitumor immunity by using OBP-301 in combination with pembrolizumab. Therefore, we initiated phase I study to evaluate the safety and efficacy of OBP-301 with pembrolizumab. **Methods:** The major eligibility criteria is patients with advanced or metastatic solid tumor not responded to or intolerant of standard chemotherapies, and with possibility of intratumoral injection. History of anti PD-1/PD-L1/PD-L2 antibody treatment is acceptable. Phase Ia part was designed to determine the recommended dose in a "3+3" cohort-based dose escalation design of OBP-301 (1x10^{10}VP on cohort 1, 1x10^{11}VP on cohort 2 and 1x10^{12}VP on cohort 3) with pembrolizumab (200mg/body q3w). OBP-301 is administered at day1, day15, and, Day29 by intratumoral injection and pembrolizumab is administered at day 8 and thereafter every 3 weeks. Primary endpoint is dose limiting toxicity. Secondary endpoint is response rate, progression free survival, and rate of adverse event. Phase Ib part was designated to evaluate the safety and efficacy of the recommended dose OBP-301 selected in phase Ia part in combination with pembrolizumab in 10 patients. We will also investigate biomarker study using paired samples of both tumor biopsy and blood. The patient enrollment has been started in October 2017. Clinical trial information: NCT03172819.

TPS3118 Poster Session (Board #323b), Mon, 8:00 AM-11:30 AM

A phase I/II Trial of CRISPR-Cas9-mediated PD-1 knockout Epstein-Barr virus cytotoxic lymphocytes (EBV-CTLs) for advanced stage EBV associated malignancies. *First Author: Jia Wei, The Comprehensive Cancer Centre of Drum Tower Hospital, Medical School of Nanjing University & Clinical Cancer Institute of Nanjing University, Nanjing, China*

Background: EBV associated malignancies exhibits high amplification of PD-L1 as distinguished from EBV non-associated malignancies (Kim et al. Gastroenterology 2015; Chen et al. Clinical Cancer Research 2013). The up-regulation of PD-L1 restricts antitumor effect of EBV-CTLs by immune tolerance and results in poor prognosis of patients. Our previous work has generated PD-1-disrupted CTLs by CRISPR-Cas9 system which could up-regulate IFN-γ production and enhance cytotoxicity in tumor cell lines and mouse model (Su et al. Oncoimmunology 2016). **Methods:** This phase I/II prospective single center clinical study (clinicaltrials.gov NCT03044743) was designed to evaluate the safety of PD-1 knockout EBV-CTLs in treating EBV positive advanced stage malignancies. Patients included should be pathologically verified EBV positive stage IV gastric carcinoma, nasopharyngeal carcinoma or lymphoma progressed after standard treatment with measurable lesions. Patients will be divided into three groups and receive 2 to 4 cycles of cell therapy according to their tolerance. PD-1 knockout EBV-CTLs from autologous origin will be generated and 2 x 10^^{7}/kg of specific T cells will be infused in one cycle. Each cycle is divided into three administrations, with 20%, 30% and 50% respectively. To modify immune microenvironment, Fludarabine at 30mg/m^2 and cyclophosphamide at 300mg/m^2 will be administered 3 days (intravenous injection, i.v.) before cell infusion. Interleukin-2 will be given daily (i.v.) from the first day of the cell infusion for 5 consecutive days at the dose of 4000,000 international unit (IU)/day to sustain the survival of infused T cells. The adverse events will be evaluated after each cycle by Common Terminology Criteria for Adverse Events (CTCAE v4.0) as primary endpoint. Progression-free survival (PFS), the duration of the normalization of tumor marker and immunological markers will be evaluated as the secondary endpoints. Immunological markers will continuously be examined every two cycles. Clinical trial information: NCT03044743.

TPS3119 Poster Session (Board #324a), Mon, 8:00 AM-11:30 AM

Phase Ib trial of nivolumab combined with metformin for refractory/recurrent solid tumors. *First Author: Toshio Kubo, Center for Clinical Oncology, Okayama University Hospital, Okayama, Japan*

Background: Although immune-checkpoint inhibitors (ICIs) have shown significant survival benefits in several cancers, optimal outcomes have been limited to subsets of patients. We obtained complete regression of an engrafted solid tumor with metformin in a murine syngeneic model. This effect could not be obtained in T cell-deficient SCID mice. These findings suggested that metformin induced immune-mediated reactions. The combination of anti-PD-1 antibody (nivolumab) and metformin resulted in significant tumor regression. This combination also increased the number of tumor-infiltrating CD8 T cells producing IL-2, TNF-α, and IFN-γ, suggesting that this combination induced clinically synergistic antitumor effects. Based on these results, we initiated the following study. Objectives: To investigate the safety, efficacy, and pharmacokinetics of combined treatment with metformin and nivolumab. **Methods:** This was an open-label, phase Ib trial consisting of two parts (part 1 and 2). The recommended dose of metformin combined with nivolumab was determined in part 1, and the safety and efficacy at the optimal dose were examined in part 2. The inclusion criteria were as follows: histologically or cytologically diagnosed refractory/recurrent solid tumors in part 1, and non-small cell lung cancer or pancreatic cancer that was refractory to standard primary treatment in part 2; use of naïve ICIs; a performance status of 0 or 1; $>$ 20 years of age; and adequate organ functions. The primary endpoints were safety, maximum tolerated dose (MTD), and dose limiting toxicity (DLT) in part 1, and pharmacokinetics and adverse event profiles in parts 1 and 2. The secondary endpoints were efficacy, tumor shrinkage, and progression-free survival. Nivolumab (3 mg/kg) was administered intravenously every 2 weeks. In part 1, metformin was started at 750 mg/day, and increased by 750 mg/day up to 2,250 mg/day. The MTD and recommended dose were determined by the 3+3 cohort method. The DLT evaluation period was 4 weeks from the start of administration. A total of 9–18 patients were enrolled in part 1, and 30 patients in part 2. Enrollment began in 2017 and will be complete by 2019. The UMIN registration number is 000028405. Clinical trial information: 000028405.

TPS3120 Poster Session (Board #324b), Mon, 8:00 AM-11:30 AM

An open-label, multidrug, biomarker-directed, multicentre phase II umbrella study in patients with non-small cell lung cancer, who progressed on an anti-PD-1/PD-L1 containing therapy (HUDSON). *First Author: John Heymach, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Immune checkpoint inhibitor (ICI) containing regimens have significantly improved survival outcomes in first- and second-line non-small cell lung cancer (NSCLC). However, the majority of patients do not respond or have non-durable responses leading to a new ICI-resistant population. HUDSON addresses the urgent need to identify treatments and understand ICI-resistance for this emerging population. **Methods:** HUDSON is a multicentre, international multi-arm umbrella study that will 1) evaluate therapies to reverse ICI-resistance and 2) define mechanisms of ICI-resistance in NSCLC patients who have progressed following standard-of-care platinum and ICI based therapies. HUDSON is a platform study that consists of two groups; a biomarker matched and a biomarker non-matched group. Within the biomarker matched group, different cohorts will test 1) homologous recombination repair (HRR) defects and 2) LKB1 aberration for response to durvalumab and olaparib (PARP inhibitor), 3) ATM deficiency for response to durvalumab and AZD6738 (ATR inhibitor) and 4) RICTOR amplification for response to durvalumab and vistusertib (mTORC1/2 inhibitor). In the biomarker non-matched group, cohorts will test durvalumab in combination with either i) olaparib, ii) AZD9150 (STAT3 inhibitor) or iii) AZD6738. New cohorts will be added as new translational hypotheses are established. Translational research will be performed on serial peripheral blood samples (including ctDNA) and tumour biopsies. HUDSON enrolls ICI-resistant/refractory patients in a signal searching manner. Biomarker matched and non-matched groups will be opened simultaneously, and all eligible patients can be allocated a treatment option irrespective of their tumour profile. Enrolment is ongoing, Clinical trial information: NCT03334617.

TPS3121 Poster Session (Board #325a), Mon, 8:00 AM-11:30 AM

Trial in progress: Platform phase 1 study investigating the safety of stereotactic body radiotherapy with immuno-oncology agents for the treatment of multiple metastases in advanced solid tumors. *First Author: Corey Christian Foster, Department of Radiation & Cellular Oncology, The University of Chicago Medicine, Chicago, IL*

Background: Stereotactic body radiotherapy (SBRT) and immuno-oncology (IO) have been associated with improved oncologic outcomes when given as monotherapy for advanced solid tumors. Furthermore, preclinical studies have suggested synergistic interactions between SBRT and IO agents with enhanced anti-tumor activity possibly mediated by the induction of CD8+ T-cells. Additionally, patients with advanced melanoma receiving dual IO therapy in the absence of SBRT experienced longer overall survival than patients receiving single-agent IO therapy. Given these findings, it is reasonable to hypothesize that dual IO therapy in combination with SBRT may be more efficacious than any of these treatments alone. However, the safety of multiple IO agents given in combination with SBRT is unknown. **Methods:** The study is a single-center, phase 1, open-label, two-arm, non-randomized clinical trial for patients with advanced solid tumors and at least 1 measurable site of disease after receiving $\leq$ 3 prior systemic therapies. Enrolled patients receive either (1) concurrent nivolumab (anti-PD-1, 240 mg IV flat dose every 2 weeks) + urelemab (anti-CD137, 8 mg flat dose IV every 4 weeks) + SBRT or (2) concurrent nivolumab (240 mg IV flat dose every 2 weeks) + cabiralizumab (anti-CSF1R, 4 mg/kg IV every 2 weeks) + SBRT. SBRT is delivered to 1-4 sites to a maximum target volume of 65 cc/site. Dual IO therapy is continued until progression or fulfilment of discontinuation criteria. We expect 42-72 patients to be enrolled on study until 5 separate organ sites receiving SBRT have accrued at least 6 participants for evaluation of dose-limiting toxicity at the starting dose and a de-escalated dose if necessary. The primary endpoint is dose-limiting toxicity defined as $>$ 33% rate of grade $\geq$3 toxicity. Secondary endpoints include response rate, PFS, and OS. Exploratory analyses include investigation of candidate biomarkers (e.g., PD-L1 status, circulating tumor DNA, gut microbiome data) for treatment efficacy. Enrollment is ongoing. Clinical trial information: NCT03431948.

TPS3122 Poster Session (Board #325b), Mon, 8:00 AM-11:30 AM

Expansion cohort of partially irradiated tumors on a phase 1 trial of pembrolizumab and ablative radiotherapy. *First Author: Sandeep Ramesh BHave, University of Chicago Medicine, Chicago, IL*

Background: Preclinical studies suggest multi-organ site ablative radiation therapy (MOSART) may enhance systemic anti-tumor response through altering the balance of innate and adaptive immunity within the tumor microenvironment and through direct tumor debulking. Previously, we opened a phase I study to evaluate the safety and efficacy of the combination of pembrolizumab with MOSART for patients with metastatic solid tumors. In the first cohort of 73 patients analyzed, the combined therapies were safe in all organ systems studied with no radiation dose reductions (Luke & Lemons et al. J Clin Oncol 2018, in press). Interestingly, large partially irradiated tumors exhibited control similar to smaller completely irradiated tumors (93% vs. 96% at 6 months, p = 0.32). In December 2017, we opened an expansion cohort to formally test the secondary hypothesis that partially irradiated tumors exhibit local control similar to completely irradiated tumors when combined with immunotherapy. **Methods:** We are accruing patients with metastatic disease progressing on standard of care treatment, two or more lesions amenable to MOSART, and have at least one lesion greater than 65cc. Enrollment is currently at six of forty planned subjects, and is actively accruing patients. MOSART dosing is based on NRG BR-001 (30 Gy in 3 fractions for osseous and spinal lesions; 45 Gy in 3 fractions for peripheral lung, liver, and abdominal-pelvic lesions; 50 Gy in 5 fractions for central lung, mediastinal, and cervical lesions). At least two lesions are targeted for each patient and not all sites of disease are treated. The maximum gross tumor volume (GTV) that is completely irradiated is 65cc. Partial tumor irradiation is administered to lesions $>$ 65cc where the target volume is created by performing volume contraction down to 65 cc within the initial radiographically defined GTV. Pembrolizumab 200mg IV Q3W is to be initiated within seven days after final MOSART treatment. RECIST 1.1 will be used used to assess radiated tumor progression. Control (defined as CR, PR, or SD) will be calculated by the Kaplan Meier method and compared between partially irradiated tumors and completely irradiated tumors with the log-rank test. Clinical trial information: NCT02608385.

TPS3123 Poster Session (Board #326a), Mon, 8:00 AM-11:30 AM

A multicenter phase 2 study of nivolumab combined with ipilimumab in patients with pediatric solid tumors in adulthood (GETHI021). *First Author: Xabier Mielgo, Hospital Universitario Fundación Alcorcón, Alcorcón, Spain*

Background: Solid pediatric tumors that appear in adulthood are a heterogeneous group that share some characteristics such as low incidence, lack of standard therapeutic options and reduced survival. Pediatric cancers usually originate from embryonic cells that likely present genetic alterations and epitopes different from mature cells. These may be targeted by the immune system, if properly stimulated by immune checkpoint inhibitors (ICI). Thus, ICIs could achieve a significant activity in these tumors. Here, we present the first phase II clinical trial of nivolumab and ipilimumab in this setting. **Methods:** A multicenter, open-label, single arm Phase II study was designed to evaluate the efficacy, safety and tolerability of the combination of nivolumab and ipilimumab in adult patients ($\geq$18 years) with locally advanced or metastatic childhood malignancies that have progressed or are not candidates to standard therapy. The Spanish Group for Infrequent and Orphan Tumors (GETHI) is the sponsor of the study and 15 associated Spanish centers are participating. Main inclusion criteria are: adult subjects, ECOG PS $\leq$2, no prior anti-PD1 or anti-CTLA4 therapy. Treatment schedule is nivolumab 3 mg/kg IV q2w + ipilimumab 1 mg/kg IV q6w for 6 months or until RECIST v1.1 progression/unacceptable toxicity. Study treatment may continue beyond disease progression and may be extended for a maximum of 24 months if clinical benefit exists. Primary endpoint is objective overall response rate (ORR) according to RECIST v1.1 criteria. Secondary endpoints are toxicity profile, quality of life, PFS and OS. In addition, a comprehensive molecular study to identify potential biomarkers will be performed. Following Simon optimal two-stage design, the first stage includes 30 evaluable patients If ORR is $>$ 10%, the study will continue to a second stage until 89 evaluable patients are recruited. The null hypothesis will be rejected if ORR $\geq$20%. This design yields a type I error rate of 0.05 and power of 80% when true response rate is 0.20. Accrual started in July 2017 and 26 patients have been enrolled up to January 2018. Scheduled recruitment period is 18 months. EudraCT number: 2016-003946-99. Clinical trial information: 2016-003946-99.

TPS3124 Poster Session (Board #326b), Mon, 8:00 AM-11:30 AM

Regorafenib and nivolumab combination therapy for advanced and metastatic solid tumors: Phase I clinical trial (EPOC1603). *First Author: Shota Fukuoka, Division of Cancer Immunology, Exploratory Oncology Research and Clinical Trial Center, National Cancer Center Hospital East, Kashiwa, Japan*

Background: Immune checkpoint inhibitors (CPIs) have shown promising efficacies in several types of malignancies. However, still around half of patients with most tumor types experienced disease progression at the initial tumor assessment. One possible reason for resistance to CPIs is suspected to be based on interaction with cancer niche which include suppressive immune cells such as myeloid-derived suppressor cells (MDSC), regulatory T cells (Tregs) and tumor-associated macrophages (TAMs). Previous in vivo study showed that selective inhibition of VEGF pathway with anti-VEGF antibody or anti-VEGF tyrosine kinase inhibitors (TKIs) suppress tumor growth and decrease MDSC, Tregs and TAMs. In addition, suppression of stem cell factor (SCF)-mediated signaling though c-Kit also decreases MDSC expansion and tumor angiogenesis, which may overcome resistance to CPIs. Therefore, we initiated phase I study to assess efficacy and safety for the combination of nivolumab and regorafenib as a multi-kinase inhibitor targeting both VEGF and SCF signaling. **Methods:** The main eligibility criteria is patients with unresectable recurrent solid tumors who are refractory or intolerant to standard chemotherapy. Primary objective is to examine the safety and tolerability of repeated dosing of regorafenib and nivolumab and to investigate the maximum tolerated dose (MTD) and recommended dose (RD). Dose escalation cohort was designed to determine the recommended expansion cohort dose in a "3+3" cohort-based dose escalation design of regorafenib (80 mg once dairy for 21 days on 7 days off on level 1, 120 mg on level 2 and 160 mg on level 3) with nivolumab (3.0 mg/kg q2w). In expansion cohort, approximately 30 patients with selected solid tumors such as gastric, coloretcal, hepatocellular cancer will be enrolled at the RD. We also investigate several biomarkers using pre- and post-treatment samples from both biopsied tumor and blood. First three patients were enrolled and treated in level 1 as of January 2018. Clinical trial information: NCT03406871.

TPS3125 Poster Session (Board #327a), Mon, 8:00 AM-11:30 AM

A phase I/II study of regorafenib (R) plus avelumab (A) in digestive tumors. *First Author: Sophie Cousin, Institut Bergonié, Bordeaux, France*

Background: Several preclinical studies have shown that simultaneous blockade of programmed death(PD) 1/PD-L1 and neoangiogenesis induces synergistic anti-tumour effect *in vivo*. R is a multikinase inhibitor approved for the treatment of metastatic colorectal (CRC) and gastro intestinal stromal tumor (GIST). A is a PD-L1 inhibitor approved for the treatment of Merkel carcinoma. We hypothesized that R in association with A could be synergistic and feasible in patients (pts) with tumors of the digestive tract. **Methods:** This is a multicenter, prospective phase I/II trial assessing R+A in 4 cohorts of pts with advanced pretreated: A) CRC not MSI-H or MMR-deficient, B) GIST, C) Oesophageal/gastric carcinoma, D) Biliary tract/hepatocellular carcinoma. Primary objectives are to determine the recommended phase II dose (RP2D) of R+A in phase I, and assess the best overall response defined as per RECIST v1.1 with A+R in phase II. In phase I, 2 doses of R will be investigated: 120mg, 160mg, daily, 3 weeks on/1 week off with fixed dose of A: 10mg/kg every 2 weeks. In phase II, all pts will received the RP2D of R with A. Main eligibility criteria are: -adult pts with metastatic, histologically confirmed tumor of 1 of the 4 cohorts, with measurable, progressive disease, after $\geq$ 1 previous line of systemic therapy. Primary endpoint is toxicity according to NCI-CTCAE v4.0 and incidence rate of DLT at each dose level during the first 28 days (I); antitumor activity in terms of best overall response (II). Secondary endpoints encompass: Objective Response Rate (ORR), Progression Free Survival (PFS), Growth modulation index, 6-months,1-year PFS and Overall Survival, PKs, Pharmacodynamics on (I) mandatory blood samples at baseline/on treatment, archived tumor tissue, (II) on optional biopsy at Baseline/after 4 weeks of R+A focusing on TAM, Lymphocytes infiltrates, PD-L1, VEGFR, PDGFR, HIF1alpha expression. Phase I will follow a classical 3+3 design with 2 dose levels and a maximum of 12 pts. A Bayesian approach will be used in phase II, with a maximum sample size of 50 pts/cohort. At each update of interim analysis, a stopping rule for inefficacy will recommend stopping the trial if there is a high predictive probability ($\geq$80%) that ORR is $<$ or = to the futility bound p0 = 20%. Clinical trial information: NCT03475953.

TPS3126 Poster Session (Board #327b), Mon, 8:00 AM-11:30 AM

An open-label, phase 2 study of nivolumab in combination with either rucaparib, docetaxel, or enzalutamide in men with castration-resistant metastatic prostate cancer (mCRPC; CheckMate 9KD). *First Author: Karim Fizazi, Gustave Roussy, Villejuif, France*

Background: Although multiple new agents have been approved for mCRPC over the last decade, median survival remains unsatisfactory at ~12-35 months. Immunotherapy targeted solely at programmed death-1 (PD-1)/PD-1 ligand-1 (PD-L1) interactions has shown limited evidence of antitumor activity in patients (pts) with prostate cancer, likely due to the immunologically "cold" nature of the tumor and low PD-L1 expression on tumor cells. However, if existing prostate cancer treatments can trigger an adaptive immune response, attracting infiltrating immune cells and increasing tumor PD-L1 expression, there is a rationale for combination with anti-PD-1/PD-L1 inhibitors to improve outcomes. The current phase 2 study will evaluate combinations of the PD-1 inhibitor nivolumab with either rucaparib (PARP inhibitor), docetaxel, or enzalutamide (androgen receptor inhibitor) in men aged $\geq$18 years with mCRPC (NCT03338790). **Methods:** Key inclusion criteria: Histologic confirmation of adenocarcinoma of the prostate, evidence of metastatic disease, ongoing androgen deprivation therapy, and evaluable tumor biopsy. Key exclusion criteria: Active brain metastases, active malignancy in prior 3 years (except apparently cured locally-curable cancers), and major surgery $\leq$14 days before treatment assignment. Pts will be assigned to nivolumab + rucaparib, nivolumab + docetaxel, or nivolumab + enzalutamide based on prior systemic treatment history and the presence/absence of measurable disease and homologous recombination deficiency (HRD). Nivolumab, rucaparib, and enzalutamide treatment will continue until disease progression/unacceptable toxicity (nivolumab treatment $\leq$2 years); docetaxel will be given for $\leq$10 cycles. Co-primary endpoints: Objective response per Prostate Cancer Clinical Trials Working Group 3 criteria and prostate-specific antigen response in HRD+ pts and all treated pts; secondary endpoints: Overall survival, progression-free survival, and response kinetics in HRD+ pts and all treated pts, and safety/tolerability in all treated pts. Enrollment began December 2017 with a target of ~300 pts. Clinical trial information: NCT03338790.

TPS3127 Poster Session (Board #328a), Mon, 8:00 AM-11:30 AM

A study of REGN3767, an anti-LAG-3 antibody, alone and in combination with cemiplimab (REGN2810), an anti-PD1 antibody, in advanced cancers. *First Author: Kyriakos P. Papadopoulos, START, San Antonio, TX*

Background: Lymphocyte activation gene 3 (LAG-3) is an immune checkpoint receptor with a biological role in T cell regulation. Analysis of immune-cell infiltrates from human tumors show that a subset of CD4+ and/or CD8+ cells co-express LAG-3 and PD-1 and may be associated with decreased T-cell effector function and tumor escape (Baitsch L et al. *J Clin Investig*. 2011;121:2350-2360; Jie HB et al. *Br J Cancer*. 2013;109:2629-2635.). Preclinical models provide evidence that dual inhibition of LAG-3 and PD-1 blockade offer synergistic anti-tumor effects and suggest a promising immunotherapy combination that warrants clinical investigation (Woo SR et al. *Cancer Res*. 2012;72(4): 917-927). This first in human study will evaluate the safety and efficacy of REGN3767 alone and in combination with cemiplimab in advanced malignancies. **Methods:** Phase 1 study enrolling patients with advanced malignancies. Dose escalation phase employs a modified 3+3 (4+3) design to assess the tolerability and pharmacokinetics (PK) of REGN3767 monotherapy and in combination with cemiplimab. Monotherapy is exploring 4 escalating REGN3767 dose levels. Combination is exploring 3 escalating REGN3767 dose levels. After tolerability and PK evaluation, doses of REGN3767 will be selected for monotherapy and combination therapy tumor-specific expansion cohorts. Solid tumor expansion cohorts will enroll per Simon's two-stage design to evaluate safety and preliminary efficacy. Lymphoma expansion cohorts will enroll 15 patients. Patients who are anti-PD-1/PD-L1 therapy naïve and experienced are eligible for separate cohorts. Patients previously exposed to anti-LAG-3 therapy are not eligible. The primary objectives are the determination of the recommended phase 2 dose (RP2D, dose escalation) and ORR (dose expansion). Secondary objectives include characterization of PK and immunogenicity in all patients, as well as anti-tumor efficacy in dose escalation, and safety in dose expansion. This trial is actively enrolling eligible patients in the US, UK, Ireland, and South Korea. Clinical Trial Information: NCT03005782.

TPS3128 Poster Session (Board #328b), Mon, 8:00 AM-11:30 AM

Phase I study of recombinant interleukin-15 in combination with checkpoint inhibitors nivolumab and ipilimumab in subjects with refractory cancers. *First Author: Geraldine Helen O'Sullivan Coyne, Early Clinical Trials Development Program, DCTD, National Cancer Institute at the National Institutes of Health, Bethesda, MD*

Background: Interleukin-15 is a stimulatory cytokine. Recombinant human IL-15 (rhIL-15), a nonglycosylated single-chain peptide, increased circulating CD8+T-cells, NK cells and inflammatory cytokines in clinical trials (Conlon *et al*, 2015. JCO). Simultaneous *in vivo* administration of IL-15 with anti-CTLA-4 and anti-PD-L1 is associated with increased levels of tumor antigen-specific CD8+T cells and T-cell tumor lytic activity, increased antigen-specific IFN-γ release, decreased tumor growth, and improved mouse survival; as well as inhibition of suppressive functions of CD4+CD25+ and CD8+CD122+ regulatory T-cells (Yu *et al*, Proc Natl Acad Sci. 2012). Therefore we postulate the combination of checkpoint inhibitors+rhIL-15, which act on different stages of T-cell activation, will enhance anti-tumor immune responses through T-cell expansion, differentiation, and cytotoxic activity. **Methods:** Open label phase I trial of the rhIL-15+ipilimumab+nivolumab combination following a 3+3 design, with safety lead-in doublets of rhIL-15 +nivolumab (Cohort A) or rhIL-15+ipilimumab (Cohort B). Estimated enrollment: 45 patients (pts). 42-day cycles: rhIL-15 administered subcutaneously on days 1-8 and 22-29 for the first 4 cycles only; nivolumab intravenously (IV) day 8, 22 and 36; ipilimumab IV day 1. Pts must be ≥18 years of age, have histologically confirmed solid tumors that have progressed on standard of care therapy, ECOG PS ≤2. Pts with treated brain metastasis with stable disease ≥4 weeks without requiring steroids/anti-seizure medication, and who do not response on any 2/3 agents, are eligible. Exclusion criteria include grade3 immune related adverse events during prior checkpoint inhibitor treatment, active/chronic autoimmune disease, systemic steroid use or HIV/hepatitis infection. Currently, cohort A has enrolled 1 of 3 planned pts. Assessment of intrinsic apoptosis biomarkers, PD-L1 levels, T-cell phenotypic markers, markers of T-cell activation/inhibition (Zap70 pY493/pY580 SHP2), cell enumeration, proximity of tumor cells to T cells at the maximally tolerated dose using a validated/quantitative immunofluorescence assay, is planned. Clinical trial information: NCT03388632.

TPS3129 Poster Session (Board #329a), Mon, 8:00 AM-11:30 AM

The "INSIGHT" trial: An explorative, open-labeled phase I study to evaluate the feasibility and safety of intra-tumoral, intra-peritoneal, and subcutaneous injections with IMP321 (LAG-3Ig fusion protein) for advanced stage solid tumor entities. *First Author: Daniel Wilhelm Mueller, Institute of Clinical Cancer Research (IKF) at Krankenhaus Nordwest, UCT-University Cancer Center, Frankfurt, Germany*

Background: The INSIGHT study evaluates feasibility and safety of intra-tumoral and intraperitoneal injections of IMP321 (mono-agent) for the treatment of advanced stage solid tumors as well as to generate first efficacy data. This proof-of-concept data could build the basis for further clinical studies exploring the therapeutic potential of active immunotherapy with IMP321 by direct injection into the tumor mass or the peritoneal space. Furthermore, safety and efficacy of combining standard-of-care (SOC) chemo(immuno-)therapies with IMP321 subcutaneous (s.c.) injections in various solid tumor entities will be assessed. IMP321 is a soluble form of the LAG-3 T cell surface receptor with a dual mode of action (MOA) consisting of activation of antigen presenting cells (primary MOA) and prevention of exhaustion of activated T-cells (secondary MOA at high local concentration). **Methods:** This is a prospective investigator initiated phase I trial consisting of three strata. Stratum A: Pretreated patients with solid tumors which are accessible for repeated injections and biopsies receive q2w intra-tumoral injections of IMP321 as a monotherapy. Stratum B: Pretreated patients with solid tumors and additional peritoneal carcinomatosis receive q2w intraperitoneal IMP321 injections via direct injection or a silicon catheter. Both strata are performed in a classical 3 patient cohort study design consisting of intra-patient dose-escalation and consolidation cohorts. Stratum C: Patients with solid tumors treated with SOC chemo(immuno-)therapy in first or second line receive concomitant s.c. IMP321 injections. It is planned to enroll 9 patients each in Stratum A and Stratum B and 20 patients in Stratum C. Main efficacy endpoint is the overall response rate according to RECIST criteria. The trial is accompanied by an extensive biomarker research program. Recruitment has started; currently (Feb 2018) 4 patients have been enrolled (3 Stratum A, 1 Stratum B). Up to now, no DLTs have been observed. ClinicalTrials.gov Identifier: NCT03252938; EudraCT: 2016-002309-20. Clinical trial information: NCT03252938.

TPS3130 Poster Session (Board #329b), Mon, 8:00 AM-11:30 AM

A sequential cohort study of combination immunotherapy with BN-brachyury vaccine, M7824, ALT-803 and epacadostat in metastatic castration-resistant prostate cancer (mCRPC) (QuEST1). *First Author: Jason M. Redman, National Cancer Institute, Bethesda, MD*

Background: Vaccine and checkpoint inhibitor monotherapies infrequently produce objective responses in mCRPC. Combination immunotherapy that 1) facilitates immune recognition of tumor, 2) increases number and function of tumor directed effector cells, and 3) decreases immune suppression in the tumor microenvironment (TME), is a promising strategy to improve outcomes in mCRPC. In pursuit of safety and efficacy, this Quick Efficacy Seeking Trial (QuEST1) will add immunotherapies to sequential study arms. QuEST1 first combines the BN-Brachyury vaccine, targeting a transcription factor involved in epithelial-mesenchymal transition and drug resistance, with a bifunctional agent (M7824) targeting PD-L1 and TGF-β. The next arm adds an IL-15 superagonist (ALT-803) to boost NK and T cell number and function. The final arm adds epacadostat, an IDO1 inhibitor that dampens immune suppression in the TME. **Methods:** Eligibility criteria: prostate cancer, castrate testosterone level, and metastases to bone, organs or lymph nodes. Exclusion criteria: ECOG > 1, immunosuppression, and regular use of narcotic analgesics. QuEST1 will enroll up to 93 patients to sequential arms; each arm evaluates 2-4 treatments. A safety cohort, open to any solid tumor, will assess safety and dose finding for M7824 + ALT-803 (enrolls simultaneously to Arm1). Arm1 will treat 13 pts with BN-Brachyury + M7824. If safety, Arm2 (adds ALT-803) will enroll 13 pts. If safety, Arm3 (adds epacadostat) will enroll 13 pts. Primary endpoints (response definition): objective response by RECISTv1.1 and/or sustained decrease in PSA ≥30% (treatment efficacy). Using a Simon minimax two stage design, if ≥2 of 13 patients in an arm demonstrate efficacy, the arm will expand to n = 25. The fraction of patients who experience efficacy will be reported with two-sided 80% and 95% confidence intervals. Secondary endpoint: PFS. Exploratory endpoints: Correlate immunologic parameters with response (number/function of circulating antigen-specific T cells, immune cell phenotype, sCD40L, sCD20, prostate-specific membrane antigen+ extracellular vesicles (EV) and immune EVs.

TPS3131 Poster Session (Board #330a), Mon, 8:00 AM-11:30 AM

A phase 1/2 study with birinapant in combination with pembrolizumab. *First Author: Russell J. Schilder, Thomas Jefferson University Hospital, Philadelphia, PA*

Background: Birinapant is a bivalent SMAC mimetic with activity against multiple members of the inhibitor of apoptosis protein (IAP) family including cIAP1 and has demonstrated tolerability with robust and durable target engagement in advanced cancers. Synergistic effects of combining birinapant with immune checkpoint inhibitors have been demonstrated in preclinical models, consistent with the reported role of cIAP1 in tumor cells and immune cells (Beug et al., 2017). Based on these observations, a phase 1/2 trial with birinapant and pembrolizumab has been initiated (NCT02587962). **Methods:** In the dose escalation part of this multi-center phase 1/2 study, patients > 18 years with advanced solid tumors without further suitable standard therapeutic options are eligible for inclusion. The primary objective is to determine the safety and tolerability of the recommended phase 2 dose (RP2D) of birinapant in combination with pembrolizumab using a standard 3+3 design. The secondary objective is to assess efficacy by RECIST 1.1. The doses of birinapant to be evaluated are 5.6, 11, 17 and 22 mg/m^2 IV on day 1 and 8 in addition to pembrolizumab 200 mg on day 1 in a 21-day cycle. RP2D will be proposed by the safety review committee. The phase 2 part plans to include 111 patients. The primary objective is to assess the clinical activity of birinapant and pembrolizumab, measured as ORR by RECIST in separate cohorts of microsatellite stable colorectal (N = 28), ovarian (N = 27) and cervical cancer (N = 26). Simon's two-stage design yields a type I error rate of 0.05 and statistical power of 0.80 for each of the three cohorts using a one-sided test based on true response rates of 20% (colorectal cancer), 25% (ovarian cancer) and 30% (cervical cancer). The study will also evaluate an exploratory cohort consisting of five patients each with small cell lung cancer, cholangiocarcinoma, gastroesophageal carcinoma, mesothelioma, head and neck squamous cell carcinoma (check-point inhibitor-naïve and experienced). The phase 2 secondary objectives are safety and tolerability, tumor response, progression-free and overall survival. Exploratory objectives will assess tumor response by iRECIST, pharmacokinetics, pharmacodynamics and predictive biomarkers. Clinical trial information: NCT02587962.

TPS3132 Poster Session (Board #330b), Mon, 8:00 AM-11:30 AM

Phase 1, multicenter, open-label study of single-agent bispecific antibody t-cell engager GBR 1342 in relapsed/refractory multiple myeloma. *First Author: Joshua Ryan Richter, John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, NJ*

Background: Therapeutic advances have improved outcomes in multiple myeloma but patients eventually relapse, requiring treatment with agents that are active in refractory disease. CD38, a transmembrane glycoprotein upregulated on myeloma cells, is a validated disease target as evidenced by the anti-myeloma activity of daratumumab, an anti-CD38 human IgG1κ monoclonal antibody. However, not all patients respond and many eventually develop progressive disease to daratumumab monotherapy.[1] GBR 1342, a CD3xCD38 bispecific antibody engineered (using Glenmark's BEAT platform) to direct T-cells to CD38-expressing myeloma cells, has the potential to overcome the limitations of existing therapies. In preclinical studies, GBR 1342 redirected the cytotoxic potential of T-cells to human myeloma cell lines in vitro and in mouse xenograft models. This ongoing, 2-part, first-in-human study aims to: (1) evaluate the safety and maximum tolerable dose (MTD) of GBR 1342 monotherapy in subjects with relapsed/refractory multiple myeloma (>3 prior therapies); and (2) further elucidate the safety, tolerability, and preliminary clinical activity of GBR 1342 at the MTD. **Methods:** In Part 1, intravenous GBR 1342 is administered on Days 1 and 15 in 28-day treatment cycles at escalating doses (Table). The first 4 cohorts consist of a single subject. Subsequent cohorts use a 3+3 enrollment design. In Part 2, 65 evaluable subjects will be treated at the MTD identified in Part 1 until disease progression or unacceptable toxicity occurs. Primary endpoints include AEs (frequency, severity), number of dose-limiting toxicities during Cycle 1 (Part 1), and objective response to GBR 1342 (Part 2). Secondary endpoints include pharmacokinetics and anti-tumor activity of GBR 1342 (progression-free and overall survival). [1]Nijhof IS et al. Blood 2016; doi.org/10.1182. Clinical trial information: NCT03309111.

Dose escalation scheme (doses in ng/kg).

		Cycle 1		Cycle 2		Subsequent Cycle(s)	
	Cohort	Day 1	Day 15	Day 1	Day 15	Day 1	Day 15

TPS3133 Poster Session (Board #331a), Mon, 8:00 AM-11:30 AM

Phase I/II dose escalation and expansion cohort safety and efficacy study of image guided intratumoral CD40 agonistic monoclonal antibody APX005M in combination with systemic pembrolizumab for treatment naive metastatic melanoma. *First Author: Daniel H. Johnson, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Checkpoint blockade has become a major modality in the treatment of metastatic melanoma (MM). However, durable remission rates remain low. CD40 activation on antigen presenting cells (APCs) initiates their ability to prime and activate $CD8^+$ T-cells through upregulation of co-stimulatory molecules (ie. CD80, CD86) as well as expression of effector cytokines. Furthermore, CD40 activation cause macrophages to develop a tumoricidal phenotype and increase MHC I expression on tumor cells. Direct IT immune modulation utilizes the tumor as a "vaccine site" to generate a tumor specific immune response. We hypothesize that IT injection of a CD40 Agonist (A), will "immunize" patients (Pts) against melanoma neoantigens through "licensing" of APCs for tumor specific T-cell priming and activation. In mouse models, we have shown that IT administration of the recombinant adenovirus encoding CD40L induces $CD8^+$ T-cell-mediated activity against B16 melanoma and, importantly, also augmented the activity of anti-PD-1. **Methods:** This phase I/II trial (NCT02706353) evaluates the safety, efficacy, and immunological impact of IT administration of APX005M (CD40 A mAb) in combination with pembrolizumab in pts with MM. The phase I escalation is an accelerated 3+3 design. Pts will receive IT APX005M every 3 weeks for a total of 4 doses. Image guidance will allow for injection of visceral, nodal, and soft tissue metastases. The single-arm phase 2 expansion will evaluate the overall response rate (ORR) 12 weeks after treatment initiation. Key inclusion criteria: confirmed, measurable, metastatic cutaneous or mucosal melanoma; and at least 2 injectable lesions. Key exclusion criteria: prior immunotherapy, uveal melanoma, or active autoimmune disease. 26 pts will have 75% power to detect an improvement from a null ORR of 33% to 55%, using a one group chi-square test and assuming a one-sided α–level of 5%. Immune analysis will be performed on pre and on-treatment tumor/liquid biopsies both in injected and non-injected tumors. Dose level 3 of escalation phase has completed with 5 pts enrolled. Clinical trial information: NCT02706353.

TPS3134 Poster Session (Board #331b), Mon, 8:00 AM-11:30 AM

An open-label, phase 1b study of NEO-PV-01 with pembrolizumab plus chemotherapy in patients with advanced or metastatic nonsquamous non-small cell lung cancer. *First Author: Ramaswamy Govindan, Washington University School of Medicine in St. Louis, St. Louis, MO*

Background: Cancer cells contain unique DNA mutations that result in altered amino acid sequences known as neoantigens. Evidence supports a central role for neoantigens as targets for tumor-directed immune responses. Tumor mutational burden as well as neoantigen load are associated with anti-tumor activity of checkpoint inhibitors. Chemotherapy plus anti-PD1 therapy in NSCLC has demonstrated improved efficacy over chemotherapy alone. This combination reduces early progression and may also modulate the tumor microenvironment. Neoantigen vaccines offer a rational combination partner for these therapies as a highly specific way to induce de novo T cell reactivity and to expand existing T cell responses against neoantigens. Here, we describe a clinical trial combining NEO-PV-01, a personal neoantigen vaccine designed specifically for the molecular profile of each individual's tumor, with anti-PD1 and chemotherapy. **Methods:** NT-002 is a single-arm, phase 1B study evaluating the safety of administering NEO-PV-01 + adjuvant (Poly-ICLC) with pembrolizumab plus carboplatin and pemetrexed in patients with advanced non-small cell lung carcinoma who have received no prior systemic treatment. Patients undergo a baseline tumor biopsy and HLA typing. DNA and RNA sequencing is performed on tumor as well as peripheral blood. NEO-PV-01 is custom designed for each individual patient and contains up to 20 peptides 14-35 amino acids in length. The peptides are pooled into four groups and mixed with Poly-ICLC at the time of administration. On Day 1, patients will begin with 4 treatment cycles of pembrolizumab plus chemotherapy. Beginning on Cycle 5 (Week 12), patients will receive pembrolizumab monotherapy Q3W up to Week 103 without pemetrexed maintenance. Also beginning at Week 12, patients receive five priming immunizations with NEO-PV-01 over a three-week period followed by boosters at Weeks 19 and 23. The primary endpoint is safety. Secondary endpoints are ORR, CBR, PFS, and assessment of response conversion between Week 12 and Week 24. Exploratory endpoints include extensive immune monitoring with antigen-specific analyses of both peripheral blood and tumor. Clinical trial information: NCT03380871.

TPS3135 Poster Session (Board #332a), Mon, 8:00 AM-11:30 AM

HepaVac-101 first-in-man therapeutic cancer vaccine phase I/II clinical trial for hepatocellular carcinoma patients. *First Author: Luigi Buonaguro, IRCCS INT Fondazione, Naples, Italy*

Background: HCC is the third leading cause of death from cancer globally with an extremely variable 5-year survival rate. The HepaVac-101 phase I/II, first-in-man, therapeutic cancer vaccine single-arm clinical trial is performed as part of the HepaVac project, funded by the European Commission's 7th Framework Program under the Grant Agreement Nr. 602893 (www.hepavac.eu). The HepaVac-101 trial identification numbers are NCT03203005 (Clinical trials.gov) and 2015-003389-10 (EudraCT). **and Methods:** The therapeutic cancer vaccine IMA970A is a multi-peptide-based HCC vaccine composed of 16 newly discovered and overexpressed tumor-associated peptides (TUMAPs) directly identified from resected HCC tissues. Of these TUMAPs, 7 are restricted to HLA-A*02, 5 to HLA-A*24 and 4 to HLA class II. CV8102 is a novel RNA based immunostimulatory agent inducing a balanced Th1/Th2 immune response. A total of 40 patients with very early, early and intermediate stage of HCC are enrolled to be treated with a single pre-vaccination infusion of low-dose cyclophosphamide, followed by 9 intradermal vaccinations consisting of IMA970A plus CV8102. The study drugs are applied without concomitant anti-tumor therapy, in order to reduce risk of tumor recurrence/progression in patients having received all indicated standard treatments and without evidence of active disease. The primary endpoints of the HepaVac-101 clinical trial are safety, tolerability, and immunogenicity. Secondary/exploratory endpoints are additional immunological parameters in circulation, infiltrating T-lymphocytes in tumor tissue, biomarkers in blood and tissue, DFS/PFS and OS. Once safety of this vaccination approach has been established in the first 10 patients the addition of a checkpoint inhibitor will be considered. Suitable patients enrolled at Tuebingen are invited to participate in a trial extension investigating an actively personalized vaccine (APVAC). The HepaVac-101 trial is conducted in 6 centers located in 5 European countries. Five centers are actively recruiting patients. As of the time of abstract submission, 4 HCC patients have been screened for HLA haplotype and 1 is eligible for vaccination. Clinical trial information: NCT03203005.

TPS3136 Poster Session (Board #332b), Mon, 8:00 AM-11:30 AM

Phase I/II study of BSK01, an artificial intelligence-driven, peptide-pulsed, mature DC immunotherapy for solid and hematological malignancies. *First Author: Leonardo Mirandola, Kiromic, Inc., Houston, TX*

Background: Despite advances in understanding the biology of hematologic malignancies (HM) and solid malignancies (SM), and the availability of new treatment options, many patients with HM and SM remain incurable. Since the majority of cancer patients display a defective immune response to tumor antigens, the ex vivo activation of dendritic cells (DC), through their exposure to tumor associated antigens, is an attractive and active area of investigation. The choice of the target antigen and the identification of immuno-dominant and immunogenic peptides to drive powerful and specific cellular responses against tumor cells are crucial for the success of cancer vaccines. We have developed a powerful artificial intelligence (AI) computational platform, K.A.I., capable of collecting, normalizing, and analyzing data from multiple data sources, and to prioritize target antigens and immuno-dominant peptides for any given malignancy. **Methods:** Currently, we are conducting 4 clinical trials for solid and hematologic malignancies, both in the consolidation and refractory settings. We hypothesize that treatment of patients with HM or metastatic SM using autologous DC pulsed with immuno-dominant tumor-specific peptide antigens will result in antigen-specific CD4+ T-cell and/or CD8+ CTL responses without significant toxicities. We also hypothesize that the responses generated against specific antigens may translate into clinical anti-tumor activity. Primary Objective: Phase I (6 subjects). To determine safety of intradermal/subcutaneous DC vaccine therapy, low-dose cyclophosphamide and GM-CSF, in patients with metastatic SM or HM. Secondary Objective: Phase II (up to 17 subjects). To determine immune responses associated with intradermal/subcutaneous DC vaccine therapy, low-dose cyclophosphamide and GM-CSF, in patients with metastatic SM or HM who demonstrate a response, or whose disease remains stable, after conventional first-line systemic therapy, or who have failed conventional systemic therapy. The study population is currently drawn from patients at various clinical institutions following contractual agreements. Clinical trial information: NCT02709993; NCT02705703; NCT02224599; NCT02223312.

3500 **Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

Preoperative chemoradiotherapy and postoperative chemotherapy with capecitabine +/- oxaliplatin in locally advanced rectal cancer: Final results of PETACC-6. *First Author: Hans-Joachim Schmoll, Martin Luther University, Halle, Germany*

Background: The PETACC-6 trial investigated the role of oxaliplatin in combination with preoperative capecitabine-based chemoradiation (CRT) and postoperative capecitabine (CT) to improve disease-free survival (DFS) in locally advanced rectal cancer. **Methods:** Between 11/2008 and 09/2011, 1090 patients with rectal adenocarcinoma within 12 cm from the anal verge, T3/4 and/or node-positive, with no evidence of metastatic disease and considered either resectable at the time of entry or expected to become resectable, to 5 weeks preoperative CRT with capecitabine, followed by 6 cycles of adjuvant capecitabine without (arm 1) or with oxaliplatin (arm 2) (before and after surgery). The primary analysis was intent-to-treat and adjusted for stratification factors (clinical T category, nodal status, distance from the tumor to the anal verge and method of locoregional staging) except the center. **Results:** An early release of DFS after a medium follow-up of 31 months per recommendation of the IDMC, did not show any difference between arms (adjusted HR = 1.04, 95% CI: 0.81 -1.33, P = 0.781) (Schmoll H et al, Proc ASCO 2014). We now report on the long-term results for DFS and OS. At median follow-up of 68 months, respectively 157 vs.156 DFS events and 97 vs. 109 deaths were observed in arm 1 and 2. In each arm, 58 patients died due to progressive disease. There is no difference in DFS between arms (adjusted HR = 1.02, 95% CI: 0.82-1.28, P = 0.835) nor in OS (adjusted HR = 1.17, 95% CI: 0.89 – 1.54, P = 0.252). 5-year DFS was 71.3% (95% CI: 67.1% - 75.0%) in arm 1, vs. 70.5% (95% CI: 66.3% - 74.3%) in arm 2. 5-year OS was 83.1 (95% CI: 79.5% - 86.1%) in arm 1, vs. 80.1% (95% CI: 76.2% - 83.4%) in arm 2. No major heterogeneity of the results for DFS according to baseline factors was identified except for the subgroup of non-german patients (N = 357) vs. german patients (N = 737) (p = 0.02 for Cochran's Q test). Adjusted HR was 1.27 (95% CI: 0.96-1.68, p = 0.091) in disfavor of oxaliplatin in german patients while adjusted HR was 0.65 (95% CI: 0.44 – 0.97, p = 0.033) in favor of oxaliplatin in non-german patients. **Conclusions:** Long-term results confirm that the addition of oxaliplatin to capecitabine plus radiotherapy does not improve DFS nor OS in the ITT population. Further prognostic and predictive factors will be defined by a multivariate analysis and be presented at the meeting, in particular the discrepancy of the german and non-german patients will be clarified as well. Clinical trial information: NCT00766155.

3501 **Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

Long-term results of the ADORE trial: Adjuvant oxaliplatin, leucovorin, and 5-fluorouracil (FOLFOX) versus 5-fluorouracil and leucovorin (FL) after preoperative chemoradiotherapy and surgery for locally advanced rectal cancer. *First Author: Yong Sang Hong, Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of (South)*

Background: To report the long-term survival outcomes of the ADORE, a randomized controlled trial, compared adjuvant FOLFOX *vs* FL in patients with resected rectal cancer whose pathologic stages of ypII/III after preoperative chemoradiotherapy (CRT). **Methods:** This is a randomized phase II study accrued patients with curatively resected rectal cancer patients whose postoperative ypStage II/III after preoperative CRT with fluoropyrimidines alone. Patients were randomly assigned (1:1) to receive adjuvant chemotherapy either with FL or FOLFOX for 4 months. Randomization was centrally coordinated and stratified by the ypStage and participating sites. The primary endpoint was disease-free survival (DFS). **Results:** A total of 321 patients were randomly assigned between Nov 2008 and Jun 2012; 161 patients to FL and 160 to FOLFOX. At a median follow-up of 74.1 months (IQR, 56.2 – 88.0), 6-year DFS rate was 68.2% in the FOLFOX arm *vs* 56.8% in the FL arm with an adjusted hazard ratio (HR) of 0.63 (95% CI, 0.43–0.93, p= 0.018) by intention-to-treat analysis. In the subgroup analysis for DFS, patients with ypStage III (HR 0.59 [0.38-0.92], p= 0.019), ypN1b (HR 0.35 [0.14-0.83], p= 0.017), ypN2 (HR 0.47 [0.22-0.99], p= 0.048), high grade histology (HR 0.28 [0.08-0.97], p= 0.045), minimally regressed tumor (0.40 [0.19-0.85], p= 0.016), absence of lymphovascular (HR 0.55 [0.34-0.88], p= 0.013) or perineural invasion (HR 0.53 [0.33-0.86], p= 0.01), male gender (HR 0.62 [0.39-0.98], p= 0.039), and younger than 65 years (HR 0.64 [0.42-0.97], p= 0.034) benefited more from FOLFOX than FL. The 6-year overall survival (OS) rate was 78.1% in the FOLFOX arm *vs* 76.4% in the FL arm (HR 0.73 [0.45-1.19], p= 0.21). In the subgroup analysis for OS, those with ypN2 (HR 0.42 [0.18-0.96], p= 0.04) and minimally regressed tumor (HR 0.42 [0.19-0.97], p= 0.043) benefited from FOLFOX than FL. **Conclusions:** Adjuvant FOLFOX clearly demonstrated improved DFS in rectal cancer patients with ypStage II/III after preoperative CRT. Subgroup analyses provided additional information on the selection of adjuvant candidates. Clinical trial information: NCT00807911.

3502 **Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

Modified FOLFOX6 with or without radiation in neoadjuvant treatment of locally advanced rectal cancer: Final results of the Chinese FOWARC multicenter randomized trial. *First Author: Yanhong Deng, Sun Yat-sen University, Guangzhou, China*

Background: The FOWARC trial compared FOLFOX6 with or without Radiation in neoadjuvant treatment of locally advanced rectal cancer to 5-FU chemoradiotherapy. First results of early secondary endpoints have been published (Deng et al., JCO 2016). Here we present the primary endpoint, disease-free survival (DFS) at 3 years. **Methods:** Between 01/2011-02/2015, patients with rectal cancer within 12 cm from the anal verge, clinical stage II-III were randomly assigned to received 5-FU with radiation(RT) (FU-RT arm), or receive mFOLFOX6 with RT (FOLFOX-RT arm), or receive 4-6 cycles of mFOLFOX6 alone (FOLFOX arm), peri-operative RT was allowed if needed. The primary endpoint was DFS at 3 years defined as the interval from randomization to incomplete surgical resection, locaregional or metastatic recurrence or death, whichever occurred first. **Results:** A total of 495 patients were randomly assigned to three arms at 1:1:1 ration. 418 patients who had available follow up and obeyed the treatment protocol, 130 in FU-RT arm, 142 in FOLFOX-RT arm and 146 in FOLFOX arm. The local recurrence rate was 10.0%, 8.5% and 8.9% respectively. After a median follow-up time of 45.2 months, 35 patients in FU-RT arm had a DFS-related event, as compared with 37 patients in FOLFOX-RT arm(HR 1.031, 95% confidence interval 0.657 to 1.620), and 41 in FOLFOX arm (HR 0.960, 95% confidence interval 0.615 to 1.497). The rate of DFS at three years was 76.4±3.8% in FU-RT arm, 77.8±3.5% in FOLFOX-RT arm and 75.7± 3.6% in FOLFOX arm (P = 0.961 by the exact stratified log-rank test). The rate of OS at three years was 93.7±2.2% in FU-RT arm, 92.0±2.3% in FOLFOX-RT arm and 92.2±2.3% in FOLFOX arm (P = 0.961 by the exact stratified log-rank test). **Conclusions:** FOLFOX with or without radiation did not improve significantly improved DFS in patients with advanced rectal cancer. However, FOLFOX alone seems to have identical local recurrence rate and 3-DFS and 3-OS compared to standard FU-RT. Clinical trial information: NCT01211210.

A UNICANCER phase III trial of hyperthermic intra-peritoneal chemotherapy (HIPEC) for colorectal peritoneal carcinomatosis (PC): PRODIGE 7. *First Author: François Quenet, Institut Régional du Cancer de Montpellier, Montpellier, France*

The full, final text of this abstract will be available at abstracts.asco.org at 7:30 a.m. ET on Monday, June 4, 2018, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2018, issue of the *Journal of Clinical Oncology*. On-site at the Meeting, this abstract will be printed in the Monday edition of *ASCO Daily News*.

3504 Oral Abstract Session, Tue, 9:45 AM-12:45 PM

Randomized trial of irinotecan and cetuximab (IC) versus irinotecan, cetuximab and ramucirumab (ICR) as 2nd line therapy of advanced colorectal cancer (CRC) following oxaliplatin and bevacizumb based therapy: Result of E7208. *First Author: Howard S. Hochster, Rutger-Cancer Institute, New Brunswick, NJ*

Background: While both anti-VEGF(R) and EGFR antibodies have activity in metastatic RAS wild type CRC, the combination of the two appeared to be detrimental when combined with chemotherapy in unselected CRC patients. We undertook this study to determine whether the anti-VEGFR antibody, ramucirumab, improved activity of Irinotecan and Cetuximab as 2nd line therapy in KRASwt CRC patients, who previously received FOLFOX or CAPOX with bevacizumab (bev) first line therapy, and were now progressing. **Methods:** Patients with advanced and measurable (RECIST 1.1) CRC who had previously been treated with a fluoropyrimidine and oxaliplatin (ox) with bev, and recently showed progression on CT scan were randomized to IC (180 mg/m2 and 500 mg/m2 respectively) or ICR (R = 8 mg/kg) every 2 weeks. After 35 pt were randomized, planned interim analysis showed excess gr 3-5 toxicity for ICR. Therefore a modified ICR (150 mg/m2, 400 mg/m2 and 6 mg/kg) arm was instituted after study hold. Patients were stratified by PS (0 vs 1), progression on ox (Y vs N), and progression within 6 months of last treatment (or longer). 100 patients were then accrued to IC vs mICR, with 85% power to detect improvement in median PFS from 4.5 to 7.65 months (with 15% type I error or $p < 0.15$) by stratified log-rank test. **Results:** Results: 102 patients were randomized and evaluable from June, 2014 - July, 2017. Patients were 65% male, 9% black and 8% Hispanic with med age 60 years, PS 0 = 52%, with 24% progressing while on ox and 15% progressing more than 6 months off rx. Gr 3-4 overall toxicity for IC vs mICR was 47% vs 54% with diarrhea = 10 v 15%; rash = 13 vs 8%; neutropenia = 9 vs 10%. Reasons off study were: 60% progression, 18% adverse events and 10% patient choice. Stratified log rank analysis showed a HR = 0.65 for PFS of mICR vs IC (overall med 5.8 months; p = 0.068), which met primary endpoint of $p < 0.15$. Survival appears to be equal with med = 20.5 months. **Conclusion:** In KRAS selected, wildtype CRC, 2nd line therapy (following ox and bev based treatment), an anti-VEGFR antibody, combined with anti-EGFR and irinotecan, prolongs PFS. This effect is similar to the reported improvement in PFS in other 2nd line anti-VEGF trials and supports the fact that antibodies against these two targets can be combined for additional benefit in the appropriate patient population. This study was coordinated by ECOG-ACRIN & supported by NCI awards: CA180820, CA180794, CA180826, CA180830, CA180888, CA180870, CA189830. Clinical trial information: NCT01079780.

3505 Oral Abstract Session, Tue, 9:45 AM-12:45 PM

First-line FOLFOX plus panitumumab (Pan) followed by 5FU/LV plus Pan or single-agent Pan as maintenance therapy in patients with RAS wild-type metastatic colorectal cancer (mCRC): The VALENTINO study. *First Author: Filippo Pietrantonio, Department of Medical Oncology, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: Since doublets plus anti-EGFRs were continued until progressive disease (PD) in mCRC first-line registration trials, there is scarce evidence if de-escalating treatment intensity after an anti-EGFR-based induction might be not inferior in terms of disease control, while reducing toxicity burden and improving quality of life. In MACRO-2, maintenance with cetuximab alone achieved a 9-month progression-free survival (PFS) rate non inferior than continued mFOLFOX + cetuximab in KRAS ex. 2 wt patients. **Methods:** RAS wt unresectable mCRC patients, stratified for prior adjuvant therapy and metastatic sites (1 vs ≥2), were randomized and received FOLFOX + Pan induction (8 cycles) followed by maintenance with Pan (arm B) or 5FU/LV + Pan (arm A) until PD/unacceptable toxicity/death. The primary endpoint was non-inferiority of PFS of arm B vs A. An overall sample size of 224 subjects (112 per arm) achieved 90% power to detect a 50% 10-month PFS rate in arm A and a maximum 15% difference in arm B, with a significance level of 0.1 and a 15% drop-out rate; non inferiority could be demonstrated if the upper boundary of the one-sided 90% CI of the hazard ratio (HR) was <1.515. Secondary endpoints were safety, quality of life, overall response rate (ORR), duration of response and overall survival. Results: From July 2015 to October 2017, 229 patients were randomized (117 arm A/112 arm B). Baseline characteristics were: males, 68%/66%; median age, 64/64; ECOG PS 0, 71%/72%; previous adjuvant therapy, 14%/18%; single metastatic site, 54%/58%; BRAF mutation, 3%/4%; right-sided primary, 15%/20%. The upper boundary of the one-sided 90% CI for the HR of Pan vs 5FU/LV + Pan was 1.946. At a median follow-up of 13.8 months, 10-m PFS was 52.8% for Pan vs 62.8% for 5FU/LV + Pan, with median time of 10.2 vs 13.0 months, respectively (stratified HR = 1.55, 95% CI: 1.09-2.20; p = 0.011). ORR was 66.6% and 67% in arm A and B, respectively. During maintenance phase, grade ≥3 adverse events (AEs) were mainly diarrhea 3.7%/1.4%; mucositis 6.2%/1.4%; hand-foot syndrome 2.5%/1.4%; neutropenia 2.5%/0%; skin rash 22.2%/13.7%. Overall, grade 1-2 AEs were 75.3%/64.4%. Conclusions: In RAS wild-type mCRC patients, maintenance with Pan alone following induction with FOLFOX + Pan achieves inferior PFS than 5FU/LV + Pan combination. Clinical trial information: NCT02476045.

3506 Oral Abstract Session, Tue, 9:45 AM-12:45 PM

Plasma *HER2 (ERBB2)* copy number to predict response to HER2-targeted therapy in metastatic colorectal cancer. *First Author: Alberto Bardelli, Istituto di Candiolo, Fondazione del Piemonte per l'Oncologia, IRCCS, Candiolo, Italy*

Background: The rate of HER2 (*ERBB2*) copy number amplification (CNA) in metastatic colorectal cancer (mCRC) ranges from 2-13%. HERACLES, a phase II trial of trastuzumab and lapatinib (T+L) in HER2-positive mCRC showed response rates of 30%, suggesting HER2 as a viable target in this population. Cell-free circulating tumor DNA (ctDNA) next-generation sequencing (NGS) may be an option for *ERBB2* CNA determination when biopsy is infeasible or tissue is insufficient. Here we determine the sensitivity of plasma CNA (pCNA) detection using a ctDNA NGS assay and suggest a cutoff predictive of response to HER2-targeted therapy. **Methods:** Pre-treatment and progression plasma samples (N = 48) from 26 HER2 FISH-positive patients in the HERACLES study were tested using the Guardant360 assay. We correlated *ERRB2* pCNA with progression free survival (PFS) and best objective response (BOR) on T+L. To establish a threshold for absolute pCNA predicting response, we analyzed *ERBB2* CN relative to panel-wide CNA profile and clonal driver co-occurrence in 819 consecutive mCRC samples tested with Guardant360. **Results:** 46/47 samples with detectable ctDNA were *ERBB2*-amplified based on ctDNA (2.55-122 copies; PPA = 96%, 95% CI 85-99%). A threshold of ≥3 copies of *ERBB2* in circulation allowed identification of 94% of FISH-positive patients, while excluding 86% of all co-occurring *KRAS, NRAS,* and *BRAF* driver mutations in the larger clinical cohort. HERACLES patients below this threshold had reduced PFS (median 4.6 vs. 1.1 months, p = 0.10). Above the threshold, plasma *ERBB2* CNA strongly correlated with BOR (r = 0.5) but weakly with PFS (r = 0.37). **Conclusions:** The ctDNA platform utilized correctly identified 96% of samples as *ERBB2*-amplified and accurately predicted HER2-targeted therapy response rates. Based on the HERACLES and large clinical cohorts, a cutoff of 3 copies of *ERBB2* in plasma is proposed to select patients who will benefit from targeting HER2.

3507 Oral Abstract Session, Tue, 9:45 AM-12:45 PM

Actionable fusions in colorectal cancer using a cell-free circulating tumor DNA (ctDNA) assay. *First Author: Katherine Clifton, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The presence of gene fusions affects clinical management of patients (pts) with NSCLC, GIST, and CML. Likewise, identification of actionable fusions provides another potential approach to offering effective therapies to pts with advanced colorectal cancer (CRC). Here we detail the frequencies and clinicopathological features of gene fusions in CRC using a comprehensive ctDNA NGS assay. **Methods:** Pts with advanced, pre-treated CRC underwent molecular profiling using a plasma-based ctDNA NGS assay (Guardant360®), which includes testing for fusions in *FGFR2, FGFR3, RET, ALK, NTRK1,* and *ROS1*. Correlations between fusions and clinicopathological features were measured using a Fisher's exact test. Relative frequencies of genomic alterations (point mutations, indels, and splice variants) were compared according to fusion status using an unpaired t-test. **Results:** 45 unique fusions were detected in 41 of 4290 pts tested (0.96%, 95% CI 0.70-1.3%): *RET* (N = 16, 0.37%), *FGFR3* (N = 13, 0.30%), *ALK* (N = 10, 0.23%), *NTRK1* (N = 3, 0.07%), *ROS1* (N = 2, 0.05%), and *FGFR2* (N = 1, 0.02%). Among pts with multiple fusions (N = 4 total), *RET* fusions accounted for 3, all subclonal. Fusions were detected at a median variant frequency of 0.31% (IQR, 0.11-1.5%). FGFR fusions were associated concomitant *RAS* mutations (OR 3.5, P = 0.03). All *NTRK1* fusions were *KRAS/NRAS/BRAF* wild-type. Genomic alterations were more common for the fusion-present cases than non-fusion cases (mean 10.2 vs. 5.1, $P < 0.0001$). **Conclusions:** This is the first large series in CRC patients to demonstrate that plasma-based detection of a broad array of actionable fusions is practical. Fusion presence was associated with a higher mutation frequency, also characteristic of microsatellite instability in CRC. Since these fusions are actionable in other solid tumors, our data provide rationale to utilize ctDNA to identify fusions for targeted therapy trials in metastatic CRC.

3508 Poster Discussion Session; Displayed in Poster Session (Board #1), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 11:30 AM-12:45 PM

Per protocol analysis and final OS update of the FIRE-3 (AIO KRK-0306) study comparing FOLFIRI plus cetuximab vs. FOLFIRI plus bevacizumab. *First Author: Sebastian Stintzing, Ludwig Maximilian University of Munich, Munich, Germany*

Background: FIRE-3 compared 1st-line therapy with FOLFIRI plus either cetuximab or bevacizumab in 592 KRAS exon 2 wt mCRC patients (pts). Extended RAS analysis showed RAS wild-type (RASwt) in tumors of 400 pts. **Methods:** Per protocol analyses were done in all patients that received at least 3 cycles of chemotherapy and who had at least one CT scan following baseline allowing to evaluate of objective response rate (ORR) as the primary endpoint. ORR and early tumor shrinkage (ETS) were compared using Fisher's exact test. Overall survival (OS) was compared using Kaplan-Meier estimation and log-rank tests. Follow up time was calculated using the inverse Kaplan-Meier method. Hazard ratios (HR) were estimated according to the Cox proportional hazard method. **Results:** With data cutoff of July 24th 2017, a total of 400 pts with RASwt tumours were evaluable. The median follow-up time was 70.8 months and 85.3% of OS events have occurred. Of the 400 pts, a total of 351 (87.8%) were evaluable according to the per protocol pre-specified analyses. The final efficacy data is shown in the table below. **Conclusions:** In the per-protocol analysis of RASwt pts treated in FIRE-3, a significantly higher ORR was demonstrated for FOLFIRI plus cetuximab compared to FOLFIRI plus bevacizumab. This advantage relates to a significantly longer OS after more than 85% of OS events had occurred. Clinical trial information: NCT00433927.

mFOLFOXIRI + panitumumab versus FOLFOXIRI as first-line treatment in patients with RAS wild- type metastatic colorectal cancer m(CRC): A randomized phase II VOLFI trial of the AIO (AIO- KRK0109). *First Author: Michael Geissler, Klinikum Esslingen, Department of Hematology/Oncology, Esslingen, Germany*

Background: Triple chemotherapy with an anti-EGFR reported promising activity with some safety concerns in single arm phase II trials. This trial evaluated activity and safety of mFOLFOXIRI + panitumumab vs FOLFOXIRI in ECOG 0-1, primarily non-resectable mCRC patients. **Methods:** Prospective 2:1 randomized, multi-center, phase II trial comparing mFOLFOXIRI (Ox 85 mg/m2, Iri 150 mg/m2, 5-FU 3000mg/m2 cont. 48h, LV 200 mg/m2) + Panitumumab 6 mg/KG (arm A) with FOLFOXIRI (Ox 85 mg/m2, Iri 165 mg/m2, 5-FU 3200mg/m2 cont. 48h, LV 200 mg/m2; arm B), both arms q2w. Cohort 1: irresectable mCRC; cohort 2: chance of secondary resection of metastatic lesions. Primary endpoint was ORR, secondary endpoints were secondary resection rate (cohort 2), DCR, PFS, OS, toxicity, quality of life (QLQ-C30). Financially supported by an unrestricted grant from Amgen. **Results:** A total of 96 patients were randomized (63 arm A, 33 arm B). ORR was 85.7% in arm A and 54.5% in arm B (p = 0.0013, OR 5.000; 95%-CI 1.870-13.370). DCR was 96.8% in arm A and 78.8% in arm B (p = 0.0071, OR 8.212). ORR in Arm A was 90.6% versus 60.0% (p = 0.0288, OR 6.400) and in Arm B 60.0% versus 50% (p = n.s.) for left and right located CRC, respectively. ORR between arms A and B comparing left and right sided CRC was 90.6% versus 60.0% (p = 0.0039, OR 6.400; 95%-CI 1.889-21.679) and 60.0% versus 50.0% (p = n.s.), respectively. Secondary resections in cohort 2 were 60% (n = 12) and 36.4% (n = 4) in arms A and B, respectively. Treatment related serious adverse advents grade 3-5 occured in 32.8% and 12.1% in arms A and B, respectively (p = 0.0297). Nevertheless, no differences in global health status, functional scales, and symptom scales were reported. **Conclusions:** mFOLFOXIRI plus Panitumumab results in significantly higher response rates compared to FOLFOXIRI in RAS wild-type mCRC. Strong effectivity was observed also in right sided and BRAF mutated CRC. High secondary resection rates could be achieved. Although toxicity (treatment related SAEs) was increased, QL reporting was similar in both arms. Final PFS, AEs, and dosing data will be presented at the meeting. Clinical trial information: NCT01328171.

REVERCE: Randomized phase II study of regorafenib followed by cetuximab versus the reverse sequence for metastatic colorectal cancer patients previously treated with fluoropyrimidine, oxaliplatin, and irinotecan—Biomarker analysis. *First Author: Yasushi Tsuji, Department of Medical Oncology, Tonan Hospital, Sapporo, Japan*

Background: REVERCE demonstrated longer overall survival (OS) with the therapeutic sequence of regorafenib (R) followed by cetuximab (C) ± irinotecan (R-C arm) compared with that of C ± irinotecan followed by R (C-R arm) for patients (pts) with pretreated metastatic colorectal cancer (mCRC; median OS 17.4 vs. 11.6 months, HR 0.61; *Shitara K*, et al. GI Symposium 2018). Biomarker analyses assessed the association of multiple candidate biomarkers with clinical outcomes. **Methods:** Pts with *KRAS* exon 2 wild-type mCRC after failure of fluoropyrimidine, oxaliplatin, and irinotecan treatment were randomized. The primary endpoint was OS. Key secondary endpoints included progression-free survival (PFS) with initial treatment (PFS1), PFS with second treatment (PFS2), safety, and QOL. Sequential biomarker analysis including oncogenic alterations from ctDNA or multiple serum proteins related to the EGF or VEGF pathway was an exploratory endpoint. **Results:** Among the randomized 101 pts, plasma and serum samples were collected from 98 pts. OS HR in the biomarker cohort (n = 98, HR 0.61) and all *RAS/RAF* wild types (n = 86, HR 0.60) at baseline were consistent with that of the overall cohort. R-C arm consistently showed longer OS in all subgroups according to serum proteins biomarkers (median value as cut off). Significant interactions between PlGF or VEGFR-3 level and PFS1 were observed, favoring R over C in higher PlGF and VEGFR-3 level. Among *RAS/RAF* wild types at baseline, emerging *RAS*, *BRAF*, *EGFR S492R* mutations, and *HER2* and *MET* amplification were observed in 1,0,0,2,2 patients after R and 11,1,2,4,4 patients (overlapping) after C. **Conclusions:** This trial consistently showed longer OS with R followed by C versus the reverse sequence for pretreated mCRC pts regardless of biomarker subgroups. Emerging oncogenic alterations are more frequently observed after C treatment than R. Clinical trial information: UMIN000011294.

Anti-EGFR resistant clones decay exponentially after progression: Implications for anti-EGFR rechallenge. *First Author: Christine Megerdichian Parseghian, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Colorectal cancers (CRC) treated with EGFR inhibitor (EGFRi) evolve by a repetitive process of genetic diversification and clonal evolution. After discontinuation of EGFRi, *KRAS/NRAS (RAS)* and *EGFR* resistance mutations no longer have a growth advantage relative to other clones. Yet, the impact of time from the last cycle of EGFRi to decreases in the mutant (MT)/wildtype (WT) allele ratio has not been well defined in mCRC. **Methods:** We analyzed a retrospective cohort of patients at MD Anderson Cancer Center with *RAS/BRAF/EGFR*^{WT} mCRC who had been treated with EGFRi and in whom plasma samples had been collected for sequencing of ctDNA on a platform optimized for very low allele frequencies (AF) (Guardant360). Relative MT allele frequency (rMAF) was defined as ((MT AF) / MT present at the max AF in that assay) and approximates the % of tumor cells shedding the MT of interest into the circulation. rMAF results were normalized to total ctDNA concentration. **Results:** 135 pts were identified. There was an inverse relationship between the rMAF of *RAS* and *EGFR* and time since last treatment, but no change in truncal *APC* and *TP53* inactivating mutations. Our analysis showed that the decline in *RAS/EGFR* rMAF is best described by an exponential decay model (r = 0.93 for *RAS* and 0.94 for *EGFR*). At progression on EGFRi, the median *RAS* rMAF and *EGFR* rMAF were 10.5% and 10.6%, respectively, and these clones exponentially decayed with a half-life of 3.4 mo and 6.9 mo, respectively. Our model predicts that at the time of progression only 30% of the cells in the tumor carry a mutation in *RAS/EGFR/BRAF/MAP2K1*. This suggests that the remaining 70% are driven by undetected autonomous mechanisms of resistance, or paracrine effects. **Conclusions:** We identified that *RAS* and *EGFR* MT alleles decay exponentially over time since last EGFRi. These results provide a molecular explanation for the efficacy of EGFRi rechallenge therapies after a period off EGFR inhibition. The half-life of these clones may help guide timing of rechallenge therapies, and could be monitored by ctDNA. Further, these results suggest that a subclonal tumor population may be exerting resistance through paracrine mechanisms. These data will be validated on an external dataset.

Distinct impacts of *KRAS*, *NRAS* and *BRAF* mutations on survival of patients with metastatic colorectal cancer. *First Author: Yucai Wang, Mayo Clinic, Rochester, MN*

Background: *RAS* and *BRAF* mutations are associated with lack of response to anti-EGFR therapy and worse survival in patients with metastatic colorectal cancer (mCRC). *NRAS* mutations are less frequent than *KRAS* and *BRAF* mutations. While the prognostic implication of *BRAF* V600E mutations in mCRC is well established, the impact of *NRAS* mutations on outcome is unclear. **Methods:** Patients with mCRC who had *RAS/RAF* mutations tested at Mayo Clinic and MD Anderson Cancer Center between 2012 and 2016 were included in this study. Clinical information was obtained by chart review, and clinical characteristics and survival outcomes were compared among patients with different mutations. Categorical data were analyzed by Chi-square test, and time-to-event data were analyzed by Kaplan-Meier and Cox proportional hazards models. Statistical analysis was done in SPSS (v22). **Results:** In 2953 patients (1076 from Mayo and 1877 from MD Anderson), the mutation frequencies were: *KRAS* 45.6%, *NRAS* 3.8%, *BRAF* V600 8.0% and *BRAF* non-V600 1.3% (all wild-type [WT] 41.3%). 2282 patients with sufficient clinical information available were included for survival analysis, including 951 WT (41.7%), 1080 *KRAS* (47.3%), 91 *NRAS* (4.0%) and 160 *BRAF* V600 (7.0%). Compared with WT, *NRAS* patients were more likely female (47% vs 36%, $P = 0.031$) and had more right-sided cancers (30% vs 20%, $P = 0.031$). *NRAS* and *KRAS* patients did not differ in age, sex, sidedness, or MSI-H/dMMR. Compared with *BRAF*, *NRAS* patients were younger (< 60, 59% vs 44%, $P = 0.018$), had more left-sided cancers (70% vs 29%, $P < 0.001$), and had less MSI-H/dMMR (1% vs 17%, $P = 0.001$). The median follow-up was 42.7 months. The median overall survival (OS) for WT, *KRAS*, *NRAS* and *BRAF* patients were 49.2, 36.2, 30.1 and 22.5 months, respectively ($P < 0.001$). In multivariate analysis adjusting for age, sex and sidedness, *NRAS* patients had worse OS than WT (HR = 1.83 [1.40-2.39], $P < 0.001$) and *KRAS* patients (HR = 1.37 [1.06-1.78], $P = 0.016$). The OS difference between *NRAS* and *BRAF* patients was not statistically significant (HR = 0.81 [0.57-1.14], $P = 0.220$). **Conclusions:** *KRAS*, *NRAS* and *BRAF* mutations have distinct impacts on survival in mCRC. *NRAS* mutations carry a poorer prognosis compared with *KRAS*.

KEYNOTE-164: Pembrolizumab for patients with advanced microsatellite instability high (MSI-H) colorectal cancer. *First Author: Dung T. Le, Johns Hopkins University, Baltimore, MD*

Background: Pembrolizumab is approved for the treatment of adult and pediatric patients (pts) with previously treated MSI-H cancer regardless of tumor type or site. This approval was based in part on data from cohort A of the phase 2 KEYNOTE-164 (NCT02460198) study of pts with MSI-H CRC after ≥2 prior lines of therapy including fluoropyrimidine, oxaliplatin, and irinotecan. In addition, in Cohort B of KEYNOTE-164, we evaluated the activity of pembrolizumab in pts with metastatic MSI-H CRC treated with ≥1 prior line of therapy. **Methods:** KEYNOTE-164 cohort B enrolled pts with metastatic CRC, MSI-H status confirmed locally by IHC or PCR, and ≥1 prior line of therapy (fluoropyrimidine, oxaliplatin, irinotecan, or anti VEGF/EGFR). Eligible pts received pembrolizumab 200 mg Q3W for 2 years or until progression, unacceptable toxicity, or withdrawal of consent. Tumor response was assessed Q9W per RECIST v1.1 by independent review. The primary endpoint was ORR. Secondary endpoints included DOR, PFS, OS, and safety. **Results:** Of 63 pts enrolled, median age (range) was 59 years (23-83), and 52% were male. Pts had a median of 2 prior therapies, and 94% had ≥1 prior therapy for advanced disease. As of Sep 12, 2017, median (range) duration of follow-up was 12.6 months (0.1-15.4). ORR was 32% (95% CI, 21-45) with 2 CRs and 18 PRs. Median DOR was not reached (NR); 95% of responses were ongoing with DOR ≥6 mo in 75% of responders. Median PFS was 4.1 month (95% CI, 2.1-NR) with a 12-month PFS rate of 41%. Median OS was NR with a 12-month OS rate of 76%. Forty (64%) pts had any grade treatment-related AEs, most commonly (≥10%) fatigue (18%), hypothyroidism (16%), and hyperthyroidism (11%); 7 (11%) pts had grade 3-4 treatment-related AEs of anemia, thrombocytopenia, diarrhea, pneumatosis intestinalis, arthritis, syncope, pneumonitis, and vasculitis (n = 1 each). There were no treatment-related deaths. Twenty (32%) pts had any grade immune-mediated AEs; 2 (3%) pts had grade 3-4 immune-mediated AEs of colitis and pneumonitis (n = 1 each). **Conclusions:** Pembrolizumab provided durable antitumor activity with a manageable safety profile in patients with MSI-H CRC that progressed after ≥1 prior line of therapy. Clinical trial information: NCT02460198.

Tumour-infiltrating CD8$^+$ lymphocytes as a prognostic marker in colorectal cancer: A retrospective, pooled analysis of the QUASAR2 and VICTOR trials. *First Author: Mark Glaire, University of Oxford, Oxford, United Kingdom*

Background: The intensity of the T cell anti-tumour response influences colorectal cancer (CRC) outcome, and may predict benefit from immunomodulatory therapies. However, previous studies have been limited by their modest size, heterogeneous non-experimental populations, and failure to adjust for confounders such as mismatch repair deficiency (MMR-D), *POLE* mutation, and chromosomal instability (CIN). **Methods:** We performed a prospective-retrospective, pooled biomarker study of 1804 CRCs from the QUASAR2 and VICTOR trials. The densities of CD8$^+$ and CD3$^+$ tumour infiltrate were quantified, and their association with clinical outcome analysed by univariable and multivariable Cox proportional hazards regression. **Results:** CD8$^+$ cell density was strongly correlated with CD3$^+$ infiltrate (Spearman rho = 0·65; $P = 2{\cdot}2 \times 10^{-16}$), and was significantly associated with stage II disease ($P = 1{\cdot}5 \times 10^{-4}$), right-sided primary tumour ($P = 4{\cdot}1 \times 10^{-6}$), MMR-D/*POLE* mutation ($P = 4{\cdot}9 \times 10^{-12}$), absence of chromosomal instability (CIN) ($P = 1{\cdot}2 \times 10^{-3}$) and *BRAF* mutation ($P = 3{\cdot}2 \times 10^{-3}$). In the QUASAR2 trial, CD8$^+$ density was a stronger predictor of CRC recurrence than CD3$^+$ alone, and showed similar discriminative ability to both markers in combination. In a pooled analysis of both studies, increasing CD8$^+$ density was associated with significantly reduced risk of tumour relapse and death. Unadjusted estimates of recurrence-free probabilities at 3 years were 76·3% (95%CI = 73·4 – 79·4) vs. 83·8% (95%CI = 81·4 – 86·3) for CRCs with CD8$^+$ cell density at the 10th and 90th centiles respectively. In multivariable analysis, CD8$^+$ density was a stronger predictor of CRC recurrence (HR for each two-fold increase = 0·92, 95%CI = 0·87–0·97, $P = 3{\cdot}2 \times 10^{-3}$) and overall survival (HR = 0·93; 95% CI = 0·87–0·99, $P = 0{\cdot}02$), than MMR-D/*POLE* mutation or CIN, which were not significantly associated with either endpoint after adjustment for CD8$^+$ infiltrate. **Conclusions:** Quantification of CD8$^+$ cell density holds promise to refine prognostication in CRC beyond current clinicopathological and molecular factors.

Serial circulating tumor DNA (ctDNA) analysis as a prognostic marker and a real-time indicator of adjuvant chemotherapy (CT) efficacy in stage III colon cancer (CC). *First Author: Jeanne Tie, The Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia*

Background: Adjuvant CT in stage III CC prevents recurrence by eradicating minimal residual disease (MRD) not visible on imaging. However, many patients (pts) will not have MRD and not all pts with MRD will benefit from standard CT. In this study, we determined (i) if the presence of ctDNA following surgery was predictive of recurrence following CT; (ii) if ctDNA could be used to determine the effectiveness of CT during treatment and (iii) if the presence of ctDNA following CT completion was predictive for later recurrence. **Methods:** Serial plasma samples from stage III CC pts planned for adjuvant CT were collected post-surgery, during CT and at treatment completion. Somatic mutations in individual tumors were identified via massively parallel sequencing of 15 genes commonly mutated in colorectal cancer. Personalized Safe-SeqS assays to quantify ctDNA in plasma samples were designed. Clinicians were blinded to ctDNA results. **Results:** 95 pts were enrolled from Nov-2014 to May-2017, median age was 64 years. All received adjuvant CT and 19 (20%) had recurred at a median follow-up of 21.1 months. We observed an inferior recurrence-free survival (RFS) in the 19 of 95 pts (20%) with positive ctDNA post-surgery (HR, 3.52; p = 0.004). ctDNA status changed from positive to negative in 10 of 17 pts (59%) after 2 months of CT; and 9 of 18 pts (50%) at CT completion. Superior RFS was observed when ctDNA became undetectable after CT (HR 5.11; p = 0.02). Conversely, ctDNA status changed from negative to positive after CT in 6 of 71 pts (8%) and was associated with an inferior RFS (HR 5.30; p = 0.006). Finally, inferior RFS was seen in the 15 of 89 (17%) with positive ctDNA after adjuvant CT completion (HR, 7.14; p < 0.001). **Conclusions:** ctDNA can reveal the presence of residual metastatic cancer cells not apparent on imaging in stage III CC patients. Serial analysis of ctDNA can define subsets of pts benefiting or not benefiting from CT and is therefore a real-time marker of adjuvant treatment efficacy in solid tumors. Further studies are needed to define how best to use ctDNA analysis to guide a personalized and risk adjusted approach to the initiation and modification of adjuvant CT in stage III CC.

Validation of neoadjuvant rectal cancer (NAR) score as a surrogate endpoint for overall survival in real-life practice settings. *First Author: Y. Nancy You, University of Texas MD Anderson Cancer Center, Houston, TX*

Validation Of Neoadjuvant Rectal Cancer (NAR) Score As A Surrogate Endpoint For Overall Survival In Real-life Practice Settings Background: Response to neoadjuvant therapy(NT) for rectal cancer(RC) correlates with long-term outcome. Pathologic complete response(pCR) has been used as an early endpoint in RC clinical trials, but is limited by its binary nature. NAR, a composite score available after resection, is a novel short-term surrogate endpoint. The association between overall survival(OS) and NAR has not been validated in clinical practice outside of clinical trials. **Methods:** The National Cancer Database (2004-2013) was queried for patients with non-metastatic RC and known staging and survival data (N = 47,833). Those who underwent neoadjuvant chemoradiation (45-54 Gy) and proctectomy formed the study cohort (N = 19,831). NAR was defined as [5 ypN - 3 (cT - ypT) + 12]^2/9.61. Patients were categorized by ypCR, pathologic stage, and NAR score (Table). OS was calculated by the Kaplan-Meier method and compared using log-rank tests. **Results:** Clinical stage was II (N = 9929, 50.0%) or III (N = 9932, 50.0%). After NT, 2490 patients (12.6%) achieved pCR (ypT0N0); another 5727 (28.9%) were downstaged (ypT1-2N0). The median NAR was 15.0 (Interquartile range: 8.4-26.6). After 4.2 years of follow-up, OS correlated with pCR, pathologic stage, and NAR categories (Table). **Conclusions:** Similar to data from clinical trials, NAR demonstrated predictive validity for OS in real-life practice. Nearly half of the RC patients nationwide had high NAR, and quartiling NAR offered best stratification of OS, highlighting the advantage of NAR as a versatile continuous measure of NT response.

Category	No. of patients (%)	5-year OS	p-value
Complete pathologic response (pCR)			< 0.001
Yes	2490 (12.6)	88.9	
No	17341 (87.4)	75.2	
Pathologic stage			< 0.001
ypT0N0	2490 (12.6)	88.9	
ypT1-2N0	5727 (28.9)	86.4	
ypT3,4 or N+	11614 (58.5)	69.8	
NAR risk (as defined from NSABP R04)			< 0.001
Low (< 8)	3629 (18.3)	88.0	
Intermediate (8-16)	9793 (49.4)	81.0	
High (> 16)	6409 (32.3)	64.6	
NAR quartiles			< 0.001
1st (< = 8.4)	3629 (25.0)	88.0	
2nd (8.5-15.0)	9793 (25.0)	81.0	
3rd (15.1-26.6)	1431 (25.0)	75.2	
4th (> 26.6)	1978 (25.0)	61.7

RIA: Randomized phase II study comparing induction (I) mFOLFOX6 with or without aflibercept followed by chemoradiation (CRT) and total mesorectal excision (TME) in high risk-rectal cancer. GEMCAD 14-02 trial. *First Author: Carlos Fernandez-Martos, Instituto Valenciano De Oncologia, Valencia, Spain*

Background: Preclinical studies suggest that VEGF blockade can have a role in the preoperative treatment of rectal cancer but how to combine it with chemotherapy (CT) and/or CRT remains controversial. Increased risk of postoperative morbidity has been reported with preop anti VEGF/CRT combination. Aflibercept (Afli) acts as a soluble receptor that binds to human VEGF-A, VEGF-B, PlGF. We hypothesized that administering Afli/FOLFOX followed by CRT would improve pathological complete response (pCR) without compromising wound healing. **Methods:** Between 1/2015-3/2017, pts selected with centrally reviewed magnetic resonance (mr) imaging with middle or distal third, mrT3/T4/N2 rectal adenocarcinoma were randomly assigned (2:1, stratified by mr extra-mural venous invasion and mrT4) to mFOLFOX6 with (arm 1) or without Afli (arm 2) prior to standard CRT (capecitabine with 50.4 Gy in 28 fractions) and TME. The study was designed to perform a hypothesis testing with an alpha = .2 and beta = .2. Due to two planned interim analyses (OáBrien), the threshold for statistical significance was p < 0.1984 in the final analysis. We present primary (pCR) and early secondary endpoints: acute toxicity and compliance. **Results:** 115/65 pts were assigned to arm 1/arm 2. The pCR rate (ypT0N0) in pts who underwent curative surgery was achieved in 25/103: 24.2%; (95% CI 16.36-33.71) in arm 1 and in 9/62: 14.5% (CI 6.86-25.78) in arm 2. p = 0.1335 Preoperative grade 3-4 toxicity occurred in 50% in arm 1 and 23% in arm 2 during the I period (difference mostly due to hypertension). Overall postoperative complications were similar between both arms (14.7% and 12.3%). Six cycles of I CT were administered in 92% and 95% and 90% and 96% completed CRT in arm 1 and 2 respectively. R0 resection rate was 87.3% and 88.7%. **Conclusions:** The addition of aflibercept to I mFOLFOX6 led to a significantly greater pCR rate compared with mFOLFOX6 alone in patients with high-risk rectal cancer. The experimental arm showed higher toxicity during the I phase, with similar toxicity afterwards and no increase in surgical complications. Funding: Sanofi Clinical trial information: NCT02340949.

3520 Poster Session (Board #13), Sun, 8:00 AM-11:30 AM

Genomic landscape, clinical characteristics and outcomes of early onset (EO) compared with average onset (AO) colorectal cancer (CRC). *First Author: Gustavo Dos Santos Fernandes, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The incidence of CRC in patients (pts) under the age of 50 has been rising over the past decade. Little is known about the biologic differences between early and AO (over the age of 50) CRC, but early reports suggest tumors in these EO patients are more aggressive and present with advanced disease. **Methods:** To better understand the differences in etiology and biology of these EO tumors, we retrospectively reviewed the charts of all pts with EO CRC (n = 384) treated at Memorial Sloan Kettering Cancer Center between 2014 and 2017 for pathology, radiology, and clinical characteristics and compared these to a cohort of AO CRC cases (n = 543). We also performed tumor sequencing using a targeted NGS panel (> 300 genes, MSK IMPACT). Pts with CRC related hereditary syndromes such as Lynch Syndrome and inflammatory bowel disease were excluded. **Results:** In the EO pts median age was 44 (17-50); 52% male and 48% female. Sixty-six % of patients had stage (St) IV disease at diagnosis, 24% had St III, 7% had St II, and 2.6% had St I. Twenty four % of pts wereBMI≥30 and 29% ever smoked. Family history of CRC in first or second degree relatives was present in 29%. The majority of pts had moderately differentiated (74%) and L sided tumors (78%). All EO and AO pts evaluated were MSS with a median mutational burden of 4.9 mut/Mb and 5.0 mut/Mb, respectively. The median age of AO pts was 61 (51-93). EO versus AO CRC identified enrichment of TP53 mutations (87v 78%, p = 0.001, q = .14) and 20q amplifications 5 vs 1% p = .006, q = 0.33). In metastatic pts median OS was higher in EO (73 vs 69, p = 0.022) months. In EO there was a trend towards no difference in outcomes between L vs R sided tumors (HR 1.53 p = 0.13). **Conclusions:** This is the largest cohort describing a broad range of clinical and genomic characteristics of the EO CRC population with comparison to AO CRC. In our initial analyses EO pts present with predominantly L sided tumors, with similar histology and few molecular differences when compared AO CRC. In contrast to prior reports, EO appears to be associated with better survival. Detailed clinical and molecular characterization and multivariate analysis of EO vs AO will be presented.

3521 Poster Session (Board #14), Sun, 8:00 AM-11:30 AM

Final overall survival (OS) analysis of first-line (1L) FOLFOX-4 ± cetuximab (cet) in patients (pts) with *RAS* wild-type (wt) metastatic colorectal cancer (mCRC) in the phase 3 TAILOR trial. *First Author: Shukui Qin, Nanjing Bayi Hospital, Nanjing, China*

Background: The survival advantage conferred by the addition of cet to FOLFOX chemotherapy was verified in TAILOR, the first prospective, randomized, phase 3 study of the addition of cet to 1L FOLFOX in pts with *RAS* wt mCRC. We previously presented the primary analysis of the TAILOR trial, with fewer OS events. Here, we provide the final OS results for this trial. **Methods:** TAILOR was an open-label, randomized, multicenter, phase 3 trial with a modified intention-to-treat (mITT) population of 393 pts from China that evaluated FOLFOX-4 ± cet in *RAS* wt mCRC. The primary endpoint was progression-free survival (PFS) time; secondary endpoints include OS time, overall response rate (ORR), and safety/tolerability. **Results:** An updated analysis (performed after 84% of events occurred) verified the survival advantage of the addition of cet to FOLFOX-4 (Table). Additionally, > 77% of pts in the cet + FOLFOX-4 arm reached ≥ 80% dose intensity of cet, confirming that cet + FOLFOX-4 has high compliance. There were no new or unexpected safety findings. Finally, 59.6% and 56.0% of pts in the cet + FOLFOX-4 and FOLFOX-4 arms, respectively, received subsequent anticancer therapy after treatment discontinuation (54.4% and 49.5% received any chemotherapy, and 17.6% and 27.0% received any targeted therapy). Clinical trial information: NCT01228734. **Conclusions:** The TAILOR study met all its endpoints, confirming cet in combination with FOLFOX-4 as an effective standard-of-care 1L treatment regimen for pts with *RAS* wt mCRC. We acknowledge that OS findings for the mITT population are likely influenced by the low percentage of pts who received further lines of treatment after progression on their 1L regimen, suggesting regional differences in access to anticancer therapy.

3522 Poster Session (Board #15), Sun, 8:00 AM-11:30 AM

Effect of matched therapy in metastatic colorectal cancer on progression free survival in the phase I setting. *First Author: Michael Lam, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The benefits of matching targeted treatments to aberrations identified by molecular profiling (MP) is unclear. Outcomes in phase 1 settings have been traditionally reported across tumor histologies. We report outcomes based on a metastatic colorectal cancer (mCRC) population. **Methods:** Patients (pts) with mCRC receiving at least one dose of treatment on a phase 1 study were annotated for variants detected by MP. A precision oncology decision support (PODS) team determined variant function and actionability. A matched therapy (MT) was defined as allocation to a novel agent that targeted the aberration or predicted pathway deemed actionable by PODS. Progression-free survival (PFS) was estimated using the Kaplan-Meier method. A Cox proportional hazards model was used to estimate hazard ratios (HR). **Results:** A total of 370 patients enrolled onto 467 phase 1 trials were identified from January 2012 to April 2017. 106 enrolments were assigned to MT. Pts with microsatellite instability-high (MSI-H), $BRAF^{V600E}$, PIK3CA mutation were more likely to be assigned a MT, while left-sided tumors and RAS mutant patients were less likely to be treated with a MT. Molecularly-targeted regimens (MTR) were utilized more frequently in MT while immune-targeting MTR was more common in non-MT. $BRAF^{V600E}$ mutations and HER2 amplification/overexpression made up 44.3% of MT. There was a significant difference in PFS between the MT vs non-MT group (HR 0.65, 95% CI 0.51-0.83, p = 0.016) in univariate analysis. The 6-month PFS probability was 31% (95% CI; 23-41%) versus 13% (95% CI; 10-17%) respectively. Other significant factors in univariate analysis associated with longer PFS were MSI-H, $BRAF^{V600E}$ and use of a regimen containing cytotoxic chemotherapy while RAS mutations were associated with shorter PFS. In multivariate analysis, after correcting for mutation status, allocation to a MT was associated with improved PFS (HR = 0.72, 95% CI 0.50-0.99, p = 0.043). **Conclusions:** Matching clinical trial enrollment to MP based on dedicated decision support is associated with improved outcomes in mCRC patients. The MT strategy is still hampered by a limited number of actionable variants, and is driven by a small number of active MTs.

3523 Poster Session (Board #16), Sun, 8:00 AM-11:30 AM

APOLLON: A phase I/II study of panitumumab combined with TAS-102 in patients (pts) with *RAS* wild-type (wt) metastatic colorectal cancer (mCRC). *First Author: Yasutoshi Kuboki, Gastrointestinal Oncology Division, National Cancer Center Hospital East, Kashiwa, Japan*

Background: APOLLON is an open-label, single-arm phase I/II study investigating the efficacy and safety of panitumumab (Pmab) in combination with TAS-102 (trifluridine/tipiracil) in pts with *RAS* (*KRAS*/*NRAS*) wt mCRC refractory to standard chemotherapy. The recommended phase II dose (RP2D) of this combination was reported in ASCO-GI 2017 as Pmab at 6 mg/kg on Days 1 and 15, every 4 weeks (Q4W) and TAS-102 at 35 mg/m² BID on Days 1–5 and 8–12, Q4W, and was well tolerated without dose-limiting toxicities. Here, we present the efficacy and safety data for pts treated with Pmab with TAS-102 at the RP2D. **Methods:** Eligible pts were aged 20–74 years (y); ECOG PS 0–1; with *RAS* wt mCRC; refractory or intolerant to fluoropyrimidines, irinotecan, oxaliplatin or anti-angiogenesis therapy; and had no prior treatment with any anti-EGFR antibody, TAS-102 or regorafenib. Primary endpoint was investigator-assessed progression-free survival (PFS) at 6 months in RP2D-treated pts (including seven pts in phase I). Secondary endpoints included PFS, response rate (RR), disease control rate (DCR) and safety. Using an exact single-stage binomial design, 47 pts were required, with a 6-month PFS of 48% deemed promising and 29% unacceptable (one-sided $\alpha = 0.05$; $\beta = 0.2$). **Results:** From 2015 to 2017, 56 pts (30 male) with a median age of 64 y (range: 38–74 y) were enrolled. Median follow-up was 10.4 months. 6-month PFS rate (n = 54) was 33.3% (90% CI: 22.8–45.3; p = 0.2414). Median PFS, RR and DCR were 5.8 months (95% CI: 4.5–6.5), 37.0% and 81.4%, respectively (n = 54). The most common grade (G) 3/4 treatment-emergent adverse events (n = 55) included neutropenia (G3: 30.9%, G4: 16.4%), febrile neutropenia (G3: 10.9%), stomatitis (G3: 9.1%), dermatitis acneiform (G3: 9.1%), fatigue (G3: 3.6%) and hypomagnesemia (G3: 3.6%). There were no treatment-related deaths or unexpected safety signals. **Conclusions:** The first phase II study of Pmab with TAS-102 at the RP2D showed favorable antitumor activity with an acceptable safety profile for pretreated pts with *RAS* wt mCRC, although the primary endpoint of PFS at 6 months did not meet the prespecified threshold. Clinical trial information: NCT02613221.

3524 Poster Session (Board #17), Sun, 8:00 AM-11:30 AM

Optimizing treatment strategy for advanced rectal cancer in the West and Japan: International multicenter cohort study. *First Author: Akira Ouchi, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The treatment strategies for locally advanced rectal cancer in the West and Japan have evolved through divergent philosophies - preoperative chemoradiation (CRT) and total mesenteric excision (TME) in the West and upfront TME with lateral pelvic node dissection (LPND) in Japan. The purpose of this study was to compare these approaches. **Methods:** Consecutive patients with ≥cT3 rectal cancer located ≤12 cm from the anal verge and diagnosed between 1998 and 2013 at 3 tertiary cancer centers (1 US and 2 Japan) were identified. Only patients who received preoperative CRT+TME in the US and those who underwent TME+/-LPND based on tumor location in Japan were included. The primary outcome was cumulative rate of local recurrence (LR) and secondary outcomes included relapse free survival (RFS). **Results:** A total of 1597 patients (836 US and 761 Japan) met study criteria and were analyzed. Adjuvant chemotherapy was given to 88.4% in the US and 24.4% in Japan. Five-year cumulative risk for LR was 4.6% in the US and 6.7% in Japan ($HR_{adjusted}$ 0.58 [95% CI 0.30-1.13]). Overall RFS was longer in the US on univariate analysis (HR 2.09 [1.64-2.66], p < 0.001), but after adjustment for (y)p stage and relevant covariates, did not differ from Japan ($HR_{adjusted}$ 0.89 [0.66-1.19]). Following CRT and TME in the US or TME+/-LPND in Japan, 63.4% and 21.2% of stage cIII patients were downstaged, respectively. On stage stratified adjusted analysis, there were no differences in RFS for stage cII and (y)pII subgroups; meanwhile RFS in stage cIII subgroup was significantly longer in the US, but did not differ for stage (y)pIII subgroup (Table). **Conclusions:** This is the first comparison of a large cohort of patients treated by CRT+TME, and TME+/-LPND within dedicated cancer centers in the US and Japan. Overall the rates of local recurrence were lower than historically reported. These results suggest good outcomes can be achieved without CRT for some stage cII patients but that neoadjuvant CRT is associated with improve survival for stage cIII patients who are downstaged.

RFS	$HR_{adjusted}$ [95% CI]	p
Stage cII	1.40 [0.73-2.68]	0.30
Stage (y)pII	1.28 [0.53-3.11]	0.57
Stage cIII	2.54 [1.79-3.61]	< 0.001
Stage (y)pIII	0.86 [0.61-1.21]	0.41

3525 Poster Session (Board #18), Sun, 8:00 AM-11:30 AM

Change in CEA as an early predictor of progression to first-line systemic therapy in metastatic colorectal cancer. *First Author: Pat Gulhati, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Carcinoembryonic antigen (CEA) levels are used in conjunction with imaging to monitor response to systemic therapy in pts with metastatic colorectal cancer (mCRC). We sought to identify a threshold for change in CEA from baseline that can predict progressive disease (PD) at first restaging scan in mCRC pts receiving first-line therapy. **Methods:** Pts from trials collected in ARCAD database were included if baseline CEA was ≥10 ng/mL and repeat CEA was available within 14 days of first restaging scan. Optimal cutoffs for CEA change were identified by ROC analysis. Prediction performance of cutoffs was evaluated by sensitivity, specificity, and negative predictive value (NPV). Analyses were conducted by treatment class: chemotherapy alone (chemo) and chemotherapy plus anti-VEGF antibody (anti-VEGF). **Results:** 2828 pts from 7 trials [M/F: 60%/40%; median age: 61 yrs; ECOG PS 0-1: 97%] with mCRC [55% pts with ≥2 metastatic sites] treated with systemic therapy were included. In chemo group (n = 957), median percent change of CEA from baseline to first restaging was -53.1% and +23.6% for pts with CR/PR/SD and PD, respectively. In anti-VEGF group (n = 1355), median percent change of CEA was -71.7% and -45.3% for pts with CR/PR/SD and PD, respectively. Optimal cutoffs based on sensitivity and specificity (AUC cutoff) or 99% NPV are shown in the table. The optimal AUC cutoff for differentiating PD from CR/PR/SD on first restaging was -7.5% for chemotherapy and -62.0% for anti-VEGF group. A drop in CEA less than optimal AUC cutoff was significantly associated with higher risk of PD at 1st restaging; chemo, $OR^{adj} = 6.51$; anti-VEGF, $OR^{adj} = 3.45$. The use of a 99% NPV cutoff for prediction of CR/PR/SD would avoid a CT scan at first restaging in 21% of chemotherapy and 16% of anti-VEGF treated patients. **Conclusions:** Change in CEA from baseline to first restaging can accurately predict PD in pts receiving chemotherapy.

PD Prediction by CEA	Change in CEA	AUC	Sensitivity	Specificity	NPV	CT scans avoided
Cutoff by optimal AUC						
Chemo only	-7.5%	0.79	71.6%	76.2%	97.3%	72.8%
Chemo + Anti-VEGF	-62.0%	0.72	66.7%	63.6%	97.9%	62.4%
Cutoff by 99% NPV						
Chemo only	-79.4%	0.79	97.0%	22.4%	99%	21.0%
Chemo + Anti-VEGF	-88.7%	0.72	96.3%	16.7%	99%	16.0%

3526 Poster Session (Board #19), Sun, 8:00 AM-11:30 AM

A validation study of stratification by the 55-gene classifier for assessing recurrence risk in stage II colon cancer: The 55 STAR study (UMIN23879). *First Author: Shigeki Yamaguchi, Gastroenterological Surgery, Saitama Medical University International Medical Center, Hidaka-Shi, Japan*

Background: Cancer subtypes classified by DNA microarray data have shown excellent abilities in predicting patient prognosis; in particular, consensus molecular subtypes (CMSs) are regarded as the most robust classification system with clear biological interpretability. Recently, we performed unsupervised clustering analysis using a public database and selected the expression of 55 gene to construct a discriminant model with the aim of classifying colon cancer (CC) into three subtypes: "microsatellite instability (MSI)-like", "chromosomal instability (CIN)-like", and "stromal"; the recurrence rates of these subtypes were shown to be different (p = 0.001). In this study, we conducted a retrospective, multi-institutional study to validate the quality of a novel 55-gene classifier (55GC) for Stage II CC and compared 55GC subtypes with the CMS categories. **Methods:** We collected formalin-fixed, paraffin-embedded cancer specimens from 232 patients with Stage II CC who underwent curative surgery (R0) without adjuvant chemotherapy at 10 institutions between 2009 and 2012. Tissue sections were prepared from each specimen and subjected to DNA microarray measurement. **Results:** Using the 55GC, patients were classified as having the MSI-like subtype in 27%, CIN-like in 41%, and stromal in 32% of the cases. The 5-year recurrence-free survival (RFS) rate of patients with the MSI-like, CIN-like, and stromal subtype cancers was 88.5%, 83.3%, and 71.2%, respectively (stromal vs. others: p = 0.0049). Multivariate analysis by Cox's proportional hazard model revealed that stromal subtype (hazard ratio, 2.3; p = 0.0063), pT4, and the number of lymph nodes examined (< 12) were independent poor prognostic factors. The overall concordance rate between 55GC and CMS was 72%: 29% (18/62) of the MSI-like subtype, 79% (75/95) of the CIN-like subtype, and 98% (74/75) of the stromal subtype were judged as CMS1, CMS2/3 and CMS4, respectively. The 5-year RFS rate of patients with CMS1, CMS2/3 and CMS4 was 100%, 86.3%, and 73.0%, respectively (CMS4 vs. others: p = 0.005). **Conclusions:** 55GC is a useful and reproducible grading system for recurrence risk stratification of Stage II CC.

3527 Poster Session (Board #20), Sun, 8:00 AM-11:30 AM

Effect of PET-CT on disease recurrence and its management in patients with potentially resectable colorectal cancer liver metastases. The long-term results of a randomized controlled trial (PET-CT Imaging prior to liver resection for colorectal adenocarcinoma metastases). *First Author: Pablo Emilio Serrano Aybar, McMaster University, Hamilton, ON, Canada*

Background: The PETCAM randomized trial evaluated the effect of preoperative PET-CT (vs. no PET-CT) on surgical management in patients with colorectal cancer liver metastases. This trial resulted in 8% change in surgical management, including a higher proportion of major liver resections in the PET-CT arm. This study is the long-term follow up of the PETCAM trial and aims to compare the disease-free (DFS), overall survival (OS), and long-term clinical course of enrolled patients. **Methods:** Recruitment to the trial occurred between 2005-2010, with last follow-up in 2013. Data on recurrence, management and mortality from 2013-2017 was collected retrospectively. Cox proportional Hazard Models were used to calculate risk for recurrence and death. OS was calculated with Kaplan-Meir method and compared with log-rank test. **Results:** At 5 years, 172/404 (43%) patients were alive. There were no differences in DFS (HR: 1.13, 95%CI: 0.89-1.43) or OS (HR: 1.02, 95%CI: 0.78-1.32) between groups. Median DFS was 17 months, 95%CI: 14-19. Risks factors for recurrence were: extrahepatic disease, liver tumour size, nodal stage and disease-free duration. Median OS was 51 months, 95%CI: 44-64. During the follow-up period, 264/368, 72% patients recurred, mostly lung (51%) and liver (41%); 120/264 (46%) received chemotherapy and 112/264, 42% were re-resected, with a recurrence of 72% (81/112). Median OS following first recurrence was 28 months, 95%CI: 24-31. Most important risks factors for death following recurrence are node-positive disease, more than one recurrence site and disease-free duration < 5 months. **Conclusions:** PET-CT did not improve DFS or OS. Recurrence following liver resection is common. Prognosis following recurrence is worse compared to first recurrence. Patients with high risk factors should not undergo surgical resection. Clinical trial information: NCT00265356.

3528 Poster Session (Board #21), Sun, 8:00 AM-11:30 AM

A randomized phase II study of perioperative chemotherapy plus bevacizumab versus postoperative chemotherapy plus bevacizumab inpatients with upfront resectable hepatic colorectal metastases (APPROACH). *First Author: You Jin Chun, Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Seoul, Korea, Republic of (South)*

Background: Whether patients with resectable colorectal cancer liver metastases (CRLM) gain a survival benefit or not from neoadjuvant chemotherapy remains controversial. The addition of bevacizumab to chemotherapy also remains unclear. **Methods:** 76 patients with CRLM were randomly assigned to either six cycles of FOLFOX or FOLFIRI with bevacizumab before and six cycles after surgery or to twelve cycles after surgery. The primary objective was to detect DFS. The primary analysis was by intention to treat and DFS were estimated by the Kaplan-Meier method and compared by the log-rank test. This trial was registered with ClinicalTrials.gov, number NCT01632722. **Results:** In patients with chemotherapy plus bevacizumab, the median DFS was 37.4 months at 5.4 years follow-up and the median overall survival (OS) was not reached. The DFS between the perioperative group and the postoperative group showed a better tendency in the perioperative group, but there was no statistical difference (HR 0.837 [95.0% CI 0.606-1.156], *p = 0.280).* The OS was statistically better in the perioperative group (*p = 0.049).* There was no difference in DFS between the two groups in patients with CEA≥5 or more than two liver metastases, but there was OS benefit in the perioperative group than in the postoperative group (CEA, HR 0.485 [95.0% CI 0.252-0.933], *p = 0.030;* number of liver metastases, HR 0.548 [95.0% CI 0.300-0.999], *p = 0.049).* BMI, the largest size of liver metastases, primary T or N stage, disease-free interval, and sidedness did not affect the difference in DFS and OS. There was no difference in postoperative complications of bevacizumab and adverse event during chemotherapy between the two groups. **Conclusions:** In patients with resectable CRLM, perioperative chemotherapy had no effect on DFS but improved OS. The perioperative chemotherapy plus bevacizumab do not increase the risk of complications in liver resection. Patients with high levels of CEA or the number of liver metastases may have benefited from perioperative chemotherapy. Clinical trial information: NCT01632722.

3529 Poster Session (Board #22), Sun, 8:00 AM-11:30 AM

Impact of the type and modalities of preoperative chemotherapy on the outcome of liver resection for colorectal liver metastases: A LiverMetSurvey study. *First Author: Yuichi Goto, Centre Hépato-Biliaire, AP-HP, Hôpital Paul Brousse, Villejuif, France*

Background: Prognostic factors of survival have been extensively reported after resection of colorectal liver metastases (CLM). However, a specific analysis of patients submitted to preoperative chemotherapy (PCT), with the real impact of type and modalities of PCT on patient outcome is lacking. **Methods:** The study population consisted of a multicentric cohort of patients who received PCT before resection of CLM within a 20-year period and whose data were prospectively collected in the LiverMetSurvey. Patients were analyzed in terms of intentions of PCT including neoadjuvant (N-CT) and conversion (C-CT) chemotherapy. Overall survival (OS) rates were analyzed by Kaplan-Meyer method and compared using the log-rank test. The distribution of potential prognostic factors for OS including age, sex, sidedness of primary tumor, timing of metastases, tumor number, diameter of largest CLM, CEA, bilaterality, and type and number of PCT cycles were analyzed by Cox regression model. **Results:** Of 7,202 eligible patients, N-CT was submitted in 4,422 (61.4%) for resectable and C-CT in 2,780 patients (38.6%) for unresectable CLM. In N-CT, 5-year OS of Irinotecan-based (Iri-) PCT was decreased compared to the oxaliplatin-based (Oxa-) PCT (40.9% vs. 47.8%, $p < 0.01$). The 5-year OS was not different with or without targeted therapy (41.1% vs. 47.0%, $p = 0.12$). As for C-CT, the 5-year OS was comparable between Iri- and Oxa-PCT (32.2% vs. 32.9%, $p = 0.32$), and also not different with regard to the use of targeted therapy ($p = 0.47$). On multivariate analysis, Iri-PCT was associated with worse OS in N-CT (HR = 1.46 [1.02-1.52], $p = 0.02$) but not in C-CT ($p = 0.89$). Use of targeted therapy was not associated with OS for both N-CT and C-CT ($p = 0.53$, $p = 0.06$, respectively). PCT > 6 cycles in N-CT (HR = 1.46 [1.23-1.76], $p = 0.04$) and > 8 cycles in C-CT (HR = 2.39 [1.73-3.30], $p < 0.01$) was associated with worse OS. **Conclusions:** For resectable CLM with N-CT, Oxa-PCT is associated with better survival compared to Iri-PCT. For unresectable CLM with C-CT, the type of PCT did not influence the outcome, provided that resection was achieved. For both, the shorter is the PCT, the best is the survival after surgery.

3530 Poster Session (Board #23), Sun, 8:00 AM-11:30 AM

Multicenter phase I/II trial of BBI608 and pembrolizumab combination in patients with metastatic colorectal cancer (SCOOP Study): EPOC1503. *First Author: Eiji Shinozaki, Department of Gastroenterology, Cancer Institute Hospital, Japanese Foundation for Cancer Research, Tokyo, Japan*

Background: The anti–PD-1 antibody pembrolizumab provided an objective response rate of 28-57% in patients (pts) with Microsatellite Instability–High (MSI-H) metastatic colorectal cancer (mCRC) vs 0% in pts with Non-MSI-H. The WNT/β-catenin signaling has been reported to prevent anti-tumor immunity and promote resistance of anti-PD-1/PD-L1 antibodies. Furthermore, STAT3 has been known to be a key driver of the immune evasion. This study investigates efficacy and safety of the combination of BBI608, which blocks phosphorylated STAT3 and downregulates WNT/β-catenin signaling, with pembrolizumab in pts with mCRC. BBI608 480mg BID with pembrolizumab was determined as RP2D in the phase I part (Kawazoe A, et al. ASCO-GI 2018). Here, we present the preliminary results of the ongoing phase II part. **Methods:** Phase II part was composed of Cohort A (MSI-H) and Cohort B (Non-MSI-H). The main eligibility criteria was pts with mCRC not responded or intolerant to standard chemotherapies. Primary endpoint was Immune-related objective response rate (irORR) determined by irRECIST. Sample size for Cohort A with 10 pts was determined in an exploratory manner. In Cohort B, according to a null hypothesis and alternative hypothesis; irORR = 5% and 20%, estimating required sample size was 40 pts with a one-sided alpha of 5% and power of 90%. **Results:** From Feb 2017 to January 2018, 10 pts were enrolled in Cohort A, and 37 pts in Cohort B. As of October 2017, tumor response was evaluated in 3 pts of Cohort A and 25 pts of Cohort B, respectively. Two out of the 3 pts in Cohort A showed confirmed partial response. Among 12pts with right-sided colon in Cohort B, one patient showed confirmed partial response with remarkable decline of CEA level, and two pts showed stable disease lasting more than 16 weeks. Immunohistochemistry before treatment demonstrated the high expressions of PD-L1, CD8, and MHC-class I in the tumor samples from the patient with partial response. No severe or unexpected adverse events occurred up to the present. **Conclusions:** BBI608 with pembrolizumab showed preliminary efficacy signals with acceptable toxicity for MSI-H as well as Non-MSI-H mCRC pts with right-sided primary. Clinical trial information: NCT02851004.

3531 Poster Session (Board #24), Sun, 8:00 AM-11:30 AM

Results of a randomized phase 3 study evaluating the potential benefit of a second-look surgery plus HIPEC in patients at high risk of developing colorectal peritoneal metastases (PROPHYLOCHIP- NTC01226394). *First Author: Diane Goere, Institut Gustave Roussy, Villejuif, France*

Background: Complete cytoreductive surgery (CRS) followed by hyperthermic intraperitoneal chemotherapy (HIPEC) allow to prolong survival in patients with colorectal peritoneal metastases (CRPM), especially with a low tumor burden. The aim of the PROPHYLOCHIP multicentric randomized phase 3 study was to evaluate the potential survival benefit of a systematic second-look surgery plus HIPEC in patients at high risk of developing CRPM. **Methods:** Patients at high risk of developing CRPM defined as minimal CRPM resected with the primary, or history of ovarian metastases, or perforated primary tumor, were eligible. After 6 months of adjuvant chemotherapy, patients without sign of recurrence were randomized into 2 arms: (1) surveillance, (2) systematic second-look surgery plus HIPEC (intraperitoneal oxaliplatin). The primary end-point was the 3-year disease-free survival (DFS). Secondary end-points included overall survival (OS), peritoneal DFS and postoperative complications. **Results:** Between 2012 and 2015, 150 patients were randomized. During the second-look laparotomy (n = 71), CRPM was diagnosed in 52%, with a median peritoneal cancer index of 4 [0-26]. No patient died postoperatively and grade 3-4 complications occurred in 41%. After a median follow-up of 51 [47-55] months, the 3-year DFS of 44% [33-56] in the second-look group and of 51% [40-62] in the surveillance group did not differ ($p = 0.75$). In the surveillance group, a peritoneal relapse occurred in 25 (33%) patients, which was accessible to CRS-HIPEC in 16, whereas in the second-look group, 24 (32%) patients had a peritoneal relapse of whom 2 were treated with a new CRS-HIPEC. The 3-year OS was not significantly different, 80% [69-88] and 79% [68-87] in the surveillance and in the second-look groups, respectively. **Conclusions:** This study confirms that criteria for high risk of developing PM are strong, and strengthens the role of a peritoneal-centered surveillance in these patients. However, a pro-active strategy including a systematic second-look surgery plus HIPEC failed to improve survival, in comparison to an adequate surveillance. Clinical trial information: NCT01226394.

3532 Poster Session (Board #25), Sun, 8:00 AM-11:30 AM

High levels of cell-free DNA (cfDNA) at baseline (BL) and increase of at least one mutation at day 14 (D14) as independent prognostic biomarkers for patients (pts) with advanced colorectal cancer (aCRC) under regorafenib. *First Author: Pashalina Kehagias, Gastro-Oncology Translational Laboratory, Institut Jules Bordet - Université Libre de Bruxelles (ULB), Brussels, Belgium*

Background: BL-cfDNA combined with plasmatic changes in tumor-specific mutations after 14 days of therapy are explored as independent determinants of outcome in pts with aCRC. **Methods:** Archival tumor tissue and plasma samples at BL and D14 after regorafenib initiation were prospectively collected in aCRC pts (n=141) in a multicentric trial (NCT01929616). Tumor-specific mutations, selected on their allelic frequency on CRC-oriented targeted sequencing of tumor tissue, were analyzed for circulating tumor DNA (ctDNA) at BL and D14 via droplet digital PCR (Bio-Rad QX200 ddPCR system) using a 12 % cutoff to assess changes in ctDNA levels. **Results:** The cfDNA's optimal cutoff at BL (Contal & O'Quigley method) is 1 μg/ml in 134/141 evaluable pts. Hazard ratio (HR) of cfDNA ≥1 vs <1 is 2.50 (95% CI, 1.73-3.63) $P<0.001$ for progression-free survival (mPFS) and 3.83 (95% CI, 2.57-5.71) $P<001$ for overall survival (mOS). The most common mutated genes (96 evaluable pts for ctDNA) are *APC* (73%), *TP53* (72%), *KRAS* (66%), and *PI3KCA* (23%). On average 2 (1-4) mutations are followed per pt. An increase of ≥1 tumor-specific mutation as compared to none is associated with a significantly worse outcome: mPFS 1.3 vs 3.0 months (mo) (HR 1.88, $P=0.002$, 95% CI 1.24-2.85) and mOS 3.9 vs 8.5 mo (HR 2.04, $P<0.001$, 95% CI 1.33-3.12). BL cfDNA level and ctDNA changes between BL & D14 are not statistically correlated ($P=0.23$), and combined, define 4 subgroups with different prognosis. (Table 1) **Conclusions:** BL cfDNA and early (D14) changes in ctDNA during treatment with regorafenib are independent predictive markers for pts' outcome and appear as potential robust tools for treatment personalization. Clinical trial information: NCT01929616.

3533 Poster Session (Board #26), Sun, 8:00 AM-11:30 AM

Circulating tumor DNA (ctDNA) as an early marker to monitor clinical benefit of regorafenib and TAS-102 in patients with metastatic colorectal cancer (mCRC). *First Author: Allan Andresson Lima Pereira, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Utilization of ctDNA has been rapidly adopted as a predictive diagnostic in advanced Non-Small Cell Lung Cancer and indications in GI cancers may be emerging. We aimed to evaluate ctDNA as an early biomarker of efficacy of new therapies for mCRC. **Methods:** mCRC patients (pts) who consented to a genomic matching protocol and had started a new line treatment with regorafenib or TAS-102 were eligible. Droplet digital PCR (ddPCR) assays were performed using 3 mL of plasma samples from pts with tumors harboring *RAS* mutations (BioRad). Serial plasma samples also underwent retrotransposable element (RE) based multiplexed qPCR assay using 300 μL of plasma; a DNA Integrity Index (DII) was calculated using a ratio of long to short DNA fragment size concentrations (Innogenomics). Progressive disease (PD) by ctDNA, defined as any increase in allele frequency (AF) by ddPCR and any decrease in DII by RE-qPCR, was compared to RECIST at first restaging. **Results:** 40 mCRC pts were included. 16 pts were treated with regorafenib and 31 with TAS-102 (7 pts received both drugs). Therefore, 47 treatment regimens were included in this study with serial monitoring completed in 22 treatments with ≥ 2 serial plasma samples. At baseline, the median AF by ddPCR was 18.1% and the median DII was 0.112. A moderate correlation was seen between baselines CEA and AF by ddPCR ($r = 0.43$; $p = 0.056$). The sensitivity and specificity of ddPCR in detecting PD by RECIST was 61.5% (95%CI: 32% - 86%) and 100%, respectively. RE-qPCR had a sensitivity of 47.4% (95%CI: 24% - 71%) and specificity of 100%. Unlike ddPCR which was limited to monitoring patients with common mutations in *KRAS* and *NRAS*, the DII was successfully obtained in all patients. There was no false-positive in either assays. Serial change in CEA was more sensitive (77.8%), but less specific (16.8%). **Conclusions:** Our findings suggest that pts with ctDNA predicted PD may be safely switched to another treatment before radiologic restaging. ctDNA by both ddPCR and RE-qPCR can predict later radiological progression with high specificity, with RE-qPCR providing benefits of a universal assay and limited sample requirements.

3534 Poster Session (Board #27), Sun, 8:00 AM-11:30 AM

Impact of primary tumor side on outcomes of every-2-weeks (q2w) cetuximab + first-line FOLFOX or FOLFIRI in patients with *RAS* wild-type (wt) metastatic colorectal cancer (mCRC) in the phase 2 APEC trial. *First Author: Timothy Jay Price, Queen Elizabeth Hospital, University of Adelaide, Woodville, Australia*

Background: In the *RAS* wt population of APEC, q2w cetuximab combined with first-line FOLFOX or FOLFIRI achieved an overall response rate (ORR), median progression-free survival (PFS), and median overall survival (OS) similar to those reported in prior first-line pivotal studies involving weekly cetuximab. In this subgroup analysis, we evaluated the impact of tumor side in the APEC study population with *RAS* wt mCRC. **Methods:** APEC was a nonrandomized phase 2 trial conducted in the Asia-Pacific region, with ORR as the primary endpoint. Patients with *KRAS* exon 2 wt tumors received q2w cetuximab + investigator's choice of FOLFOX or FOLFIRI. Tumor side was categorized in evaluable patients with *RAS* wt tumors (left [L]-sided = splenic flexure, descending colon, sigmoid colon, and rectum; right [R]-sided = appendix, cecum, ascending colon, hepatic flexure, and transverse colon). **Results:** Among 167 patients with *RAS* wt mCRC, 159 were evaluable for tumor side; 130 (81.8%) had L-sided and 29 (18.2%) had R-sided mCRC. Baseline characteristics in the tumor side subgroups reflected the known differences between L- and R-sided mCRC; indeed, 95.4% and 75.9% of patients had *BRAF* wt disease, respectively. Efficacy data are summarized in the Table. **Conclusions:** Consistent with prior first-line pivotal studies with weekly cetuximab, a prognostic effect of tumor side in patients receiving first-line q2w cetuximab was confirmed in APEC. In patients with R-sided mCRC, ORR remained ≥ 50%, and resection rate was comparable to that of L-sided patients, in line with prior evidence showing that use of cetuximab may be appropriate when rapid tumor shrinkage is the goal. These hypothesis-generating data raise the possibility of a synergy between cetuximab and irinotecan in patients with R-sided tumors, although numbers are small. Clinical trial information: NCT00778830.

3535 Poster Session (Board #28), Sun, 8:00 AM-11:30 AM

Induction chemotherapy (CT) with FOLFIRINOX or FOLFOX/FOLFIRI, plus cetuximab (CET) or bevacizumab (BEV) (by RAS status), in patients (pts) with primarily unresectable colorectal liver metastases (CRLM): Results of the randomized UNICANCER PRODIGE 14-ACCORD 21 (METHEP-2) trial. *First Author: Marc Ychou, Institut du Cancer de Montpellier (ICM), Univ Montpellier, Montpellier, France*

Background: pts with unresectable CRLM who respond to induction CT allowing curative-intent liver surgery have longer overall survival (OS) than pts who do not. Triplet (3-) or doublets (2-) CT, combined with CET or BEV, are often used in this setting. However, the best CT regimen remains to be determined. **Methods:** METHEP2 assessed whether 3-CT (FOLFIRINOX) compared to 2-CT (FOLFOX or FOLFIRI), combined with CET or BEV (by KRAS/RAS status), would increase R0/R1 liver-resection rate in pts with initially unresectable CRLM. Randomization was stratified by KRAS (amended to RAS) status, meta- vs. synchronous CRLM, and reason for non-resectability (technical vs. oncological). It was designed to demonstrate a 20% increase in the R0/R1 liver-resection rate (2-CT arm, 50% vs. 3-CT arm, 70%; bilateral α-test, 5%; β, 10%). **Results:** 256 pts were included, 126 in the 2-CT arm (FOLFIRI, 56; FOLFOX4, 70) and 130 in the 3-CT arm. KRAS and RAS were mutated in 91 pts (35.5%) and in 109 pts (42.6%), respectively. After a median follow-up of 45.6 months (mo), R0/R1 liver resection was achieved in 74/130 pts (56.9%; 95%CI, 48-66) in the 3-CT arm vs. 61/126 pts (48.4%; 95%CI, 39-57) in the 2-CT arm ($p = 0.17$). The odds for R0/R1 resection were higher in the 3-CT than in the 2-CT arm (OR, 1.8; 95%CI, 1.1-2.7; $p < 0.02$) when using a logistic regression model adjusted on stratification factors. Median OS was 42.9 mo in the 3-CT arm vs. 37.6 mo in the 2-CT arm (HR = 0.80; 95%CI, 0.56-1.16). Efficacy by targeted agent was as follows: R0/R1 resection 86/153 (56.2%; 95%CI, 48-64) and 49/103 (47.6%; 95%CI, 38-58), objective response: 120/153 (78.4%; 95%CI, 71-85) and 58/103 (56.3%; 95CI, 46-66), mPFS: 12.8 mo (95%CI, 11.6-13.1) and 10.7 mo (95%CI, 9.7-13.1), OS: 43.6 mo (95%CI, 40.0-51.8) and 34.2 mo (95%CI, 27.8-40.4), for CET- and BEV-treated pts, respectively. **Conclusions:** Despite not reaching our primary objective, FOLFIRINOX tends to be superior to FOLFIRI/FOLFOX, combined with CET or BEV, in terms of R0/R1 liver-resection rate in pts with initially unresectable CRLM. Clinical trial information: NCT01442935.

3536 Poster Session (Board #29), Sun, 8:00 AM-11:30 AM

Safety analysis of a phase III randomized trial comparing FOLFOX + Bevacizumab vs FOLFOXIRI + Bevacizumab as 1st line treatment in patients with metastatic colorectal cancer (mCRC) with ≥3 circulating tumor cells (CTCs) (VISNÚ-1 TTD TRIAL). *First Author: A. Gomez, Reina Sofia Hospital, University of Cordoba, Maimonides Institute of Biomedical Research, Spanish Cancer Network, Instituto de Salud Carlos III, Cordoba, Spain*

Background: FOLFOXIRI plus bevacizumab has demonstrated a survival benefit compared with FOLFIRI plus bevacizumab (TRIBE Lancet Oncol 2015) in first-line mCRC. This schedule is not routinely recommended in all patient groups due to toxicity. VISNÚ-1 trial compared FOLFOX + Bevacizumab (arm A) vs FOLFOXIRI + Bevacizumab (arm B) in non-elderly patients(p) with ≥ 3CTCs at baseline as a poor prognostic factor. Preliminary safety analysis is presented here. **Methods:** This is an open, multicentric, randomized phase III trial. Patients aged ≤ 70 years, ECOG 0-1 were randomized to arm A or arm B, stratified per *KRAS* mutation. The data presented here were generated from a snapshot of the database from Oct-31st-2017. **Results:** 350 p have been included in the study, 347 p were available for safety analysis. General characteristics in arms A and B: Median age (59 vs 60.5 years), gender (Male/Female: 67.2/32.8 vs 69.4/30.1%), ECOG 0/1 (48/52 vs 47/53%), primary tumor unresected (32.2 vs 37.1%), previous adjuvant chemotherapy (4.0 vs 5.3%). Most common grade ≥3 toxicities and treatment modifications are shown in table 1. Only neutropenia, asthenia, diarrhea and mucositis were more frequent in arm B. Fourteen patients dead due to treatment-related adverse events (6 in the FOLFOX- BEV arm and 8 in the FOLFOXIRI-BEV arm): 7 sepsis, 5 bowel perforation, 2 pulmonary toxicity). **Conclusions:** In our study, the use of FOLFOXIRI + Bev in mCRC did not result in an increase in treatment delays, dose reductions or treatment interruptions as compared with FOLFOX+Bev despite an increased incidence of neutropenia, diarrhea, asthenia and mucositis. Clinical trial information: NCT01640405.

3537 Poster Session (Board #30), Sun, 8:00 AM-11:30 AM

Subgroup analysis by prior anti-VEGF or anti-EGFR target therapy in FRESCO, a randomized, double-blind, phase 3 trial comparing fruquintinib versus placebo plus best supportive care in Chinese patients with metastatic colorectal cancer (mCRC). *First Author: Ruihua Xu, Sun Yat-Sen University Cancer Center, Guangzhou, China*

Background: Patients with mCRC are typically offered chemotherapy and might also receive target therapy-drugs targeting VEGF or EGFR. In phase 3 FRESCO trial, fruquintinib demonstrated a statistically significant and clinically meaningful overall survival benefit in third-line mCRC patients in China. To explore possible effects of prior target therapy on fruquintinib, we conducted subgroup analysis of patients with prior target therapy (PTT) and those without (non-PTT). **Methods:** Overall survival (OS) and progression-free survival (PFS) were evaluated by Kaplan-Meier method. Hazard ratio (HR) was estimated through Cox proportional hazards model. P-value was generated from log rank test. **Results:** Among a total of 278 fruquintinib-treated patients, 111 received prior target therapy (84 with anti-VEGF;40 with anti-EGFR and 13 with both). In PTT subgroup, fruquintinib significantly prolonged OS (Median OS: 7.69 months (m) vs 5.98 m;HR = 0.63; p = 0.023) and PFS (Median PFS:3.65m vs 1.84m;HR = 0.24;p $<$ 0.001) compared to placebo. Patients who received prior anti-VEGF treatment (N = 84) also benefited from fruquintinib in OS (HR = 0.68,95%CI: 0.45-1.03) and PFS (HR = 0.24,95%CI: 0.15-0.38). In non-PTT subgroup, the median OS was 10.35 m for fruquintinib vs 6.93 m for placebo (HR = 0.63,p = 0.01) and the median PFS for fruquintinib was 3.81 m vs 1.84 m for placebo (HR = 0.28, p $<$ 0.001). There were no observed accumulative Grade$\geq$3 treatment-emergent adverse events (TEAEs) in PTT subgroup. Grade$\geq$3 TEAEs rates of fruquintinib were similar in PTT and non-PTT subgroup (61.3% and 61.1%). The most common drug-related Grade $\geq$3 TEAEs of fruquintinib in PTT and non-PTT subgroup were hypertension (20.7% and 21.6%), hand-foot-skin reaction (7.2% and 13.2%) and proteinuria (5.4% and 1.8%). **Conclusions:** This subgroup analysis result is consistent with previously reported FRESCO intent-to-treatment population result. Fruquintinib showed clinically meaningful benefits in third-line mCRC patients regardless of prior target therapy without observed accumulative toxicity. Clinical trial information: NCT02314819.

3538 Poster Session (Board #31), Sun, 8:00 AM-11:30 AM

Outcomes of oxaliplatin-based (Ox) chemotherapy (CT) on R0 resection of colonic liver metastases (CLM). *First Author: Nicholas Adam Bosma, Tom Baker Cancer Centre, University of Calgary, Calgary, AB, Canada*

Background: In resected CLM, randomized studies of Ox CT have not demonstrated improvements in overall survival (OS) and Ox CT has not been compared to non-Ox CT. The aim of this study was to assess the impact of Ox CT regimens on OS in patients that have undergone resection of CLM in a real world setting. **Methods:** Patients who underwent resection of CLM in the provinces of Alberta and British Columbia, Canada were identified from 1996-2016. Perioperative (pre and/or post) CT regimens were reviewed and categorized as Ox CT, non-Ox CT or no CT. OS was measured from the time of metastatic diagnosis to death or last follow-up using the Kaplan-Meier method. CT regimens were compared using the log-rank test and a Cox regression model, adjusting for possible confounders including age, gender, primary tumor sidedness and the presence of synchronous metastatic disease. **Results:** 516 patients were identified who underwent R0 resection of CLM for mCRC, including 205 that received Ox CT, 129 non-Ox CT and 182 with no CT. Of these patients, 24% and 56% received pre-operative and post-operative CT, respectively. 70% of these patients received a fluoropyrimidine (5-FU or capecitabine), 40% oxaliplatin, 13% irinotecan, 7% received bevacizumab and 1% panitumumab. Median age of these patients was 64, with 60% male and 57% demonstrating synchronous metastatic disease and 38% right-sided primary. The median OS for patients receiving Ox CT was 98 months, for non-Ox CT 60 months and no CT 56 months, p = 0.01. After adjusting for potential confounders with a Cox-proportional hazard model, patients who received Ox CT had a lower risk of death HR of 0.65 (95% CI 0.48-0.87, p $<$ 0.01), while the non-OX CT group did not, HR 0.84 (95% CI 0.62-1.13, p = 0.25) compared to no CT. **Conclusions:** Perioperative Ox CT appears to improve OS in conjunction with R0 resection of CLM in this multicenter population based study. This observation remained significant even after controlling for potential confounders. Ox CT should be considered in patients that undergo R0 resection of CLM, in favor of non-Ox CT. The addition of biologic agents to CT remains limited. Further studies should evaluate the optimal timing and duration of perioperative CT.

3540 Poster Session (Board #33), Sun, 8:00 AM-11:30 AM

First-in-human dose escalation of monalizumab plus durvalumab, with expansion in patients with metastatic microsatellite-stable colorectal cancer. *First Author: Neil Howard Segal, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Monalizumab (IPH2201) is a humanized IgG4 antibody targeting CD94/NKG2a to suppress inhibitory signaling by tumors on NK cells. The combination of monalizumab and durvalumab (anti-PD-L1) may promote antitumor immunity via complementary mechanisms targeting both innate and adaptive immune systems. This is a first-in-human, phase 1 dose escalation and expansion study to evaluate monalizumab plus durvalumab in patients with select advanced solid tumors. **Methods:** Patients received durvalumab 1500 mg every 4 weeks in combination with monalizumab at increasing doses. Escalation was determined using a modified toxicity probability interval. Antitumor activity was based on RECIST v1.1. Following initial efficacy in escalation, an expansion cohort of metastatic microsatellite-stable colorectal cancer (MSS-CRC) was enrolled. **Results:** We report the experience of 55 patients treated with monalizumab plus durvalumab, including 15 patients in escalation and 40 in MSS-CRC expansion. In escalation, there were no treatment-related adverse events (TRAEs) that led to discontinuations, no grade 3/4 TRAEs, no DLTs, and no deaths; MTD was not reached. Any grade TRAEs were observed in 12 patients (80%); most frequent was diarrhea (n = 4). Safety in expansion was similar to escalation: 19 patients (48%) had any grade TRAEs, 1 patient had a grade 3/4 TRAE (sepsis). PK of both drugs in combination showed no interactions. Monalizumab PK approached linearity at the highest dose level, which was thus chosen for expansion. In MSS-CRC expansion (58% with 3+ lines of prior therapy, n = 37 evaluable for efficacy), there were 3 confirmed PR and 11 SD, including 3 patients with tumor reduction who continued therapy for $>$ 200 days; DCR at 16 weeks was 24%. Updated clinical and biomarker data will be presented. **Conclusions:** Dose escalation of this first-in-human combination of monalizumab plus durvalumab has been completed, demonstrating a manageable toxicity profile. Preliminary data indicate that the combination has promising activity in patients with MSS-CRC, a population historically nonresponsive to PD-1/PD-L1 blockade. Clinical trial information: 02671435.

3541 Poster Session (Board #34), Sun, 8:00 AM-11:30 AM

Effect of time to resection of colorectal liver metastases on recurrence risk. *First Author: Emerson Yu-sheng Chen, Oregon Health and Sciences University, Portland, OR*

Background: Resection of colorectal liver metastases (CRLM) with perioperative chemotherapy is curative in only 20-30% of patients. There are no biomarkers or robust clinical predictors that can effectively select patients curable by resection. The time interval from diagnosis of liver metastasis to hepatic resection (time to resection, or TTR) has not been studied to risk-stratify patients who would benefit. **Methods:** A retrospective analysis of patients who underwent resection for CRLM from 2003 to 2017 was conducted at our institution. Patients were categorized as: 1) no evidence of disease (NED) or 2) disease relapse or death. NED patients with $<$ 1 year follow-up were excluded. Factors including TTR (short = $<$ 3 months; intermediate = 3-6 months; and long = $>$ 6 months) were compared between the two groups (all p $<$ 0.05 unless noted). Logistic regression was used to identify factors associated with NED. **Results:** We identified 264 patients with a median follow-up of 30 months. Of these, 60% presented with synchronous liver metastases, 42% had bilateral liver disease, and 76% received preoperative chemotherapy. Preoperative MRI was performed in 19% of patients. R0 resection was achieved in 88%. Overall, 27% of patients were NED at one year. Patients with intermediate TTR had a higher proportion of NED compared to short TTR and long TTR (45% vs. 27% vs. 28%). Primary tumor location, grade, metachronous CRLM, and response to chemotherapy were not associated with NED. Long TTR was associated with synchronous CRLM, bilateral disease, and more liver lesions compared to intermediate and short TTR. On multivariate analysis, patients with long TTR (OR: 0.65), older age (OR: 0.97), more liver lesions (OR: 0.80), and positive resection margin (OR: 0.08) were less likely to achieve NED. Preoperative MRI use was predictive of NED (OR: 2.6). **Conclusions:** Intermediate TTR is associated with NED status at $>$ 1 year when compared to short TTR. This suggests liver resection should wait 3-6 months to assess for more indolent tumor biology. Lack of benefit seen with long TTR was likely due to high tumor burden in our dataset. Use of preoperative MRI may better quantify extent of liver involvement to help select patients who will benefit from resection. Analysis is ongoing.

3542 Poster Session (Board #35), Sun, 8:00 AM-11:30 AM

Bevacizumab (B) + bi-weekly capecitabine (C) and oxaliplatin (O) (XELOX2) or FOLFOX4 in first-line treatment of metastatic colorectal cancer (mCRC): Final results of a multicenter randomized phase II trial of the Gruppo Oncologico dell'Italia Meridionale (GOIM protocol 2802). *First Author: Evaristo Maiello, U.O. Oncologia, IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy*

Background: B plus bi-weekly FOLFOX4 or three-weekly XELOX represents a standard 1-line therapy for mCRC pts. In our previous phase II study (Fedele P et al, ASCO 2009) we demonstrated a similar efficacy of a bi-weekly schedule of C combined with O (XELOX2). In this randomized phase II trial, pts with mCRC, previously untreated, ECOG PS 0-1, age 18-75, were randomized to receive, in a 2:1 ratio, XELOX2 + B (experimental arm) vs. FOLFOX4 + B (calibration arm). Primary endpoint was ORR; secondary endpoints were PFS, OS and toxicity. **Methods:** B (5 mg/kg on d1 of a 2-week cycle) was administered before O, with FOLFOX4 (Arm A) or XELOX-2 (Arm B; O 100 mg/m2 on d1 followed by oral C 1,000 mg/m2 twice daily on d1 through 7 of a 14-day cycle). After a maximum of 12 cycles (induction phase), pts in CR,PR and SD were randomized to maintenance with B alone or B+Fluoropyrimidine (C or FU). Sample size of experimental arm was calculated according to Simon's two-stage design, with a type I error rate 0.05 and 0.90 power. With null hypothesis ORR 32% and alternative hypothesis ORR 48%, 46 pts had to be accrued in the first stage, for a final number of 80 pts. Study design was formally non comparative, but exploratory comparison between arms was performed. **Results:** One-hundred thirty-two pts were randomized (45 arm A; 87 arm B). The main characteristics of the entered pts were well balanced. ORR (Arm A vs B) was 55.6% vs 48.3% (p = 0.43). With a median follow-up of 47.2 months, PFS was 10.0 vs 9.9 months (HR 0.96, 95%CI 0.65-1.41; p = 0.84) and OS was 29.8 vs 25.0 months (HR 1.21, 95%CI 0.77-1.92; p = 0.41). Main G3-4 toxicity rate (A vs B) were as follows: thrombocytopenia 2/2, anemia 4/3, neutropenia 15/3, nausea 9/5. vomiting 2/3, diarrhea 7/7, neurotoxicity 2/2 and hypertension 2/1. **Conclusions:** GOIM study 2802 showed that the XELOX2+B regimen is active as FOLFOX4+B in pts with mCRC. Given the extreme tolerability and convenience of administration of therapy, XELOX2 + B appears to be indicated even in frail or elderly patients. Clinical trial information: 2010-022091-31.

3543 Poster Session (Board #36), Sun, 8:00 AM-11:30 AM

Phase 2 study of veliparib plus FOLFIRI ± bevacizumab versus placebo plus FOLFIRI ± bevacizumab in metastatic colorectal cancer. *First Author: Vera Gorbunova, N. N. Blokhin Cancer Research Center, Moscow, Russian Federation*

Background: Survival rates for patients with metastatic colorectal cancer (mCRC) are low. Current front-line therapy includes a combination of irinotecan/5-fluorouracil/leucovorin (FOLFIRI) ± bevacizumab. Veliparib (Vel) is a potent, competitive poly (ADP-ribose) polymerase (PARP)-1/2 inhibitor that enhances the activity of irinotecan in pre-clinical models. This study assessed if addition of oral Vel concurrent to FOLFIRI, with the goal to potentiate irinotecan activity, improves survival in patients with previously untreated mCRC. **Methods:** This is a randomized, blinded, phase 2 study (NCT02305758) comparing Vel (200 mg BID administered for 7 days of each 14-day cycle) to placebo (PBO), each in combination with FOLFIRI. Bevacizumab was allowed in both arms. Endpoints were progression-free survival (PFS), overall survival (OS), objective response rate (ORR) by RECIST 1.1, duration of overall response (DOR), safety and tolerability. **Results:** As of October 31, 2017, 130 patients were randomized to receive either Vel (n= 65) or PBO (n= 65). Median PFS was 12 vs 11 months (Vel vs PBO) [HR = 0.94 (95% CI: 0.60, 1.48)]. Median OS was 25 vs 27 months (Vel vs PBO) [HR = 1.26 (95% CI: 0.74, 2.16)]. There were 27 OS events each in the Vel and PBO arms. ORR was 56.9% (Vel) and 61.5% (PBO). Median DOR was 11.1 vs 9.4 months (Vel vs PBO) [HR = 0.73 (95% CI: 0.38, 1.40)]. Common adverse events (AE) (in ≥20% patients) assessed as related to Vel that did not differ from Vel to PBO arm were nausea, fatigue, and vomiting. Grade 3/4 AE (in ≥5% patients) assessed as related to Vel (for Vel vs PBO) include neutropenia (22% vs 11%), diarrhea (5% vs 9%), nausea (8% vs 2%), and asthenia (6% vs 0%). SAE assessed as related to Vel (for Vel vs PBO) include febrile neutropenia (3% vs 3%) and diarrhea (2% vs 3%). All grade hematopoietic cytopenias were more common with Vel than PBO (79% vs 52%, p= 0.003). Two treatment-emergent AE deaths occurred in each Vel and PBO arm. 14% of patients in Vel arm and 15% in PBO arm prematurely discontinued treatment due to AEs. **Conclusions:** Vel added on to FOLFIRI ± bevacizumab demonstrated similar efficacy as FOLFIRI ± bevacizumab in frontline mCRC patients. Overall, there were no unexpected safety concerns. Clinical trial information: NCT02305758.

3544 Poster Session (Board #37), Sun, 8:00 AM-11:30 AM

Quality-adjusted time without symptoms or toxicity (Q-TWiST) of patients with metastatic colorectal cancer (mCRC) treated with fruquintinib in the randomized phase III FRESCO trial. *First Author: Yu-Xian Bai, Harbin Medical University Cancer Hospital, Department of Medical Oncology, Harbin, China*

Background: The FRESCO Study is a randomized, double-blind, phase III trial comparing fruquintinib + best supportive care (BSC), to placebo + BSC in the treatment of metastatic colorectal cancer (mCRC). This ad-hoc analysis aims to compare the quality-adjusted survival between the two arms using quality-adjusted time without symptoms or toxicity (Q-TWiST) methodology, and to investigate the Q-TWiST benefit of fruquintinib treatment among sub-groups. **Methods:** The survival time for each patient was divided into 3 portions: TOX (time with ≥ grade 3 toxicity before progression), TWiST (time without symptoms or ≥ grade 3 toxicity), and REL (time from progression or relapse until death or end of follow-up). Q-TWiST was calculated as the sum of the utility-weighted mean durations for each health state. Threshold analyses were conducted to understand Q-TWiST gains associated with utility weight and subgroup analyses were performed according to baseline clinical characteristics. **Results:** Of 416 patients randomized, 278 received fruquintinib treatment. Survival benefit was seen in Q-TWiST in patients in the fruquintinib arm when compared to those in the placebo arm (mean: 7.0 vs. 4.8 months, difference [95% CI]: 2.2[1.4, 3.0]) in the base case scenario (TOX = 0.5 and REL = 0.5). Threshold analyses suggested that Q-TWiST gains ranged from 16.7% to 39.9% and favored fruquintinib across all possible utility weight combinations. The differences in Q-TWiST favored patients in the fruquintinib arm across pre-specified subgroups. Patients benefited from fruquintinib treatment in terms of Q-TWiST gain regardless of prior targeted treatment (32.3% and 22.9% of those with and without prior targeted treatment, respectively). **Conclusions:** In mCRC patients who failed 2 lines of standard therapy, fruquintinib treatment resulted in more quality-adjusted survival benefits when compared to placebo arm. The benefits seen may have been achieved by good disease control and safety profile. Both patients with and without prior targeted therapy can benefit from fruquintinib treatment.

3545 Poster Session (Board #38), Sun, 8:00 AM-11:30 AM

Correlation of measurements of tumor heterogeneity based on next-generation sequencing (NGS) of circulating tumor DNA (ctDNA) with clinical outcomes in STEAM, a prospective, randomized, multicenter study in metastatic colorectal cancer (mCRC). *First Author: Stephanie Yaung, Roche Sequencing Solutions, Pleasanton, CA*

Background: STEAM (clinical trial NCT01765582) assessed efficacy and safety of concurrent and sequential FOLFOXIRI-bevacizumab (BEV) vs FOLFOX-BEV for first-line treatment of mCRC. The AVENIO ctDNA Expanded and Surveillance Kits (Research Use Only) were used to detect somatic mutations by NGS in tissue, and pre- and post-induction plasma samples. **Methods:** Plasma-based molecular measures of tumor heterogeneity were defined as: 1) Plasma Recovery Rate (PRR), a ratio of shared plasma and matched tissue variants to total plasma variants; 2) Mutant-Allele Tumor Heterogeneity (MATH), a measure of variant allelic frequency dispersion, applied here to plasma; and 3) Multi-Variant Gene Count (MVGC), a count of genes harboring > 1 somatic mutations in plasma. **Results:** Overall, greater pre-induction tissue-plasma discordance correlated with shorter OS, and subjects with complete tissue-plasma concordance (defined as PRR = 1, suggesting monoclonality) had longer PFS (18.3 vs 9.5 mo, HR 0.43, 95% CI 0.2 - 0.91, logrank p = 0.023). High plasma allele frequency dispersion, assessed as MATH in the top quartile, correlated with shorter PFS in pre-induction plasma (8.1 vs 11.7 mo, HR 1.8, 95% CI 1.1 - 3.1, logrank p = 0.026) and in post-induction plasma (7.4 vs 12.2 mo, HR 2.9, 95% CI 1.7 - 5.2, logrank p = 0.00012). Similar trends were seen for OS. Subjects with > 1 somatic mutation in a gene, classified as MVGC > 0, in post-induction plasma had shorter OS. An increase in MVGC from pre- to post-induction correlated with shorter OS (14.8 vs 26.4 mo, HR 4.6, 95% CI 1.9 - 10.9, logrank p = 0.00029). **Conclusions:** Analyses with AVENIO ctDNA Kits on STEAM reveal the potential prognostic value of measuring plasma-based tumor heterogeneity, with higher heterogeneity correlating strongly with poor outcomes. Pre-induction, a lower rate of recovery of plasma variants in tissue and high plasma dispersion correlated with shorter survival. Post-induction, high plasma dispersion and intragenic heterogeneity correlated with shorter survival. These hypothesis-generating results require further validation.

3546 Poster Session (Board #39), Sun, 8:00 AM-11:30 AM

A phase I expansion study of trifluridine and tipiracil (FTD/TPI) in combination with irinotecan (IRI) and bevacizumab (BEV) in patients with metastatic colorectal cancer (mCRC). *First Author: Anna M. Varghese, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: FTD/TPI is an oral antineoplastic agent that was developed to overcome resistance to fluoropyrimidines. FTD/TPI is approved for use in previously treated patients with mCRC. This Phase I expansion study investigated the safety, pharmacokinetics (PK), and preliminary efficacy of FTD/TPI and IRI with BEV. The dose-escalation phase determined the maximum tolerated dose of FTD/TPI and IRI to be FTD/TPI 25 mg/m^2 and IRI 180 mg/m^2. **Methods:** Patients aged ≥18 years with mCRC with disease progression following ≥1 line of chemotherapy were included. Patients who had required any prior IRI dose reductions, dose delay, or growth factor support in the first 8 weeks of treatment with IRI were excluded. FTD/TPI was administered at 25 mg/m^2 twice daily on days 1-5 of 14-day cycles with IRI 180 mg/m^2 preceded by BEV 5 mg/kg on day 1 of each 14-day cycle. PK samples were collected on days 1-3 of cycle 1. **Results:** Twenty-four patients with mCRC were enrolled; 67% were female and the median age was 55.5 years (range 19-73). The median number of prior regimens was 4; all patients had received prior fluoropyrimidine and oxaliplatin treatment, 3 patients were IRI-naïve, and 5 patients were BEV-naïve. Grade ≥3 adverse events were reported in 20 patients (83%); the most common were neutropenia (33%), leukopenia (25%), diarrhea (13%), and hypertension (13%). Based on RECIST v1.1 of the 24 evaluable patients, 3 had a partial response and 17 experienced stable disease. Median progression-free survival was 7.9 months (95% CI 5.1, 13.4). PK analysis did not show any significant correlation between the plasma concentrations of FTD/TPI and IRI or their metabolites. **Conclusions:** No new safety findings or cumulative adverse events were reported with the addition of BEV to FTD/TPI and IRI. Preliminary efficacy results indicate promising anti-tumor activity using FTD/TPI and IRI with BEV for patients who had failed a median of 4 prior regimens with most having had prior IRI. This triple chemotherapy combination warrants further evaluation in patients with mCRC. Clinical trial information: NCT01916447.

3547 Poster Session (Board #40), Sun, 8:00 AM-11:30 AM

A meta-analysis exploring the role of PET and PET-CT in the management of potentially resectable colorectal cancer liver metastasis. *First Author: Julian Daza Vargas, McMaster University, Hamilton, ON, Canada*

Background: It has been proposed that PET alone or combined with CT imaging improves detection of extra-hepatic disease in colorectal cancer liver metastasis (CRCLM). The objective of this study was to determine whether PET/PET-CT has a role in the preoperative workup of patients with potentially resectable CRCLM. **Methods:** From 2000 to April 2017, MEDLINE, EMBASE, and CENTRAL were searched for randomized and non-randomized studies investigating the use of PET and/or PET-CT in CRCLM. Screening and data collection were performed in duplicate. The primary outcome was overall survival (OS). Secondary outcomes included disease-free survival (DFS), change in surgical management, and futile laparotomy. The quality of the evidence was assessed using GRADE. Random effect models were used to pool treatment effects. Moderate to high heterogeneity was explored via subgroup analyses established *a priori*. **Results:** Of 4034 reviewed articles, 22 were included for subsequent analysis. PET/PET-CT did not improve OS (HR 0.94, 95% CI 0.69 – 1.26, I^2 = 0%) or DFS (HR 1.01, 95% CI 0.82 – 1.26, I^2 = 0%) when used preoperatively to determine surgical candidacy. In subgroup analyses, PET/PET-CT changed surgical management in 8% of cases (95% CI 5 – 11%, I^2= 0), and did not reduce futile laparotomies (RR 0.59, 95% CI 0.24 – 1.47, I^2= 47%) in randomized studies. In contrast, PET/PET-CT changed surgical management in 20% of cases (95% CI 17 – 22%, I^2 = 0) and resulted in fewer futile laparotomies (OR 0.51, 95% CI 0.32 – 0.81, I^2 = 0%) in non-randomized studies. **Conclusions:** The use of pre-operative PET/PET-CT does not improve OS or DFS in CRCLM. In addition, there is moderate to high quality evidence demonstrating it has a minimal impact on planning surgical management, and does not prevent unnecessary surgeries.

3548 Poster Session (Board #41), Sun, 8:00 AM-11:30 AM

FOLFIRINOX plus cetuximab (CET) or bevacizumab (BEV) in patients (pts) with initially unresectable colorectal liver metastases (CRLM) with BRAF mutated (mut) tumors: A subgroup analysis of the UNICANCER PRODIGE 14-ACCORD 21 (METHEP2) trial. *First Author: Evelyne Lopez-Crapez, Institut régional du Cancer de Montpellier ICM, Montpellier, France*

Background: The treatment of metastatic colorectal cancer (mCRC) pts with BRAF-mut tumors is a major challenge for physicians. They account for < 10% of mCRC, correlate with poor prognosis, and respond poorly to standard first-line regimens including chemotherapy doublets (2-CT) plus a targeted agent. Guidelines suggest treating BRAF-mut mCRC with a triplet CT regimen (3-CT; fluorouracil, irinotecan, and oxaliplatin combination) plus BEV, based on a subgroup analysis of the TRIBE study. In this analysis of 16 mCRC pts with BRAF-mut tumors, median PFS (mPFS) and OS (mOS) were 7.5 and 19 months (mo), respectively. Since the impact of 3-CT plus CET on outcomes in pts with BRAF-mut tumors is largely unexplored, we aimed to assess this subpopulation in the METHEP2 trial. **Methods:** This trial assessed whether 3-CT (FOLFIRINOX) compared to 2-CT (FOLFOX or FOLFIRI), combined with CET or BEV (by KRAS exon 2/RAS status), would increase R0/R1 liver resection rates in pts with initially CRLM. As an exploratory analysis, we assessed the outcome of the subset of BRAF-mut mCRC pts. **Results:** 256 pts were included. KRAS exon 2 and RAS (KRAS/NRAS: exon 2, exon 3, exon 4) were mutated in 91/256 pts (35.5%) and in 109/218 pts (50%), respectively. The R0/R1 liver resection rate was 57% in the 3-CT arm vs. 48% in the 2-CT arm. mPFS was 12.8 mo in the 3-CT arm vs. 11.5 mo in the 2-CT arm (HR, 1.05; 95%CI, 0.79-1.39). mOS was 42.9 mo in the 3-CT arm vs. 37.6 mo in the 2-CT arm (HR, 0.80; 95%CI, 0.56-1.16). Nine out of 230 (3.9%) mCRC pts were BRAF-mut: 8/9 pts received CET and 1 (in the 2-CT arm) received BEV as the targeted agent. Efficacy results in the 2-CT (n = 4) vs. the 3-CT (n = 5) arms were as follows: objective tumor response, 0/4 vs. 4/5; R0/R1 resection, 0/4 vs. 2/5; mPFS, 1.8 vs. 6.1 mo; and mOS, 6.6 vs. 21.3 mo. **Conclusions:** In this small series, pts with BRAF-mut tumors treated with 3-CT plus a targeted agent had better PFS and OS than those treated with 2-CT plus a targeted agent. Moreover, intent-to-treat survival outcomes with 3-CT plus CET are in the same range than those with 3-CT plus BEV from TRIBE. Clinical trial information: NCT01442935.

3549 Poster Session (Board #42), Sun, 8:00 AM-11:30 AM

Proteomic profiling of phosphatidylinositol 3-kinase (PI3K) altered metastatic colorectal cancer (mCRC) after protein kinase B (Akt) inhibition: Insulin like growth factor 1 receptor (IGF1R) mediates adaptive resistance. *First Author: Maliha Nusrat, Cancer Medicine Fellowship Program, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: We have reported earlier that Akt inhibition is clinically ineffective as monotherapy in PI3K altered (PIK3CA mutant or PTEN loss) mCRC patients (pts). The reasons for this are unknown yet vital for developing effective treatments. We hypothesized that mCRC evades Akt inhibition via adaptive signaling activation. **Methods:** KRAS^{wt} BRAF^{wt} PI3K altered mCRC pts were treated with single agent oral Akt inhibitor, MK2206 (200 mg/week), on a CTEP-sponsored clinical trial (n = 18). Metastases were biopsied at baseline and on day 15. Pt derived xenografts (PDXs) were established for a co-clinical trial with either MK2206 or carrier (30% Captisol) for 3 weeks. Signaling pathways were profiled by reverse phase protein array (RPPA) on tumors from pts and PDXs, as well as on 2 CRC cell lines (KM12L4 and SW480) treated with MK2206. Protein levels from treated and untreated samples were compared by paired or student's t-test, or ANOVA as applicable. **Results:** Out of 18 pts, 16 progressed and 2 had stable disease. Similarly, all treated PDXs progressed after a brief response. RPPA data was available for 15 paired biopsies, 9 treated PDXs and 10 control PDXs. MK2206 adequately inhibited pharmacodynamic (PD) markers (including pAkt T308 and pAkt S473) in PDXs, with a similar but nonsignificant trend in pAkt in pts' biopsies. In cell lines, IGF1R rose after 24 hours and was maintained up to 7 days ($P < 0.01$). Similarly, treated PDXs had increased IGF1R, insulin receptor beta (INSRB) and HER3 levels ($P < 0.001$ for all) with a nonsignificant rise in platelet-derived growth factor receptor (PDGFR). In pts' biopsies, IGF1R, PDGFR and STAT3 increased after two weeks of MK2206 treatment ($P < 0.05$ for all). MK2206 did not affect MAPK signaling. **Conclusions:** Akt inhibition with MK2206 in mCRC induces adaptive upregulation of receptor tyrosine kinases, namely IGF1R but also HER3 and PDGFR, resulting in reactivation of the Akt pathway. Combined analysis of cell lines, PDXs and pts' samples allows in-depth interrogation of adaptive resistance and identifies rational combination therapies worthy of further investigation.

3550 Poster Session (Board #43), Sun, 8:00 AM-11:30 AM

Folate gene prediction of treatment response to 5-FU and leucovorin in advanced colorectal cancer. *First Author: Bengt Gustavsson, Surgical Oncology Laboratories at Sahlgrenska University Hospital, Gothenburg, Sweden*

Background: 5-fluorouracil (5-FU) with the folate pro-drug leucovorin (LV) has long been backbone of chemotherapy for colorectal cancer (CRC). Low expression of folate-related genes may lead to poor response to 5-FU + LV (FLV) since poor transport and metabolization of LV yield insufficient co-factor ([6R]-5,10-methylenetetrahydrofolate) and weak inhibition of the target gene thymidylate synthase (TYMS). We have previously found a positive correlation between survival and expression of folate pathway genes in stage III CRC treated with adjuvant FLV. The aim of the present study was to relate progression-free survival (PFS) with gene expression in tumors from patients with metastasizing CRC (mCRC). **Methods:** Tissue samples of primary tumors were obtained at surgery from patients with mCRC (n = 143) prior to FLV-based chemotherapy. Outcome data were extracted from the Sahlgrenska University Hospital data base. Gene expression was determined with qPCR. **Results:** Significant positive correlations between PFS and expression of several folate relevant genes were found. After adjustment in a multiple Cox analysis of all analyzed genes, only ABCC3 remained significant ($p < 0.0002$). The ABCC3 protein is involved in outward transport of folates, and has preference for 10-formyltetrahydrofolate. This folate inhibits the first conversion step of LV to active co-factor. High expression of ABCC3 may therefore cause a high conversion rate of LV to co-factor, and enhanced inhibition of TYMS. After Cox analysis, ABCC3 expression levels were divided into tertiles; the low, intermediate and high levels. The intermediate and low tertiles had near identical outcomes and were combined. The high expression group had a median PFS of 10.1 months compared to 6.5 months among patients in the low expression group. **Conclusions:** Folate-related genes predict response to treatment with FLV in stage III and IV CRC. Outcome study after direct treatment with the direct co-factor diastereoisomer is warranted.

3551 Poster Session (Board #44), Sun, 8:00 AM-11:30 AM

Real-world data on overall survival (OS) impact of anti-EGFR sequence in patients (pts) with microsatellite stable (MSS) all-RAS and *BRAF*^{V600E} wild-type metastatic (met) colorectal cancer (CRC). *First Author: Elena Elez, Medical Oncology Department, Vall d'Hebron University Hospital; Vall d'Hebron Institute of Oncology (VHIO)., Barcelona, Spain*

Background: Pts with MSS all-RAS and *BRAF*^{V600E} wild-type met CRC are more likely to respond to anti-EGFR drugs, irrespective of treatment (tx) line, particularly if left-sided primaries (prim). The best sequence of targeted agents is still under investigation in molecularly-selected pts. **Methods:** From a prospective clinical-molecular cohort of CRC pts, the subset with all-RAS and *BRAF*^{V600E} wild-type tumors (2010-2016) plus MSS status (2015-2016) was used to investigate the impact of anti-EGFR sequence (1st vs. 2nd/3rd lines) in OS after met diagnosis. A propensity-score-weighted (PSW) Cox proportional hazard model was built to adjust for tx selection bias based on stage at diagnosis (dx), number and site of met, type of first-line chemotherapy (chem), and curative resection of met. **Results:** In total, 913 pts were registered in the database and 416 (45%) fulfilled the molecular criteria. From these pts, 98% received two chem regimens, 70% anti-EGFR tx, 60% anti-angiogenic tx and 45% had surgery of met. Clinical variables associated with no administration of anti-EGFR tx were older age at dx, single met site and surgery of met ($p < .05$). The only factor linked to preference for anti-EGFR tx as 1st line was year: 30% from 2010-2014 and 56% from 2015-2016 ($p < .01$). In anti-EGFR treated pts not eligible to curative surgery of met (n = 152), OS in pts with left-sided prim (splenic flexure-rectum, 85% of all cases) was 47.5 months and in those with right-sided prim (cecum to transverse, 15%) it was 33.6 months (HR 1.58; CI95% 1.03-2.41; p = .04). In a PSW Cox model with molecularly-selected pts (n = 275), offering an anti-EGFR regimen at 1st line in pts with left-sided prim did not impact on OS (HR = 0.96, CI95% 0.8-1.2, p = .72). The same was true for right-sided prim (HR = 1.26, CI95% 0.8-2.1, p = .36; interaction p = .32). **Conclusions:** In a real-world cohort before the "sidedness" era we found that anti-EGFR sequence did not affect OS of pts with left-sided prim, but 1st line therapy was preferred setting in more recent years. Only 15% of molecularly-selected pts have poor outcome right-sided prim, limiting subgroup analysis.

3552 Poster Session (Board #45), Sun, 8:00 AM-11:30 AM

A phase I/II study of nintedanib and capecitabine in refractory metastatic colorectal cancer. *First Author: Patrick McKay Boland, Roswell Park Cancer Institute, Buffalo, NY*

Background: Refractory metastatic colorectal cancer patients (mCRC) have a median survival of 4-6 months. Nintedanib is a TKI which inhibits VEGFR, PDGFR, and FGFR with preclinical efficacy in bevacizumab resistant CRC. This phase I/II study sought to evaluate the recommended phase II dose (RP2D) and efficacy of nintedanib and capecitabine in refractory mCRC patients. **Methods:** Key eligibility criteria included histologically proven mCRC, ECOG PS of 0 or 1, progression/intolerance to a fluoropyrimidine, oxaliplatin, irinotecan, and anti-EGFR therapy for RAS wt patients. Prior regorafenib was exclusionary. The primary endpoint was 18-week progression free survival (PFS). A one-sided binomial test (at $\alpha = 0.1$) compared the observed 18-week PFS to a historic control of 0.25. Secondary endpoints included median PFS, median OS, ORR, and AE profile. **Results:** 40 patients were enrolled across 2 dose levels. Nintedanib 200 mg po bid and Capecitabine 1000 mg/m2 po bid was established to be the RP2D. 36 patients were treated at the RP2D and evaluable for efficacy. The 18 week progression free survival (PFS) was 36% (13/36 patients), p = 0.0922, indicating a statistically significant increase in PFS over historic control. No responses were observed; 19 (53%) patients experienced SD. Median PFS was 3.3 mos. Median OS was 7 mo. 16 (44%) patients experienced a grade 3/4 AE, with the most common evens being fatigue (8%), palmoplantar erythrodysesthesia (8%), AST elevation (6%), asthenia (6%), pulmonary embolus (6%), and dehydration. PK/PD and plasma biomarker data will be presented. **Conclusions:** The combination of Capecitabine and Nintedanib was well tolerated. Efficacy compares favorably to historic data with regorafenib or TAS-102 monotherapy and is similar to results from other investigations of multi-kinase TKIs and flouropyrimidines in the refractory setting. Further investigation is warranted. *This study was approved and funded by the National Comprehensive Cancer Network (NCCN) Oncology Research Program from general research support provided by Boehringer Ingelheim Pharmaceuticals, Inc.* Clinical trial information: NCT02393755.

3553 Poster Session (Board #46), Sun, 8:00 AM-11:30 AM

Association between genotypes, clinical scores and survival outcome in metastatic colorectal cancer. *First Author: Moreno Reinaldo, Hospital Clínic Barcelona, Barcelona, Spain*

Background: Several prognostic clinical scores for metastatic colorectal cancer (mCRC) GEMCAD (Ann Oncol 25 (Supp 4)), 2014; GERCOR (Oncologist 16, 2011); Köhne (Ann Oncol 13, 2002) are useful for treatment guidance. Next generation sequencing (NGS) allows the evaluation of multiple deregulated pathways (WNT, TGFB, PI3K-RTK-RAS and p53 signaling) (Nature, 2012). We hypothesize that complex vs simple genotypes evaluated by NGS, could be distributed differently according sidedness and clinical scores and would provide independent prognostic value.**Methods:** NGS by Ion Torrent in 22 CRC significant genes was employed to process samples from 141 consecutive mCRC patients (pts) diagnoses from February 2016 to November 2017 in a single institution. Genotype was defined as Complex:1) BRAF mutant 2) RTK-RAS-PI3K+/-p53+FBXW7 mutant 3) RTK-RAS-PI3K+/-p53+SMAD4 mutant; Simple: 1) RTK-RAS-PI3K mutant alone 2) p53 mutant alone 3) RTK-RAS-PI3K mutant+p53 mutant 4) no mutations. Associations were analyzed with Fisher-t test. Cox proportional hazard models and interaction analyses were used to explored the effect of genotype, primary sidedness and clinical scores with overall survival (OS). **Results:** Informative cases (128/141); 91%. Complex genotype; 29%; *p53* (67%), *KRAS* (45%), *BRAF* (14%), *SMAD4* (13%), *PI3K* (12%), *FBXW7* (8%), *NRAS* (3%), other (< 3%). Complex genotype was not associated with sidedness (p = 0.997) but was associated with high-risk GEMCAD score (p = 0.03). In the Cox model, genotypes by NGS remain significant for OS independently of clinical scores (see Table). **Conclusions:** NGS genotype provides independent prognostic information beyond clinical scores. The combination of both variables should allow optimal prognostic stratification in mCRC.

Prognostic value for overall survival (cox proportional hazard model).

	GEMCAD		GERCOR		Köhne

3554 Poster Session (Board #47), Sun, 8:00 AM-11:30 AM

What is the prognostic impact of *BRAF* mutation in patients undergoing resection of colorectal liver metastases? Results of nationwide intergroup (ACHBT, FRENCH, AGEO) cohort of 249 patients. *First Author: Jean-Baptiste Bachet, Hospital Pitié-Salpêtrière, Paris, France*

Background: *BRAF* mutation is associated with poor prognosis in patients with metastatic colorectal cancer. In patients with resectable colorectal liver metastases (CRLM), the prognostic impact of *BRAF* mutation is unknown and the benefit of surgery is debated. This study aims to evaluate oncologic outcome of patients undergoing liver resection for *BRAF*-mutated CRLM. **Methods:** From 2012 to 2016, 66 patients underwent resection for *BRAF*-mutated LM in 24 centers. Case-matched comparison was made with 183 patients who underwent resection for *BRAF* wild-type CRLM during the same period. The matching criteria were: synchronous or metachronous CRLM, initially resectable or unresectable CRLM, uni- or bilobar distribution, and number ($\leq$ or $>$ 4) of CRLM. Patients with extra-hepatic disease were excluded. **Results:** Mean follow up was 28.7 $\pm$ 19.8 months after surgery. The 1- and 3-year disease-free survival (DFS) rates were 46.1% and 19.3% in *BRAF*-mutated and 55.4% and 27.8% in *BRAF* wild-type patients (p = 0.430). In multivariate analysis, *BRAF* mutation was not a predictor of worse DFS (p = 0.574, OR: 1.12 95%CI: 0.74-1.71). The 1- and 3-year overall survival rates after surgery were 93.5% and 54.3% in *BRAF*-mutated and 95.8% and 82.9% in *BRAF* wild-type patients (p = 0.004). The median survival after disease progression was 23.0 months (11-34.9) in *BRAF*-mutated and 44.3 months (35.9-52.6) in *BRAF* wild-type patients (p = 0.049). Multisite disease progression was more common in *BRAF*-mutated than in *BRAF* wild-type patients (48 vs 30%, p = 0.034) and was less likely to be surgically treated with curative intent (27% vs 42%, p = 0.085). **Conclusions:** Our results support the interest of surgical therapy of *BRAF*-mutated resectable CRLM as *BRAF* mutation by itself does not increase the risk of relapse after surgery. By analogy to non-metastatic CRC, *BRAF* mutation has a negative impact on survival in patients who relapse after resection of LM.

3555 Poster Session (Board #48), Sun, 8:00 AM-11:30 AM

A phase I/II trial of cabozantinib (C) with or without panitumumab (P) in patients (pts) with RAS wild-type (WT) metastatic colorectal cancer (mCRC): Clinical outcomes in pts with *MET* amplification (amp) detected in blood. *First Author: Jingquan Jia, Duke University Medical Center, Durham, NC*

Background: *MET* amp is a well described driver of acquired EGFR antibody (Ab) resistance. Blood-based genomic profiling of cell free (cf)DNA is a safe and efficient means to identify pts with acquired *MET* amp. To determine whether a MET targeting strategy is feasible and clinically active in pts with *MET* amp RAS WT mCRC, we studied pts treated with an anti-c-MET multi-kinase inhibitor (C) combined with an anti-EGFR Ab (P) or (C) alone. **Methods:** Pts with RAS WT mCRC were enrolled in 2 cohorts: 1) C+P combination (C+P); or 2) C monotherapy (C) (NCT02008383). Peripheral blood was sequenced for up to 73 single nucleotide variants, insertions/deletions, fusions, and amps, including *MET* amp (Guardant360, Guardant Health). Pts enrolled in the C+P cohort received retrospective cfDNA profiling for *MET* amp. Pts enrolled in the C cohort were prospectively screened for *MET* amp; only those pts with *MET* amp in blood were treated in the C cohort. **Results:** 64/65 pts (98%) had detectable cfDNA (C+P = 13; C = 51). *MET* amp was identified in 12 pts (18%) (C+P = 4; C = 8). Among pts with *MET* amp detected in blood the median copy number was 2.6 (range 2.3-6.4). 8 pts with *MET* amp received treatment (C+P = 4; C = 4); 7 pts were evaluable for efficacy (C+P = 4; C = 3). 1 pt (C+P cohort) had a RECIST PR, and this pt had low grade *EGFR* and *MET* co-amp (*MET*= 2.3 copies; *EGFR*= 2.2 copies). 4/7 pts (57%) had a reduction of measurable RECIST target lesions, 3 of whom received C+P (PR = 1; SD = 1; PD = 1) and 1 (SD; 27% reduction) received C. 3/4 pts in the C+P cohort had *EGFR* and *MET* co-amp, 2 of these pts had a reduction in RECIST lesions (PR = 1; PD = 1). No evaluable pts in the C cohort had *EGFR* and *MET* co-amp. **Conclusions:** This study demonstrates the feasibility of utilizing cfDNA to identify *MET* amp in pts with RAS WT mCRC. Although there are signals of clinical activity for the C+P combination and C alone in this limited sample, further study is needed. The ideal *MET* amp copy number threshold, the role of EGFR co-amp, and the additive value of combined EGFR blockade remain to be determined. Clinical trials utilizing cfDNA to identify and treat *MET* amp mCRC are ongoing. Clinical trial information: NCT02008383.

3556 Poster Session (Board #49), Sun, 8:00 AM-11:30 AM

Apatinib as a salvage treatment for refractory metastatic colorectal cancer. *First Author: Xiaofeng Chen, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China*

Background: Apatinib, an oral VEGFR2 inhibitor, has been approved as third line treatment for metastatic gastric cancer in China. The aim of this study was to evaluate the efficacy and safety of apatinib, in the treatment of refractory metastatic colorectal cancer patients who failed from two or more lines of chemotherapy. **Methods:** In this open-label, single-arm, phase II study, patients were treated with apatinib in daily dose of 500 mg, po, in the third - or more line setting. Capture sequencing was dynamically performed to identify somatic variants in circulating tumor DNA (ctDNA) with a panel of 1021 cancer related genes.The primary endpoint was progression-free-survival (PFS) and the tumor response was determined according to the Response Evaluation Criteria in Solid Tumors (RECIST) Version 1.1. Interim analyses was applied as predefined. **Results:** From June 01, 2016 to December 31, 2017, 26 patients were enrolled. The median PFS of the whole group was 3.9m (95% CI: 2.1-5.4). Patients with PS 0-1 had longer PFS than those with PS 2 (4.17m vs 1.93m, p = 0.0014). Patients without iver metastasis also had longer PFS than those who had live metastasis (5.87m vs 3.33m, p = 0.0274). Median overall survival was not reached. 10-month survival rate was 55%. The common side effects of apatinib were hypertension, hand-foot syndrome, proteinuria and diarrhea. The incidence for grade 3-4 hypertension, hand-foot syndrome, proteinuria and diarrhea were 76.92%, 11.54%, 73.08%, and23.08%, respectively. All of the patients received dose reduction due to adverse effect. Results of capture sequencing showed APC, TP53 and KRAS were most frequently mutant genes.Patients with high tumor mutation burden (TMB) in baseline blood had a trend of prolonged overall survival than those with low TMB (p = 0.077). The molecular tumor burden from ctDNA increased before the radiographic assessment in 10 patients. **Conclusions:** Apatinib monotherapy showed promising efficiency for refractory colorectal cancer patients, especially in patients with PS 0-1 or no liver metastasis. TMB is a potential prognostic biomarker. In addition, tumor molecular burden may be a predictor in serial monitoring of tumor load. Clinical trial information: NCT03190616.

3557 Poster Session (Board #50), Sun, 8:00 AM-11:30 AM

ENCORE 601: A phase 2 study of entinostat in combination with pembrolizumab in patients with microsatellite stable metastatic colorectal cancer. *First Author: Nilofer Saba Azad, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD*

Background: In studies reported to date, no objective responses have been observed with PD-1 inhibitors in advanced/metastatic CRC (mCRC) pts with microsatellite stable (MSS)/mismatch repair proficient (pMMR) tumors. About 95% of mCRC pts have this phenotype; additional strategies are needed to improve effectiveness of immunotherapies in these pts. Entinostat (ENT), an oral, class I-selective histone deacetylase inhibitor, enhances anti-PD-1 activity by downregulation of immunosuppressive cell types in the tumor microenvironment *in vivo* and has shown promising activity with pembrolizumab (PEMBRO) in pts with melanoma and lung cancer. This study evaluates the safety and efficacy of ENT + PEMBRO in MSS/pMMR CRC pts. **Methods:** This study is a multi-cohort, Simon 2-stage, phase II trial. Main eligibility criteria for pts in the CRC cohort are: documented MSS/pMMR status, $\geq$1 prior regimen in the metastatic setting, and no prior anti-PD-(L)1 therapy. All pts received ENT 5 mg PO QW + PEMBRO 200 mg IV Q3W. The primary endpoint is objective response rate (ORR) as assessed by irRECIST. Results of the first stage are reported. **Results:** 16 pts were enrolled in Stage I with a median age of 58 (range 36-68) and 4 lines of prior therapy. Median follow up is 4.7 mos. To date, 2 pts had documented pseudoprogression (1 subsequently became a confirmed PR). As of data cutoff, 6 pts (1 PR, 5 SD) remain on study (median time on treatment of 18 wks). Common ($>$ 15%) treatment-related AEs include fatigue (37.5%), arthralgia (18.8%), and increased alkaline phosphatase (18.8%). Grade 3/4 related AEs were observed in 3 patients, and two deaths occurred on study – one due to sepsis secondary to cholangitis and the other due to progression. Serial blood and pre-treatment biopsies were obtained in all pts, with paired post-treatment biopsies in a subset of pts. Evaluation of PD-L1 expression, gene expression, myeloid and lymphoid compartments in biospecimens is in progress. **Conclusions:** ENT + PEMBRO demonstrates acceptable safety and encouraging preliminary activity in a small cohort of MSS/pMMR CRC pts, a patient population in which objective responses have not been reported with PD-(L)1 monotherapy. Clinical trial information: NCT02437136.

3558 Poster Session (Board #51), Sun, 8:00 AM-11:30 AM

EORTC-ESSO 1409 GITCG: A prospective colorectal liver metastasis database with an integrated quality assurance program (CLIMB). *First Author: Carmela Aves Caballero, EORTC, Brussels, Belgium*

Background: The European Organization for Research & Treatment of Cancer & European Society of Surgical Oncology joined forces to build an infrastructure for surgical quality assurance (QA) in clinical trials (SURCARE) and advance the surgical research agenda in Europe. Benchmarking is a critical step to achieve this. Their first project is CLIMB, a prospective study to evaluate complications and identify indicators for improvement in surgery for unresectable or borderline resectable colorectal liver metastasis (CRLM). **Methods:** CLIMB (NCT02218801) opened in 2015 in 9 countries and 14 specialised centers for liver surgery. Eligible patients were registered after multidisciplinary evaluation and before surgery. Primary endpoint was 30 and 90 day surgical complication rate. On-site visits and central review ensured prospective data inclusion of the following: biomarker, imaging, chemotherapy, surgery, complications graded by Clavien-Dindo classification and survival. Data until post op day 90 were analysed but long term outcome will be reported after all patients were followed for two years after registration. **Results:** Among 210 patients registered, 126 (60%) who had at least one liver surgery were analysed. 73% had left-sided or rectal primary tumor, 95.2% had synchronous primary and liver metastasis, 19.8% had extra-hepatic lesions and CRLM. Most patients (N = 95, 75.4%) had one stage liver surgery while 30 (23.8%) had two stage liver surgery, 10 of whom had ALPSS. Over-all complication rates for one stage was 53.7% (95% CI [43%, 64%]), 17.9% (95% CI [11%, 27%]) with grade≥3 and 93.3% (95% CI [78%, 99%]) for two stage, 46.7% (95% CI [28%, 66%]) with grade≥3 including two deaths. Intra-abdominal, wound and urinary tract infections, bile leak and post hepatectomy liver failure grade A were most commonly reported over-all. **Conclusions:** CLIMB prospectively collected data from complex surgery for unresectable CRLM. Two stage surgery had more grade≥3 complications. Harmonizing standards in multidisciplinary evaluation, biomarker testing and imaging may improve this outcome. SURCARE will use these indicators to develop trials with enhanced QA methods to improve cancer surgery. Clinical trial information: NCT02218801.

3559 Poster Session (Board #52), Sun, 8:00 AM-11:30 AM

Surgical quality and the impact of liver resection on outcome in the New EPOC study. *First Author: Sian Alexandra Pugh, University of Southampton, Southampton, United Kingdom*

Background: The New EPOC study demonstrated a shorter overall survival (OS) with the addition of cetuximab to chemotherapy for operable colorectal liver metastasis. The combination of a liver resection with EGFR inhibition is unique to this study. Consequently this analysis explores both surgical quality and the impact of volume of liver resected on outcome. **Methods:** Data is presented for 257/271 patients (early study withdrawals excluded). Details of surgery were completed by the operating or lead surgeon in 19 UK specialist centres. The report of no residual tumour in the pathological specimen was queried in each case. Volume of liver resected was estimated and patients divided into tertiles (tertile 1: ≤20.5%, tertile 2 20.6-50.0%, tertile 3: > 50.0%) to investigate association with OS. **Results:** Operations were performed on 221/257 patients (113 chemo alone CT, 108 chemo and cetuximab CTX) of which 207 (108 CT, 99 CTX) underwent a resection. A further 15 had surgery that included ablation (5 CT, 10 CTX). 159 had major resections (88 CT, 71 CTX) and the median estimated volume of total liver volume resected was the same in both groups (CT 30.6% IQR 17.4-63.4, CTX 28.1% 17.0-63.4). Those with a small volume (tertile 1, ≤20.5%) of liver resected appeared to have a shorter OS with cetuximab (median OS for CT: not reached, CTX: 55.3 months, HR: 2.45 (95% CI: 1.14-5.24), p = 0.021). By contrast those with a larger volume of liver resected (tertiles 2 & 3) had similar outcomes irrespective of the use of cetuximab (median OS for CT: 81.0 months, CTX: 79.0 months, HR: 1.18 (95% CI: 0.72-1.95), p = 0.509). Examination of the pathological specimen revealed no residual tumour (complete pathological response) in 17 patients (10 CT, 7 CTX) of whom 5 subsequenly died (3 CT, 2 CTX). Other surgical data, including the number of R1 resections (13 CT, 19 CTX), was similar between the study arms. **Conclusions:** These exploratory analyses suggest the technical aspects of surgery are similar between the treatment groups and that those patients having smaller volume resections may be disadvantaged by the addition of cetuximab. Clinical trial information: 2006-003121-82.

3560 Poster Session (Board #53), Sun, 8:00 AM-11:30 AM

Screening and stepped care targeting psychological distress in patients with metastatic colorectal cancer: The TES cluster randomized trial. *First Author: Claudia Schuurhuizen, Department of Medical Oncology, VU University Medical Center, Cancer Center Amsterdam, Amsterdam, Netherlands*

Background: Psychological distress occurs frequently in patients with cancer. Effective management requires targeted selection of patients (T), followed by enhanced care (E), and the application of stepped care for psychological distress (S). This study aimed to evaluate the effectiveness of a screening and stepped care program (the TES program) compared to usual care in reducing psychological distress in patients with metastatic colorectal cancer (mCRC) starting with first line systemic treatment. **Methods:** In this cluster randomized trial, 16 hospitals were assigned to either the TES program or care as usual (CAU). Patients in the TES arm were screened for psychological distress with the Hospital Anxiety and Depression Scale (HADS) and Distress Thermometer/Problem List (at baseline, 10 and 18 weeks). Stepped care was offered to those with distress, as well as to patients expressing the need for psychosocial care. Stepped care consisted of watchful waiting, guided self-help, face-to-face problem-solving therapy, or referral to specialized mental health care. The primary outcome was change in psychological distress over time (HADS); secondary outcomes were quality of life (QOL), satisfaction with care and recognition and referral of distressed patients by clinicians. Measures were assessed at baseline, after 3, 10, 24 and 48 weeks of follow-up. Linear mixed models were used to evaluate the outcome. **Results:** A total of 349 patients were included; 184 to the TES program and 165 to CAU. In the TES arm, 60.3% of the patients screened positive for psychological distress; 26.1% of patients entered the stepped care program (14.7% only used watchful waiting, and 11.4% used at least one of the following steps).There was no difference in the course of psychological distress over time between treatment groups ($p > 0.05$). The TES group reported higher satisfaction with the received treatment over time and better cognitive QOL (all p-values < 0.05). **Conclusions:** Screening and subsequent treatment for psychological distress does not improve psychological distress. Our results suggest that enhanced discussion of psychosocial concerns may improve aspects of patient's well-being. Clinical trial information: NTR4034.

3561 Poster Session (Board #54), Sun, 8:00 AM-11:30 AM

Avelumab and cetuximab in combination with FOLFOX in patients with previously untreated metastatic colorectal cancer (MCRC): Results of the safety run-in phase of the phase II AVETUX trial (AIO-KRK-0216). *First Author: Alexander Stein, Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany*

Background: Single agent PD-1/L1 inhibition is efficacious in mismatch repair deficient tumours - about 5% of MCRC patients (pts). For the remaining MCRC pts the role of immunotherapy still needs to be determined. FOLFOX and cetuximab in combination with avelumab (AVETUX regimen) in 1st line RAS/BRAF wildtype MCRC is currently evaluated in a phase II trial independent of mismatch repair status (NCT03174405). **Methods:** This is a single arm exploratory investigator-initiated trial planned to include 43 pts to receive mFOLFOX6 and cetuximab in combination with avelumab (AVE) (10mg/kg day 1 from cycle 2 onwards). Primary endpoint is 12 months progression-free survival rate. Secondary endpoints are response rate, tolerability and translational research evaluating tissue and serial ctDNA. A safety analysis was planned after the 15th patient has passed 2 months to inform about tolerability. **Results:** As of 1st of February 2018 24 of 43 pts were enrolled and treated with the AVETUX regimen at 8 German sites. The safety analysis of the run-in phase was conducted on the 1st of February after a median of 3.2 months of treatment. The following adverse events were noted: 19/5 grade 3/4 (CTC AE 4.03) in 9 patients, including neutropenia (n = 11/4), nausea (n = 3), and infection (n = 3/1), mostly related to chemotherapy with only two grade 3 AE related to AVE. In 7 out of 15 patients 9 SAEs (one related to AVE), were noted including one case of grade 3 hepatitis, which resolved quickly with steroid treatment, 4 infections/fever, one diarrhea and three nausea (in one patient). Despite the relatively high absolute rate of G3/4 toxicity and SAEs, adverse events were manageable and did not relevantly impact on treatment feasibility. Two pts developed uncomplicated fever the day after the first infusion of AVE, both among the highest T cell infiltrated tumors. The IDMC recommended trial continuation based on these safety data. Updated safety and translational data and efficacy results will be presented at the meeting. **Conclusions:** The interim safety analysis has supported the feasibility of the AVETUX regimen in 1st line MCRC. The trial is ongoing. Clinical trial information: NCT03174405.

3562 Poster Session (Board #55), Sun, 8:00 AM-11:30 AM

Update survival analysis from a multicenter, randomized phase 3 study on the optimization of the combination of bevacizumab with FOLFOX/OXXEL in patients with metastatic colorectal cancer (mCRC). *First Author: Antonio Avallone, Istituto Nazionale Tumori Fondazione G.Pascale, Naples, Italy*

Background: Bevacizumab is a humanized anti-vascular endothelial growth factor (VEGF) monoclonal antibody, approved in combination with chemotherapy in the treatment of mCRC. It has been hypothesized that the schedule of administration might be critical and that anticipating bevacizumab to chemotherapy might improve treatment efficacy. Present analysis updates 2016 findings **Methods:** mCRC pts, ≤ 75 years, ECOG PS ≤1, were randomized (1:1) to receive standard (S) administration of bevacizumab (5mg/kg d1 Q14) with chemotherapy (mFOLFOX/OXXEL regimen for 12 cycles) *vs* experimental (E) bevacizumab given whenever 4 days before chemotherapy (same dose and cycles number). Pts could receive maintenance bevacizumab with fluoropyrimidines until disease progression or unacceptable toxicity. Primary end point was the objective response rate (ORR). With 80% power and 2-tailed alpha 0.05, an expected 20% increase in response rate, 230 pts were planned. Analyses were based on the intention to treat. Correlative studies on biomarkers and FDG-PET were also planned. **Results:** From May 2012 to Dec 2015, 230 pts were randomised to E (n = 115) and S (n = 115) arm. Median age was 62 years (IQ range 53-68), 79% were PS 0, 93% were not pretreated, 53% had a single metastatic site, 71% had a left primary site (71% and 74% in S and E, respectively), 54% were RAS-mutant (47% and 62% in the S and E arm, respectively). ORR was 54% in both arms (p = 0.89). With a median follow-up of 42 months, 209 PFS events and 150 deaths were reported. Median PFS was 10.5 and 11.7 months (HR 0.80, 95% CI: 0.61-1.06; multivariate adjusted p = 0.12) and median OS was 23.8 and 29.1 months (HR 0.70, 95% CI: 0.51-0.97; multivariate adjusted p = 0.03), in the S and E arm, respectively. Distribution of patients receiving treatment after progression was similar across the arms. **Conclusions:** Anticipating bevacizumab to chemotherapy does not improve ORR and PFS, but results associated with a significantly longer OS. Further studies are required to confirm whether this schedule might improve treatment efficacy in mCRC patients. Supported by the Italian Ministry of Health. Clinical trial information: NCT01718873..

3563 Poster Session (Board #56), Sun, 8:00 AM-11:30 AM

Comparison of mismatch repair status between primary and matched metastatic sites in patients with colorectal cancer. *First Author: Wen-Zhuo He, Sun Yat-sen University Cancer Center; State Key Laboratory of Oncology in South China; Collaborative Innovation Center for Cancer Medicine, Guangzhou, China*

Background: Mismatch repair (MMR) status is crucial in the management of patients with metastatic colorectal cancer (mCRC) to predict responses to anti-PD-1 therapy. This study compares the MMR status between primary and matched metastatic tumors in patients with mCRC. **Methods:** 331 patients were analyzed in this study. The expression of four most common MMR proteins, MLH1, MSH2, MSH6 and PMS2 were tested by immunohistochemistry. Polymerase chain reaction (PCR) analysis was performed to test microsatellite instability (MSI) when MMR status was inconsistent between primary and metastatic sites. **Results:** A total of 331 patients were included; 23 patients had dMMR primary tumors. Among these, 17 (73.9%) and 6 (26.1%) patients showed dMMR and pMMR metastatic tumors, respectively. The remaining 308 patients showed pMMR primary tumors:11 (3.6%) dMMR and 297 (96.4%) pMMR metastatic tumors were observed. For patients who had inconsistent MMR status between primary and metastatic sites, the detailed results were shown in the table, including PCR results. **Conclusions:** Our study suggests a notable discrepancy in mismatch repair status between primary and matched metastatic tumors in patients with mCRC.

						Primary tumor					Metastatic tumor				
Case	Age	Sex	Primary	Metastatic	Synchronous /metachronous	MLH1	MSH2	MSH6	PMS	Microsatellite	MLH1	MSH2	MSH6	PMS	Microsatellite

3564 Poster Session (Board #57), Sun, 8:00 AM-11:30 AM

Health related quality of life in elderly or frail patients with advanced colorectal cancer treated with dose reduced capecitabine. *First Author: Daniel Adam Breadner, Schulich School of Medicine and Dentistry, London, ON, Canada*

Background: Palliative chemotherapy's role is to prolong survival while minimizing treatment toxicities to preserve or improve quality of life. We have recently published a phase 2 trial of dose reduced capecitabine in elderly or frail patients with advanced colorectal cancer (aCRC). We herein provide a robust analysis of the HRQoL data from our trial. **Methods:** A single arm multi-centered phase II trial of dose reduced capecitabine in elderly or frail patients. Capecitabine was given at 2000 mg/m^2 days 1-14 q21 days; or 1500 mg/m^2 for patients with prior pelvic RT, as determined in the phase I portion of the study. Phase II participants (182 patients) were asked to complete FACT-G questionnaires at enrollment, after each cycle of capecitabine and once after cessation of the study drug, if possible. **Results:** 157 patients completed a baseline questionnaire (86%), and 137 patients (75%) completed at least one subsequent questionnaire. The mean baseline score was 81.6, out of a possible 108. The mean score peaked at 92 after cycle 10. The mean change from baseline was always positive. Patients achieving the minimal clinically important difference (MCID) ranged from 30% to 45% during treatment cycles. Higher baseline FACT-G score and Physical Well-being score were independently prognostic for improved survival (p = 0.006 and p < 0.0001, respectively). Time until definitive deterioration (TUDD) was longer, but not significant, in patients with a higher baseline FACT-G (p = 0.18). **Conclusions:** Baseline HRQoL scores were independently prognostic for survival, supporting their importance in clinical trials. Compared to full dose, reduced dose capecitabine has previously demonstrated equivocal efficacy and reduced toxicity. We have reported dose reduced capecitabine improves quality of life in elderly or frail patients with aCRC while on treatment, further supporting its use in the management of aCRC.

3565 Poster Session (Board #58), Sun, 8:00 AM-11:30 AM

Prognostic impact of residual HPV ctDNA detection after chemoradiotherapy for anal canal carcinoma. *First Author: Luc Cabel, Institut Curie, Paris, France*

Background: Chemoradiotherapy (CRT) is the current standard of care for patients diagnosed with locally advanced anal squamous cell carcinoma (ASCC), but some patients will present a local and/or a distant relapse during follow-up. We previously reported the analytical validity of HPV circulating tumor DNA (HPV-ctDNA) detection by droplet digital PCR in HPV-related cancers. The current study aimed at monitoring HPV ctDNA levels during CRT in locally advanced ASCC. **Methods:** We analyzed prospectively collected samples from patients with HPV16 or HPV18-positive locally advanced ASCC. Plasma samples collected at diagnosis (before CRT initiation) and at the end of CRT. Cell-free DNA from serum or plasma was extracted, quantified and subjected to HPV16 or HPV18 ctDNA detection as previously published with droplet digital PCR. **Results:** 36 stage II-IV ASCC patients were included. HPV-ctDNA detection had a sensitivity of 89% (n = 32/36). All 4 patients with no ctDNA detected had a stage II ASCC (detection rate 33% versus 100% for higher stage, p = 0.001). In patients with detectable ctDNA before CRT, median ctDNA levels were significantly associated with lymph node(s) status: the median ctDNA level was 102 copies/ml (range 8.7-9333) in N+ ASCC vs 32 copies/ml (range 3-1350) in N- ASCC (p = 0.026). Among 18 patients with available paired samples (before and after RCT), only 3 (17%) displayed residual detectable HPV-ctDNA at the end of CRT. Residual ctDNA detection was correlated with the patients' outcome, such as these 3 patients were the only patients to experience a metastatic relapse (Fisher exact test, p = 0.001). Residual HPV-ctDNA after CRT was strongly associated with relapse-free survival (p < 0.0001). **Conclusions:** This is to our knowledge the first proof of concept study assessing the prognostic value of ctDNA after CRT in locally advanced ASCC. In most patients, HPV-ctDNA can be detected before CRT but drops below detection limits during CRT. We show here that residual ctDNA levels at the end of CRT are associated with a very poor outcome, suggesting the use of HPV-ctDNA as tool to select high-risk patients that may be eligible for further systemic treatments

3566 Poster Session (Board #59), Sun, 8:00 AM-11:30 AM

Phase II study of panitumumab, 5-fluorouracil, mitomycin-c and radiotherapy treatment in patients with non-metastatic squamous cell carcinoma of the anal canal: safety and efficacy results (VITAL study)—GEMCAD 09-02. *First Author: Jaime Feliu, Hospital Universitario La Paz, Madrid, Spain*

Background: More than 80% of squamous cell carcinoma of the anal canal (SCCAC) express epidermal growth factor receptor protein (EGFR). VITAL was a phase II, multicentre, single arm study, which aimed to evaluate efficacy and safety of the addition of panitumumab (Pmab) to fluorouracil (5-FU), mitomycin C (M) and radiotherapy (RT) standard treatment in patients with SCCAC (NCT01285778). **Methods:** Treatment naïve patients $\geq$ 18 years old, with SCCAC (Stage T2-T4, any N, M0 defined by MRI) with $\leq$ 2 ECOG performance status, received Pmab (6 mg/kg, day 1 and q2w during 8 weeks), 5-FU (1000 mg/m2/day; IV infusion, days 1-4 and 29-32) and M (10mg/m2, days 1 and 29) plus RT 45 Gy (1.8 Gy/fraction) to the primary tumour and mesorectal, iliac and inguinal lymph nodes, plus boost dose of 10-15 Gy to primary tumour and affected lymph nodes. The primary objective was disease free survival (DFS) at 3 years (anticipated DFS: 73.7% $\pm$ 12%) estimated by Kaplan-Meier. Multivariable analysis of efficacy variables adjusting for key baseline covariates will be presented. **Results:** A total of 58 patients (31 women; median age: 59 years; ECOG performance status: 0 [41%] / 1 [57%] / 2 [2%]; TNM II [29%] / IIIA [21%] / IIIB [47%]/ non-evaluable [NE] [4%]) were evaluated. The 3-year DFS rate was 61.1% (95% CI 47.1 - 72.4). The median follow-up was 45 months. The 3-year overall survival rate and progression free survival rate were 78.4% (95%CI 65.1-87.1) and 57.5% (95%CI 43.6 - 69.2) respectively. Eighteen patients (31.0%) had a colostomy within the first 2 years post-treatment. Grade 3-4 toxicities were experienced by 53 (91%) patients. Radiation skin injury (19%), diarrhoea (10%), neutropenia (9%) and leukopenia (19%) were the most common ($>$ 10%) grade 3-4 adverse events associated with Pmab. There were no toxic deaths. Potential predictive efficacy and safety biomarkers are currently being assessed. **Conclusions:** The overall 3-year DFS rate does not reach the anticipated level for the main objective of the study. The multivariable analysis will determine if any subgroup of patients may benefit from this treatment scheme. Financed by Amgen S.A. Clinical trial information: NCT01285778.

FOLFCIS regimen for treatment of cancer of the anal canal. *First Author: Sebastián Mondaca, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The combination of cisplatin and 5-fluorouracil (5-FU) is a standard chemotherapy regimen for advanced anal squamous cell cancer (AC) and is associated with significant toxicity. We examined the efficacy of a modified schedule, FOLFCIS, and performed an integrated clinical and genomic analysis of advanced AC. **Methods:** We reviewed all patients with metastatic or recurrent locally advanced AC treated with first line FOLFCIS chemotherapy at Memorial Sloan Kettering Cancer Center (MSK) between January 2007 and July 2017. FOLFCIS, which is essentially FOLFOX with cisplatin substituted for oxaliplatin, consisted of cisplatin 40 mg/m^2 day 1, leucovorin 400 mg/m^2 day 1, 5-FU 400 mg/m^2 day 1, 5-FU 1000 mg/m^2/d days 1 and 2 in a 14-day cycle. Forty-one advanced AC patients underwent targeted next generation tumor sequencing of $>$ 300 genes (MSK-IMPACT), including 23 of the patients treated with FOLFCIS. **Results:** Fifty-three AC patients (48 metastatic; 5 unresectable, locally advanced) received first line FOLFCIS during this period; all were platinum naive. Median age was 59 years, and 32% had metastatic disease at diagnosis. Thirteen patients (25%) received multimodal treatment for metastatic disease. Administered dose intensity of both cisplatin and 5-FU was $>$ 70%. Response rate was 48% (95% CI, 32.6 - 63). With a median follow up of 41.6 months, progression free survival (PFS) and overall survival (OS) were 7.1 months (95% CI, 4.4 - 8.6) and 22.1 months (95% CI, 16.9 - 28.1), respectively. Among all advanced AC, most frequent genomic alterations consisted of chromosome 3q amplification (17%) and mutations in PIK3CA (24%) and KMT2D (24%). Genomic alterations affecting the phosphatidylinositol 3-kinase pathway in PIK3CA, PTEN, or AKT2 were detected in 54% of cases. TP53 mutation, YAP1 amplification, and TERT promoter mutations appeared enriched in HPV-negative AC. No genomic alteration correlated with response to platinum-containing treatment. **Conclusions:** FOLFCIS is effective and safe as first line chemotherapy in advanced AC patients and represents an alternative treatment option for patients with AC.

3568 Poster Session (Board #61), Sun, 8:00 AM-11:30 AM

Association of postoperative carcinoembryonic antigen (CEA) levels with survival in stage III colon cancer (CC): Post hoc analysis of the MOSAIC and PETACC-8 studies. *First Author: Edouard Auclin, Gastrointestinal Oncology Department, European Georges Pompidou Hospital, Paris, France*

Background: CEA is a CC biological marker that correlates with tumor stage. Its measurement is recommended for follow up after surgery. CEA above 5 ng/mL is of poor prognosis, however this cutoff is debated. Thus, we explored the prognostic value of postoperative CEA, in its continuous form. **Methods:** Eligible patients (pts) in MOSAIC and PETACC-8 studies had postoperative CEA available. The association between CEA and overall (OS) and disease free survival (DFS) was explored in the MOSAIC discovery cohort. It was assessed in 3 groups of pts (group 1: 0 to 1.30 ng/ml, n = 630; group 2: 1.30 to 5 ng/ml, n = 613; group 3: $>$ 5 ng/ml, n = 49) by the Kaplan Meier method. Then relation of CEA and outcomes was continuously modelled with the restricting cubic splines (RCS) and multiple polynomial fractional (MFP) methods. Cox uni- and multivariate models were constructed. Findings were confirmed in a PETACC-8 validation cohort. **Results:** CEA was available in 1292 (96%) and 2477 (97%) pts in the discovery and validation cohorts, respectively with 96.2% and 95.9% of pts having a CEA below 5 ng/ml. In the discovery cohort, 5y OS were 79% (95%CI: 76-82), 70% (95%CI: 66-74) and 47% (95% CI: 35-64) in groups 1, 2 and 3, $p < 0.001$. Five-year DFS rate were 68% (95%CI: 65-72), 58% (95%CI: 54-62) and 42% (95%CI: 31-61), in groups 1, 2 and 3, $p < 0.001$. RCS and MFP showed that relation between CEA and survival was following a square root function, suggesting that values over 1.3 ng/ml were associated with prognosis. CEA over 1.3 ng/ml was an independent prognostic factor for OS and DFS (Table 1). All those results were confirmed in the validation cohort (Table 1). **Conclusions:** In 2 cohorts from large phase III trials, we showed that postoperative CEA was highly prognostic for OS and DFS. This was true for CEA levels above and below 5 ng/ml, suggesting that this single cutoff is not sufficient and that CEA should be used more precisely as stratification factors in future adjuvant trials.

SATB2 loss and the immune milieu of colorectal cancer (CRC). *First Author: Darran O'Connor, Department of Molecular and Cellular Therapeutics, Royal College of Surgeons in Ireland, Dublin, Ireland*

Background: SATB2 orchestrates gene expression by regulating higher-order chromatin structure. Antibody screening of 48 normal human tissues and 20 cancers, showed SATB2 as almost exclusively expressed in gastrointestinal tissue. We confirmed this in 10,533 further samples. **Methods:** Tissue microarray (TMA) analysis was used to determine SATB2 expression in CRC, Kaplan-Meier analysis and the log rank test were used to illustrate differences between disease-specific survival (DSS) according to SATB2 expression. Cox regression proportional hazards models were used to estimate the relationship between outcome and SATB2 expression, grade, age, stage, differentiation and gender. Gene set enrichment analysis (GSEA) was used to identified pathways associated with loss of SATB2 expression and RNAi was used to modulate SATB2 in cell lines. **Results:** Differential SATB2 expression was observed in CRC, with loss occurring along the adenoma-carcinoma sequence (n = 320, p = 0.023). SATB2 expression was decreased in metastatic SW620 cells and knockdown of SATB2 in SW480 cells increased their growth and migratory capacity. By automated image analysis of SATB2 expression in CRC (n = 309), SATB2 was found to be an independent predictor of DSS (HR = 0.52, 95% CI 0.32-0.83, p = 0.006). SATB2 was examined in a second cohort (n = 290) and again, found to be an independent predictor of DSS (HR = 0.40, 95% CI 0.18-0.92, p = 0.031). SATB2 significantly correlated with CD3+ infiltrates (p = 0.006) and inversely correlated with COX2 expression (p = 0.019). In two independent CRC cohorts (n = 467), SATB2-low tumours were found to be significantly enriched in the CMS1 (immune-related) subtype ($p < 0.001$). GSEA revealed that SATB2-low tumours demonstrated altered immune signalling with significant increases in IFNγ (p = 0.001), IL6 (p = 0.001), IL8 ($p < 0.001$) TFGβ ($p < 0.001$), which was mirrored by manipulation of SATB2 in CRC cells. Furthermore, in a longitudinal cohort of ulcerative colitis patients, we found a significant correlation between loss of SATB2 and occurrence of future cancers (p = 0.013). **Conclusions:** We postulate that SATB2 acts as a master regulator of inflammation in the gut and loss of expression is significantly associated with the progression of colorectal cancer.

3570 Poster Session (Board #63), Sun, 8:00 AM-11:30 AM

Causal modeling of CALGB 80405 (Alliance) to identify network drivers of metastatic colorectal cancer (CRC). *First Author: Rahul K Das, GNS Healthcare, Cambridge, MA*

Background: CALGB 80405 is a phase III clinical trial of FOLFOX/ FOLFIRI with randomly assigned cetuximab/ bevacizumab. Novel causal machine learning approaches to the study dataset may lead to valuable insights into CRC prognosis and management of CRC progression. **Methods:** Using a Bayesian causal machine learning and simulation platform, we built an ensemble of network models for overall survival (OS). We used 78 baseline clinical and demographic variables for 947 patients with wild-type KRAS tumors. Causal modeling identifies the set of conditional dependencies between variables leading to outcomes. Building an ensemble of causal models estimates model uncertainty and identifies key drivers by model consensus as measured by ensemble frequency (*f*). Counterfactual simulations were performed on this ensemble to identify causal drivers of disease. **Results:** Key causal variables of OS ($f > 50\%$) include primary tumor side ($f =$ 85%), aspartate aminotransferase (AST) and hemoglobin (HGB) concentrations (f = 100%, 91%), and tumor sites: local primary and intra-abdominal metastases (f = 85%, 89%). Counterfactual simulations, controlling for confounders, suggested a significant causal effect of the following variables on driving OS: AST (median hazard ratio (HR) = 1.3, 75^{th} vs. 25^{th} percentile value; 10^{th} - 90^{th} percentile interval: 1.2-1.4), HGB (0.8, 0.7-0.9), primary side (1.5, 1.0-1.7; right vs. left), and tumor sites (present vs. absent): local primary (1.3, 1.0-1.5), intra-abdominal (1.4, 1.1-1.6) and liver (1.1, 1.04-1.14) metastases. AST was a stronger biomarker of OS in patients with liver metastases (1.6, n = 705) than without (1.2, n = 242). **Conclusions:** Primary side, AST, HGB, and tumor sites (local primary, intra-abdominal, and liver) play a central role as independent drivers/biomarkers of OS. Availability of these measures at baseline will allow better risk stratification at initiation of treatment. Clinical trial information: U10CA180821, U10CA180882.

3571 Poster Session (Board #64), Sun, 8:00 AM-11:30 AM

Night shift work duration and risk of colorectal cancer according to IRS1 and IRS2 expression. *First Author: Yan Shi, Chinese PLA General Hospital, Beijing, China*

Background: Although accumulating evidence supports an association between night shift work and an increased risk of colorectal cancer (CRC), the mechanism remains elusive. Notably, metabolic disorders, including insulin resistance, play an important role in both CRC development and other chronic diseases caused by circadian disruption. IRS1 (insulin receptor substrate 1) and IRS2 are the primary mediators of insulin-dependent mitogenesis and could respond to the metabolic microenvironment. We therefore hypothesized that the risk of CRC in night shift workers might be different according to IRSs expression level. **Methods:** Among 77,470 eligible women with available night work data in the Nurses' Health Study, we documented a total of 1,397 physician-confirmed CRCs during 24 years of follow-up, of which 304 and 308 had available data on IRS1 and IRS2, respectively. We used duplication method Cox proportional hazards regression analysis for competing risks data to calculate age-adjusted and multivariable-adjusted hazard ratios (HRs) and 95% confidence intervals (CIs) for each CRC subtype. We measured tumor IRS1 or IRS2 protein expression by immunohistochemistry. **Results:** Compared with women who never worked night shifts, those working a rotating night shift for 15 years or more had a trend of increased overall risk of CRC [P_{trend}= 0.06, multivariable HR = 1.20, 95%CI, 0.99 to 1.45]. For the same comparison, longer of night shift duration was associated with a higher risk of IRS1-positive tumors (multivariable HR = 1.81, 95%CI 0.94 to 3.48, P_{trend}= 0.06) but not with IRS1-negative tumors (multivariable HR = 1.13, 95%CI 0.71 to 1.80, P_{trend}= 0.56, $P_{heterogeneity}$ for IRS1 subtypes = 0.02). The corresponding multivariable HRs were 2.69 for IRS2-positive tumors (95%CI 1.48 to 4.89, P_{trend}= 0.001) and 0.90 for IRS2-negative tumors (95%CI 0.54 to 1.51, P_{trend}= 0.72, $P_{heterogeneity}$ for IRS2 subtypes = 0.008). **Conclusions:** Working 15 years or more of rotating night shift was associated with higher risk of CRC with IRS1-positive or IRS2-positive, but not negative tumors. This molecular pathological epidemiology data suggest a potential role of insulin receptor substrate in mediating carcinogenesis induced by night shifts.

3572 Poster Session (Board #65), Sun, 8:00 AM-11:30 AM

Impact of MLH1, PMS2, MSH2, and MSH6 alterations on tumor mutation burden (TMB) and PD-L1 expression in 1,057 microsatellite instability-high (MSI-H) tumors. *First Author: Mohamed E. Salem, Levine Cancer Institute, Carolinas HealthCare System, Charlotte, NC*

Background: MSI-H tumors are associated with higher TMB. We examined the yet uncharacterized relationship between TMB and individual MMR gene alterations in MSI-H tumors. **Methods:** MSI-H was determined by examining altered microsatellite (MS) loci using NextGen sequencing (cutoff: $> = 46$) on a 592-gene panel. TMB was calculated by enumerating somatic missense mutations. MMR protein expression was evaluated by IHC. ANOVA and chi-square tests were used for comparisons. **Results:** A total of 1057 MSI-H tumors (283 colorectal cancer [CRC]; 449 endometrial cancer [EC]; and 325 others from 29 cancer types) were examined. High TMB ($\geq$ 17 mutations/megabase [mt/MB]) was seen in 74% of tumors. MSI-H CRC had the highest TMB compared to MSI-H EC and "all others" (mean TMB: 39 vs. 23 vs. 31 mt/MB, respectively; $p < 0.0001$). There was no difference in TMB between *BRAF* V600 mutant and wild type MSI-H CRC (38.7 vs. 39 mt/MB). In general the most frequently altered (IHC loss or mutation) MMR genes were MLH1 and PMS2 (72% and 83%, CRC; 90% and 95%, EC). MSH2 and MSH6 were more frequently altered in CRC than EC (21% vs. 5% and 49% vs. 28%, respectively; $p < 0.0001$). In CRC, MSH2 and MSH6 were more frequently altered in left than right sided MSI-H tumors (45% vs. 12% and 67% vs. 40%; $p = 0.01$). Overall MSH2 or MSH6 alterations were associated with higher TMB (48.5 and 40 mt/MB, respectively) than MLH1 or PMS2 (27 mt/MB for both); $P < 0.0001$. Tumors with MSH2/6 co-alterations (4%) had a higher TMB compared to those with MLH1/PMS2 (39%) co-alteration (50 vs. 24 mt/MB; $p < 0.0001$). PD-L1 overexpression was seen at a higher frequency in tumors with MSH2 (23%) than MSH6 (16%), MLH1 (16%), or PMS (14%); $P = 0.01$. MSH2/6 alterations in EC were associated with higher MS alterations (MSH2, 88; MSH6, 73; MLH1, 68; PMS2, 68; $p < 0.0001$), while all genes were equal in CRC. MSH2 alterations were associated with higher frameshift mutation rates in 36 genes in EC, and in different 10 genes in CRC. **Conclusions:** TMB varies significantly across MSI-H tumors. MSH2/MSH6 alterations were associated with a significantly higher TMB than MLH1/PMS2 across several cancer types. The MS alterations associated with MSH2/6 were tumor-type specific.

3573 Poster Session (Board #66), Sun, 8:00 AM-11:30 AM

Association between density of tumor infiltrating lymphocytes and disease-free survival (DFS) in patients with resected stage I-III colorectal cancer in the FACS randomized trial. *First Author: Sian Alexandra Pugh, University of Southampton, Southampton, United Kingdom*

Background: Accumulating evidence demonstrates an association between density of tumor infiltrating lymphocytes and outcome in colorectal cancer (CRC). This study sought to assess the prognostic utility using an accurately staged cohort of patients followed up in a clinical trial. **Methods:** Observational analysis of data from the FACS (follow-up after CRC surgery) trial after 5 years of follow-up. All patients had undergone treatment with curative intent for stage I-III primary CRC, with microscopically clear margins, no evidence of metastases on axial imaging and CEA $< 10\mu g/l$ following completion of treatment. Immune cell densities were quantified in the centre (CT) and invasive margin (IM) of all tumors for both CD3 and CD45RO. For each tumor region high (Hi) and low (Lo) CD3 and CD45RO densities were determined according to the median of the cohort to investigate association with disease free survival (DFS). **Results:** Tumor samples have been analyzed from 297 patients to date for which the combined 5 year DFS is 83% (left sided CRC 81%, right sided CRC 85%). High densities of CD3 and CD45RO positive cells in both tumor regions were associated with a superior outcome: $CD3^{Hi}_{CTIM}CD45RO^{Hi}_{CTIM}$ 94% 5yr DFS vs $CD3^{Lo}_{CTIM}CD45RO^{Lo}_{CTIM}$ 81%, HR 0.36 95% CI 0.15-0.89 p = 0.04. This difference was most notable in left sided CRC: $CD3^{Hi}_{CTIM}CD45RO^{Hi}_{CTIM}$ 96% 5yr DFS vs $CD3^{Lo}_{CTIM}CD45RO^{Lo}_{CTIM}$ 78%, HR 0.13 95%CI 0.04-0.41 p = 0.02. In right sided CRC the difference was not significant: $CD3^{Hi}_{CTIM}CD45RO^{Hi}_{CTIM}$ 91% 5yr DFS vs $CD3^{Lo}_{CTIM}CD45RO^{Lo}_{CTIM}$ 83%, HR 0.70 95%CI 0.17-2.89 p = 0.62. **Conclusions:** In a well characterized and followed up cohort of CRC patients within a clinical trial we have demonstrated that $CD3^{Hi}_{CTIM}CD45RO^{Hi}_{CTIM}$ left sided tumors have a significantly better outlook. The potential for these data to impact on the need for clinical follow up in patients with left sided CRC should be examined in a prospective study. Clinical trial information: 61091474.

3574 Poster Session (Board #67), Sun, 8:00 AM-11:30 AM

MSI-high and MSI-stable colorectal carcinomas (CRC): A comprehensive genomic profiling (CGP) study. *First Author: Siraj Mahamed Ali, Foundation Medicine, Inc., Cambridge, MA*

Background: High levels of microsatellite instability (MSI-H) is an approved biomarker for the selection of immunotherapy across solid tumor types. Given the high prevalence of MSI high in CRC, we used CGP to uncover additional therapy targets associated with MSI status. **Methods:** Hybrid capture-based CGP was performed on 8,004 clinically advanced CRC. Tumor mutational burden (TMB) was determined on 1.1 Mbp of sequenced DNA and microsatellite instability status (MSI-H or MS-Stable, MSS) was determined by principal components analysis of optimal homopolymer loci. **Results:** Of the 8,004 mCRC, 402 (5%) MSI-H and 7,602 (95%) MSS. Patient age and gender distribution did not differ between the 2 groups. Significant GA differences were found: MSS mCRC featured more *KRAS*, *TP53* and *APC* GA, whereas MSI-H mCRC had more *BRAF*, *PIK3CA*, *BRCA2* and *ALK* GA (Table). As expected, GA in the 4 genes associated with heritable CRC (HNPCC) were significantly enriched in MSI-H tumors. In addition, *RNF43* correlated with MSI-H status. Median TMB was markedly higher in the MSI-H samples, 96% of which featured ≥20 mutations/Mb, compared to only 1% of MSS mCRC. Mutation frequencies and false discovery rate corrected p values from chi-squared analysis are presented below. **Conclusions:** MSI-H mCRC feature GA in *RNF43*, *BRAF*, *PIK3CA*, *ALK* and *BRCA2* and near universal high TMB, impacting potential responses to both targeted and immunotherapies. MSS mCRC is characterized by more *KRAS* and *TP53* GA frequencies and low TMB. GA in receptor kinases such as in *ERBB2* and *ALK* are more often found in MSI-H mCRC, but are present in both types and represent additional potential targets for treatment strategies.

	MSI-High CRC (402)	MSI-Stable CRC (7,602)	Significance
Median Age and (range) in years	62 (8-201)	58 (13-88)	
Gender	50% female	46% female	
Mean GA/tumor	18.5	5.8	P < < 0.0001
KRAS	30%	52%	P < 0.0001
TP53	34%	78%	P < < 0.0001
BRAF	36%	8%	P < < 0.0001
PIK3CA	33%	18%	P < 0.0001

TMB ≥20 mut/Mb	96%	1%	P < 0.0001

3575 Poster Session (Board #68), Sun, 8:00 AM-11:30 AM

Genetic variation in TET3 and survival in metastatic colorectal cancer (mCRC) from FIRE-3, TRIBE, and MAVERICC clinical trials. *First Author: Stephen B. Gruber, USC Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: Patients enrolled in FIRE-3, TRIBE, and MAVERICC clinical trials for mCRC were genotyped using Illumina Oncoarray to identify predictive and prognostic biomarkers. Here we report results of a genome-wide association study (GWAS) of overall survival (OS) and progression-free survival (PFS) in 790 patients from 3 clinical trials. **Methods:** DNA samples from patients of European descent (≥80% estimated European ancestry) treated on all arms of FIRE-3, TRIBE, and MAVERICC were genotyped on the Infinium OncoArray through the Colorectal Transdisciplinary (COLORECT) Study. We performed a GWAS of directly genotyped markers with a minor allele frequency ≥ 1% (403,467 SNPs) in 790 patients with mCRC from three trials (FIRE-3 n = 235, TRIBE n = 320, MAVERICC n = 235). Cox proportional hazards regression adjusted for age, sex, principal components for global ancestry, and trial was performed in R using GenABEL to identify associations between genetic variants and OS and PFS. Subgroup analysis by study arm, sex, and primary location was performed. Bonferroni correction for the number of independent genetic markers was applied to minimize false positives. **Results:** Males were 514 (65.1%) and females were 276 (34.9%) of the patients meeting eligibility criteria and genotype data passing QC. The median OS was 21.0 months and median PFS was 9.2 months. Genomic control lambda values for OS = 1.03 and PFS = 1.03 showed minimal population stratification. One SNP, rs7597070 on 2p13.1 within an intron of *TET3*, was significantly associated with OS and exceeded the Bonferroni correction threshold for genome-wide significance < 1.67E-07. The A allele (MAF = 0.016) was associated with increased OS versus the T allele (HR = 0.29; 95% CI, 0.19-0.45; P-value = 5.9E-08). Suggestive evidence also supported an association with PFS (HR = 0.53 (A allele); 95% CI, 0.34-0.81; p = 3.4E-03). The frequency of the A allele was 1.6% in our European patients, 10% in East Asians and 42% in Africans in the 1000 Genomes data. **Conclusions:** Our data identify a new promising prognostic biomarker for OS and PFS among patients with mCRC, and population genetic differences may contribute to disparities in survival by ancestry.

3576 Poster Session (Board #69), Sun, 8:00 AM-11:30 AM

Polymorphism in the circadian clock pathway to predict outcome in patients (pts) with metastatic colorectal cancer (mCRC): Data from TRIBE and FIRE-3 phase III trials. *First Author: Francesca Battaglin, Division of Medical Oncology, USC Norris Comprehensive Cancer Center, Keck School of Medicine, Los Angeles, CA*

Background: The clock machinery comprises a complex network of transcription-translation feedback loops which regulates the circadian expression of target genes involved in key cellular functions. The disruption of the circadian clock has been associated with increased CRC risk, and the expression levels of core clock genes with clinicopathological features, survival and treatment response. We therefore hypothesized that genetic variants in clock genes may predict first-line treatment outcome in mCRC pts. **Methods:** Genomic DNA from blood samples of pts enrolled in two independent randomized phase III trials, TRIBE and FIRE-3, was genotyped through the OncoArray, a custom array manufactured by Illumina including approximately 530K SNP markers. The impact on outcome of 22 selected SNPs in 11 genes of the clock pathway (*CLOCK*, *BMAL1*, *NPAS2*, *PER 1-2-3*, *CRY 1-2*, *RORa*, *hTIM*, *SIRT1*) was analyzed. **Results:** A total of 451 pts were included in the analysis. TRIBE FOLFIRI/bevacizumab (bev) arm served as discovery cohort (n = 215, median PFS/OS: 9.7/26.2 mo), FIRE-3 FOLFIRI/bev arm as validation (n = 107, mPFS/OS: 11.5/31.4 mo) and FOLFIRI/cetuximab arm as control (n = 129, mPFS/OS: 12.8/49.8 mo). In the discovery cohort, the overall population carrying the 3'UTR CLOCKrs3749474 T/T variant showed a shorter mPFS (8.8 vs 10.4 mo) compared to pts with any C allele both in univariate (HR = 1.69; 95%CI 1.11-2.59; p = 0.012) and in multivariable analysis (HR = 2.06; 95%CI 1.26-3.37; p = 0.004). This effect was stronger in female pts (p < 0.001), and left-sided CRCs (p = 0.002). Significant interaction was found with gender (p = 0.005); however, no interaction was found with tumor location or *RAS* status. Findings were validated in overall pts in FIRE-3 bev cohort both in univariate (HR = 1.99; p = 0.027) and in multivariable analysis (HR = 2.45; p = 0.013). No significant association was observed in the control arm. **Conclusions:** Our results provide the first evidence that CLOCKrs3749474 polymorphism may have a predictive value in mCRC pts treated with first-line FOLFIRI/bev. This finding supports a possible role of clock genes in contributing to resistance to anti-VEGF treatment.

3577 Poster Session (Board #70), Sun, 8:00 AM-11:30 AM

Molecular analyses of left- and right-sided tumors in adolescents and young adults (AYA) with colorectal cancer (CRC). *First Author: Megan Jagosky, Levine Cancer Institute, Charlotte, NC, US*

Background: The incidence of CRC, particularly left sided tumors, in AYA is rising. Epigenetic events appear to play an important role in tumorigenesis and cancer progression, especially in AYA. We compared molecular features of left-sided colorectal tumors (LT) in AYA to right-sided tumors (RT) in AYA and to LT in older patients. **Methods:** Primary tumors annotated by site of origin were examined by NextGen Sequencing (592 genes), protein expression, and gene amplification. Tumor mutation load (TML) was calculated by enumerating somatic missense mutations. Chi-square testing was used for comparisons. **Results:** In total, 1,064 primary CRCs were examined. Comparing LT (n = 220) with RT (n = 47) in AYA (≤ 40 years; see table), RT had higher mutation rates in *RNF43* (33.3% vs. 3.4%, *P* < 0.001), *PIK3CA* (31% vs. 11.1%, *P* = 0.005), *KMT2D* (29.6% vs. 4.1%, P < 0.001), *MSH6* (14.8% vs. 2%, *P* = 0.002), *PTEN* (13.8% vs. 2%, *P* = 0.003), *BRCA2* (13.3% vs. 3.9%, P = 0.038), *MLH1* (10.3% vs. 2%, *P* = 0.022) and *MSH2* (10% vs. 1.3%, *P* = 0.009). MSI-H was seen in 25% of RT compared to 5.5% of LT (*P* = 0.001). RT had a higher frequency of TML-high compared to LT (32% vs. 6.9%, *P* < 0.001). When we compared LT from AYA (≤ 40 years; n = 220) with LT from older pts (≥ 65 years; n = 589), AYA exhibited higher mutation rates of *BRCA2* (3.9% vs. 0.8%, *P* = 0.014), *MSH2* (1.3% vs. 0%, *P* = 0.031), and *TSC2* (1.4% vs. 0%, *P* = 0.031). Genes responsible for histone modification were significantly more frequently mutated in AYA than older pts: *KMT2A* (1.5% vs. 0%, P = 0.027), *KMT2C* (4.5% vs. 0%, P = 0.003), and *KMT2D* (4.1% vs. 0.4%, P = 0.004). High TML was seen more frequently in AYA (6.9% vs. 2.8%, P = 0.031) **Conclusions:** LT in AYA carry genetic alterations that are different from RT in AYA, as well as LT in older pts. Our data suggest that histone modification warrants further exploration and may be a promising target in treatment of CRC in AYA.

Molecular differences between lt and rt in aya.

Results from a phase I study of andecaliximab in combination with FOLFIRI and bevacizumab in patients with second line metastatic colorectal cancer. *First Author: Zev A. Wainberg, David Geffen School of Medicine at UCLA, Los Angeles, CA*

Background: Matrix metalloproteinase 9 is highly expressed in several malignancies, including metastatic colorectal cancer (mCRC) and is an adverse prognostic feature. In preclinical colorectal cancer models, inhibition of MMP-9 was associated with tumor growth inhibition. Andecaliximab (ADX) is a chimeric antibody directed against MMP-9 engineered to remove T cell epitopes and reduce risk of immunogenicity. In this phase I multi-cohort study, we combined ADX with standard of care chemotherapy in patients with 2nd line mCRC. (Clinicaltrials.gov NCT# 01803282) **Methods:** Patients were eligible if they progressed on a front line chemotherapy backbone of a fluoropyrimidine and a platinum with or without bevacizumab. All patients received ADX 800 mg IV every two weeks in combination with standard dose FOLFIRI + bevacizumab. The primary endpoints of this study were safety and tolerability. Exploratory endpoints were investigator assessed objective response rate (ORR), progression free survival (PFS) and overall survival (OS). **Results:** We enrolled 44 patients (25 female) with measurable disease who had received prior treatment for metastatic colorectal cancer. The median age was 58 years (range 23-81). As of September 22, 2017, the median ADX treatment duration for this study was 5.9 months. The most common adverse events (AEs) were diarrhea (57%), fatigue (57%), nausea (57%), stomatitis (34%), and vomiting (32%). Serious AEs were reported in 25% of pts. The most common serious AE was pulmonary embolism, which occurred in 2 patients. Median PFS was 9.2 months (90% CI 7.4-10.2 months) and the ORR was 21% (90% CI 11-33%). The median OS was not reached at the time. Study treatment continues in 27% of patients. **Conclusions:** The combination of ADX with FOLFIRI and bevacizumab was safe and effective. The activity of the combination appears encouraging in 2nd line treatment of metastatic colorectal cancer. Updated data will be presented at the time of the presentation. Clinical trial information: NCT01803282.

LBA3579 Poster Session (Board #72), Sun, 8:00 AM-11:30 AM

Comparison of chemotherapy use, cost, and survival in patients with metastatic colorectal cancer in Western Washington and British Columbia. *First Author: Todd Yezefski, University of Washington School of Medicine, Seattle, WA*

The full, final text of this abstract will be available at abstracts.asco.org at 2:00 p.m. ET on Friday, June 1, 2018, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2018, issue of the *Journal of Clinical Oncology*. On-site at the Meeting, this abstract will be printed in the Sunday edition of *ASCO Daily News*.

3580 Poster Session (Board #73), Sun, 8:00 AM-11:30 AM

Prognostic value of tumour infiltrating lymphocytes in stage II colon cancer. A nationwide population-based study. *First Author: Ann Christina Eriksen, Danish Colorectal Cancer Center South, Vejle Hospital, Vejle, Denmark*

Background: Patients with high-risk stage II colon cancer (CC) may benefit from adjuvant chemotherapy, but additional prognostic markers are needed for better treatment stratification. We investigated the prognostic value of tumour infiltrating lymphocytes (TILs) in a true population-based cohort of patients with stage II CC. **Methods:** A total of 573 patients were included, representing all patients operated for stage II colon cancer in Denmark in 2002. Tumour blocks representing the deepest invasive part of the primary tumour were used for analysis. CD3+ and CD8+ TILs at the invasive front were evaluated by immunohistochemistry on whole tumour sections. The invasive area was manually outlined, and Visiopharm Integrator System software was used for quantification. Data were dichotomized for comparison with clinical data. The prognostic value was investigated in Cox proportional hazard models for recurrence-free survival (RFS) and overall survival (OS). **Results:** Low CD3+ or CD8+ TILs were significantly associated with poor RFS and OS, ($p = 0.0021$ and $p \leq 0.0009$, respectively, log-rank test). In multiple Cox regression analysis low CD3+ and CD8+ TILs were associated with reduced RFS with hazard ratio (HR) 1.386 (95% CI 1.039-1.850), $p = 0.026$, and HR 1.394 (95% CI 1.029-1.890), $p = 0.032$, respectively, independent of age, T-stage, localization, perforation, and microsatellite instability (MSI). In the subgroups of patients with low CD3+ or CD8+ TILs, there were no differences in survival between patients with MSI and microsatellite stable tumours, ($p = 0.821$ and $p = 0.907$, respectively). **Conclusions:** Low CD3+ and CD8+ TILs in the invasive area are both related to inferior prognosis in patients with stage II CC, and we recommend either of these parameters to be considered as an additional high-risk factor.

3581 Poster Session (Board #74), Sun, 8:00 AM-11:30 AM

Early response metrics for predicting trial outcomes: A report from volumetric CT for precision analysis of clinical trials (Vol-PACT). *First Author: Patrick Hilden, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The high frequency of negative phase III oncology trials following positive phase II results indicates a need for improved metrics which assess treatment effect. Vol-PACT is an ongoing private-public partnership launched to collect source imaging data from phase III trials with a goal of developing improved methods of assessing therapies in randomized clinical trials. With 8 phase III industry sponsored datasets received and more expected, Vol-PACT is among the largest collective cancer imaging databases with fully annotated measurements of target, non-target, and new lesions. **Methods:** Images from 4 phase III trials in metastatic colorectal cancer (mCRC) were evaluated and benchmarked against 4 phase III trials in other solid tumors. Lesions were measured directly on CT images using semi-automated algorithms. Four metrics quantifying change from baseline through 2 cycles (week 8-16) were evaluated: RECIST response rate, percent change over time, absolute change over time, and log change over time. One thousand phase II trials were simulated by resampling without replacement (50 pts/arm). The average standardized difference between arms was determined across simulations. The weighted linear correlation was estimated between average standardized difference and hazard ratios estimating progression-free survival benefit (PFS HR). **Results:** With sample sizes of 289 to 921 patients per trial ($n = 4,074$ across the 8 trials), PFS HR values ranged from 0.4 to 1.2 (6 significant, $p < 0.05$). For mCRC trials, correlations with PFS HR were 0.87 for RECIST response rate, 0.86 for percent change over time, 0.96 for absolute change over time, and 0.73 for log change over time. For other trials they were 0.80, 0.94, 0.94, and 0.95, respectively. Across the full set of 8 trials, observed correlations were 0.64, 0.90, 0.93, and 0.87. **Conclusions:** Continuous response metrics derived from original CT images correlated strongly with PFS HR across mCRC and other trials, and may be more informative than RECIST response categories. Development of metrics based on volumetric measurements are ongoing, as is the analysis of data from emerging immunotherapy trials.

3582 Poster Session (Board #75), Sun, 8:00 AM-11:30 AM

Genome-wide association with survival in stage II-III colon cancer clinical trials (NCCTG N0147, Alliance for Clinical Trials in Oncology; NSABP C-08, NRG Oncology). *First Author: Kathryn Penney, Harvard T.H. Chan School of Public Health, Boston, MA*

Background: Many genetic variants have been identified as associated with colorectal cancer (CRC) risk; few have been associated with CRC survival. Identification of variants associated with survival may further explain the biology of disease progression and aid in outcome prediction. We performed a genome-wide association study (GWAS) in 2 CC clinical trials to identify genetic variants associated with overall survival (OS). **Methods:** We included patients from N0147, a phase III adjuvant trial in stage III CC patients, and C-08, a phase III trial comparing adjuvant therapy regimens for patients with stage II/III CC. 4974 samples were genotyped with the Illumina HumanOmniExpress + Exome array, consisting of 964,193 SNPs. Genotypes were imputed using 1000 Genomes Project data. We calculated OS as time from randomization to death from any cause and used Cox proportional hazards regression to evaluate association of each SNP with OS, adjusting for age, sex, treatment arm and principal components. Analysis was performed in N0147 and C-08 separately; results were combined in a fixed-effects meta-analysis. **Results:** Follow-up after diagnosis was similar for the 2 trials; median OS for N0147 and C-08 was 1678 days (IQR = 1238-2071) and 2224 days (IQR = 1901-2494), respectively. A locus on chromosome 7p15.2 was significantly associated with improved OS. The most significant variant at this locus, rs76766811 (p = 1.59e-8), is exceedingly rare in this primarily European American population but much more common in African Americans (AAs) (~19%). When the analysis is stratified by self-reported ancestry, the signal is only present in AAs (n = 359) (HR = 0.30, 95% CI: 0.21-0.43, p = 1.81e-10). **Conclusions:** This GWAS nested within 2 CC trials identified rs76766811 on 7p15.2 as significantly associated with OS among AA patients. This finding should be confirmed in additional study populations, particularly focusing on identifying variants associated with survival in AAs. Support: NIH R01 CA176272, U10CA-180868, -180821, -180822, UG1CA-189867, U24CA-196067, PA DoH (which disclaims certain responsibilities), Genentech, Inc., Sanofi-Synthelabo Inc.

3583 Poster Session (Board #76), Sun, 8:00 AM-11:30 AM

Validation of tumor infiltrating lymphocytes (TIL) and tumor budding as predictors of prognosis in patients with stage III colon cancers treated in a FOLFOX-based adjuvant trial: NCCTG N0147 (Alliance). *First Author: Frank A. Sinicrope, Mayo Clinic, Rochester, MN*

Background: TIL density reflects the anti-tumor immune response; tumor budding indicates an epithelial to mesenchymal transition (EMT). We determined if these features are prognostic in a single colon cancer (CC) stage with known DNA mismatch repair (MMR) status. **Methods:** TIL densities (per HPF) and tumor buds (per .785 mm^2 field) were quantified at light microscopy in 1,532 CC. Tumor budding at invasive margin was defined as single or cluster of $\leq$ 4 tumor cells. We divided the cohort into training and validation sets. Optimal cutpoints were identified; associations with 3-year disease-free survival (DFS) were evaluated by multivariable Cox regression. **Results:** TIL and tumor budding cutpoints identified in training set were confirmed in validation set for prognosis. Patients whose tumors had low ($\leq$ 3) *vs* high TILs were significantly more likely to have higher T, N stage, low histologic grade, left sidedness, worse performance status, non mutated *BRAF*, and proficient (p) MMR. Tumors with high budding ($>$ 3) had higher T, N stage; most had pMMR. Overall, significantly shorter DFS was found for tumors with low TILs [HR_{adj}= 1.74 (95% CI 1.35, 2.24), p $<$ .0001], or with high budding [HR_{adj}= 1.37 (1.13, 1.67), p = .0011]. When combined, low TILs plus high budding showed poor DFS [HR_{adj}= 2.07 (1.50, 2.88), p $<$ .0001]. Similar results were found for pMMR tumors (Table). Within dMMR, patients whose tumors had low ($\leq$ 3) *vs* high TILs had significantly shorter DFS (HR_{adj}= 2.14; p = .0173); budding was not prognostic (Table). **Conclusions:** Low TILs and high budding were each validated as markers of poor prognosis in FOLFOX-treated stage III CC, indicating that reduced anti-tumor immunity and an EMT phenotype increase tumor aggressiveness. Whereas TILs and budding each stratified pMMR tumors by DFS, only TILs were prognostic in dMMR tumors and identified the subset with poorest survival.

	pMMR (n = 1357)			dMMR (n = 153)

3584 Poster Session (Board #77), Sun, 8:00 AM-11:30 AM

Prognostic value of CD73 expression in resected colorectal cancer liver metastasis. *First Author: Nouredin Messaoudi, Research Centre of the Centre hospitalier de l'Université de Montréal (CRCHUM), Montreal, QC, Canada*

Background: As approximately 80% of patients recur and die of their cancer after undergoing curative-intent resection of colorectal cancer liver metastasis (CRLM) combined with systemic chemotherapy, novel prognostic biomarkers and therapeutic targets are needed to improve outcomes. We investigated in CRLMs whether the expression of the cell-surface enzyme CD73, rate limiting for the degradation of extracellular AMP into immune-suppressive adenosine, could define a subset of patients with distinct prognosis. **Methods:** A tissue microarray-based analysis of 391 CRLMs resected in 214 patients (2011-2014) and followed prospectively until 10/2017. Each CRLM was arrayed with six 0.6 mm intratumoral punch biopsies, with automated quantification of CD73, cytokeratins 8/18 (CK) and DAPI expression measured by multiplex immunofluorescence. We tested associations between CD73 and pathological variables, time to recurrence (TTR) and disease specific survival (DSS). **Results:** The mean patient age was 62.7 years, 78.5% received pre-operative chemotherapy (mean of 6 cycles), and a median of 2 CRLMs/patient were resected. The median TTR and DSS of patients was 15.4 and 56.7 months, respectively. CD73 expression was similar whether patients received or not pre-operative chemotherapy, but was higher in patients with larger CRLMs ($>$ 5cm vs. $\leq$5cm, p = 0.01), poor pathologic response to pre-operative chemotherapy (Rubbia-Brandt TRG score 4-5 vs. 1-2-3, p = 0.01), and more necrosis ($>$ 25% vs. $\leq$25% surface necrosis, p = 0.004). In patients who received pre-operative chemotherapy, those with $CD73^{high}$ CRLMs (n = 62, 38.3%) had significantly shorter median TTR (11 vs. 18 months, p $<$ 0.001) and DSS (47 vs. 58 months, p = 0.007) than $CD73^{low}$ patients. Pathologic response to chemotherapy was only associated with TTR, not DSS. By multivariate analysis, $CD73^{high}$ CRLMs was a poor prognostic factor independent of clinicopathological features for both TTR and DSS. **Conclusions:** Our results support that CD73 expression in CRLMs may identify a subset of patients with poor prognosis after exposure to systemic chemotherapy, providing insights to guide now-designed trials targeting CD73 with antibodies or the adenosine A2A receptor with inhibitors.

3585 Poster Session (Board #78), Sun, 8:00 AM-11:30 AM

The impact of skeletal muscle and adipose tissue on long-term survival in patients with resectable colorectal cancer. *First Author: Michael B. Sawyer, Cross Cancer Institute, Edmonton, AB, Canada*

Background: Computed tomography-derived body composition parameters are emerging prognostic factors in colorectal cancer. This study aimed to determine the roles of sarcopenia, myosteatosis and adiposity as independent and overlapping parameters in resectable colorectal cancer patients. **Methods:** This was a retrospective cohort study from a prospectively collected database. It included all adult patients with early-stage colorectal cancer, who underwent curative resection from 2007-09. All patients were seen in a tertiary care cancer center in Northern Alberta. Computed tomography-derived quantification of skeletal muscle and adipose tissues were used to determine cohort-specific cut-offs for sarcopenia, myosteatosis and total adiposity using an optimal stratification analysis. Multivariate cox proportional hazards models were performed to assess for associations between body composition parameters and overall, disease-free and cancer-specific survival. **Results:** In the 968 patients included, there were a total of 254 disease recurrences and 350 deaths. Body mass index and computed tomography-derived measures of adiposity did not result in worse survival outcomes. Sarcopenia was independently predictive of worse overall (HR 1.45; 95% CI 1.16, 1.84), recurrence-free (HR 1.32, 95% CI 1.00, 1.75) and cancer-specific survival (HR 1.46, 95% CI 1.09, 1.94) in a multivariate model. Myosteatosis was also independently predictive of overall survival (HR 1.53, 95% CI 1.19, 1.97). In a multivariate model considering joint effects of sarcopenia and myosteatosis, the presence of both parameters predicted the worst overall (HR 2.23, 95% CI 1.62, 3.06), recurrence-free (HR 1.53, 95% CI 1.06, 2.21) and cancer-specific survival (HR 2.40, 95% CI 1.69, 3.42). **Conclusions:** Sarcopenia and myosteatosis are independent predictors of worse survival in early-stage colorectal cancer. Their joint effect is highly predictive of reduced overall, recurrence-free and cancer specific survival. Sarcopenia and myosteatosis represent prognostic factors that may be easily integrated into clinical practice.

3586 Poster Session (Board #79), Sun, 8:00 AM-11:30 AM

Prognostic immune scoring of colorectal cancer liver metastasis with MHC class-I expression combined to T cell quantification. *First Author: David Henault, Research Centre of the Centre hospitalier de l'Université de Montréal (CRCHUM), Montreal, QC, Canada*

Background: Approximately 80% of patients recur after curative-intent resection of colorectal cancer liver metastasis (CRLM) and systemic chemotherapy. Immune profiling may help prognostication to individualize follow-up and lead to novel therapeutic strategies. We tested whether adding major histocompatibility class I (MHC-I) expression to T cell immune scoring in CRLMs could group patients with distinct prognosis. **Methods:** Tissue microarray analysis of 391 CRLMs resected in 214 patients (2011-2014) followed prospectively until 10/2017. Each CRLM arrayed with twelve 0.6 mm punch biopsies, 6 at the interface (IF) with normal liver and 6 intratumoral (IT). Automated quantification of $CD3^+$ cells and MHC-I^+ surface area stained by immunohistochemistry. We tested associations between immune, clinicopathological, and time to recurrence (TTR) and disease specific survival (DSS) outcome variables. **Results:** The mean patient age was 62.7 years, 78.5% received pre-operative chemotherapy (mean of 6 cycles), and a median of 2 CRLMs/patient were resected. The median TTR and DSS were 15.4 and 56.7 months, respectively. Pre-operative chemotherapy was associated with higher CD3 infiltration and lower MHC-I expression at IF and IT. Good pathological response to chemotherapy (Rubbia-Brandt TRG score 1-2-3) compared to lack of response (TRG 4-5) was associated with higher CD3 infiltration but no significant difference in MHC-I expression. CD3 immune scoring integrating the IF and IT areas had no prognostic value. MHC-I expression prognostically stratified patients with $CD3^{low}$ but not $CD3^{high}$ CRCLMs. Compared to the rest of the cohort, patients with at least one $CD3^{low}$MHC-I^{hi} CRLM (n = 35, 16.4 %) had significantly shorter median TTR (8.3 vs. 17.1 months, $p < 0.001$) and DSS (42.6 vs. 61.5 months, $p < 0.001$). $CD3^{low}$MHC-I^{hi} CRLMs were found in 41.2% of recurrent CRLMs in patients without this type of metastasis at first resection. $CD3^{low}$MHC-I^{hi} CRLM was an independent predictor of poor outcomes by multivariate analysis. **Conclusions:** $CD3^{low}$$MHC^{hi}$ CRLMs may identify patients with poorly immunogenic tumors associated with worst outcome and suboptimal response to systemic chemotherapy.

3587 Poster Session (Board #80), Sun, 8:00 AM-11:30 AM

Prognostic significance of number versus location of positive mesenteric nodes in node positive colon cancer. *First Author: Kozo Kataoka, Department of gastrointestinal surgery, Kanagawa Cancer Center, Yokohama, Japan*

Background: Metastasis to locoregional lymph nodes (LN) is one of the most powerful predictors of recurrence free survival (RFS) in colon cancer (CC). Debate persists on the prognostic value of the location of positive LN in addition to the positive lymph node ratio (LNR) or the number of invaded LN (LN+). The recently introduced technique of complete mesocolic excision (CME) presupposes a prognostic role of removal of high level (apical) LN. We analyzed the prognostic significance of positive LN location in a cohort of CC patients who underwent extensive (D3) lymphadenectomy. **Methods:** Colon cancer patients from Kanagawa Cancer Center, Japan, who underwent extensive (D3) lymphadenectomy from 2000 to 2016 were analyzed. Lymph nodes were classified according to anatomical location as paracolic (L1), intermediate (L2), or along the main vascular trunk (L3). RFS hazards were evaluated with their trends over the groups. Univariate and multivariate Cox proportional hazards models were used to evaluate the association of LN count and L level (L1, L2 and L3) with RFS. **Results:** 843 patients were included and 446 were node positive of whom only 25 (5.6%) had positive L3 nodes. The mean number of examined/positive nodes per patient was 42.5/2.6 in L1 (n = 310), 40.9/4.8 in L2 (n = 111), and 44.0/9.8 in L3 (n = 25). In univariate analysis, RFS was significantly lower for L3 vs. L2 positive patients (HR: 2.00, 95%CI [1.05-3.75], p = .034) and L3 vs. L1 (HR: 2.62 [1.45-4.71], p = 0.001) but the difference between L1 and L2 was not nominally significant (HR: 1.32 [0.89-1.95], P = 0.17). A multivariate Cox model built with T stage, tumor location (right vs. left), LNR, LN+ and L level identified T stage ($p < 0.001$) and LNR (p = 0.001) as prognostic factors with no significant contribution from the L level (p = 0.42). **Conclusions:** In this cohort of patients who underwent standard extensive (D3) lymphadenectomy for CC, apical (L3) nodes are infrequently invaded and confer a significantly worse RFS. The anatomical location of invaded nodes adds no prognostic information to T-stage and LNR. These findings question the value of standard extensive lymphadenectomy in CC.

3588 Poster Session (Board #81), Sun, 8:00 AM-11:30 AM

Prognostic evaluation of a new class of liquid biopsy biomarkers in patients with metastatic colorectal cancer: Using the tumor microenvironment as a source of protein biomarkers. *First Author: Stephanie Nina Kehlet, Technical University of Denmark, Kgs. Lyngby, Denmark*

Background: The local microenvironment of a tumor plays an important role in colorectal cancer (CRC) progression. A desmoplastic stroma surrounding the tumor, characterized by excessive collagen deposition, can result in reduced drug delivery into the tumor, leading to poor prognosis and lack of therapy response. Here we present a new class of liquid biopsy proteins, reflecting collagen formation (desmoplasia) and evaluate their prognostic use in CRC. **Methods:** Pro-peptides from collagen type III (PRO-C3) and collagen type VI (PRO-C6) were measured with ELISAs in pre-treatment (standard of care chemotherapy) serum from 40 patients with metastatic CRC (mCRC) and 40 healthy donors. Biomarker levels in patients and healthy donors were compared using unpaired, two-tailed Mann-Whitney test. The biomarkers were further evaluated by univariate Cox-regression analysis for their association with overall survival (OS) and progression-free-survival (PFS). **Results:** Serum levels of PRO-C3 and PRO-C6 were significantly elevated in patients with mCRC compared to healthy donors (PRO-C3: 11.5 ng/mL vs. 6.8 ng/mL, $p < 0.0001$, PRO-C6: 8.0 ng/mL vs. 5.9 ng/mL, $p < 0.0001$). The median OS was 266 or 213 days in biomarker high patients (75^{th} percentile) vs. 1330 or 979 days in biomarker low patients (25^{th} percentile) for PRO-C3 (HR 8.7, 95%CI 2.7-28.2) and PRO-C6 (HR 6.8, 95%CI 2.3-20.3), respectively. The median PFS was 251 or 267 days in biomarker high patients (75^{th} percentile) vs. 329 or 496 days in biomarker low patients (25^{th} percentile) for PRO-C3 (HR 2.3, 95%CI 0.7-7.1) and PRO-C6 (HR 2.6, 95%CI 0.8-9.0), respectively. **Conclusions:** This study evaluated the prognostic use of a new class of liquid biopsy biomarkers, namely small peptides originating from the tumor microenvironment that are released into the circulation as a consequence of tumorigenesis. High serum levels of PRO-C3 and PRO-C6 (collagen formation) were significantly associated with poor OS and shorter PFS in patients with mCRC. This may suggests that increased collagen deposition around the tumor, limits cancer therapy delivery into the tumor, resulting in a lack of response to therapy.

3589 Poster Session (Board #82), Sun, 8:00 AM-11:30 AM

Adjuvant chemotherapy and survival outcomes in diabetic patients with colon cancer: A population-based analysis. *First Author: Shiru Lucy Liu, BC Cancer Agency, Vancouver, BC, Canada*

Background: Diabetes can pose challenges when using adjuvant chemotherapy (AC), as specific cytotoxic drugs, including oxaliplatin, may potentiate certain diabetic complications, such as neuropathy. We performed a provincial analysis of resected colon cancer patients to evaluate the prevalence of diabetes, type of chemotherapy used, and survival outcomes. **Methods:** We examined 5,440 patients with resected stage 2 or 3 colon cancer who were diagnosed from 2004 to 2015 in Alberta. Baseline patient, tumor, and treatment characteristics were compared between those with and without diabetes. Survival analysis was conducted based on Kaplan-Meier methods. **Results:** 608 patients (11%) had uncomplicated diabetes (UDM) and 436 (8%) patients had diabetes with complications (CDM), defined as neuropathy or other micro/macrovascular end-organ damage. CDM patients were older and had worse Charlson comorbidity index ($p < 0.001$). While 34% of UDM patients and 35% of non-diabetic patients received AC, only 15% of CDM patients received AC ($p < 0.001$). Among those who received AC (N = 1574), an oxaliplatin-based regimen was given to 45% and 52% of UDM and non-diabetic patients, respectively, but only 35% of CDM patients ($p < 0.001$). Kaplan-Meier analysis revealed significantly worse overall survival (OS) in the CDM group when compared to the UDM or non-diabetic groups ($p < 0.001$). Of those treated with AC however, there were no statistical differences in OS (p = 0.188) or cancer-specific survival (CSS) (p = 0.461) across all groups regardless of diabetes or complication status (see Table). Receipt of oxaliplatin was associated with improved OS among patients with stage 3 disease compared to monotherapy (p = 0.006). **Conclusions:** Patients with CDM are less likely to receive AC; however, patients treated with oxaliplatin-AC appear to have similar survival outcomes as their UDM and non-diabetic counterparts.

N = 1574	5-year OS	5-year CSS
Non-Diabetic (N = 1345)		
Monotherapy	75%	80%
Oxaliplatin	80%	82%
UDM (N = 175)		
Monotherapy	72%	78%
Oxaliplatin	75%	79%
CDM (N = 54)		
Monotherapy	60%	72%
Oxaliplatin	64%	79%

3590 Poster Session (Board #83), Sun, 8:00 AM-11:30 AM

Clinico-pathological and molecular characterisation of *BRAF* mutant metastatic colorectal cancer (mCRC): Are all mutations created equal? *First Author: Marta Schirripa, Unit of Medical Oncology 1, Department of Clinical and Experimental Oncology, Veneto Institute of Oncology IOV – IRCCS, Padua, Italy*

Background: Functional studies on preclinical models (Yao, Nature 2017) identified 3 classes of *BRAF* mutations: activating *RAS*-independent *BRAF* mutations signaling as monomers (class 1-*BRAF* V600E) or as dimers (class 2-codons 601/597) and *RAS*-dependent *BRAF* mutations with impaired kinase activity (class 3-codons 594/596). While clinico-pathological and molecular features of class 1 mutation are well known, limited data are available with regard to class 2 and 3 mutations, due to their rarity in CRC. **Methods:** Clinico-pathological, molecular and outcome data from *BRAF* mutated mCRC patients were collected. A group of *BRAF* wild-type (wt) patients was included as control. IHC analyses were performed to determine the consensus molecular subtypes (CMS). Clinical features were compared by chi-square or fisher's exact test. PFS and OS were evaluated by Kaplan-Meier and log-rank test. **Results:** Class 1, 2 and 3 included 92, 12 and 13 patients respectively. *BRAF* wt patients were 540. No clinico-pathological differences were observed comparing class 1 to class 2 *BRAF* mutated. Conversely, *BRAF* class 3 mutated were more frequently left sided ($p = 0.0028$), well differentiated ($p = 0.0120$), pN0 ($p = 0.0159$), and with no peritoneal metastases ($p = 0.0176$) compared to class 1. With regard to CMS, class 2 and 3 tumors were all assigned to CMS2-3. Class 1 tumors were assigned to CMS1, 2 or 3 in 39%, 44% and 17% of cases. Outcome results are reported in the Table below. **Conclusions:** Our data confirm previous findings describing specific features associated with *BRAF* rare mutations. For the first time clinico-pathological characteristics and outcome data are reported according to the 3 classes categorization of *BRAF* mutations. In particular, class 1 and 2 share similar features and worse outcome compared to class 3 and wt patients.

	Overall Survival			Progression Free Survival		
	Median (months)	HR (95% CI)	p-value	Median (months)	HR (95% CI)	p-value
BRAF wild type (N = 540)	42.2	-	< 0.0001	10.1	-	< 0.0001
BRAF mutant class 1 (N = 92)	21.0	2.38 (1.61-3.54)		7.3	2.02 (1.39-2.94)	
BRAF mutant class 2 (N = 12)	23.4	1.90 (0.85-4.26)		7.0	2.49 (0.92-6.74)	
BRAF mutant class 3 (N = 13)	44.5	0.93 (0.51-1.69)		13.8	0.85 (0.47-1.54)	

3591 Poster Session (Board #84), Sun, 8:00 AM-11:30 AM

Somatic DNA mutations, tumor mutational burden (TMB), and MSI Status: Association with efficacy in patients (pts) with metastatic colorectal cancer (mCRC) of FIRE-3 (AIO KRK-0306). *First Author: Volker Heinemann, Department of Medicine III, University Hospital, LMU Munich, Munich, Germany*

Background: FIRE-3 compared 1st-line therapy with FOLFIRI plus either cetuximab or bevacizumab in 592 KRAS exon 2 wt mCRC patients (pts). **Methods:** Tumor DNA was profiled by next-generation sequencing to explore molecular markers of prognosis. The biomarker evaluable subpopulation (n = 373) was representative of the ITT population. Treatment efficacy was determined in the quadruple wild-type (wt) population (RAS, BRAF, AKT, PI3K = "MAPK/mTOR wt"). Kaplan-Meier estimation and log-rank tests were employed for overall survival (OS). Hazard ratios (HR) were estimated using the Cox proportional hazard method. P-values were not adjusted for multiple testing **Results:** Overall frequencies were (%,n): MSI-h 2.7% (10); BRAFmut 12.1% (45); RASmut 32.7% (122); quadruple wt: 47.7% (178); TMB > 8: 15% (56). RAS, BRAF, MSI-h and quadruple-wt status were prognostic. Pts with low-frequent RAS mutations (RASmut < 5%) had a significantly longer OS when compared to pts with higher RAS mutational frequency. **Conclusions:** NGS analysis revealed distinct subgroups of mCRCs with different prognosis. MSI status had prognostic impact, but TMB could not be validated as a prognostic or predictive marker.

Overall survival.

3592 Poster Session (Board #85), Sun, 8:00 AM-11:30 AM

Distinct somatic alterations in right- versus left-sided colorectal cancers. *First Author: Robin Imperial, University of Missouri - Kansas City, Kansas City, MO*

Background: Right-sided (RCC) and left-sided colon cancers (LCC) have different clinical/biological characteristics. Comprehensive genomic analysis (Whole exome/genome, Copy number, RNA, MicroRNA) using The Cancer Genome Atlas (TCGA) was performed to identify underlying genomic differences between RCRC, LCRC and rectal cancers (RC). **Methods:** 443 microsatellite stable RCC, LCC and RC samples were analyzed. Transverse and rectosigmoid tumors were excluded. MutsigCV and ConsensusDriver were used for significantly mutated gene analysis, GISTIC for copy number alterations (CNA), deSeq2 for RNA and microRNA analysis. Supervised clustering was applied to somatic mutations using Fuzzy ARTMAP. **Results:** AMER1 (gene in Wnt pathway) was mutated in 24% of RCC, 3% of LCC and 3% of RC. Mutations in AMER1 and other key Wnt family members (CTNNB1, GSK3, AXIN1, AXIN2, LRP5, LRP6) were mutually exclusive of each other. A novel driver B Melanoma Antigen Family, Member 2 (BAGE2) not previously described in CRC was discovered in a subset of samples using Fuzzy ARTMAP. KRAS, PIK3CA, SOX9 (all $p < 0.05$) mutations were enriched in RCC. New driver mutations in BCOR, MUC4, RELN, ROBO2, RP1L1, and MGAM were also enriched in RCC (all $p < 0.05$). Hotspot mutation analysis revealed distinct oncogenic mutations in RCC, including in APC (R1450*, $p = 0.0246$). We identified unique amplifications and deletions in RCC (1 amplification/10 deletions) and LCC (13 amplifications/10 deletions). Somatic mutation, CNA and hotspot analysis revealed similar changes in LCC and RC. RNA analysis revealed 53 genes differentially expressed between RCC and LCC and 73 genes between RCC and RC. The top upregulated and downregulated genes were common between the two groups (n = 32). INSL5 and PRAC1 are among the most downregulated genes while SLC10A2, DRD5, and APOA4 are among the most upregulated genes. MicroRNA analysis showed 12 miRNA differentially expressed between RCC and LCC. **Conclusions:** RCC and LCC have distinct molecular profiles, whereas LCC and RC appear to be similar at the genomic level. Several specific/novel gene mutations are associated particularly with RCC (APC and AMER1 genes among others). A novel driver gene, BAGE2, was discovered in a subset of colorectal cancers.

3593 Poster Session (Board #86), Sun, 8:00 AM-11:30 AM

Differences in the characteristics of younger and older MSI-H colorectal cancer (CRC) as determined by universal reflex testing. *First Author: Aaron J Franke, University of Florida, Gainesville, FL*

Background: DNA mismatch repair deficient (dMMR) or microsatellite instability high (MSI-H) CRC is found in ~15% of early stage and ~5% of metastatic disease. Universal or reflex testing to identify dMMR/MSI-H has been proposed. The CRC incidence in young patients (pts) is also rising with unclear etiology. We present a large, single-institutional database of universal reflex dMMR/MSI-H testing in CRC comparing clinicopathologic and molecular profiles of younger (≤50) and older (> 50) pts. **Methods:** For all CRC pts diagnosed at University of Florida between 2009-2017, reflex somatic testing for dMMR by IHC (MLH1, PMS2, MSH2, MSH6), MSI by PCR (Promega MSI kit) and NGS was performed with appropriate positive and negative controls. IHC protein loss was confirmed by second GI pathologist. Equivocal IHC results triggered MSI testing. Review of associated clinical EMR data was retrospectively performed and analysis conducted with student's t-test. Study was IRB approved. **Results:** 375 pts were analyzed by ≤50yo (n = 80; median age 44, range 17-50) or > 50yo (n = 295; median age 66, range 51-98). There was 100% concordance of MMR and MSI of all patient samples. dMMR/MSI-H incidence was 14% (11/80) in pts ≤50, compared to 22% (64/295) in pts > 50 ($p < 0.001$). For stage IV CRC, dMMR/MSI-H incidence was 4% vs. 13% ($p = 0.003$) between the age groups. Younger pts presented with more advanced disease (36% Stage III, 36% Stage IV) compared to older pts (32% Stage III, 26% Stage IV). Associated BRAF mutations were more common in pts > 50 (20% vs. 67%; $p = 0.005$). **Conclusions:** In our dataset, younger CRC pts are diagnosed with more advanced disease but with dMMR/MSI-H cancers at the expected rate. However, we identified more (likely sporadic) dMMR/MSI-H stage IV cancers in pts > 50yo than expected. Further studies to identify risk factors for younger patients and the ultimate clinical impact of universal reflex MSI testing is warranted to maximize IO therapy offering and survival.

3594 Poster Session (Board #87), Sun, 8:00 AM-11:30 AM

International harmonization of diagnostic criteria for *HER2*-amplified metastatic colorectal cancer and application of targeted next-generation sequencing panel as a diagnostic method. *First Author: Satoshi Fujii, National Cancer Center, EPOC, Chiba, Japan*

Background: *HER2* amplification (*HER2*$^+$) in metastatic colorectal cancer (mCRC) is associated with resistance to anti-EGFR antibodies and response to HER2 targeted therapies. This study assessed the diagnostic criteria on *HER2*$^+$ mCRC among four groups (GI-SCREEN-Japan, SWOG-USA, HERACLES-Italy, and Korea) and harmonized the criteria for patient enrollment in clinical trials that target these patients (pts). **Methods:** Samples from 475 and 16 pts with mCRC were used in exploratory and validation cohorts, respectively. We assessed *HER2* status by immunohistochemistry (IHC) and *HER2/CEP17* ratio and gene copy number (GCN) by fluorescence in situ hybridization (FISH) and copy number variations (CNV) by targeted next-generation sequencing (NGS) panel. OCA by ThemoFisher and AMC v3 by illumina were used in exploratory and validation cohorts, respectively for the cross-validation of NGS panels. **Results:** The consensus diagnostic criteria for *HER2*$^+$ mCRC was reached; IHC 3+ or IHC 2+ and *HER2/CEP17* ratio by FISH $\geq$ 2.0, and tumor content $>$ 10% for surgically resected specimens (separate quantity criteria were established for biopsy specimens). The median GCN and CNV for pts who met consensus criteria for *HER2*$^+$ was 10.9 and 27.7 compared to 2.5 ($P<$ 0.0001) and 3.5 ($P<$ 0.0001), respectively in pts who were *HER2*$^-$. These findings were validated in validation cohort (GCN: 16.2 v 2.4, $P=$ 0.0002; CNV: 42.5 v 2.0, $P=$ 0.0003). GCN also showed strong correlation with CNV in both cohorts (r: exploratory: 0.90, validation: 0.97; $P<$ 0.0001). CNV in cross validation of OCA and AMC v3 also showed strong correlation (r: 0.97, $P<$ 0.0001). The CNV for pts fulfilling the consensus criteria was more than 4.0 in the two cohorts. The accuracy of the IHC/FISH criteria was validated for mCRC pts, providing cross-validation of NGS panels. **Conclusions:** We were able to verify the HER2 classification consistency between CNV by NGS and IHC/FISH by harmonizing diagnostic criteria for *HER2*$^+$. This strategy can help establish diagnostic criteria for *HER2*$^+$ cancer by allowing for different methodologies to be used for pts screening for trial eligibility.

3595 Poster Session (Board #88), Sun, 8:00 AM-11:30 AM

The characteristics of ARID1A mutations in colorectal cancer. *First Author: Amir Mehrvarz Sarshekeh, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: AT-rich interactive domain 1A (ARID1A) is a component of the SWI/SNF chromatin remodeling complex that regulates gene expression. Inactivating mutations of ARID1A have been reported in a variety of cancers but data on characteristics and associated clinicopathologic features in colorectal cancer (CRC) are limited. **Methods:** Data for patients (pts) with CRC whose tumors underwent comprehensive genomic profiling were reviewed using the Cancer Genome Atlas (TCGA), Nurses' Health Study and Health Professionals' Follow-up Study (NHS/HPFS), AACR Project GENIE and MD Anderson Cancer Center databases. **Results:** Among 3127 pts, 196 (6.2%) had a mutation in ARID1A. Across the datasets, 249 mutations in ARID1A were identified. Mutations were more likely to be frameshift or nonsense as compared with mutations in other genes (64.0% vs. 9.1%, OR = 7.0, 95% CI 5.6-8.7; $p<$ .001) and the majority were considered clonal by allele frequency (defined as $>$ 25%). The mutation locations were broadly distributed, although 10 recurrent (hot-spot) regions were identified. ARID1A mutations were associated with MSI-H status (OR = 8.1, 95% CI 4.4-14.8; $p<$ .001), with PIK3CA mutations (OR = 2.8, 95% CI 2.1-3.9; $p<$ .001), and BRAF mutations (OR = 3.1, 95% CI 2.2-4.4; $p<$ .001) but had inverse correlation with TP53 mutations (OR = 0.5, 95% CI 0.4-0.7; $p<$ .001). Of note, 18/23 (74%) of tumors with ARID1A mutations were classified as consensus molecular subtype-1 (CMS-1) with OR of 17 (95% CI 4.8-63.7; $p<$ .001). The mutations were associated with PPAR and HNF4 transcription factor activity. ARID1A mutations were more common in early stages (OR = 1.83, 95% CI 1.09-3.07; $p=$ 0.019) and right-sided tumors (OR = 1.66, 95% CI 1.01-2.71; $p=$ 0.034). There was no association between ARID1A mutation and race, gender, age at the time of diagnosis, grade, or presence of distant metastases. **Conclusions:** This is the largest study evaluating ARID1A mutations in CRC. The majority of mutations appear to be truncating and clonal, suggesting that they have functional significance. ARID1A-mutated tumors demonstrate enrichment of wild-type TP53 but they are more likely to have MSI-H, PIK3CA and BRAF mutations. The transcriptional signature may indicate future therapeutic strategies for this subgroup.

3596 Poster Session (Board #89), Sun, 8:00 AM-11:30 AM

A prospective cohort study in colorectal cancer assessing the relationship between post-surgery detection of methylated *BCAT1* or *IKZF1* ctDNA and risk for residual disease and survival. *First Author: David Murray, Clinical Genomics Technologies Pty Ltd., North Ryde, Australia*

Background: The methylated ctDNA biomarkers *BCAT1* and *IKZF1* are common events in colorectal cancer (CRC), play a role in its development and drugs targeting *BCAT1* are available. As these biomarkers disappear from blood after surgery in most patients, a prospective study was conducted to assess the relationship between their persistence post-surgery and presence of and risk for residual disease as well as survival. **Methods:** ctDNA status using these biomarkers was determined within 12 mo of initial surgical resection. Detection of either marker was related by logistic regression and survival analysis (Cox proportional hazards) to pathologically-determined presence or risk of residual disease ("RD", margins involved, metastases present or nature of node involvement) and to recurrence-free survival. **Results:** 172 CRC patients were tested for the biomarkers and then followed for a median 37.1mo (IQR 22.6-49.8) during which 23 experienced recurrence and 10 died from CRC. 28 (16%) were ctDNA positive post-surgery. Univariate analysis showed that a positive result was more likely if any of three markers of RD was present (OR 7.7, 95% CI: 2.3-25.0 p = 0.001); while increasing number of lymph nodes (OR 8.3, 95% CI: 1.8-37.7 p = 0.004) and involved peritoneum (OR 3.8, 95% CI: 1.6-9.2 p = 0.003) where also associated with a positive result. Multivariate modelling with adjustment for treatment status at time of venesection indicated that features of RD was an independent predictor of post-surgery ctDNA status: cases with 3 features (margins or apical node involved, distant metastases) were 5.3 times (95% CI: 1.5-18.4, p-value = 0.008) more likely to be positive. Modelling recurrence-free survival showed that post-surgery ctDNA positivity was associated with an increased risk of recurrence (HR 3.8, 1.5-9.5, p = 0.004). **Conclusions:** CRC cases positive for these ctDNA biomarkers within 12 months of surgery are at increased risk of residual disease and subsequently for recurrence. This has implications for adjuvant therapy and monitoring of cases; randomised studies are now indicated to determine if such can provide survival benefit. Clinical trial information: 12611000318987.

3597 Poster Session (Board #90), Sun, 8:00 AM-11:30 AM

Prognostic impact of BRAF V600E mutation in patients with non-metastatic colorectal cancer with microsatellite instability: A systematic review and meta-analysis. *First Author: Sashidhar Manthravadi, University of Kansas Medical Center, Kansas City, KS*

Background: Colorectal cancer (CRC) displaying high levels of microsatellite instability (MSI-H) has been associated with improved survival in colorectal cancer. MSI-H CRC is also known to be enriched in V600E mutations in the BRAF gene (BRAF-Mut). BRAF-Mut is a known adverse prognostic factor in patients with non-metastatic MSI-low CRC. However, the prognostic role of BRAF V600E mutations in non-metastatic MSI-H CRC remains unclear. **Methods:** Following PRISMA guidelines, a systematic review of PubMed and Embase was performed from inception through January 2018 to identify studies which described the impact of BRAF-Mut on outcomes in patients with non-metastatic MSI-H CRC. Summary hazard ratios (HR) with 95% confidence intervals (CI) for overall survival (OS) and recurrence-free survival (RFS) were estimated using a random effects model and heterogeneity was estimated using the inconsistency index (I^2). **Results:** After reviewing 988 reports, 8 studies which described the association between BRAF status and outcomes in non-metastatic MSI-H CRC were selected for inclusion. These were reported from Europe, North America and Asia. A total of 1164 patients with MSI-H CRC were included of whom 553 were found to carry BRAF V600E mutation. Data regarding RFS and OS for BRAF-Mut vs BRAF-Wild type was provided in 5 and 8 studies respectively. No association was found between BRAF-Mut and RFS in patients with non-metastatic MSI-H CRC (HR 1.13; 95% CI 0.77- 1.67, I^2= 0%). In contrast to these findings, BRAF-Mut had an adverse impact on OS in patients with non-metastatic MSI-H CRC (OS = HR 1.53; 95% CI 1.15- 2.03, I^2= 0%). **Conclusions:** BRAF V600E mutation appears to have no association with disease recurrence but does correlate with adverse overall survival in patients with non-metastatic colorectal cancer with high levels of microsatellite instability. Clinical trials planned in the future must therefore consider adding BRAF status as a stratification factor.

3598 Poster Session (Board #91), Sun, 8:00 AM-11:30 AM

$CD3^+$ and $CD8^+$ tumor-infiltrating lymphocyte (TIL) densities to prognostically stratify DNA mismatch repair-deficient (dMMR) colon cancer patients (pts): NCCTG N0147 (Alliance). *First Author: Harry H. Yoon, Mayo Clinic, Rochester, MN*

Background: Colorectal cancers (CRC) with dMMR typically have abundant TILs indicating an enhanced host immune response. However, the prognostic impact of TILs identified by $CD3^+$ and $CD8^+$ T cells has not been adequately studied in dMMR tumors. While dMMR is considered a predictive biomarker for anti-PD-1 therapy in advanced CRC, ~60% of dMMR pts do not respond, which may be relevant in dMMR stage III where adjuvant PD-L1 blockade is being studied. We report the first evaluation of $CD3^+$/$CD8^+$ TILs with prognosis in dMMR tumors from a clinical trial cohort. **Methods:** $CD3^+$ and $CD8^+$ TILs at the invasive margin (IM) and central tumor (CT) were analyzed in 561 stage III colon cancers (dMMR n = 278; randomly selected pMMR n = 283) from a phase 3 trial of FOLFOX-based adjuvant therapy (N = 3270 [dMMR 376, pMMR 2894]). Median follow up was 6.3 y. Immunostaining was quantified by image analysis (0-100 scale). Associations with overall survival (OS) were evaluated by multivariable Cox regression. **Results:** Densities of $CD3^+$ and $CD8^+$ TILs were higher in dMMR *vs* pMMR tumors ($P < .001$), and were heterogeneous between pts in each MMR group. $CD3^+$ IM was the strongest prognostic marker; the other markers ($CD3^+$ CT, $CD8^+$ IM, $CD8^+$ CT), alone or combined, did not add further value. Among dMMR tumors, using an optimized cutpoint, 58% had low $CD3^+$ IM, and these pts had significantly shorter OS *v* dMMR tumors with high $CD3^+$ IM, independent of covariates. See Table for full results. OS of dMMR tumors with low $CD3^+$ IM was comparable to the overall pMMR cohort (n = 2611; $P = .8$). Pts with high $CD3^+$ IM pMMR tumors had an OS similar to TIL-unselected dMMR tumors (n = 376; $P = .3$). **Conclusions:** $CD3^+$ IM TILs can prognostically stratify pts with dMMR stage III colon cancer for OS. These findings of heterogeneity within dMMR may have implications for immunotherapy responsiveness in dMMR tumors.

	$CD3^+$ IM (cutpoint)	n (%)	HR_{adj}	P_{adj}	5y OS rate
dMMR	Per 10-unit decrease		1.1	.015	
	High (≥ 49)	111 (42)	Ref	.026	84%
	Low (≤ 48)	167 (58)	2.1		70%
pMMR	Per 10-unit decrease		1.2	.009	
	High (≥ 21)	177 (63)	Ref	.073	83%
	Low (≤ 20)	106 (37)	1.7		73%

3599 Poster Session (Board #92), Sun, 8:00 AM-11:30 AM

Effect of age, gender, and performance status (PS) on the duration results of adjuvant chemotherapy for stage III colon cancer: The IDEA collaboration. *First Author: Anthony Frank Shields, Karmanos Cancer Institute, Wayne State University, Detroit, MI*

Background: The IDEA collaboration pooled data from nearly13,000 patients (pts), comparing 3 vs. 6 months (m) of adjuvant fluoropyrimidine plus oxaliplatin to test noninferiority for disease-free survival (DFS) in stage III colon cancer. We reported that duration of adjuvant therapy (Rx) should be individualized with consideration of recurrence risk, regimen, and toxicity. Here we consider the influence of age, gender, and PS. **Methods:** Using stratified Cox proportional hazard models we stratified the IDEA cohort by age (≤ 70 or > 70), gender, and PS (0 v 1/2), testing for interactions with subgroups and duration of Rx. **Results:** Overall, DFS results comparing 3 vs 6m of Rx did not significantly differ across age, gender or PS subgroups. However, significant (sig) interactions were detected within subgroups (Table). For pts ≤ 70 who received CAPOX, 3m Rx is as good as 6m (HR 0.9). 6m of Rx is required for pts ≤70 (HR 1.16) with FOLFOX and may be best for pts > 70 on either regimen (p = .068, 3 way interactions). It was found that gender influenced the impact of risk group on the duration comparison (p = .078, 3 way interaction); 3m Rx was as good as 6m for male low-risk pts (HR 0.94) but 6m is required for high risk male (HR 1.18). For females, risk group did not alter the relative merits of 3 v 6m of Rx. PS did not influence the impact of regimen/risk group on the duration comparison. **Conclusions:** Overall age, gender, or PS didn't modify the comparison of 3 v 6m Rx. The biologic and clinical rationales for the differences observed within certain subgroups need to be explored before they are used to make treatment choices. Clinical trial information: NCT01150045.

Total neoadjuvant treatment versus chemoradiotherapy in locally advanced rectal cancer: A propensity score analysis from two prospective phase II clinical trials. *First Author: Jianwei Zhang, Sixth Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China*

Background: Fluorouracil-based neoadjuvant chemoradiotherapy (CRT) is still the standard of treatment for locally advanced rectal cancer, but it delays administration of systemic chemotherapy, leading to high incidence of distant metastases. To enhance systemic chemotherapy and improve the outcome of rectal cancer, totally neoadjuvant therapy (TNT) has been investigated recently. Here, we aimed to compare the efficacy of TNT with CRT in locally advanced rectal cancer. **Methods:** A total of 180 patients with clinical stage II or III locally advanced rectal cancer who received either total neoadjuvant treatment (n = 79) or CRT (n = 101) followed by total mesorectal excision (TME) were identified from two prospective clinical trials (NCT01211210 and NCT02217020) in our institutional database. Propensity score analysis was performed to mitigate selection biases. The patients in TNT group received 1 cycle of mFOLFOX6 as induction chemotherapy and radiotherapy would be delivered accompanied with 3 cycles of mFOLFOX6. Another 4 cycles would be added after radiotherapy and before TME. The CRT group received five 2-week cycles of infusional fluorouracil plus radiotherapy. **Results:** Of the 180 patients, the pathologic complete response (pCR) rate was 21.7%. Following propensity score matching, each group contained 79 patients. The baseline characteristics were well balanced. The pCR rate of TNT group and CRT group was 34.2% vs. 15.2%, respectively ($p < 0.005$). And the tumor downstaging rate was 60.8% vs. 35.4%, respectively (p = 0.001). Grade3/4 neutropenia was the more common in TNT group, which was 30.4% vs. 8.9% (P = 0.0007) in the TNT group and CRT group, respectively. Grade 3/4 Leukopenia (21.5% vs. 12.7%, p = 0.14) and thrombocytopenia (5.1% vs. 11.4%, p = 0.15) was similar between the two groups. **Conclusions:** TNT showed higher pCR rate and tumor downstaging rate than that of CRT, which was a promising strategy for improving outcome of rectal cancer, although the grade 3-4 adverse events were a little bit higher in TNT group. But this finding requires further analysis from long-term survival data. The phase III study comparing TNT with CRT is ongoing.

3601 Poster Session (Board #94), Sun, 8:00 AM-11:30 AM

Association of adverse events (AEs) with outcomes in early stage colon cancer (CC): An analysis of 10,695 CC patients from the ACCENT database. *First Author: Winson Y. Cheung, Tom Baker Cancer Centre, University of Calgary, Calgary, AB, Canada*

Background: Initial dosing of adjuvant chemotherapy (ACT) is largely based on body surface area, but studies show that drug metabolism can vary significantly across patients. ACT-related toxicities may serve as proxies for these pharmacodynamics and pharmacokinetic variations. Thus, AEs may predict for treatment efficacy and survival. In some tumors, dose titration until toxicity has been proposed. We aimed to explore the relationship between AEs and outcomes in early stage CC. **Methods:** A retrospective analysis of individual CC patient data from 12 randomized trials of ACT was conducted. Severity of selected AEs was categorized as per NCI criteria. Using stratified Cox models with a landmark approach, we examined overall survival (OS), disease-free survival (DFS), time to recurrence (TTR), and time from recurrence to death (TRD) in relation to AEs, adjusting for treatment duration as well as clinical and pathological factors. Analyses were performed based on the type of ACT that patients received, including fluoropyrimidine (FP) alone, FP + irinotecan (Iri), or FP + oxaliplatin (Ox). Due to multiple comparisons, the significance level was set at 0.001. **Results:** We included 10,695 patients of whom 79.5%, 5.8%, and 14.7% received FP, FP + Iri, and FP + Ox, respectively. Women were more likely to experience worse toxicities than men, independent of ACT regimen (all $p < 0.001$). Diarrhea and neutropenia were the most common grade 3+ AEs across all ACT while neuropathy was a frequent grade 3+ AE in the FP + Ox group. Other AEs, such as grade 3+ thrombocytopenia and transaminitis, were rare. Grade 3+ transaminitis was associated with worse OS (3-year OS 68.9 vs. 87.3%; adjusted hazard ratio 2.46, 95% CI 1.49 – 4.06, $p < 0.001$), but not DFS, TTR and TRD, in patients who received FP + Ox. There were no consistent correlations between additional AEs and outcomes in all other ACT regimens. No differences were observed when the analyses were stratified by disease stage. **Conclusions:** In this large cohort of clinical trial patients, most clinically observable AEs do not appear to be reliable biological correlates of optimal dose intensity or survival outcomes.

3602 Poster Session (Board #95), Sun, 8:00 AM-11:30 AM

Patients' preferences for 3 months versus 6 months of adjuvant chemotherapy (ACT) for colon cancer in the SCOT trial: what survival benefits make longer chemotherapy worthwhile? *First Author: Prunella Louise Blinman, Concord Repatriation General Hospital, Concord, NSW, Australia*

Background: The optimal duration of ACT following surgery for colon cancer remains controversial. SCOT is an international, randomised trial that compared 3 months versus 6 months of ACT in this setting. We sought the survival benefits that patients participating in SCOT judged necessary to make extra 3 months of ACT worthwhile. **Methods:** SCOT participants from Australia & New Zealand completed a validated questionnaire 3 and 18 months after randomisation to elicit the minimum survival benefit each participant judged necessary to make it worthwhile having ACT for 6 months rather than 3 months. Standardised hypothetical scenarios used the following baseline survivals with 3 months of ACT: life expectancies (LE) of 5 years (5Y) and 15 years (15Y), and 5-year survival rates (5YS) of 65% and 85%. Comparisons were non-parametric, 2-sided, and considered statistically significant if $p < 0.05$. **Results:** Questionnaires were completed by 160 participants, 82 allocated 3 months ACT, and 78 allocated 6 months ACT. ACT was FOLFOX in 121 (75%), XELOX in 39 (25%), and the mean age was 64. Preferences varied substantially among participants, and did not differ according to the randomly allocated treatment group. The median survival benefits judged necessary to make the extra 3 months of ACT worthwhile were an extra: 3 years beyond a LE of 5Y; 3 years beyond a LE of 15Y; 15% beyond a 65% 5YS; and 5% beyond an 85% 5YS. Preferences were similar at 3 months and 18 months. Participants with symptomatic peripheral neuropathy (132, 82%) judged a median benefit of an extra 5% beyond a 65% 5YS necessary to warrant their symptoms. **Conclusions:** Participants' preferences varied substantially, and many judged much larger benefits needed to warrant having ACT for 6 months rather than 3 months than the estimates of the benefits based on the IDEA meta-analysis.

3603 Poster Session (Board #96), Sun, 8:00 AM-11:30 AM

Association of sex and adverse events (AEs) of adjuvant chemotherapy (ACT) in early stage colon cancer (CC): A pooled analysis of 28,636 patients (pts) in the ACCENT database. *First Author: Anna Dorothea Wagner, Department of Oncology, Lausanne University Hospital, Lausanne, Switzerland*

Background: Sex is one of several factors known to affect drug efficacy and toxicity. Preliminary data in different types of cancers suggest a higher toxicity of chemotherapy in women. Aim of this pooled analysis was to understand the clinical relevance of sex differences in toxicity of ACT in CC. **Methods:** The primary aim was to compare these major AEs: nausea, vomiting, stomatitis, diarrhea, leucopenia, neutropenia, anemia, thrombocytopenia, and neuropathy (pts receiving oxaliplatin) between men (M) and women (W) treated with ACT after curative resection. Severity of AEs was categorized as per NCI criteria. Comparisons were conducted by chi-squared test and logistic regression based on type of ACT, including fluoropyrimidine (5-FU) as single-agent, 5-FU + irinotecan (FOLFIRI), or 5-FU + oxaliplatin (FOLFOX). $P < 0.001$ was considered significant due to multiple comparisons. **Results:** AE data were available in 28,636 pts (54% M) from 26 studies. Overall, women were at greater risk for the majority of toxicities (see Table). **Conclusions:** Further investigations are needed to better understand the impact of sex on toxicity and efficacy of chemotherapy. Possible differences in perception do not explain the significant differences in neutropenia. These results suggest that sex-specific strategies for drug dosing and supportive care may need consideration.

Impact of adjuvant chemotherapy in higher risk stage II colon cancer with a deficient mismatch repair (dMMR)/ microsatellite instability-high (MSI-H) profile. *First Author: AMR Mohamed, Karmanos Cancer Institute, Detroit, MI*

Background: Randomized phase III trials have shown that patients with dMMR/ MSI-H stage II colon cancer (CC) do not benefit from adjuvant chemotherapy. However, a subgroup of stage II patients have a higher risk for recurrence but it is unclear whether those patients who also have dMMR/MSI-high tumors will in fact benefit from adjuvant chemotherapy. **Methods:** In this retrospective analysis of National Cancer Database (NCDB) we studied the impact of adjuvant chemotherapy in high risk stage II with dMMR/MSI-high CC. Higher risk was defined by at least one of the following criteria: < 12 lymph nodes examined, lymphovascular invasion (LVI), positive surgical margin, T4 tumor, and poorly differentiated/undifferentiated histology. No data were available for obstruction or perforation at diagnosis. **Results:** Between 2010 and 2013, 3851 CC patients (56.1% females, median age 69, 49.5% clinicopathologically high risk) were determined to have dMMR/MSI-high status. 24.6% of dMMR/MSI-high patients received adjuvant chemotherapy, of whom 67.8% received multiagent therapy. On univariate analysis no adjuvant chemotherapy, pT4A/B tumor, pathologic stage IIB/C, < 12 lymph nodes, LVI positive, positive margin, and older age at diagnosis were associated with worse overall survival (OS). On multivariable analysis no adjuvant chemotherapy, male sex, stage IIC, positive surgical margin, older age at diagnosis were associated with worse OS. High risk dMMR/MSI-high patients had better OS when given adjuvant chemotherapy, HR 0.50 (0.34-0.74, p < 001). Single and multiagent adjuvant chemotherapy were associated with better OS, HR 0.38 (0.19-0.76, p = 0.006) and 0.58 (0.37-0.90, p = 0.02), respectively. **Conclusions:** Adjuvant chemotherapy was associated with better OS in stage II CC patients with high-risk features plus dMMR/MSI-high profile. Benefit was observed with both single and multiagent chemotherapy. In the absence of prospective studies, this study supports the consideration of adjuvant chemotherapy in the subgroup of stage II CC patients with dMMR/MSI-high status if they also have high recurrence clinico-pathological features risk.

3605 Poster Session (Board #98), Sun, 8:00 AM-11:30 AM

Fish oil supplementation and inflammatory response during neoadjuvant chemoradiation for rectal cancer: Results from a prospective, randomized, controlled trial. *First Author: Juliana De Aguiar Pastore Silva, A.C. Camargo Cancer Center, São Paulo, Brazil*

Background: It has been proposed that omega-3 fatty acids can modulate inflammatory response and contribute to improve anti-cancer therapies. **Methods:** Patients clinically staged as T3,4 and / or N + rectal carcinoma were randomized to receive oral ingestion of encapsulated fish oil during neoadjuvant conventional chemoradiation (intervention group – IG) or chemoradiation without supplement (control group – CG). All patients were operated about 8 weeks after chemoradiation. Glasgow Prognostic Score (GPS) was the primary endpoint. Other inflammatory and nutritional parameters and quality of life (QOL) measurements were also collected at 4 moments: M1: at diagnosis; M2: at the end of chemoradiation; M3: at 4 weeks after end of chemoradiation; and M4: preoperatively. Eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) were quantified in blood samples by gas chromatography. **Results:** 179 patients were referred for neoadjuvant treatment between January, 2013 and July, 2017. 120 met eligibility criteria. 114 were randomized (IG: 55 and CG: 59). Mean age were 59.5 years, ranging from 30-86 years. There was no difference between groups in M1. In M2 and M3 there were differences between the supplemented group (IG) and the CG in systemic inflammatory response measured by Glasgow Prognostic Score (M2:P = 0.001; M3:P = 0.027), serum protein C reactive (PCR)(M2: P = 0.001; M3: P = 0.045) and ratio CRP / Albumin (M2:P = 0.00; M3: P = 0.005) - the lowest values in the IG. About QOL, CG presented more symptoms in M2 for dysuria (P = 0.031), M3 for pain (P = 0.023), buttock pain (P = 0.005) and dyspareunia (P = 0.041); IG presented less anxiety (P = 0.040). In M4 the differences between the groups were about recent lost weight (P = 0.025), with lowest values in IG, and CG present more symptoms for appetite loss (P = 0.016), buttock pain (P = 0.044) and bloating (P = 0.007). There were no differences in food intake, body composition, global subjective assessment and classification of nutritional status at any study moment. **Conclusions:** This dietary intervention was able to modulate inflammatory response, has impact on some nutritional markers and some components of quality of life. Clinical trial information: NCT02534389.

3606 Poster Session (Board #99), Sun, 8:00 AM-11:30 AM

Who should undergo lateral pelvic node dissection after neoadjuvant chemoradiation for rectal cancer? *First Author: Songphol Malakorn, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The optimal surgical strategy for rectal cancer patients with suspected lateral pelvic lymphadenopathy (LPN) in unknown. Despite the use of neoadjuvant chemoradiation (CRT), lateral compartment treatment failure has emerged as an important clinical problem. The purpose of this study was to evaluate association between preoperative LPN size on imaging and disease diagnosed at pathology in order to determine the indication for lateral pelvic lymph node dissection (LPND). **Methods:** Rectal cancer patients with lateral pelvic node metastasis who underwent TME with LPND between 2006 and 2017 were identified from the institutional database of a tertiary cancer center and their medical records were retrospectively reviewed for information regarding patient, tumor, and treatment. Indication for LPND was suspected LPN based on CT or MRI. Patients with locally recurrent cancers at presentation were excluded. Primary outcome was rate of pathologic LPN positivity. Associations between LPN size on post-neoadjuvant CRT imaging and pathologic lateral pelvic lymph node positivity were evaluated. **Results:** A total of 70 patients who underwent TME & LPND met criteria and were analyzed. The median number of LPN evaluated was 3 (IQR 1 – 5) per patient. The mean LPN size before and after CRT was 15.7 ± 12.7 mm and 11.0 ± 10.0 mm, respectively and the minimum size of positive LPN was 6 mm on post-treatment imaging. Overall, a total of 56 of 256 LPN were positive (22%). Twenty patients (28.6%) had only ≤ 5 mm LPN after CRT; none were positive at pathology. Among 50 (71.4%) patients who had > 5 mm LPN after CRT; 34 patients (68%) were positive at pathology. 3 year OS was higher among patients who had ≤ 5 mm LPN vs > 5 mm LPN after CRT (OS 90.9% vs 70.4%, P = 0.05) but the difference in DFS was not statistically significant (77.9% vs 56.7%, P = 0.12). After a median 43 months of follow-up, one patient developed local recurrence (≤ 5 mm group). **Conclusions:** Post-CRT LPN size > 5 mm was strongly associated with pathologically positive LPN but no patients with size ≤ 5 mm had positive LPN at pathology. Following LPND no patients with positive LPN developed local recurrence. Therefore, patients with LPN > 5 mm on post-CRT MRI should undergo TME with LPND.

3607 Poster Session (Board #100), Sun, 8:00 AM-11:30 AM

Mesorectal excision with or without lateral lymph node dissection for clinical stage II, III lower rectal cancer: Long-term follow-up data of Japan Clinical Oncology Group study JCOG0212. *First Author: Mitsuyoshi Ota, Gastroenterological Center, Yokohama City University Medical Center, Yokohama, Japan*

Background: We conducted the non-inferiority study of mesorectal excision (ME) alone to ME with lateral lymph node dissection (LLND) for clinical stage II/III rectal cancer without lateral pelvic lymph node enlargement. Non-inferiority of ME to ME with LLND was not confirmed in terms of efficacy in the primary analysis. This is the long-term follow-up data of the study with a median follow- up of 84 months for all randomized patients. **Methods:** Eligibility criteria included clinical stage II/III; main lesion located in the rectum with the lower margin below the peritoneal reflection; no lateral pelvic lymph node swelling larger than 10 mm. After surgeons had confirmed R0 resection by the ME procedure, patients were randomized intraoperatively to ME alone or ME with LLND. The primary endpoint was relapse-free survival (RFS), with a non-inferiority margin for the hazard ratio (HR) of 1.34. The planned sample size was 700 with a power of 75% and a one-sided alpha of 5%. **Results:** A total 701 of patients enrolled from 33 institutions were randomized to ME+LLND (n = 351) or ME (n = 350) between June 2003 and August 2010. The 7-year RFS was 71.1% and 70.7% in the ME+ LLND group and the ME group, respectively. The HR was 1.09 [95% CI: 0.84-1.42] (non-inferiority P =0.064). In subgroup analysis shown in the table, RFS of clinical stage III patients in the ME+LLND group was significantly better than that of those in the ME group (HR: 1.49 [95% CI: 1.02-2.17]). **Conclusions:** Long-term follow-up data supported that the non-inferiority of ME to ME with LLND was not confirmed in terms of efficacy in the primary analysis. ME with LLND is recommended especially for clinical stage III patients who do not undergo preoperative chemoradiotherapy. Clinical trial information: NCT00190541.

Characteristics	HR	95% CI
Sex		
Male	0.95	0.69-1.29
Female	1.54	0.92-2.56
Clinical stage		
II	0.82	0.56-1.19
III	1.49	1.02-2.17
Distance from anal verge		
≤ 5 cm	1.11	0.78-1.56
> 5 cm	1.03	0.68-1.56

3608 Poster Session (Board #101), Sun, 8:00 AM-11:30 AM

Predicting treatment outcome of rectal cancer patients underwent neoadjuvant chemoradiotherapy by ctDNA: The potential use of ctDNA monitoring as organ-sparing approach. *First Author: Lifeng Yang, Department of Radiation Oncology, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: Neoadjuvant chemoradiotherapy (nCRT) is widely accepted for the treatment of locally advanced rectal cancer (LARC). Watch & wait (W&W) strategy can improve life quality, but needs strict patient selection. We investigated the ability of circulating tumor DNA (ctDNA) to predict treatment outcome and improve risk stratification. **Methods:** Between 2015 and 2016, we enrolled LARC (T3/T4 and/or N+) patients planned for nCRT. Plasma samples were collected pretreatment, in the middle of nCRT, post-nCRT, before surgery and one week after surgery. Somatic mutations in individual patient were identified via massively parallel sequencing of 455 genes. Responders (ypTRG 0–1) or non-responders (ypTRG 2–3) were recorded. Chi-square test was used to compared ctDNA levels to clinical, radiological and pathological response. **Results:** We analysed 440 serial plasma samples from 88 patients. Ten cases were pathological complete response (pCR). CtDNA was detectable in 65.9% (58/88), 14.7% (13/88) and 3.4% (3/88) of pretreatment, post-nCRT and post-surgery samples, with most frequent mutations as TP53, APC, KRAS. The rates of responders and non-responders are 24.1% (14/58) and 75.9% (44/58), but no difference was found in baseline ctDNA. 65.5% (38/58) of the patients' ctDNA level decreased *sharply* to zero before the end of nCRT, which was consistent to their radiological and pathological changes. CtDNA was detectable in 60% (6/10) pCR cases, most of their ctDNA vanishing at the middle of nCRT. 29.3% (17/58) of the patients' ctDNA status changed in irregular patterns. However, 5.2% (3/58) of the patients' ctDNA status goes up during nCRT, all of the three developed metastatic disease during the follow up period. Increased level of ctDNA post-nCRT indicated high rates of disease progression, which was not appropriate for W&W strategy. **Conclusions:** The baseline ctDNA were not helpful in distinguishing responders from non-responders. Post-nCRT analysis stratifies patients with LARC into subsets at high or low risk of progression. CtDNA analysis could potentially be used to guide patient selection for W&W strategy or adjuvant chemotherapy.

3609 Poster Session (Board #102), Sun, 8:00 AM-11:30 AM

Reasons for urban-rural differences in colon cancer outcomes: A population-based analysis. *First Author: Nicholas Adam Bosma, Tom Baker Cancer Centre, University of Calgary, Calgary, AB, Canada*

Background: Previous studies showed that rural patients with colon cancer tend to have worse overall survival (OS). In the US, this disparity is due in part to poorer healthcare access or lack of insurance in rural populations. It is unclear what drives this disparity in single payer healthcare systems. **Methods:** Patients diagnosed with stage II and III colon cancer from 2004 to 2015 in a large Canadian province were identified. Demographics, disease, treatment, and outcome data were collected. Using residential postal codes, we classified patients as living in urban, regional, or rural areas. OS was measured from the time of diagnosis to death and analyzed using the Kaplan-Meier method. Multivariate Cox regression models were used to assess the impact of residence on outcomes, while adjusting for measured confounders. **Results:** We included 6,163 patients: 3,691 in urban, 693 in regional, and 1,779 in rural areas. Median age at diagnosis was 71 years, with 52% men, 51% stage II disease, 54% left-sided colon cancer, and 59% Charlson score 0. In comparison, there were more younger patients ($p = 0.033$) and more right-sided colon cancers ($p = 0.042$) in urban areas. In addition, urban patients experienced shorter times from diagnosis to surgery ($p < 0.001$), but longer delays from surgery to adjuvant chemotherapy ($p = 0.002$) (see Table). In survival analysis, median OS among urban, regional, and rural populations was 104, 83, and 94 months, respectively (log-rank $p < 0.001$). After adjusting for measured confounders and observed variations in baseline characteristics across patient populations, residence continued to predict for OS (HR 1.3, 95% CI 1.1-1.4, $p < 0.001$) for regional and HR 1.1, 95% CI 1.0-1.2, $p = 0.040$) for rural, when compared to urban. **Conclusions:** Urban-rural differences in colon cancer survival persist, even in settings with universal healthcare coverage. These findings may be partly driven by a younger population and more expedited surgical intervention in urban populations, but they do not fully explain the disparities.

Median time to surgery and adjuvant chemotherapy.

	Urban	Rural	Regional
Time to Surgery	12 days	16 days	15 days
Time to Adjuvant Chemotherapy	61 days	60 days	55 days

3610 Poster Session (Board #103), Sun, 8:00 AM-11:30 AM

Prognostic impact of CDX2 in stage II colon cancer: Results from two nationwide cohorts. *First Author: Torben Hansen, Danish Colorectal Cancer Center South, Vejle Hospital, Vejle, Denmark*

Background: The aim of the present study was to validate the prognostic impact of CDX2 in stage II colon cancer and confirm its clinical potential. **Methods:** Individual patient data and formalin fixed, paraffin embedded tumor tissue were collected from two unbiased, population-based cohorts representing all patients operated for stage II colon cancer in Denmark in 2002 and 2003. The CDX2 expression was evaluated by immunohistochemistry on whole tumor sections. Patients were classified into three groups, of CDX2 expression: *positive, intermediate, and negative,* for comparison with the clinical data. The endpoint was disease free survival (DFS). **Results:** A total of 1,157 patients was included. We found a significant relationship between loss of CDX2 expression and poor DFS in both cohorts, p = 0.0267 and p = 0.0118, respectively. Five-year DFS rates were 66%, 72%, and 74% in the test cohort and 62%, 65%, and 75% in the validation cohort for the negative, intermediate, and positive CDX2 expressing groups, respectively. Multiple Cox regression analysis performed on the combined cohorts confirmed an independent prognostic impact of CDX2 on DFS, hazard ratio 1.543 (95% confidence interval 1.129-2.108), p = 0.0065. CDX2 loss was also associated with an adverse prognosis in patients with tumors harboring microsatellite instability (MSI) (p = 0.0001). Tumors with focal loss of CDX2 expression in the budding cells constituted a specific group with a very poor prognosis, demonstrating a 5-year DFS of only 60%. **Conclusions:** The present study provides further strong evidence regarding prognostic impact of CDX2 in patients with stage II colon cancer. CDX2 expression should be considered when deciding on adjuvant chemotherapy, especially in the group of patients with MSI tumors.

3611 Poster Session (Board #104), Sun, 8:00 AM-11:30 AM

Molecular characterization of appendiceal cancer and comparison with right-sided (R-CRC) and left-sided colorectal cancer (L-CRC). *First Author: Ryuma Tokunaga, Division of Medical Oncology, USC Norris Comprehensive Cancer Center, Keck School of Medicine, Los Angeles, CA*

Background: The natural history and prognosis of appendiceal adenocarcinomas (AA) differ from that of adenocarcinomas arising in other large bowel sites. Compared to CRC, AA has more peritoneal dissemination and worse outcome. **Methods:** A total of 184 samples from AA (42 pseudomyxoma peritonei (PMP), 70 mucinous (MU), 24 signet ring (SR) and 48 adenocarcinoma, NOS (NOS)), 1080 samples from L-CRC, and 994 from R-CRC were tested with Next-Generation Sequencing (NGS) on a 592-gene panel and immunohistochemistry (IHC). Microsatellite instability (MSI) and tumor mutational burden (TMB) were tested by NGS, and PD-L1 by IHC (SP142). Statistical comparisons of AA and L-and R-CRC were done by Chi-square test. **Results:** High mutation rates in AA were seen in *KRAS* (55%), *TP53* (40%), *GNAS* (31%), *SMAD4* (16%), *APC* (10%), *ARID1A* (8%), *RNF43* (7%), *PIK3CA* (6%) and *BRAF* (5%). MSI-high was seen in 2.2%, TML-high (> = 17mut/MB) in 2.2% and PD-L1 expression in 2.8%. Compared to both L- and R-CRC, AA showed significantly higher mutation rates of *GNAS, SMAD4* and lower *TP53*, *APC*, *PIK3CA* and *FBXW7*. Alterations associated with immune checkpoint inhibitor responses (MSI-high, TML-high, PD-L1) showed similar frequency in AA compared to L-CRC, but not R-CRC. Histopathological subtypes of AA showed different molecular patterns: PMP carried the highest *KRAS* (78%), *GNAS* (63%) and no *PIK3CA* or *BRAF* mutations. SR showed the lowest *KRAS* (17%) and *APC* (0%) mutation rates. MU was characterized by *GNAS* mutation rate of 36%. SR and PMP had no MSI-high or TML-high cases. **Conclusions:** Molecular characterization of AA revealed different characteristics compared with CRC; similarities were observed between AA and L-CRC despite anatomical distance, and molecular heterogeneity among histological subtypes were seen. These molecular differences may be critical to develop new treatments for appendiceal adenocarcinoma.

3612 Poster Session (Board #105), Sun, 8:00 AM-11:30 AM

***HER2* positive rates are enriched amongst colorectal cancer brain metastases: A study amongst 1,920 consecutive patients.** *First Author: Ryan Tan, National Cancer Centre Singapore, Singapore, Singapore*

Background: Brain metastases (BM) from colorectal cancer (CRC) are a rare but increasing event as patients survive longer. While human epidermal growth factor receptor 2 (*HER2*) gene amplification in breast cancer is well described and known to increase risk of brain metastases, information in CRC patients with brain metastases is lacking. **Methods:** A retrospective review of all radiologic imaging amongst 1920 consecutive CRC patients seen at National Cancer Centre Singapore identified 40 patients with radiological evidence of brain metastases. We retrieved resected primary tumour specimens or biopsies of metastatic sites from these 40 patients for fluorescence in situ hybridization (FISH) testing for *HER2* gene amplification. *HER2* amplification was defined as *HER2/CEP17* ratio ≥2.0. Clinical characteristics were evaluated in relation to *HER2* status. **Results:** The incidence of clinically evidence brain metastases in this cohort of CRC patients was 2% (40 of 1920). *HER2* amplification was observed in 20% (8 of 40) of CRC patients who develop brain metastases. *HER2* amplification was observed across most CRC primary sites (4 rectum, 3 right colon and 1 left colon) and was also seen in *KRAS* mutant CRC (2 of 8 patients). Mean *HER2* copy number of *HER2* positive (*HER2+)* patients was 10.7 (range 5.7 – 17.5). Brain metastases was preceded by metastases in either the lung or liver in 95% of patients (38 or 40) including all of the *HER2+* patients. In 1 patient, *HER2+* brain metastases was observed after Trastuzumab/Lapatinib therapy. **Conclusions:** Brain metastases in CRC is rare. However, compared to a reported *HER2* positive rate of 5% amongst 912 KRAS wild-type metastatic CRC patients in the HERACLES study and 0% (0/44) amongst KRAS mutant patients reported in literature, *HER2* amplification was observed in 20% (8 of 40) of all CRC patients in our study who develop brain metastases. This is one of the first studies to point to *HER2+* disease being enriched amongst patients with brain metastases providing insight into a potential organotrophic site of metastases in *HER2+* positive CRC.

3613 Poster Session (Board #106), Sun, 8:00 AM-11:30 AM

Age-related real-world outcomes for patients (pts) with metastatic colorectal cancer (mCRC). *First Author: Melissa Curtis, Flatiron Health, New York, NY*

Background: There are scant data regarding the diagnosis, treatment, and outcomes for mCRC pts diagnosed at a very young age (< 30 yrs). We therefore explored age-related pt and tumor characteristics, treatment patterns and OS among mCRC pts treated in routine clinical practice. **Methods:** We retrospectively analyzed a national sample of pts ≥18 yrs old with confirmed mCRC diagnosed on or after 01/1/2014 (N = 10,990) using the Flatiron Health database. Descriptive statistics summarized pt and tumor characteristics and treatment patterns. Overall survival (OS) was indexed to mCRC diagnosis date. OS curves were estimated with Kaplan-Meier method. P-values were calculated for trend across all age groups. **Results:** Pt characteristics, mutation testing and 1st-line (1L) therapy trends differed significantly across age groups (results for < 30 and > 70 yrs age groups in Table). Median OS significantly differed by age, with a peak for those 40-49 yrs at diagnosis: 21.8 mos (< 30 yrs), 21.0 mos (30-39 yrs), 27.5 mos (40-49 yrs), 26.5 mos (50-59 yrs), 22.3 mos (60-69 yrs), 15.8 mos (> 70 yrs), p-value < 0.0001. **Conclusions:** 1L treatment and OS for mCRC pts differed significantly by age at diagnosis in unadjusted analysis. Despite more often receiving 1L aggressive therapy (FOLFOX/FOLFIRI/FOLFOXIRI +/- ab), younger age groups had worse OS compared to all other age groups except > 70 yrs. Over-representation (compared to US 2010 census) of young African Americans supports earlier screening. Documentation of standard mutational testing significantly differed by age, and mutation positivity differed for BRAF. These findings suggest that a complex interplay between biologic, diagnostic and treatment factors may affect age- and race-based disparities in mCRC outcomes.

	Age group (yrs)

3614 Poster Session (Board #107), Sun, 8:00 AM-11:30 AM

Effects of proton pump inhibitors (PPIs) on FOLFOX and XELOX regimens in colorectal cancer (CRC). *First Author: Grace Wong, Cross Cancer Institute, Edmonton, AB, Canada*

Background: First-line adjuvant chemotherapy options for stage II-III CRC include XELOX (capecitabine (cape), oxaliplatin) and FOLFOX (oxaliplatin, leucovorin, 5FU). Cape is an oral 5FU prodrug, and recent studies suggested that PPIs may detrimentally affect cape efficacy. Conversely, some literature posits that PPIs may negatively impact CRC itself. Our primary objective was to compare 3-year recurrence-free survival (RFS) rates between XELOX-treated PPI-users and non-PPI users, and FOLFOX-treated PPI users and non-PPI users. Our main secondary objective was to compare overall survival (OS). **Methods:** We conducted a retrospective chart review of 389 stage II-III CRC patients (pts) who received adjuvant XELOX or FOLFOX from a tertiary cancer center in Alberta, Canada between 2004-2013. Information regarding PPI use, cancer treatment, and pt outcomes were gathered and analyzed from pharmacy databases. **Results:** 23.4% of XELOX-treated pts and 28.0% of FOLFOX -treated pts used PPIs concurrently with treatment. 3-year RFS was significantly lower in XELOX-treated PPI pts than non-PPI pts (69.5 vs. 82.6%, $P = 0.029$). Unadjusted analysis showed that XELOX-treated PPI pts were twice as likely to experience cancer recurrence or death as XELOX-treated non-PPI pts (HR 2.03, $P = 0.033$). FOLFOX-treated PPI pts had a non-significant increase in three-year RFS versus non-PPI pts (82.9 vs. 61.7%, $P = 0.066$), and no significant difference in recurrence or death (HR 0.51, $P = 0.071$). No significant differences were seen in OS. **Conclusions:** Our results suggest that PPIs negatively impacted RFS in early-stage XELOX-treated CRC pts, and yielded no significant effect amongst FOLFOX-treated patients. Further studies are required to corroborate our findings.

RFS in stage II-III CRC.

Chemotherapy	Overlapping PPI use	3-year RFS (%)	*P* value
FOLFOX	Yes (n = 49)	82.9	0.066
	No (n = 126)	61.7	
XELOX	Yes (n = 50)	69.5	0.029
	No (n = 164)	82.6	

Cox Proportional Hazards Model: RFS Analysis

Patients analyzed	HR	*P* value
XELOX PPI vs. no PPI	2.03	0.033
FOLFOX PPI vs. no PPI	0.51	0.071
PPI XELOX vs. FOLFOX	1.93	0.161
No PPI XELOX vs. FOLFOX	0.41	< 0.001

TPS3615 Poster Session (Board #108a), Sun, 8:00 AM-11:30 AM

Colorectal Cancer Metastatic dMMR Immuno-Therapy (COMMIT) study (NRG- GI004/SWOG-S1610): A randomized phase III study of mFOLFOX6/ bevacizumab combination chemotherapy with or without atezolizumab or atezolizumab monotherapy in the first-line treatment of patients with deficient DNA mismatch repair (dMMR) metastatic colorectal cancer. *First Author: James J. Lee, NSABP Foundation, and The University of Pittsburgh, Pittsburgh, PA*

Background: DNA mismatch repair defect (dMMR) colorectal cancer (CRC) cells are highly immunogenic. Preclinical data showed that oxaliplatin-containing chemotherapy in combination with anti-VEGF enhances the antitumor activity of programmed cell death-1 (PD-1) pathway blockade in murine CRC models. Prior phase I study showed that mFOLFOX6/ bevacizumab (bev) plus atezolizumab was well tolerated and enhanced intratumoral infiltration of $CD8^+$ T cells. We hypothesize that the dMMR subset of CRC may be effectively targeted with the combination of PD-1 pathway blockade and mFOLFOX6/bev to promote tumor regression. **Methods:** This is a prospective randomized phase III open-label trial. Patients (pts) (N=347) with metastatic dMMR CRC will be randomized to 3 trial arms (1:1:1): mFOLFOX6/bev; atezolizumab monotherapy; or mFOLFOX6/ bev plus atezolizumab. Stratification factors include *BRAF* status, metastatic site, and prior adjuvant therapy for CRC. Primary objective is to evaluate the efficacy of mFOLFOX6/bev/atezolizumab and atezolizumab monotherapy as compared to mFOLFOX6/bev. Primary endpoint is progression-free survival (PFS) assessed by study investigator. Secondary endpoints include overall survival, objective response rate, safety profile, surgical conversion rate, disease control rate, duration of response, and PFS by retrospective central review. Exploratory objective includes health-related quality of life. Archived tumor tissue and blood samples will be collected for correlative studies. Key inclusion criteria are: Metastatic CRC without prior chemotherapy for metastatic disease; Tumor determined to be dMMR by local CLIA-certified IHC assay (MLH1/MSH2/MSH6/PMS2); Availability of archived tumor tissue for central confirmation of dMMR status; and measurable disease per RECIST. Activated as of Nov 7, 2017, the 1st of the planned 347 pts has been enrolled. **Clinical trial #:** NCT02997228. **SUPPORT:** U10CA180868, -180822, UGICA189867, U24CA196067 Clinical trial information: NCT02997228.

TPS3616 Poster Session (Board #108b), Sun, 8:00 AM-11:30 AM

Novel PET/CT imaging biomarkers of CB-839 in combination with panitumumab and irinotecan in patients with metastatic and refractory RAS wildtype (WT) colorectal cancer: A phase I/II study. *First Author: Satya Das, Vanderbilt University Medical Center, Nashville, TN*

Background: Irinotecan plus panitumumab is active in RAS WT metastatic CRC (mCRC) patients who progress on 5-FU based regimens. Inevitably, patients develop resistance to EGFR inhibition; one such pathway is mediated by the enzyme glutaminase, which converts glutamine to glutamate and is a downstream effector of the EGFR/RAS pathway. Inhibition of this pathway with the selective glutaminase inhibitor CB-839 has stopped growth of cetuximab-sensitive and -resistant HLA-7 CRC cell lines. Greater antitumor response with the doublet of cetuximab (or panitumumab) and CB-839 was seen in mouse xenografts of the human CRC line SW48 than with either agent alone. Given this data, we proposed the combination of CB-839 plus panitumumab in RAS WT mCRC patients; to demonstrate on target effect of the therapy, we are utilizing two PET tracers, one which recognizes glutamine and the other glutamate. In addition to safety and efficacy aims, another aim of our study is to correlate SUV changes in pre-treatment and post-cycle 1 carbon-11-labeled glutamine (11C-glutamine) and (4S)-4-(3-[18F]fluoropropyl)-L-glutamate (18F-FSPG) PET with clinical outcome and glutamate levels in plasma. **Methods:** NCT03263429 is a single arm phase I/II study exploring the combination of CB-839, panitumumab ± irinotecan in RAS WT mCRC patients with at least one prior line of chemotherapy exposure. Phase I has 2 dose levels of CB-839 BID (600 mg and 800 mg) administered with panitumumab 6 mg/kg and irinotecan 180 mg/m2 D1 and D15 each 28-day cycle. Dose escalation is being performed according to a Bayesian continual reassessment method. The Phase II study evaluates CB-839's ability to reverse panitumumab resistance in EGFR inhibitor refractory patients. Irinotecan is included in the phase I for future potential studies in panitumumab-naïve patients. The primary objectives of the phase I and II portions of the study are to demonstrate the maximum tolerated dose and overall response rate of the combination, respectively. A Simon two-stage design is being used in phase II; if ≥ 1 response is seen in the first 10 patients, accrual will continue until 29 patients are enrolled. Clinical trial information: NCT03263429.

TPS3617 Poster Session (Board #109a), Sun, 8:00 AM-11:30 AM

NuTide 302: A phase IB study to assess the safety, pharmacokinetics and clinical activity of NUC-3373 in combination with standard agents used in colorectal cancer treatment. *First Author: Sarah Patricia Blagden, University of Oxford, Oxford, United Kingdom*

Background: 5-FU and its other forms, floxuridine and capecitabine, exert their anti-cancer activity mainly due to the active metabolite, fluorodeoxyuridine-monophosphate (FUDR-MP), which inhibits the enzyme thymidylate synthase (TS). Although these agents remain the cornerstone of combination treatments for colorectal cancer (CRC), key cancer resistance mechanisms of breakdown, activation and transport limit their effectiveness. NUC-3373 is a phosphoramidate transformation of FUDR-MP designed to bypass the key resistance mechanisms associated with 5-FU. NuTide 301 is an ongoing first-in-human study of NUC-3373 in patients with advanced solid tumors. PK/PD data obtained to date demonstrate NUC-3373 has a long plasma $t_{1/2}$ (9.7 h v 8-14 mins for 5-FU) and generates high levels of the active intracellular anti-cancer metabolite, FUDR-MP (Ghazaly *et al* ESMO, 2017). TS is efficiently inhibited and sequestered into TS-ternary complexes (TS-T), depleting the pool of dTMP within 2-4 hours. **Methods:** NuTide:302 is a two-part, Phase Ib study in patients with CRC who have relapsed after ≥2 prior lines of therapy. The primary objective is to identify a recommended NUC-3373 dose when administered every 2 weeks in combination with standard agents used in CRC treatment. Secondary objectives included safety, PK/PD and anti-tumor activity. In Part 1, NUC-3373 is being administered with leucovorin (LV) to determine if the folate is beneficial in the formation of TS-T. Approximately 12 patients will be enrolled in Part 1 of the study. If LV augments TS-T formation, it will be administered in Part 2. In Part 2, the following combination agents will be administered with NUC-3373 (±LV): oxaliplatin; oxaliplatin + bevacizumab; oxaliplatin + panitumumab; irinotecan; and irinotecan + cetuximab. In Part 2, patients will be enrolled in cohorts of 3-6, in a modified 3+3 design. Up to 62 patients will be recruited, depending on cohort expansion. Clinical trial information: NCT03428958.

TPS3618 Poster Session (Board #109b), Sun, 8:00 AM-11:30 AM

First-line treatment with panitumumab plus FOLFIRI in elderly patients with *RAS/BRAF* wild-type unresectable metastatic colorectal cancer and good performance status: OPALO trial. *First Author: Jaime Feliu, Hospital Universitario La Paz, Madrid, Spain*

Background: Approximately 60% of colorectal cancer (CRC) patients are ≥ 70 years, of whom 50-60% already have metastasis at the time of diagnosis. Available data indicate that elderly patients with good performance status may, like younger patients, benefit from intensive treatment approaches. The objective of this trial is to assess the efficacy and safety of first-line therapy with panitumumab + FOLFIRI in elderly patients with *RAS/BRAF* wild-type unresectable metastatic colorectal cancer and good performance status. **Methods:** OPALO is a phase II, single-arm, multicentre clinical trial. Primary objective: progression-free survival (PFS) at one year. Main eligibility criteria: 1. Patients ≥70 years; 2. colorectal carcinoma with unresectable metastatic disease; 3. *RAS/BRAF* wild-type status; 4. Independence in activities of daily living (ADL) based on the Katz Index and in instrumental activities of daily living (IAL) based on the Lawton Index; 5. To have one or no comorbidity according to the Charlson Comorbidity Index; 6. Patients starting therapy with FOLFIRI + panitumumab with a treatment aim other than achieving potential resectability of the disease. Treatment: all patients are receiving panitumumab (6 mg/kg) plus FOLFIRI every two weeks. Tumour response is evaluated every 8 weeks till disease progression. A blood sample is taken at baseline and at the time of disease progression to determine the *RAS/BRAF* mutation status. Statistical design: a sample size of 80 patients is deemed appropriate (assuming a precision of 11.45%, a two-sided confidence interval of 95%, a proportion of interest of 60% and a loss to follow-up rate of 10%). The recruitment of patients has begun in October 2017.

TPS3619 Poster Session (Board #110a), Sun, 8:00 AM-11:30 AM

ABT-165 plus FOLFIRI vs bevacizumab (bev) plus FOLFIRI in patients (pts) with metastatic colorectal cancer (mCRC) previously treated with fluoropyrimidine/oxaliplatin and bev. *First Author: Zev A. Wainberg, David Geffen School of Medicine at UCLA, Los Angeles, CA*

Background: The dual variable domain immunoglobulin ABT-165 targets human vascular endothelial growth factor (VEGF) and delta-like ligand 4 (DLL4). Combined VEGF and DLL4 blockade increased inhibition of subcutaneous xenograft growth of human colon cancer-derived cell lines vs blockade of either axis alone. *In vivo*, ABT-165 plus chemotherapy (CT) induced tumor regression with improved efficacy, vs anti-VEGF monoclonal antibody plus CT. In a phase 1 study, a tolerable recommended phase 2 dose was identified for ABT-165 plus FOLFIRI and showed promising efficacy. This phase 2 trial in progress assesses the efficacy/safety of ABT-165 plus FOLFIRI vs bev plus FOLFIRI in pts with second-line mCRC. **Methods:** This is an open-label, multicenter, phase 2 randomized (1:1) trial (NCT03368859) in pts (≥18 years; Eastern Cooperative performance status: 0–1) with histologically/cytologically confirmed mCRC who progressed after fluoropyrimidine/oxaliplatin and bev. ABT-165 (2.5 mg/kg) plus FOLFIRI (irinotecan: 180 mg/m^2; leucovorin: 400 mg/m^2; fluorouracil bolus: 400 mg/m^2, infusion: 2400 mg/m^2) or bev (5 mg/kg) plus FOLFIRI are given intravenously on day 1 of each 14-day cycle, until disease progression/intolerable toxicity. The primary endpoint is progression-free survival (PFS). Secondary endpoints include overall survival (OS), objective response rate (ORR), and safety. Exploratory endpoints include biomarkers predictive for efficacy/safety, correlation of DLL4 levels with PFS, OS, and ORR, pharmacodynamic effects, and the efficacy/safety-exposure relationships in the ABT-165 arm. The hazard ratios of PFS and OS comparing the 2 groups are estimated using the Cox proportional hazard model. Kaplan-Meier methodology is used to estimate the PFS and OS curves, median PFS and OS, and their 90% confidence intervals. Safety is assessed by ABT-165 exposure, adverse events (AEs), serious AEs, all deaths, and changes in laboratory data and vital signs. Archival tissue is collected and evaluated for DLL4 expression and angiogenesis signature. Approximately 100 pts are planned to be enrolled, with recruitment initiated in January 2018. Clinical trial information: NCT03368859.

TPS3620 Poster Session (Board #110b), Sun, 8:00 AM-11:30 AM

A randomized phase II study of trastuzumab and pertuzumab (TP) compared to cetuximab and irinotecan (CETIRI) in advanced/metastatic colorectal cancer (mCRC) with HER2 amplification: S1613. *First Author: Kanwal Pratap Singh Raghav, Department of GI Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Despite advances in systemic therapy, few patients are cured, creating a large unmet need for strategies targeting novel signaling and resistance pathways. The HER2 pathway, which has been successfully targeted in breast and gastric cancer, is one such unique potential target in mCRC. HER2 amplifications (HER2amp) have been identified in a small but distinct subset (6-8%) of KRAS wild-type mCRC. HER2amp is associated with resistance to anti-EGFR therapy (cetuximab/panitumumab) and short progression-free survival (PFS) (< 3 mos.) (*Raghav ASCO 2016*). Preliminary clinical data (MyPathway Study) has shown promising activity of dual-anti-HER2 inhibition using TP in HER2amp and KRAS wild-type mCRC (Response rate 52%, 95% CI 31 - 72%; and median PFS 5.7 months, 95% CI 4 – 12 mos.) (*Hurwitz GIASCO 2017*). **Methods:** S1613 is a multicenter, randomized phase 2 study assessing efficacy of TP relative to CETIRI in HER2amp mCRC. This is a 2 step study. All anti-EGFR naïve mCRC patients (pts) without known activating mutations in KRAS/NRAS/BRAF will be screened in step 1 for HER2amp by a central lab using immunohistochemistry and dual-probe in-situ hybridization. Screening can be performed at any time, even during treatment on 1st/2nd line of therapy. If HER2amp positive, pts will be randomized in step 2 after progression on 1st/2nd lines of therapy to either TP [pertuzumab (840mg loading dose + 420mg every 3 weeks) and trastuzumab (8mg/kg loading dose + 6mg/kg every 3 weeks)] or CETIRI [irinotecan (180 mg/m2 IV every 14 days) and cetuximab (500 mg/m2 IV every 14 days)]. Prior irinotecan is allowed. Crossover to TP will be allowed after progression on CETIRI arm. A total of 122 eligible patients will provide 80% power to detect an increase in median PFS to 5.1 months from 3 months (HR 0.59) based on a two-sided type I error of 5%, 33 months of accrual and 7 months of follow-up. The primary endpoint of PFS will be analyzed in all eligible patients per intent-to-treat. Randomization will be stratified by prior use of irinotecan and HER2/CEP17 ratio. The study is now activated and open to enrollment to all NCI - NCTN institutions. Clinical trial information: NCT03365882.

TPS3621 Poster Session (Board #111a), Sun, 8:00 AM-11:30 AM

Physical activity program in patients with metastatic colorectal cancer who receive palliative first-line chemotherapy: A randomized controlled phase III trial—(ACTIVE-2 SAKK 41/14). *First Author: Viviane Hess, University of Basel and University Hospital Basel, Medical Oncology, Basel, Switzerland*

Background: Exercise has become a main focus of basic and clinical research worldwide during the current pandemic of physical inactivity. A clear link between inactivity and cancer incidence/relapse has been established, particularly for colon cancer, the third most common cancer. However, whether exercise has an impact on disease course and survival in advanced disease is unknown. Exercise modifies key host factors that are determinants of chemotherapy efficacy such as metabolic and immunologic tumor microenvironment, drug tolerability and treatment adherence. Thus, we aim to assess whether a supervised exercise program concomitant to first-line palliative chemotherapy for patients with metastatic colorectal cancer (mCRC) enhances chemotherapy efficacy and, therefore, increases survival and decreases symptom burden as compared to patients treated with chemotherapy alone. **Methods:** Patients with newly diagnosed mCRC are stratified (pre-diagnosis physical fitness, RAS-mutational status, primary tumor location, alkaline phosphatase levels) and randomly assigned to undergo standard systemic treatment and care-as-usual or standard systemic treatment combined with a 12-week structured physical activity (PA) program with twice weekly supervised, heart-rate guided interval training on a bike ergometer. Both groups undergo regular imaging with CT/MRI in order to assess the 1°endpoint of progression-free survival (PFS), i.e. the time between diagnosis and disease progression or death. Radiologists who are blinded to the group assignment will review imaging. A total of 439 events occurring in 524 patients will be needed to show a clinically meaningful HR of 0.75 for PFS with 80% power and an α of 0.03. Co-primary endpoint is self-reported symptom burden as measured by the revised Edmonton Symptom Assessment Scale (rESAS). 50 patients from 17 Swiss and Austrian Centers have been randomized. A planned feasibility analysis of the first 40 patients is ongoing. Clinical trial information: NCT02597075.

TPS3622 Poster Session (Board #111b), Sun, 8:00 AM-11:30 AM

PRODIGE 52-UCGI 29-CCTG/CO.27 (IROCAS): A multicenter, international, randomized phase III trial comparing adjuvant modified (m)FOLFIRINOX to mFOLFOX6 in patients with high-risk stage III (pT4 and/or N2) colon cancer (a UNICANCER GI-PRODIGE trial). *First Author: Jaafar Bennouna, Centre Hospitalier Universitaire Nantes, Digestive Oncology, Nantes, France*

Background: According to the IDEA trial (Shi Q et al. ASCO 2017;LBA1), 6-month adjuvant chemotherapy should remain the standard in stage III T4 or N2 colon cancer. The relatively poor survival in this high-risk subgroup (3-year disease-free survival ([DFS] rate, 66%) and the potential synergistic efficacy of 5-fluorouracil (5-FU), oxaliplatin, and irinotecan (demonstrated in stage IV colon and pancreatic cancers) suggest FOLFIRINOX as a regimen of particular interest in this setting. **Methods:** This multicenter, international, phase III trial (NCT02967289) conducted in 47 centers in France and Canada, plans to include 640 patients, aged 18 to 70 years, ECOG performance status $\leq$1, within 42 days (start treatment, within 56 days) after curative-intent R0 surgical resection of a pT4N1 or pT1-4N2 colon adenocarcinoma. Patients are randomized (1:1; minimization method) between adjuvant mFOLFIRINOX (oxaliplatin 85 mg/m^2, leucovorin 400 mg/m^2, irinotecan 150 mg/m^2, and 5-FU 2.4 g/m^{2}over 46 h) or mFOLFOX6 (oxaliplatin 85 mg/m^2, leucovorin 400 mg/m^2, 5-FU bolus 400 mg/m^2 then 2.4 g/m^{2}over 46 h), every two weeks for 24 weeks (12 cycles). Patients will be followed up for 5 years after the end of adjuvant chemotherapy. A gain of 9% in 3-yr DFS (primary endpoint) is expected (74% in the experimental arm vs. 65% in the control arm; α, 5% [two-sided log-rank test]; 1-b, 80%). Secondary endpoints include 2-yr DFS, overall survival, and toxicity. Since April 2017, 49 patients have been enrolled to date (accrual period, 4 years). Clinical trial information: NCT02967289.

TPS3623 Poster Session (Board #112a), Sun, 8:00 AM-11:30 AM

Phase I trial of TAS-102 and concurrent radiation therapy for patients with locally recurrent, unresectable or metastatic, rectal cancer. *First Author: Joleen Marie Hubbard, Mayo Clinic, Rochester, MN*

Background: After primary therapy for rectal cancer (chemotherapy, surgery, and/or radiotherapy), 7-10% of patients will develop locally recurrent disease. Re-irradiation +/- resection of recurrent rectal cancer is possible for select patients. Trifluridine/tipiracil (TAS-102) is a combination nucleoside analog and thymidine phosphorylase inhibitor (TPI) with activity in colorectal cancer refractory to fluoropyrimidines. Trifluridine has a similar mechanism of action as the fluoropyrimidines, which are known radiosensitizing agents, and pre-clinical data shows TPI can potentiate the effects of radiation on colon cancer cell lines. TAS-102 in combination with radiation therapy may have a synergistic effect treating recurrent rectal cancers in patients previously exposed to a fluoropyrimidine. The primary objective of this trial is to determine the maximum tolerated dose and dose-limiting toxicity of TAS-102 when administered in combination with concurrent radiation therapy in patients with locally recurrent rectal cancer. **Methods:** This is a phase I trial with a standard 3 + 3 dose escalation design (see table). All patients will receive TAS-102 administered PO twice daily on days 1-5 and days 8-12. All patients will also receive radiation therapy at a dose of 300 cGy/day, for a total dose of 3000 cGy in 10 fractions, Monday through Friday for days 1-5 and days 8-12. Patients $\geq$ 18 years with histological confirmation of locally recurrent rectal adenocarcinoma within the pelvis after primary therapy are eligible. Patients with pelvic disease that is resectable or unresectable and metastatic disease outside the pelvis are allowed. Patients with the first occurrence of rectal cancer amenable to treatment with trimodality therapy will be excluded. Prior treatment with TAS-102 and cancer treatment $\leq$ 28 days prior to registration is not allowed. Patients with prior pelvic radiation therapy $>$ 54 Gy are ineligible. This trial is currently accruing patients to the first cohort. Clinical trial information: NCT03297710.

Dose Level	Dose	**TAS-102 Dose (2X daily)
-1	-57%	15 mg/m^2
0*	-43%	20 mg/m^2
1	-29%	25 mg/m^2
2	-14.3%	30 mg/m^2
3	100%	35 mg/m^2

*Starting dose. **Round dose to the nearest 5 mg. Maximum dose 80 mg.

TPS3624 Poster Session (Board #112b), Sun, 8:00 AM-11:30 AM

NSABP FR-2: Phase II study of durvalumab following neoadjuvant chemotherapy (NAC) in stage II-IV rectal cancer. *First Author: Thomas J. George, NSABP Foundation and The University of Florida Health Cancer Center, Gainesville, FL*

Background: Locally-advanced rectal cancer (LARC) remains a clinical challenge with few improvements noted over the past few decades. Although immunotherapy has no current clinical role in microsatellite stable (MSS) colorectal cancer, preclinical models suggest that radiotherapy (RT) can induce neoantigen presentation, modulate the microenvironment, and improve the likelihood of immunogenic activation with checkpoint inhibitor use. This prospective phase II study will test that hypothesis in addition to confirming safety of this approach using a "window-of-opportunity" study design with the anti-PDL1 agent durvalumab (MEDI4736). **Methods:** This multi-center phase II trial is currently enrolling patients (pts) with rectal cancer who are undergoing standard NCCN guideline-compliant NAC and RT. Eligibility includes pts with MSS stage II-IV rectal cancer with adequate organ function and pre-treatment diagnostic tumor available for profiling who are undergoing NAC with intentions to proceed to surgical resection. Stage IV disease must be limited such that the primary pelvic tumor requires definitive management. Standard ineligibility criteria include active infections, systemic steroid use, or other conditions making immunotherapy use unsafe. Treatment includes durvalumab (750mg IV infusion once every 2 wks) for 4 total doses beginning within 3-7 days after NAC completion. Surgery must be within 8-12 wks of the final RT dose. Primary endpoint is a demonstrated improvement in Neoadjuvant Rectal Cancer (NAR) score compared to historical controls representing a 20% relative risk reduction in DFS HR and 3-4% absolute OS improvement. Secondary endpoints include comparisons of OS, DFS, toxicity, pCR, cCR, therapy completion, negative surgical margins, sphincter preservation, off-target "abscopal" effects for the subset of stage IV pts, and exploratory assessments of tumor infiltrating lymphocytes, circulating immunologic profiles, and molecular predictors of response. A safety run-in portion of the study will precede full enrollment. Enrollment continues to 47 total pts to achieve 41 surgically evaluable pts. Support: AstraZeneca-Medimmune, NSABP Foundation Clinical trial information: NCT03102047.

4000 **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

FOLFIRINOX until progression, FOLFIRINOX with maintenance treatment, or sequential treatment with gemcitabine and FOLFIRI.3 for first-line treatment of metastatic pancreatic cancer: A randomized phase II trial (PRODIGE 35-PANOPTIMOX). *First Author: Laetitia Dahan, La Timone University Hospital, Marseille, France*

Background: Metastatic pancreatic cancer (mPC) still harbors a dismal prognosis (5-year overall survival [OS] <5%). Our previous trial (PRODIGE4-ACCORD11) has demonstrated the superiority of 6-month [m] chemotherapy with FOLFIRINOX over gemcitabine in terms of progression-free survival [PFS] (6.4 vs. 3.3 m; HR: 0.47; 95%CI: 0.37-0.59; p<0.001) and OS (11.1 vs. 6.8 m; HR: 0.57; 95%CI: 0.45-0.73; p<0.001), at the expense of higher toxicity, notably cumulative, often limiting, peripheral neuropathy with oxaliplatin. In this randomized Phase II trial, we aimed to assess an oxaliplatin 'stop-and-go' strategy and an alternative sequential strategy in mPC. **Methods:** Patients (pts) were randomized to receive either 6m FOLFIRINOX (arm A), 4m FOLFIRINOX followed by LV5FU2 maintenance treatment for controlled pts, and treatment reintroduction at disease progression (arm B), or a sequential treatment alternating gemcitabine and FOLFIRI.3 every 2m (arm C). The primary endpoint was to evaluate the 6m-PFS rate (H0: 30%, H1: 45%, Fleming design) in order to select the best therapeutic strategy for a future Phase III clinical trial. **Results:** Between Jan 2015 and Nov 2016, 273 pts (mean age: 63 years; range: 40-76) were enrolled (A: 91; B: 92; C: 90). The median durations of treatment were 5.1, 6.2, and 4.4 m in A, B, and C respectively. Grade 3/4 neurotoxicity occurred in 10% of pts in arm A and 19% of pts in arm B. Median ratio of oxaliplatin was 83% in A and 92% in B. 6m-PFS rates were 47% in A, 44% in B, and 34% in C. 4m objective response rates were 35% in A, 41% in B, and 17% in C. Median PFS was respectively 6.3, 5.7 and 4.5 m in A, B and C. Median OS was 10.1 in A, 11.2 in B and 7.3 m in C. The median duration of first maintenance therapy in B was 3.3 m (range: 0.03-22.6). **Conclusions:** Maintenance with LV5FU2 appears to be feasible and effective in patients with mPC controlled after 4m of induction chemotherapy with FOLFIRINOX. Severe neurotoxicity rate was higher in the maintenance therapy arm, likely because of higher cumulative oxaliplatin dose.[1]*Conroy NEJM 2011.* Clinical trial information: NCT02352337.

4003 **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

REACH-2: A randomized, double-blind, placebo-controlled phase 3 study of ramucirumab versus placebo as second-line treatment in patients with advanced hepatocellular carcinoma (HCC) and elevated baseline alpha-fetoprotein (AFP) following first-line sorafenib. *First Author: Andrew X. Zhu, Harvard Medical School, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Patients (pts) with advanced HCC and elevated AFP have a poorer prognosis compared to the general HCC population, and need effective, well tolerated treatment options. Increased VEGF and VEGFR2 expression is associated with high AFP expression in HCC tumors. Ramucirumab (RAM), a human IgG1 mAb, inhibits activation of VEGFR2. REACH-2 was designed to confirm the benefit of RAM treatment observed in the REACH study in pts with baseline AFP ≥400 ng/mL. **Methods:** Eligible pts were ≥18 yrs, had HCC with BCLC stage C or B disease refractory or not amenable to locoregional therapy, baseline AFP ≥400 ng/mL, Child-Pugh A, ECOG PS 0 or 1, adequate hematologic and biochemical parameters, had progressed on or following, or were intolerant to sorafenib. Pts were randomized (2:1) to receive RAM 8 mg/kg iv or placebo (PL) Q2W plus best supportive care, until disease progression or unacceptable toxicity. Primary endpoint was overall survival (OS). Secondary objectives included progression-free survival (PFS), objective response rate (ORR) per RECIST v1.1 and safety. **Results:** 292 pts were randomized to RAM (197) or PL (95). Baseline characteristics were generally balanced between arms. RAM treatment significantly improved OS (median OS 8.5 mo vs 7.3 mo PL; HR 0.710; 95% CI 0.531, 0.949; p=.0199). RAM significantly improved PFS (median PFS 2.8 mo vs 1.6 mo PL; HR 0.452; 95% CI 0.339, 0.603; p<.0001). ORR was 4.6% RAM vs 1.1% PL (p=.1156) and disease control rate (ORR + stable disease) was 59.9% RAM vs 38.9% PL (p=.0006). Grade ≥ 3 adverse events occurring in ≥ 5% pts in the RAM arm were hypertension (12.2% RAM, 5.3% PL) and hyponatremia (5.6%, 0%). **Conclusions:** REACH-2 met its primary endpoint showing a significant survival benefit, with RAM treatment reducing the risk of death (29%) in pts with HCC and AFP ≥ 400 ng/mL who progressed on or were intolerant to sorafenib. Treatment was well tolerated, with a safety profile consistent with the established profile for single agent RAM. REACH-2 is the first positive phase 3 study conducted in a biomarker-selected pt population with HCC. Clinical trial information: NCT02435433.

4004 **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

A randomized study of temozolomide or temozolomide and capecitabine in patients with advanced pancreatic neuroendocrine tumors: A trial of the ECOG-ACRIN Cancer Research Group (E2211). *First Author: Pamela L. Kunz, Stanford University School of Medicine, Stanford, CA*

Background: Patients with advanced pancreatic neuroendocrine tumors (pNETs) have few treatment options that yield objective tumor regression. Somatostatin analogues, everolimus, and sunitinib yield prolonged progression-free survival (PFS) but low response rates (RRs). Retrospective and small, prospective studies suggest that temozolomide-based therapies may have activity and the combination of temozolomide and capecitabine (TC) is associated with high RRs and relative long PFS. However, there are no randomized, prospective studies of these agents and this trial was initiated to establish a role for the combination of TC. **Methods:** E2211 was a two-arm, randomized, phase II trial comparing T (200 mg/m2 PO QD days 1-5) vs. TC (T 200 mg/m2 PO QD days 10-14; C 750 mg/m2 PO BID days 1-14) in patients with advanced pNETs. Eligibility criteria included: metastatic or unresectable, low or intermediate grade pNETs, progression within preceding 12 months, and no prior T, C, DTIC, or 5-FU. The primary endpoint was PFS; secondary endpoints were Overall Survival (OS), RR, safety, and predictive value of MGMT as evaluated by immunohistochemistry and promoter methylation. This trial had at least 81% power to detect a difference in median PFS of 9 vs. 14 months (hazard ratio of 0.64) using a two-sided log-rank test at the 0.20 significance level. **Results:** 144 patients were enrolled at 66 US sites between 8/2013 to 3/2016 to T (n = 72) or TC (n = 72) (intention to treat population). Median age, 62 years; women, 44%. Median PFS was 22.7 months for TC vs. 14.4 months for T (HR = 0.58, p = 0.023) and crossed the pre-specified protocol efficacy boundary. Median OS was 38.0 months for T and has not been reached for TC (HR = 0.41, p = 0.012). Median follow-up was 29 months. RR data will be presented at the meeting. The treatment was well-tolerated with expected AEs and higher rates in the combination arm. **Conclusions:** In E2211, TC was associated with improved PFS and OS compared to T alone in advanced low or intermediate grade pNETs. This is the first prospective randomized trial of these agents and shows the longest PFS reported for pNET-directed therapy. Clinical trial information: NCT01824875.

4005 **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

Azedra (iobenguane I 131) in patients with malignant, recurrent and/or unresectable pheochromocytoma or paraganglioma (PPGL): Updated efficacy and safety results from a multi-center, open-label, pivotal phase 2 study. *First Author: Daniel Pryma, Abramson Cancer Center of the University of Pennsylvania, Philadelphia, PA*

Background: AZEDRA, a high-specific-activity iodine-131 meta-iodobenzylguanidine (HSA I-131 MIBG), has been developed for the treatment of iobenguane-avid malignant (metastatic) or recurrent or unresectable pheochromocytoma or paraganglioma (PPGL). **Methods:** MIBG-avid PPGL patients (pts) ineligible for curative surgery or chemotherapy, and on a stable antihypertensive regimen for tumor-related hypertension were enrolled. Pts received a dosimetric dose (111-222 MBq) followed by up to 2 therapeutic doses (each at 296 MBq/kg to a maximum of 18.5 GBq) approximately 3 months (mths) apart. Pts were followed for 12-mths (efficacy period) and an additional 4 years for long-term follow-up. The primary endpoint was defined as proportion of pts with at least 50% reduction, including discontinuation, of all antihypertensive medications lasting ≥6 mths beginning during the efficacy period. Secondary endpoints included objective tumor response (OTR) by RECIST and overall survival (OS). **Results:** Of 81 pts enrolled, 74 pts received a dosimetric dose of AZEDRA. 68 pts received 1 therapeutic dose (full analysis; FA) and 50 received two (per protocol; PP). At study entry, 52% (35/68) had prior surgery and systemic therapy (I-131 MIBG and/or chemotherapy) for PPGL. 50% (32/64) of evaluable pts had lung and/or liver metastases at baseline. The primary endpoint was met by 25% (95% CI 16%-37%) of FA and 32% (95% CI 21%-46%) of PP pts, achieving pre-specified success criteria. For OTR, 23% and 30% of FA and PP populations achieved partial response (PR). The 12-month OS was 91% in FA pts. Median OS was 36.7 mths (95% CI 29.9, 49.1), and median survival appeared similar in pts with and without lung/liver metastasis at baseline (42.6 and 41.1 mths, respectively). The most common (≥50%) treatment-emergent adverse events were myelosuppression, nausea, and fatigue. No acute drug-related hypertensive events were observed. **Conclusions:** Updated results from this pivotal phase 2 study suggest that AZEDRA is an efficacious and safe treatment for an ultra-orphan disease with no approved therapies in the United States. Clinical trial information: NCT00874614.

4007 **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

A randomized phase III study comparing S-1 plus docetaxel with S-1 alone as a postoperative adjuvant chemotherapy for curatively resected stage III gastric cancer (JACCRO GC-07 trial). *First Author: Yasuhiro Kodera, Nagoya University, Nagoya, Japan*

Background: Although postoperative adjuvant chemotherapy with S-1 is among the standard treatments for curatively resected pStage II/III gastric cancer (GC) in Asia, the outcome of pStage III GC remains unsatisfactory. Postoperative S-1/docetaxel had been among candidates for the new standard treatment. **Methods:** JACCRO GC-7, a randomized controlled trial to explore postoperative S-1/docetaxel, was participated by 138 Japanese institutions. After R0 resection by D2 gastrectomy, patients with pStage III GC were randomly assigned to either the S-1/docetaxel group (oral S-1 at 80-120mg/body on days 1-14 with 7 days of rest was followed by 6 cycles of S-1 at the same dosage and schedule combined with docetaxel 40mg/m^2 on day 1 of each cycle, and then 4 further cycles of S-1 at 80-120mg/body on days 1-28 every 42 days) or the control group (8 cycles of S-1 at 80-120mg/body on days 1-28 every 42 days). Block randomization was performed by a central interactive computerized system stratified by the institution, stage (IIIA, IIIB, or IIIC) and histological type (differentiated or undifferentiated). The sample size of 1,100 was necessary to detect a 7% increase in the 3-year RFS, the primary endpoint, in the S-1/docetaxel group (HR 0.78, 2-sided alpha = 0.05, beta = 0.2). The secondary endpoints were OS, TTF and safety. **Results:** At the planned second interim analysis, the 3y RFS of the S-1/docetaxel arm (65.9%) was significantly superior to that of the S-1 arm at 49,6% (HR 0.632, 99% CI: 0.400~0.998, p = 0.0007), and the independent data and safety monitoring committee recommended termination of the trial. S-1/docetaxel suppressed all types of recurrences including hematogenous, lymphatic and peritoneal. Although ≥grade 3 adverse events including leucopenia, anorexia, stomatitis and anemia were more frequent, postoperative S-1/docetaxel was safe and manageable. **Conclusions:** Postoperative adjuvant S-1/docetaxel after D2 gastrectomy is recommended as the new standard of care for patients with pStage III GC. Clinical trial information: UMIN 000010337.

Phase III study comparing triplet chemotherapy with S-1 and cisplatin plus docetaxel versus doublet chemotherapy with S-1 and cisplatin for advanced gastric cancer (JCOG1013). *First Author: Yasuhide Yamada, National Cancer Center Hospital, Tokyo, Japan*

Background: Doublet chemotherapy with S-1 and cisplatin (CS) is one of the standard first-line chemotherapy for advanced gastric cancer in Japan. Triplet chemotherapy with docetaxel added to CS (DCS) showed a promising activity associated with feasible toxicities in a phase II study. We conducted a phase III study, JCOG1013, to investigate whether DCS improved overall survival (OS) compared with CS. **Methods:** Patients with previously untreated, human epidermal growth factor receptor 2 negative or unknown, unresectable or recurrent gastric adenocarcinoma, performance status 0 to 1, and adequate organ function were eligible. They were randomly 1:1 assigned to receive CS (S-1 40-60 mg orally twice a day for 3 weeks, cisplatin 60 mg/m^2 on day 8, repeated every 5 weeks), or DCS (docetaxel 40 mg/m^2, cisplatin 60 mg/m^2 on day 1, S-1 40-60 mg orally twice a day for 2 weeks, repeated every 4 weeks). The primary endpoint was OS. A total of 740 patients were required to detect an increase in median OS from 13.5 months in the CS arm to 16.5 months in the DCS arm, corresponding to a hazard ratio (HR) of 0.8435, with a one-sided alpha of 5% and power of 80%. **Results:** From Apr 2012 to Mar 2016, 741 patients were enrolled in total (CS 371, DCS 370). Median OS was 14.2 and 15.3 months for DCS and CS, respectively (HR 0.99; 95% confidence interval [CI] 0.85-1.16; one-sided stratified log-rank p = 0.47). By histological subtypes, median OS was 13.3 months for DCS and 14.2 months for CS (p = 0.83) in the diffuse type (n = 482), and 17.5 months for both DCS and CS (p = 0.65) in the intestinal type (n = 259). Median progression-free survival was 7.4 months for DCS and 6.5 months for CS (HR 0.99; 95% CI, 0.86-1.15; p = 0.92). The overall response rate was 59.3% for DCS and 56.0% for CS (p = 0.50). The most common adverse events of grade 3 or 4 were neutropenia (DCS 58.5%, CS 32.1%), febrile neutropenia (DCS 7.6%, CS 5.7%), and diarrhea (DCS 7.0%, CS 7.4%). **Conclusions:** Addition of docetaxel to CS failed to improve OS of patients with untreated advanced gastric cancer. Therefore, CS remains the standard treatment for first-line chemotherapy for advanced gastric cancer. Clinical trial information: UMIN000007652.

4010 Poster Discussion Session; Displayed in Poster Session (Board #199), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 4:45 PM-6:00 PM

The BRIGHTER trial: A phase 3 randomized double-blind study of napabucasin (NAPA) plus paclitaxel (PTX) versus placebo (PBO) plus PTX in patients (pts) with pretreated advanced gastric and gastroesophageal junction (GEJ) adenocarcinoma. *First Author: Manish A. Shah, Weill Cornell Medicine/ New York Presbyterian Hospital, New York, NY*

Background: NAPA is an oral investigational agent, hypothesized to inhibit cancer stemness pathways, including STAT3 pathway implicated in cancer stem-cell viability. Synergistic antitumor activity of NAPA + PTX was observed in preclinical and early clinical testing. **Methods:** BRIGHTER is a randomized, double-blind, placebo-controlled phase 3 trial (NCT02178956), assessing efficacy and safety of NAPA + PTX versus PBO + PTX in pts with pretreated, advanced gastric and GEJ adenocarcinoma. The primary endpoint is overall survival (OS). Secondary endpoints include progression-free survival (PFS), objective response (ORR) and disease control (DCR) rates, and safety. Pts were randomized 1:1 to NAPA (960 mg total daily dose) + weekly PTX (80 mg/m^2) or PBO + weekly PTX (80 mg/m^2). **Results:** 714 pts were randomized from October 2, 2014, to December 12, 2016. At interim analysis of 380 events, the data safety monitoring board recommended trial unblinding when meeting the primary endpoint at final analyses appeared unlikely, though no safety concerns of clinical significance were identified. OS follow-up continued with median follow-up of 6.8 m (0.10-32.4) with final analysis performed at 565 events: 36.7%/63.2% (ECOG 0/1), 72.1%/27.9% (M/F), 74.6%/25.4% (gastric/GEJ). The mOS was 6.93 m vs 7.36 m in NAPA and PBO arms (HR 1.01 [95% CI, 0.86-1.20] p=0.8596), respectively. The mPFS was 3.55 m vs 3.65 m in NAPA and PBO arms (HR 1.00 [95% CI, 0.84-1.17] p= 0.9679), respectively. Among evaluable pts, DCR was 55 % vs 58% in NAPA and PBO arms Diff -3% (95% CI, -11%-5%, p= 0.6555), respectively, with an ORR of 16% vs 18% in NAPA and PBO arms Diff -2% (95% CI, -8%-4%, p=0.7358), respectively. The overall incidence of adverse events (AEs) was 98.6% vs 96.6% in NAPA and PBO arms without any additive toxicity. AEs $\geq$ Grade 3 occurred in 69.2% vs 59.7% in NAPA and PBO arms, with $\geq$Grade 3 diarrhea in 16.0% vs 1.4%, respectively. **Conclusions:** An international, placebo controlled phase 3 2nd line study of NAPA + PTX did not improve OS or PFS in pts with gastric and GEJ adenocarcinoma. Addition of NAPA to PTX was tolerable. Clinical trial information: NCT02178956.

4011 Poster Discussion Session; Displayed in Poster Session (Board #200), Sun, 8:00 AM-11:30 AM, Discussed in Poster Discussion Session, Sun, 4:45 PM-6:00 PM

A randomized phase II study of weekly paclitaxel ± trastuzumab in patients with HER2-positive advanced gastric or gastro-esophageal junction cancer refractory to trastuzumab combined with fluoropyrimidine and platinum: WJOG7112G (T-ACT). *First Author: Akitaka Makiyama, Department of Hematology/Oncology, Japan Community Health Care Organization Kyushu Hospital, Kitakyushu, Japan*

Background: Trastuzumab (Tmab) is a key drug for HER2-positive breast and gastric or gastro-esophageal junction (G/GEJ) cancer. While continuous use of Tmab beyond progression (TBP) showed a benefit in HER2-positive metastatic breast cancer, it has not been studied in HER2-positive G/GEJ cancer. We compared weekly paclitaxel alone (P) with weekly paclitaxel plus Tmab (PT) in patients (pts) with HER2-positive advanced G/GEJ cancer progressing during Tmab-containing therapy. **Methods:** Pts with HER2-positive advanced G/GEJ cancer progressing during first-line chemotherapy with Tmab + fluoropyrimidine + platinum were enrolled, and randomized to receive either P (80mg/m2, day1, 8, 15, q4w) or PT (P + initial Tmab 8mg/kg followed by 6mg/kg, q3w). The primary endpoint was progression-free survival (PFS). Major secondary endpoints included overall survival (OS), response rate, safety, and translational biomarker research. A total of 69 events was required to achieve 80% power for one-sided log rank test with 10% significance level, expecting median PFS of P and PT arms was 3 and 5 months, respectively. **Results:** From December 2012 to October 2016, 91 pts were randomized to P (n = 45) or PT (n = 44) arms. Median PFS was 3.19 (95% CI 2.86-3.48) and 3.68 (95% CI 2.76 to 4.53) months in the P and PT arms, respectively (HR = 0.91, 95% CI 0.67-1.22, p = 0.33). Median OS was 9.95 months in the P arm and 10.2 months in the PT arm (HR = 1.23, 95% CI 0.75-1.99, p = 0.20). In the P and PT arms, the overall response rates were 31.6 and 33.3% (p = 1.00), and the disease control rates were 71.1 and 61.5% (p = 0.47), respectively. PT treatment was associated with longer PFS in pts whose interval between the last Tmab administration and the randomization $\geq$30 days (HR = 0.45, 95% CI 0.21-0.96), but not in pts $<$ 30 days (HR = 1.40, 95%CI 0.82-2.37). Safety was comparable between the arms. HER2-positivity of tumor tissues obtained from 16 pts before the study entry was lost in 69%. **Conclusions:** TBP strategy failed to improve PFS in pts with HER2-positive advanced G/GEJ cancer. Clinical trial information: UMIN000009297.

Survival outcomes from CALGB 80803 (Alliance): A randomized phase II trial of PET scan-directed combined modality therapy for esophageal cancer. *First Author: Karyn A. Goodman, University of Colorado, Denver, CO*

Background: We evaluated use of early PET response after induction chemotherapy (CT) to direct changing to alternative CT during preoperative chemoradiation (CRT) among patients (pts) with resectable esophageal and gastroesophageal junction (GEJ) adenocarcinomas who are PET nonresponders. We previously reported the primary endpoint of improving pathologic complete response (pCR) in PET nonresponders; pre-specified efficacy criteria were met for improvement in pCR rates with changing CT during CRT. We now report survival outcomes by PET response status. **Methods:** 257 pts enrolled, underwent baseline PET and were randomized to 1 of 2 induction CT arms: modified FOLFOX-6 (oxaliplatin, leucovorin, 5-FU) days 1, 15, 29 or carboplatin/paclitaxel (CP) days 1, 8, 22, 29. Repeat PET was performed days 36-42; change in maximum standardized uptake value (SUV) from baseline was assessed. PET nonresponders ($<$ 35% decrease in SUV: PET-NR) crossed over to alternative CT regimen during CRT (50.4 Gy/28 fractions). PET responders ($\geq$35% decrease in SUV: PET-R) continued on same CT during CRT. Pts underwent surgery at 6 weeks post-CRT. Overall survival (OS) was measured from randomization to death from any cause; 2-year (yr) OS rates were estimated using the Kaplan-Meier method. **Results:** 240 eligible pts received protocol treatment and 222 had an evaluable repeat PET. With median follow-up of 35.9 months (mo) (95% CI: 33.1-41.2), median OS was 34.4 mo (95%CI: 28.4-49.7) and 2-yr OS was 61.8% (95%CI: 55.7-68.5%). Median OS for PET-R was 40.2 mo (95% CI: 31.0, not estimable [NE]) and for PET-NR was 27.4 mo (95% CI: 20.3, NE). Median and 2-yr OS by induction CT and PET response appear below. Clinical trial information: NCT01333033. **Conclusions:** PET response after induction CT is prognostic for outcome in pts with esophageal and GEJ adenocarcinomas. Outcomes for PET-R pts receiving induction and concurrent FOLFOX are encouraging. Support: U10CA180821, U10CA180882

Response Group	Events/N	Median OS (mo)	95% CI (mo)	2-yr OS (%)	95% CI (%)
CP N = 111					
PET-R	31/63	31.0	(20.4, NE)	57.4	(46.2, 71.3)
PET-NR	28/48	26.4	(16.0, NE)	52.4	(39.8, 69.0)
FOLFOX N = 111					
PET-R	29/72	48.7	(33.1, NE)	73.3	(63.4, 84.7)
PET-NR	20/39	30.9	(25.4, NE)	64.0	(50.0. 82.0)

A multi-center, randomized, prospective study evaluating the optimal radiation dose of definitive concurrent chemoradiation for inoperable esophageal squamous cell carcinoma. *First Author: Yanjun Xu, Zhejiang Cancer Hospital, Hangzhou, China*

Background: To determine the optimal radiation dose for definitive concurrent chemoradiation in esophageal squamous cell carcinoma (ESCC) using modern radiation technology. **Methods:** Pathologically confirmed ESCC patients with stage IIA-IVA were randomized into high-dose (60Gy) and low-dose group (50Gy). The total radiation doses were delivered 2 Gy per fraction, 5 fractions per week, by intensity-modulated radiation therapy (IMRT). Concurrent weekly docetaxel (25 mg/m^2) followed by cisplatin (25 mg/m^2) and 2 cycles consolidation chemotherapy with docetaxel 70mg/m^2 plus cisplatin 25mg/m^2 day1-3 were administrated. The primary endpoint was local/regional progression-free survival (LRPFS). **Results:** From April 2013 to May 2017, 305 patients were randomized into the high-dose (n = 152) and low-dose group (n = 153). There were no significant differences in gender, age, KPS, clinical stage, location, the length of tumor between the two groups. The radiotherapy completion rate was 87.5% (133/152) and 95.4% (146/153) in the high and low dose groups respectively (*P*= 0.002) . The concurrent weekly chemotherapy completion of receiving 5, 4, ≤3 weeks drugs were 61.2% (93/152) 、66.7% (102/153) ; 21.1% (32/152) 、20.9% (32/153) ; 17.8% (27/152) 、12.4% (19/153) (*P*=0.406) . There was no significantly difference in the completion of consolidation chemotherapy (*P*= 0.207). At a median follow-up of 14.4 months (1.3-51.4 months) , The disease progression rate was 15.8% (24/152) 、15.7% (24/153) in the high-dose and low-dose group, respectively. The 1, 2-year LRPFS rate was 85.8%、74.4% and 85.1%、78.4% (*P*= 0.676) . The 1, 2-year PFS and OS rate was 78.6%、67.6%, 76.9%、67.7% (*P*= 0.859) ; 84.6%、67.3%, 86.4%、72.2% (*P*= 0.981) . The treatment toxicity equal to or greater than grade 3 included leukopenia; radiation esophagitis and pneumonitis. There were no significant differences between the two groups. **Conclusions:** There was no difference towards LRPFS, PFS, OS and toxicity between high-dose (60Gy) and low-dose (50Gy) group. A total radiation dose of 50Gy was recommended for definitive concurrent chemoradiation in ESCC. Clinical trial information: NCT01937208.

Randomized phase III study of gemcitabine plus S-1 combination therapy versus gemcitabine plus cisplatin combination therapy in advanced biliary tract cancer: A Japan Clinical Oncology Group study (JCOG1113, FUGA-BT). *First Author: Makoto Ueno, Department of Gastroenterology, Hepatobiliary and Pancreatic Medical Oncology Division, Kanagawa Cancer Center, Yokohama, Japan*

Background: Gemcitabine (GEM) plus cisplatin (GC) is the standard of care for advanced biliary tract cancer (BTC). However, GC is considered to be toxic because of nausea, vomiting, and appetite loss, and inconvenient due to requiring hydration before and after administration. GEM plus S-1 (GS) was reported to be promising with preferable efficacy and acceptable toxicity profile. This phase III study aimed to confirm the non-inferiority of GS to GC in terms of overall survival (OS). **Methods:** Eligibility criteria included chemotherapy-naïve patients with recurrent or unresectable biliary tract adenocarcinoma (gallbladder, intrahepatic biliary tract, extrahepatic biliary tract, or ampulla of Vater), an ECOG-PS of 0–1, and adequate organ function. In the GC arm, 1 g/m^2 of GEM and 25 mg/m^2 of cisplatin was infused on days 1 and 8 of a 21-day cycle. In the GS arm, 1 g/m^2 of GEM was infused on days 1 and 8, and S-1 60, 80, or 100 mg/day according to body-surface area was administered from days 1 to 14 of a 21-day cycle. The primary endpoint was OS and the secondary endpoints included progression-free survival (PFS), response rate (RR), adverse events (AEs), clinically relevant AEs predefined as any of grade 2 or more fatigue, appetite loss, nausea, vomiting, oral mucositis, and diarrhea. The sample size was calculated to be 350 with a one-sided alpha of 5%, a power of 80%, non-inferiority margin of 1.155 in terms of hazard ratio (HR). **Results:** From May 2013 to March 2016, 354 patients were enrolled. The non-inferiority of GS to GC was demonstrated (median OS: 13.4 months (m) in GC and 15.1 m in GS, HR 0.95; 90% confidence interval (CI), 0.78 to 1.15; P = 0.046 for non-inferiority). Median PFS was 5.8 m in GC and 6.8 m in GS (HR 0.86, 95% CI, 0.70-1.07). RR was 32.4% in GC and 29.8% in GS. Both treatments were generally well tolerated. Clinically relevant AEs were observed 35.1% in GC and 29.9 % in GS. **Conclusions:** GS demonstrated non-inferiority to GC in OS with good tolerability and was considered as new convenient option of standard of care without hydration for advanced BTC. Clinical trial information: UMIN000010667.

Phase 2 trial of the IDO pathway inhibitor indoximod plus gemcitabine / nab-paclitaxel for the treatment of patients with metastatic pancreas cancer. *First Author: Nathan Bahary, University of Pittsburgh Medical Center Cancer Center Pavilion, Pittsburgh, PA*

Background: The indoleamine 2,3-dioxygenase (IDO) pathway is a key counter-regulatory mechanism that is exploited by tumors to prevent and evade anti-tumor immunity. Inhibitors of the IDO pathway, such as indoximod, are an increasingly validated class of potential cancer therapeutics. The combination of gemcitabine (G) and nab-paclitaxel (N) is a current SOC for metastatic pancreas cancer (MPC). Pre-clinical models have demonstrated synergy between indoximod and chemotherapy. **Methods:** Single arm study with indoximod (1200mg BID continuous) plus G / N (1000mg/m^2 / 125mg/m^2 q week x3 per 4-week cycle). Patients had treatment naïve MPC or 1st line therapy after previous resection and adjuvant therapy. Treatment continued until disease progression or toxicity. Primary endpoint was an improvement in median overall survival (mOS) from a historical 8.5 months for G / N to 12.1 months (hazard ratio (HR) of 0.70). Secondary endpoints included overall response rate (ORR) by site review RECIST 1.1. An expansion cohort enrolled patients undergoing pre and on-treatment (end Cycle 2) tumor biopsies. **Results:** A total of 135 patients initiated treatment in Phase 2 including 36 in the biopsy group. 104 were efficacy evaluable (EE) per the pre-specified definition of completing one cycle of therapy with one on-treatment imaging study. The ORR in the EE was 46.2% (48/104) with 1% CR (1/104) and 45.2% PR (47/104). The mOS in the EE was 10.9 months. Combination was generally well tolerated with fatigue, nausea, and anemia being the most commonly observed adverse events. Immunologic data by immunohistochemistry from biopsy samples (n = 11) indicate responders have increased intra-tumoral CD8 density after 2 cycles of therapy compared to non-responders (p = 0.030). **Conclusions:** EE patients had a mOS of 10.9 months and ORR of 46.2%; responding patients had an increased intra-tumoral CD8 density. The study did not meet the pre-specified primary goal of a 30% reduction in HR. However, the combination demonstrated activity with a promising ORR and immunologic correlation with response. These data support the continued development of combination indoximod immunochemotherapy for MPC. Clinical trial information: NCT02077881.

Effect of anti-CTGF human recombinant monoclonal antibody pamrevlumab on resectability and resection rate when combined with gemcitabine/nab-paclitaxel in phase 1/2 clinical study for the treatment of locally advanced pancreatic cancer patients. *First Author: Vincent J. Picozzi, Virginia Mason Hospital and Medical Center, Seattle, WA*

Background: Pancreatic ductal adenocarcinomas exhibit high degree of desmoplasia with extensive connective tissue growth factor (CTGF) expression and extracellular matrix production. CTGF overexpression is associated with aberrant fibrous tissue in mouse model, in which progression of tissue adhesion was inhibited by pamrevlumab. We hypothesize that pamrevlumab, an anti-CTGF antibody, may influence resectability of locally advanced pancreatic cancer (LAPC) by inhibiting effects of CTGF. **Methods:** Pamrevlumab + gemcitabine/Nab-paclitaxel (G/N) (Arm A) vs G/N (Arm B) was given to treatment-naïve LAPC patients to improve resection rate and overall survival (OS). Patients (N = 37) were randomized 2:1 in Arm A vs Arm B. Patients who completed 6 cycles of treatment underwent resectability assessment per protocol criteria (NCCN, CA 19-9, PET, RECIST) and, if found eligible, underwent resection. No adjuvant therapy was given; second line therapy was administered per investigator discretion. **Results:** In the ITT population, a higher percentage of patients discontinued treatment in Arm B (46.2%) vs Arm A (25%), mainly due to disease progression or adverse events. More patients normalized PET in Arm A (35%) vs Arm B (23%). Thirty percent of patients overall had best objective RECIST response (CR + PR). More patients were eligible for surgery and were resected in Arm A vs Arm B; 70.8% vs 15.4% and 33.3% vs 7.7%, respectively. Improvement in OS was noted in patients eligible for surgery vs not (27.73 vs 18.40 months, p-value = 0.0766) and in patients resected vs not (NE vs 18.56 months, p-value = 0.0141). Progression-free survival showed similar trend (16.39 vs 10.09 months, p-value = 0.1049) and (16.39 vs 10.38 months, p-value = 0.3778), respectively. No increase in serious adverse events or delay in wound healing post-surgery was observed in Arm A vs. Arm B. **Conclusions:** These findings indicate that pamrevlumab may be a valuable addition to neoadjuvant therapy in LAPC without added toxicity. These results warrant a follow-on study in a larger patient population. Clinical trial information: NCT02210559.
